Rules for Technical Supervision During Construction of Ships and Manufacture of Materials and Products for Ships (RTSC)

Rules for Classification and Construction of Ships (RCCS)

Rules for Prevention of Environment Pollution from Ships (RPPS)

MOSCOW
RUSSIAN RIVER REGISTER

RULES
FOR TECHNICAL SUPERVISION
DURING CONSTRUCTION OF SHIPS
AND MANUFACTURE OF MATERIALS
AND PRODUCTS FOR SHIPS
(RTSC)

MOSCOW 2015

The Rules for Technical Supervision during Construction of Ships and Manufacture of Materials and Products for Ships (RTSC) have been approved by the Order of Federal Autonomous Institution “Russian River Register” No. 36-п dated 09.09.2015 and brought into force since 19.07.2016 by the Order of Federal Autonomous Institution “Russian River Register” No. 29-п dated 11.07.2016.

The present re-edition of the Rules for Technical Supervision during Construction of Ships and Manufacture of Materials and Products for Ships (RTSC) includes amendments and additions approved by the following Orders of the Federal Autonomous Institution “Russian River Register”:
- Order No. 50-п dated 09.09.2016 (Notice No. 1);
- Order No. 78-п dated 07.11.2016;
- Order No. 100-п dated 27.12.2016;
- Order No. 24-п dated 09.03.2017 (Notice No. 2), came into force since 15.03.2017;
- Order No. 65-п dated 14.08.2017 (Notice No. 4), came into force since 20.08.2017.

1 GENERAL PROVISIONS

1.1 APPLICATION

1.1.1 The present Rules for Technical Supervision During Construction of Ships and Manufacture of Materials and Products for Ships (hereinafter referred to as the Rules), which are based on and develop further the Regulations for Classification and Survey of Ships (hereinafter referred to as the Regulations for Classification), establish the types, procedures, methods and scope of technical supervision performed by the River Register in order to check compliance with requirements of the Rules for Classification and Construction of Inland Navigation and River-Sea Navigation Ships (hereinafter referred to as the RCCS) and Rules for Prevention of Environment Pollution from Ships (hereinafter referred to as the RPPS).

1.1.2 These Rules are used by the River Register for technical supervision during construction, conversion, modernization and repair of ships, manufacture of materials and products, repair of products to be used on the ships and during review and approval of technical documentation.

1.2 TERMS AND DEFINITIONS

1.2.1 Terms and their definitions related to the general terminology of the Rules are given in 2.1 Part 0 of RCCS.

1.2.2 For the purpose of these Rules the following terms and definitions are used:

.1 Random inspection — see 2.2.6 Part 0 of RCCS;

.2 Statement of conformity means the manufacturer's document confirming compliance of the manufactured items under technical supervision with the Rules and technical documentation approved by the River Register. The form of the Statement of Conformity is established by the River Register;

.3 Manufacturer means a legal entity or individual entrepreneur constructing a ship, manufacturing and supplying materials and/or products for ships or transferring a right to supply to another legal entity or individual entrepreneur, modernizing the products for ships, officially applying the trademark or other distinctive mark on ships and products, thus assuming the manufacturer's obligations;

.4 Product of mass production (mass produced product) means a product which belongs to periodically repeated batches of manufactured or repaired products;

.5 Type approval tests mean check tests of materials or products carried out to determine compliance of their properties (characteristics) with the approved technical documentation and Rules;

.6 Testing laboratory means a legally independent testing laboratory or subdivision of the organization performing the tests prescribed by the Rules during construction, conversion, modernization and repair of ships, manufacture of materials and products, repair of products (see 2.8.1.5);

.7 Approved is a term used by the River Register upon satisfactory results of checking compliance of materials and products with the requirements of the Rules;

.8 Type approval of a material or product means defining the compliance of type specimens of the material or product manufactured in the course of continuous production with the requirements of the Rules by the River Register;
9 Classification organization means an organization authorized by the RF Ministry of Transport for classification and survey of ships;

10 Test program means a document establishing the item, types, sequence and scope of the performed tests, procedure, terms, place and time frame of the tests, support and reporting for the tests as well as responsibility for their support and performance;

11 Test report means a document containing the information on the item under test, used methods, means and conditions of the tests, test results as well as evaluation of the test results;

12 Single delivery means a material or product delivered one time for the ships classed by the River Register or constructed to this class;

13 Ship repair means a set of operations on recovery of serviceable or operable condition of the ship for a specific period of time;

14 Certificate means a document of the River Register confirming that the considered materials or products comply with the requirements of the Rules and approved technical documentation;

15 "APPROVED" is a stamp used by the River Register to confirm compliance of technical documentation with the requirements of the Rules;

16 Bench tests mean tests performed using test equipment;

17 Technical documentation means design and process documentation as well as other technical documents for items under technical supervision which include data required to check compliance with the requirements of the Rules;

18 Type material or product means a material or product related to a group of materials or products with similar physical and mechanical properties or structural and technological features. They are used as intended without attributing to a specific ship or item under technical supervision;

19 Type specimen means a specimen of type material or product used during the test and inspection;

1.3 HEAD OFFICE ACTIVITIES

1.3.1 As regards technical supervision during designing, construction of ships, manufacturing of materials and products, the Head Office:

.1 reviews and approves engineering designs for construction of ships;

.2 reviews draft national standards;

.3 reviews and approves technical documentation for materials and products when approving a material or product type as well as technical documentation for overhaul of internal combustion engines;

.4 reviews and approves engineering designs for transfer of class for the ships;

.5 reviews and approves software applications used for designing;

.6 participates in technical supervision during trials of prototype ships (items) constructed according to the designs approved by the River Register;

.7 undertakes technical supervision during tests of material and product type specimens manufactured according to the documentation approved by the River Register and issues material or product type approval certificates;

.8 checks ship document copies issued by Branch Offices for prototype ships after construction or conversion;

.9 reviews and approves a list of replacements equivalent to the requirements of the Rules;

.10 undertakes technical supervision for compliance with the Rules during manufacture of materials and products when manufacturers are outside the activity of Branch Offices and issues respective documents;

.11 carries out surveys of firms engaged in manufacturing of materials/products and in work according to the requirements of the River Register, as well as testing laboratories performing tests prescribed by the Rules, if they are outside the activity of Branch Of-
1 General Provisions

1.12 ensures overall management of Branch Offices, makes technical and other decisions regarding issues arising from Branch Offices activities;

1.13 improves normative classification documents.

1.4 BRANCH OFFICE ACTIVITIES

1.4.1 As regards technical supervision during designing, construction, modernization, conversion and repair of ships, manufacture of materials and products, repair of ship equipment, the Branch Office:

1. reviews and approves engineering (detailed) designs:
   for floating objects, industrial ships, custom-built self-propelled and non-self-propelled ships of other types and purposes, except tugboats, icebreakers, high-speed craft, WIG craft and ships of new design;
   for hull stiffening or ship preparation for operation or single voyage (passage) outside the specified area of navigation;
   for conversion, modernization and repair of ships of all types and purposes, except for transfer of class for the ships;
   for repair of boilers;
   for repair of custom-built ship machinery;
   for repair of hoisting gear;

2. reviews and approves detailed documentation for ships under construction, conversion, modernization and repair;

3. reviews and approves technical documentation for materials and products for which type approval is not provided;

4. undertakes technical supervision for compliance with the Rules during construction, conversion, modernization and repair of ships, manufacture of materials and products;

5. undertakes technical supervision for compliance with the Rules during repair of ship machinery and overhaul of engines;

6. prepares and issues documents of the River Register for constructed, converted, modernized and repaired ships as well as submits copies of these documents to the Head Office in the specified extent;

7. reviews and approves standards of firms and process procedures;

8. carries out survey of firms and testing laboratories, except those outside the activity of the Branch Office, draws up and issues recognition certificates;

9. carries out other activities on behalf of the Head Office including those specified in 1.3.
2 GENERAL PROVISIONS ON TECHNICAL SUPERVISION

2.1 GENERAL REQUIREMENTS

2.1.1 Technical supervision during manufacture of items under technical supervision is performed by stage-wise inspections of these items during manufacture, including the final stage of manufacture (finished materials or products).

Inspections are carried out by the River Register's surveyor or the firm's person authorized by the River Register after inspection of the manufactured materials and products by the manufacturer's personnel and preparation of documents on workmanship, manufacture or installation of items under technical supervision by this firm.

During inspections, the River Register's Surveyor or the firm's person authorized by the River Register shall not make decisions different from those prescribed by the Rules.

For the Nomenclature of items under the River Register technical supervision (herein after referred to as the Nomenclature) and types of technical supervision, see Table A1.1.

2.1.2 All the activities related to technical supervision are carried out by the River Register upon request and normally against the contracts with the firms in charge of design, construction, conversion, modernization and repair of ships as well as manufacture of materials and products for shipbuilding and ship repair.

2.1.3 Quality checks of items under the River Register technical supervision are performed using the methods specified in these Rules and cover only the properties of items prescribed by these Rules.

2.1.4 While performing technical supervision the River Register does not replace the functions of the firm's and ship owner's quality control departments.

2.1.5 Technical supervision during manufacture of materials and products, construction, modernization and conversion of ships is performed according to the approved technical documentation and production processes.

If the materials and products specified in the Nomenclature are manufactured and/or tested according to national standards, the use of which provides compliance with requirements of the Rules, technical supervision is performed considering the requirements of these standards.

2.1.6 The procedure for review and approval of technical documentation on items under technical supervision, scope of surveys during technical supervision in the firm and process operations subject to inspection are determined in the relevant sections of the Rules.

2.1.7 The River Register on a contract basis may assign (entrust) technical supervision during construction of ships or manufacture of materials and products to another classification society or competent organization recognized by the River Register as well as accept an assignment of another classification society or other organization to perform technical supervision.

Scope and procedure for technical supervision as well as the form and list of documents issued in these cases are specified in respective agreements (see 2.7).
2.1.8 Materials and products which are items under technical supervision can be installed on board the ship if there are certificates or other documents issued by the River Register or documents of another classification organization issued on behalf of the River Register confirming compliance of concerned materials and products with requirements of the Rules.

2.1.9 Technical supervision of materials and components manufactured by the organization and used in this organization for manufacturing products as well as during construction or repair of ships is performed by the surveyor within technical supervision during manufacture of products, construction and repair of ships. Performance of technical supervision is confirmed by a record in the Notice of surveyor invitation (hereinafter referred to as the Notice), the form of which is given in Appendix 2.

When manufacturing the above materials and components to be further delivered to other organizations, including when they serve as interchangeable parts, technical supervision is performed according to the forms specified in the Nomenclature with issue of the documents specified in 2.2.6.

The Notice of submitting the work shall include information on the welders who carried out the submitted work, if the requirements for welding the structures and items are prescribed by the Rules (see 2.9.1) including their family name, name and patronymic (if any) as well as details of the Welder Approval Certificate.

2.1.10 New materials and products (including those under preservation) without documents of the River Register, may be allowed for installation on board ship or for manufacture of products according to the results of their survey as follows:

1. Shipbuilding or ship repair organization, manufacturer of products shall submit the manufacturer's documentation on materials and products in the scope sufficient to determine compliance of materials or products with requirements of the Rules as well as a test program which allows to assess compliance with the requirements of the Rules.

The documentation shall be sent with the Notice which includes the name of the material or product and its identification details (e.g., name of the manufacturer, serial or batch number);

2. The “Taken into consideration” stamp shall be put on the reviewed documentation and test program in case of compliance with the requirements of the Rules;

3. In case of compliance of the documentation with the requirements of the Rules, tests shall be performed in the testing laboratory recognized by the River Register according to the test program taken into consideration. According to the test results, the testing laboratory which tested the material or product shall draw up a test report;

4. The surveyor shall perform survey of the material or product in the scope specified by the Rules;

5. Compliance of the material or product with the requirements of the Rules is confirmed by issue of a Certificate (Form PP-1.25.1) for the products with a personal identification number. For the products without a personal identification number and materials – with a record in the Notice which was sent with the material or product to the surveyor to perform survey.

The test report and documentation taken into consideration (copy of documentation) are to be attached to the Notice on the basis of which the surveyor performed survey of the material or product.

The survey results apply only to the materials or products which were submitted under the Notice, specified in 2.1.10.1 and which were subject to the survey specified in this paragraph.

At repeated submission of the materials or products specified in this paragraph for survey to the River Register, survey shall be performed according to the requirements of this paragraph in full.

2.1.11 The procedure specified in 2.1.10 shall not be applied in the following cases:
1. Materials and products have a valid material or product type approval certificate;
2. A material or product is used for construction of the ship series;
3. Products with similar characteristics have a valid material or product type approval certificate.

2.1.12 Materials and products which are planned to be installed on ships during modernization, conversion or repair, are dismantled from the ships which are/were classed by the River Register as agreed with the Branch Office.

Dismantling of the materials or products which are planned to be installed on ships during modernization, conversion or repair, is performed in the presence of the River Register's surveyor.

A report on survey of the dismantled materials and products (Form PP-10.3) is prepared for the dismantled materials and products, except for the cases specified in the fourth and fifth subparagraphs of this para.

If the dismantled products have no documents required to determine their technical condition, and the main and auxiliary engines have no files, datasheets or other documents including information of the manufacturer on the assigned and remaining life (service life), a Report on survey of the dismantled products is not prepared and it is not allowed to install the products on the ships classed by the River Register.

A Report on survey of the dismantled products is not prepared if the product has River Register documents confirming their compliance with the requirements of the Rules (Forms PP-8.1, PP-8.3, PP-1.25) or a report on survey of the dismantled materials and products (Forms PP-10.3), as well as documentation required by RSSS to determine technical condition of products.

Main and auxiliary engines, in addition to the above, shall have files, datasheets or other documents including information of the manufacturer on the assigned and remaining life (service life).

The decision on possibility of installing the materials and products dismantled from other ships classed by the River Register shall be taken by the Branch Office performing technical supervision during modernization, conversion or repair of the ship by results of determining technical condition of materials and products.

Technical condition of materials or products specified in the first subparagraph of this para and planned to be installed on ships is determined according to Appendices 2 to 4 of RSSS as regards products or according to Part X of RCCS as regards materials.

According to results of determining technical condition, repair of products is performed in the required scope, if necessary. Technical supervision during repair of the products is performed according to the requirements of these Rules.

According to results of determining technical condition of the products, satisfactory results of mechanical tests and determining chemical composition of the materials as well as technical supervision during repair of the products, a Certificate (Form PP-1.25.1) is drawn up for the products with a personal identification number or a Certificate (Form PP-8.3) for a thoroughly repaired engine. For the products without a personal identification number and materials, records are made in the Notices which were sent with the material or product to the surveyor to perform survey.
2.2 FORMS OF TECHNICAL SUPERVISION

2.2.1 The following types of technical supervision during construction, conversion, modernization and repair of the ships, manufacture of the materials and products are prescribed by these Rules:

.1 Technical supervision of the surveyor (Form P) means technical supervision performed by the River Register;

.2 Technical supervision of the River Register and organization (Form OP) means technical supervision during manufacture of materials and products performed together with the River Register's surveyor and organization personnel;

.3 Technical supervision of the surveyor using a type approval (Form OT) means technical supervision during manufacture of materials and products performed by the River Register at type approval without participation in acceptance of the end material or product;

.4 Technical supervision in the form of Recognized documentation (Form ПД) means technical supervision when compliance of the material or product with the requirements of the Rules is confirmed only by review and approval of technical documentation without supervision during its manufacture or installation (assembly) on the ship;

.5 Technical supervision by another classification organization means technical supervision performed by another classification society on behalf of the River Register (under agreement with the River Register).

2.2.2 Forms of technical supervision specified in columns 2 and 3 of the Nomenclature apply to the materials and products subject to repeated deliveries. Technical supervision during single deliveries is performed according to 2.3.18 and 2.3.19. The results of documentation review and of the tests during single deliveries apply only to the declared item under technical supervision.

2.2.3 In the cases prescribed by the Nomenclature (column 3), the organization together with the River Register may select a form of technical supervision — P or OP.

The possibility of using a form of technical supervision (OP) is determined by the Branch Office (Head Office) by results of the manufacturer survey. The decision on the used form of technical supervision is specified in the Recognition Certificate.

2.2.4 Technical supervision during construction, modernization, conversion and repair of ships, approval of material and product type is performed only by the River Register's surveyor or personnel of another classification organization on behalf of the River Register or under agreement with the River Register (see 2.7).

The tests prescribed by the Rules shall be carried out by the testing laboratories with a Recognition Certificate of the River Register to perform these tests. The tests in the presence of the surveyor are performed if is prescribed by the Rules, or if the testing laboratory is not recognized by the River Register to perform these tests.

Participation of the surveyor in ship trials and tests of materials and products as well as in welders' qualification tests, is confirmed by the surveyor's signature under "Carried out at surveyor's technical supervision/survey" inscription applied to the document prepared by results of trials/tests (report).

2.2.5 For the procedure of technical supervision during manufacture of materials and products, see Table 225.

The applicant may send a request to the River Register for each procedure separately or for a few procedures of technical supervision.

In case of single deliveries (see 2.2.2), recognition of the manufacturer is not required.

2.2.6 According to results of technical supervision of the materials and products depending on the used form of technical supervision (third column of the Nomenclature), the following documents confirming their compliance with the requirements of the Rules are issued:
### Table 2.2.5

1. Form P — for manufacture of the materials and products (Form PP-8.1), repair of the products — Certificate (Form PP-1.25), overhaul of the engines — Certificate (Form PP-8.3);

2. Form OP — Certificate (Form PP-8.1);

3. Form OT — manufacturer's document with information on Type Approval Certificate (see 2.3.13) specifying its date and number or attaching copy of this Certificate;

4. Form ПД — manufacturer's document with the date and number of the letter on approval of technical documentation according to which the material or product is manufactured.

2.2.7 One Certificate is issued for materials and products manufactured in batches.

In this case each product shall be delivered with the manufacturer's documents with references to this Certificate. The supporting documentation on the delivered product (batch or its part) shall include a copy of a Certificate endorsed by the manufacturer.

If the Certificate was issued for a unit of product, it shall be delivered with the original Certificate.

2.2.8 According to results of technical supervision, documents prescribed by RSSS are issued for the ship, depending on type of survey, which is the completion of technical supervision during construction, conversion, modernization or repair of the ship.

2.3 TECHNICAL SUPERVISION
BY THE SURVEYOR (FORM P)

2.3.1 To determine the scope and procedure of inspections, the items under technical supervision opposite which symbol P is placed in columns 3, 5 to 7 of the Nomenclature, the River Register and manufacturer shall prepare a checklist for the items and process operations (hereinafter the Checklist). The Checklist includes items under technical supervision specified in the Nomenclature as well as separate process operations and works carried out under technical supervision of the River Register. For the Form of the Checklist, see Appendix 3.

2.3.2 The Checklist is prepared on the basis of the requirements of the Rules considering specific conditions of technical supervision.

The Checklist is an Appendix to the Agreement on technical supervision.

Each presentation to the River Register, covering one or several uniform items under technical supervision or scope of works completed at the particular stage of manufacture shall correspond to each item of the Checklist. Construction sequence and conditions of manufacture of critical parts and product assembly shall be taken into account.

For the standard Checklist, see Appendix 4.

2.3.3 To perform inspections and participate in the tests of the items under technical supervision, a written Notice shall be sent to
the surveyor not later than one day before the date of the inspections and tests.

If the requirements of the Rules are violated, the surveyor shall impose requirements on elimination of the detected violations and repeated submission of the item under technical supervision for inspection or tests. After observing the requirement, a repeated Notice shall be sent to the surveyor.

2.3.4 The surveyor shall record the results of the inspections and tests of the items under technical supervision in the Notice as well as in the construction book (if any), the form of which is given in Appendix 5.

2.3.5 In addition to the inspections according to the Checklist, the surveyor checks quality of the manufactured parts, assemblies and structural components included in the items under technical supervision submitted according to the Checklist, observing the production processes approved by the River Register (see 3.1.10), compliance with the conditions of issue of a Recognition Certificate and/or Agreement on technical supervision. The results of the inspections are recorded in the Record Book of Technical Supervision, the form of which is given in Appendix 6.

2.3.6 When detecting defects which require elimination, the item under technical supervision shall be submitted for repeated inspection by the River Register after elimination of these defects.

2.3.7 According to results of the performed inspections and tests of the materials or products, the surveyor shall draw up respective documents of the River Register. In the cases specified in 2.1.12 and Appendix 1, the materials and products are sealed. Information on availability of the River Register seal on these materials and products is specified on the issued documents of the River Register.

Approval of material and product type

2.3.8 As regards items under technical supervision, opposite which symbol P is put in column 2 of the Nomenclature, type approval procedure is performed.

2.3.9 To receive a material or product type approval certificate, the organization shall send a request to the River Register.

Together with the request, technical documentation on the material or product (see 3.4) shall be submitted in the scope sufficient to determine compliance of the declared material or product with the requirements of the Rules.

2.3.10 During review and approval of technical documentation, scope and procedure of technical supervision during tests of the declared items under technical supervision is established. The scope of tests shall be not less than that prescribed by the Rules for type materials and products.

2.3.11 For different sizes of the product, tests of type specimen, the structure of which considers the main features of the whole range of products, shall be performed.

Tests of the materials and products shall be performed by the testing laboratories and manufacturer's Branch Offices recognized by the River Register (see 2.8.7).

During type approval, the test results performed maximum six years before the date of type approval in the presence of the River Register's surveyor or another classification society employee acting on behalf of the River Register (see 2.7) as regards type approval of this material or product may be considered.

2.3.12 The results of the inspections and tests are recorded in the type specimen survey report (Form PP-10.1).

2.3.13 A material/product type approval certificate (Form PP-11.1, PP-11.2, PP-11.3) is issued by the River Register in order to make sure that by results of the tests and inspections, the structure, properties, parameters and characteristics of the type material or product comply with the approved technical documentation and requirements of the Rules for the intended use on the ships and other items under technical supervision of the River Register.

The material or product type approval certificate does not replace a Certificate issued for the serial materials and products.
2.3.14 The material or product type approval certificate is valid before the expiry date of approval of technical documentation on the material or product (see 3.1.8).

2.3.15 After expiry of the material or product type approval certificate, the manufacturer shall undergo the procedure specified in 2.3.9 to 2.3.11.

When determining the scope of inspections and tests, the results of the manufacturer's survey during the procedure of recognition by the River Register, the results of technical supervision during manufacture of materials or products for the expired period as well as information on the scope and type of claims from the consumers and other persons concerned shall be considered.

2.3.16 The issued material or product type approval certificate shall expire before its validity period in the following cases:
- Structure of the product, its properties or other characteristics are changed without approval with the River Register;
- The requirements prescribed by the Rules as regards suitability of the material or product for further operation on the ship;
- If approval of technical documentation as regards material or product expires.

Technical supervision during manufacture of the materials and products performed by the surveyor

2.3.17 In the cases prescribed by the Nomenclature (symbol P in column 3), technical supervision during manufacture of materials and products is performed by the River Register surveyor.

2.3.18 To receive a Certificate for materials or products, the manufacturer shall send a request to the River Register with attached technical documentation on the materials or products in the scope prescribed by the Rules (see 3.4). According to results of review of technical documentation, the requirements to the scope of inspections and tests as well as its approval shall be determined (see 3.4.8).

If documentation on the materials or products was approved earlier and has valid approval status (see 3.1.8 and 3.1.9), the request (Notice) shall include the number of the letter on approval of technical documentation (repeated approval is not required).

2.3.19 If the results of inspections and tests (see 5 to 10 of these Rules) prove the compliance of the material or product with requirements of the approved technical documentation and Rules, the surveyor shall issue certificates (Form PP-8.1).

2.4 TECHNICAL SUPERVISION PERFORMED BY THE RIVER REGISTER AND ORGANIZATION (FORM OP)

2.4.1 In the cases, prescribed by the Nomenclature (symbol OP in column 3) if performance of technical supervision by the River Register together with the manufacturer is confirmed (see 2.2.3), Form of technical supervision OP is used.

2.4.2 To use this form of technical supervision, the organization shall send a request to the River Register. When confirming use of the Form of technical supervision OP (see 2.2.3), a contract on technical supervision is concluded with the organization.

2.4.3 The Form OP is used when meeting the following conditions:
- Use of this form is confirmed by a record in the Recognition Certificate at recognition of the manufacturer (see 2.2.3);
- The manufacturer has a Recognition Certificate confirming the ability of the organization to manufacture the declared products (see 2.8.11);
- The manufacturer has a Type Approval Certificate issued for the manufactured products, if it is prescribed by the Nomenclature (see 2.3.13);
- Technical documentation on the basis of which the materials and products are manufactured, has valid approval with the River Register (see 3.1.8, 3.1.9);
- The manufacturer assigned a person/persons authorized to control compliance with the requirements of the Rules, terms of the agreement and drawing up documentation.
submitted to the River Register (hereinafter the authorized person);

.6 An agreement on technical supervision during manufacture of materials or products is concluded between the River Register and manufacturer.

2.4.4 The manufacturer's authorized person controls compliance of the structures, properties, parameters and characteristics of the materials or products which are covered by the agreement, technical documentation approved by the River Register and requirements of the Rules.

Upon satisfactory results of control the authorized person sends a request on compliance to the River Register, the form of which is determined by the River Register and attaching the acceptance/check test reports.

2.4.5 Upon satisfactory results of review of the request on compliance and attached test results or other documents confirming compliance of the materials or products with the approved technical documentation and Rules, the River Register surveyor shall issue a Certificate (Form ÐÐ-8.1) or another type of the document for this type of the products if it is prescribed by the Rules.

2.5 TECHNICAL SUPERVISION IN THE FORM OF A TYPE APPROVAL (FORM ÏÒ)

2.5.1 In the cases specified in the Nomenclature (symbol ÏÒ in column 3), the Form of technical supervision ÏÒ is used during manufacture of the materials and products.

2.5.2 Technical supervision according to the Form ÏÒ includes performing the procedure of approval of the material or product type without further supervision of their manufacture.

2.5.3 The Form OP is used when meeting the following conditions:

.1 The manufacturer has a valid Recognition Certificate at the moment of material or product manufacture confirming ability of this organization to manufacture these products (see 2.8.11);

.2 The manufacturer has a Type Approval Certificate issued for the manufactured products and valid at the moment of material or product manufacture (see 2.3.13).

2.5.4 In order to confirm compliance of the welding consumables and their quality with the approved technical documentation as well as to confirm the possibility of using the Form OT, tests of these welding consumables are performed annually in the presence of the surveyor.

At annual tests of the welding consumables, the type approval tests shall be performed for the respective welding consumables, except for the tests for determination of the cold-cracking resistance and the sea water corrosion resistance of the weld metal and the welded joint.

A mark on the performed test shall be put on the back of the welding consumable approval certificate (Form PP-11.3).

2.5.5 Technical supervision according to the Form OT shall not be performed if the conditions specified in 2.5.3 and 2.5.4 are not met.

2.6 TECHNICAL SUPERVISION IN THE FORM OF RECOGNIZED DOCUMENTATION (FORM ÏÄ)

2.6.1 Technical supervision in the form of recognized documentation during manufacture of materials and products is used in the cases specified in the Nomenclature (symbol ÏÄ in column 3).

2.6.2 Quality control of the products according to the Form ÏÄ is performed by the manufacturer's quality control departments according to the approved technical documentation.

2.6.3 The Form OP is used when meeting the following conditions:

.1 Technical documentation on the materials or products has valid approval with the River Register (see 3 of these Rules);

.2 Materials and products comply with the approved River Register documentation.
2.6.4 In case of non-compliance of the materials and products with the approved documentation, the River Register does not allow to use them on the ships regardless of availability of the documents issued by the manufacturer.

2.7 TECHNICAL SUPERVISION PERFORMED BY ANOTHER CLASSIFICATION ORGANIZATION ON BEHALF OF THE RIVER REGISTER OR BY THE RIVER REGISTER ON BEHALF OF ANOTHER CLASSIFICATION ORGANIZATION

2.7.1 Technical supervision performed by another classification organization authorized for classification and survey of ships according to the laws of the Russian Federation, on behalf of the River Register or by the River Register on behalf of another classification organization is performed under an agreement on mutual substitution and/or according to a specific assignment.

2.7.2 The following shall be determined in the agreement on mutual substitution and/or assignment:

.1 items and scope of tests;
.2 applicable requirements of the Rules;
.3 procedure for technical documentation approval;
.4 issued documents;
.5 payment procedure for the work carried out within technical supervision.

2.7.3 During technical supervision performed by another classification organization on behalf of the River Register or by the River Register on behalf of another classification organization, certificates or other documents of the organization which performed technical supervision are issued for the items under technical supervision.

Unless otherwise specified in the agreement and/or assignment, certificates or other documents issued by the classification organization performing technical supervision on behalf of another classification organization, shall have the following mark:

On behalf _________________________
(name of the classification organization)
No.____ dated __________ 20____.

2.7.4 Unless otherwise specified in the agreement and/or assignment, the tests during technical supervision shall be performed using the methods and according to the River Register Rules.

2.7.5 Assignment on technical supervision from another classification organization is accepted by the Head Office. The Branch Offices carry out work on behalf of another classification organization only in case of the Head Office’s written instruction.

2.8 RECOGNITION OF ORGANIZATIONS

2.8.1 The River Register recognizes the organizations carrying out the following types of activities: design, construction, modernization, conversion, refitment and repair of ships, manufacture and repair of products, manufacture of materials to be installed on the ships. Furthermore, River Register recognizes the organizations carrying out works, the results of which are used by the River Register when performing classification, as well as the test laboratories performing tests required for construction of ships and manufacture of materials and products.

2.8.2 The conditions of the organization recognition by the River Register generally include the following:

.1 compliance of the test results performed according to the test program approved by the River Register with the Rules (for the following types of activities: construction, modernization, conversion, refitment and repair of ships, manufacture of products and/or materials for installation onboard the ships, repair of products, tests regulated by the Rules, survey of defects of ship’s components and shipborne facilities);

.2 availability of the resources in the organization to manufacture products, carry out works, render services complying with the Rules, as well as used methods for product quality control:
own or leased production areas (except for the cases when the works can be carried out without own or leased areas);
workers who are qualified for the works and tests prescribed by the Rules and/or approved technical documentation, production process (e.g., ultrasonic control and penetrant test specialists);
equipment (machines, bench equipment, welding equipment, test equipment, etc.) used by the organization to carry out the declared works as well as instruments;
approved technical documentation and production processes (see 3.1.10);
provision by the organization with the used production procedure, carrying out of the works or tests and internal control systems to provide appropriate level and stability of product quality, carrying out of the works and tests;
provision of reliable results of the inspections and tests by the organization by certification of test equipment, testing and calibration of instruments;
for the organizations assigning some of the production, design processes or tests to the concerned organizations (contract) — availability of documents which allow to provide monitoring and control of the assigned processes by the concerned organization (organizations) (contractors).

The clarified conditions for recognition of types of activities specified in 2.8.1, are determined in 2.8.3 to 2.8.7.

2.8.3 The organization engaged in activity specified in 2.8.1 shall submit the following establishing and registration documents according to national law of the country where the organization is registered:

for legal entities:
constitutive documents (charter, articles of association or provision, decision on assigning sole/another executive body);
a document (Certificate) confirming the fact of making an entry on the legal entity in the Unified State Register of Legal Entities (for organizations outside the Russian Federation — document confirming its registration as a legal entity of the respective state);
a certificate on registering the organization in a taxation body (for the organizations registered on the territory of the Russian Federation);

for individual entrepreneurs:
a document (Certificate) confirming the fact of making an entry on the individual entrepreneur in the Unified State Register of Individual Entrepreneurs (for an individual entrepreneur outside the Russian Federation — document confirming its registration as an individual entrepreneur of the respective state);
a certificate on registering the individual entrepreneur in a taxation body (for the individual entrepreneurs registered on the territory of the Russian Federation).

2.8.4 The following requirements additional to 2.8.2.2 are established for the organization constructing and repairing the:

1. availability of own or leased lifting facilities or equipment in the organization;
2. availability of welders with a Welder Approval Test Certificate (see 2.9);
3. availability of internal quality system in the organization for the carried out works including incoming inspection, functional inspection, outgoing inspection, periodic verification and/or calibration of instruments;
4. availability of the approved production processes for the works required by the Rules.

2.8.5 In addition to 2.8.2.2, the following requirements are established for the organization manufacturing materials and products to be installed on board the ships:

1. availability of welders with a Welder Approval Test Certificate (if the requirements to welding the structures and items are prescribed by the Rules);
2. availability of approved technical documentation with the help of which the materials and products are manufactured.

2.8.6 The following requirements additional to 2.8.2.2 are established for the specialized area (station) performing maintenance, inspection and tests of inflatable and personal life-saving appliances:

1. availability of the document of the inflatable life-saving appliance manufacturer
confirming the possibility to carry out these works according to its requirements (for inflatable life-saving appliances);

.2 availability of a closed, heated, ventilated and lighted room, the area and height of which provide the possibility of capsizing of the largest inflated rafts (or other efficient means for bottom inspection without raft capsizing shall be provided) and/or a room of the required height with a concrete floor for life-buoy tests. Temperature and moisture shall be controlled in the room;

.3 availability of a room for maintenance of the inflatable life-saving appliances equipped with:

- means and devices for maintenance of the life-saving appliances and release mechanisms according to the manufacturer's requirements to maintenance, inspections and tests of the inflatable life-saving appliances, including their gas inflation systems;
- materials and components for repair of the inflatable life-saving appliances, the quantity and quality of which shall be approved by the manufacturers.

The room for inspection and test of personal life-saving appliances shall be equipped with:

- a pool for flotation test. Water to test the life-saving appliances shall be fresh and shall arrive from a drinking water pipeline or shall be preliminary purified from suspended articles and oil products;
- a facility for strength tests;
- a set of calibrated loads of different weights when providing all the loading diagrams during the life-saving appliance tests;
- a compressor or an air pump for leakage tests;
- calipers and instruments to check the shape and linear dimensions of the life-saving appliances;
- pressure gauges and thermometers.

Places for separate storage of different types of life-saving appliances to be inspected, tested, repaired or delivered, shall be provided. Storage conditions shall comply with the manufacturer's requirements;

.4 availability of qualified personnel with the manufacturer's documents enabling to carry out works on maintenance and repair (for inflatable life-saving appliances);

.5 availability of a set of technical documentation required for maintenance, inspection and test of life-saving appliances.

2.8.7 Competency of the organization Branch Offices performing the tests prescribed by the Rules during construction, conversion, modernization and repair of the ships and floating objects, manufacture of the materials and products, repair of the products is checked during survey of these organizations.

Competency of legally independent testing laboratories performing the tests prescribed by the Rules is checked during their survey.

2.8.8 In order to receive a Recognition Certificate the organization sends a request to the River Register attaching reports with information (data) on compliance of the organization with the recognition conditions (see 2.8.2 to 2.8.7).

In case of detecting non-compliance of the organization with the recognition conditions at review of the submitted request and its attached information (see 2.8.2), the River Register refuses to perform survey of the organization by sending motivated causes of refusal in writing.

2.8.9 According to results of review of the request and its attached information in case of establishing their compliance with 2.8.2 to 2.8.7, the surveyor performs survey of the organization to evaluate its ability to carry out works/render services or manufacture products according to the requirements of the Rules, compliance of the organization with the recognition conditions specified in 2.8.2 to 2.8.6 as well as checking the data specified in the request and its attached information.

If the organization claiming to receive a Recognition Certificate assigns operations of the production process approved by the River Register (see 3.1.10) or tests prescribed by the Rules to other organizations (contractors), the River Register takes a decision on contractor survey. Contractor survey is performed by the organization claiming to receive a Recognition Certificate.
2.8.10 During survey of the testing laboratories (organization Branch Offices performing tests prescribed by the Rules during construction, conversion, modernization and repair of the ships and floating objects, manufacture of the materials and products, repair of the products), possibility of performing the test methods prescribed by the Rules is checked using the check tests performed in the presence of the surveyor according to the program approved by the River Register.

The scope of tests is established according to the requirements of the Rules. During survey of the organization manufacturing the materials and products, the River Register considers the test results of the items under technical supervision in this organization performed during approval of type material or product in the presence of the River Register surveyor not later than two previous days before the date of the organization survey.

2.8.11 According to results of the performed organization survey the surveyor draws up a Survey Report of the organization (Form PP-10.2) where the results of the performed survey and possible forms of technical supervision are specified.

According to results of review of the request and its attached information, as well as Survey Report, the River Register shall take a decision on issuing (refusing to issue) a Recognition Certificate for the organization for those types of works/services, the performance of which was confirmed during survey. The Recognition Certificate of the testing laboratories or organizations which have Branch Offices performing the tests prescribed by the Rules, specifies the list of tests for which the organization is recognized.

The Recognition Certificate is issued for those types of activities which are actually performed by the organization.

2.8.12 The period of validity of the Recognition Certificate is two years.

Upon expiry of the Recognition Certificate, the organization is subject to survey according to the procedure specified in the requirements in 2.8.8 to 2.8.11.

It is allowed not to submit the establishing and registration documents specified in 2.8.3 if they were not changed since last request submission. The report (see 2.6.8) shall include a reference to the previously submitted documents.

2.8.13 Compliance of the organization with the recognition conditions is checked in the following cases:

- violation of the requirements specified in 2.8.2 by the organization;
- amendment of technical documentation without approval with the River Register, if necessity of such an approval is established by the Rules;
- detection of inadmissible defects or violations of quality stability of the product manufactured by the organization;
- performance of works or tests with violated requirements established by the Regulations for Classification and Rules or submission of unreliable information on the results of the performed works or tests to the River Register;
- decrease of manufacturing facilities in the organization as well as other changes in the result of which performance of works by the organization for which a Recognition Certificate was issued, according to the requirements of the Rules becomes impossible;
- detection of deficiencies in the work of the organization when performing technical supervision in the organization.

Compliance with the recognition conditions is not checked for the organizations designing the ships. In case of repeated detection of previously detected violations which were not eliminated by the design organization during review of design documentation by the River Register, the River Register sends a notification to the design organization on the necessity of remedial actions aimed at increase of quality of the design works with further notification of the River Register on the taken actions. The Recognition Certificate is invalidated in case of detection of the deficiencies specified in the notification which were not eliminated.

In case of detecting a ground to check compliance with the recognition conditions,
the River Register notifies the organization on the performed test and its terms.

2.8.14 According to results of checking compliance of the organization with the recognition conditions, a report is drawn up, on the basis of which the River Register takes one of the following decisions:

.1 confirm validity of the Recognition Certificate;

.2 recommend remedial actions to the organization in the terms approved by the River Register on elimination of the detected deficiencies in the activity of the recognized organization and their consequences;

.3 suspend the Recognition Certificate for one or several types of activity for which the Certificate is issued, if the remedial actions specified in 2.8.14.2 were not taken within the terms approved by the River Register during the approved period for the remedial actions;

.4 cancel the Recognition Certificate for one or several types of activity for which the Certificate is issued, if the remedial actions were not taken within the terms approved by the River Register.

.5 cancel the Recognition Certificate, if:

the works, for which the Recognition Certificate was issued, are carried out with defects;

the works or tests are carried out with violation of requirements specified by the Rules;

decrease of manufacturing facilities in the organization as well as other changes in the result of which performance of works by the organization for which a Recognition Certificate was issued, according to the requirements of the Rules becomes impossible.

The River Register controls implementation of the remedial actions within the terms approved by the organization. According to results of the check, a report is drawn up which serves as a basis to suspend, confirm or cancel the Recognition Certificate.

In case of cancelling the Recognition Certificate for one or several types of activity, specified in the Certificate, the Recognition Certificate for the works, for which the Certificate was cancelled, is issued again according to the procedure specified in this section to receive the Recognition Certificate.

2.8.15 During validity of the Recognition Certificate, the organization:

notifies the River Register on any changes in its activity specified in the Recognition Certificate within 2 weeks;

provides access for the River Register to information on measures taken to provide quality, test procedures, tests, equipment, reporting documents and statistical data related to own activity specified in the Recognition Certificate.

2.8.16 The Recognition Certificate is reissued in the following cases:

.1 reorganization of the legal entity in the form of a transformation;

.2 change of the organization name or legal address, or of the individual entrepreneur name or place of residence not changing actual address where works are carried out;

.3 increase of scope of the works for which the Recognition Certificate was earlier issued;

.4 exclusion of the operations for which the Recognition Certificate was earlier issued.

2.8.17 The basis to reissue the Recognition Certificate in the cases specified in 2.8.16.1, 2.8.16.2 and 2.8.16.4 is a written request of the organization with the Certificate attaching copies of the documents which confirm the specified changes as well as the original valid Recognition Certificate.

The basis for reissue of the Recognition Certificate in the case specified in 2.8.16.3 is the procedure of the organization recognition according to 2.8.8 to 2.8.11.

A new number is assigned to the reissued Recognition Certificate. Validity period of the reissued Recognition Certificate starts from the date of its signing and is not extended.

2.9 WELDER APPROVAL

2.9.1 The conditions of receiving the Welder (Operator) Approval Test Certificate
for the following works are given in this chapter:

1. welding of hulls;
2. welding of ship's pipelines;
3. welding of ship boilers and pressure vessels;
4. welding of defects in forgings and castings.

2.9.2 To receive the Welder Approval Test Certificate the welder shall pass tests which include checking of his theoretical and practical knowledge. Approval tests shall be performed according to the procedure specified in Appendix 7.

The approval test of a welder may be combined with the qualification tests at the place of the welder’s work or training.

2.9.3 A request to receive the Welder Approval Test Certificate shall include the following data: full name, year of birth, place of work, date and place of certification issue. A copy of the welder’s certification, a report on work experience as a welder, copies of certificates on welding consumables and base materials of the samples which shall be used for operational tests are attached to the request.

2.9.4 Materials for manufacture of the samples shall be approved by the River Register and have relevant certificates.

Test assemblies shall be welded using welding consumables and procedures approved by the River Register.

2.9.5 If malfunctions of equipment (voltage drop, de-energising etc.), peeling of an electrode coat or other defects not depending on the welder, occur during the welding of test assemblies, the same number of test assemblies shall be re-prepared.

2.9.6 A protocol shall be drawn up on the basis of the test results. The protocol shall be signed by the surveyor who participated in the tests.

2.9.7 Upon satisfactory results of the tests the River Register issues a Welder Approval Test Certificate (Form PP-1.23), confirming welders’ approval for welding operations specified in 2.9.1 with the determined conditions (material, welding method, welding position).

The validity period of the welder approval certificate is two years.

2.9.8 The Certificate becomes invalid in the following cases:

1. If during validity of the Certificate the welder did not perform welding operations on the items under technical supervision of the River Register specified in the Welder Approval Test Certificate for more than six months in a row;
2. If during technical supervision (record in the Notice) the River Register determined that more than 10% of the welds performed by the welder do not meet the requirements of the Rules.

2.9.9 Confirmation of the works performed by the welder and specified in the Certificate shall be a record on the back of the Certificate by the welder’s senior or authorized employee of the employer confirming that the welder performed the works specified in the Certificate according to the requirements of the Rules during the last six months from the date of the last record or Certificate issue. This record is made every six months.

2.9.10 To receive a new Certificate, the welder shall pass the approval tests according to 2.9.2 to 2.9.7.
3 REVIEW AND APPROVAL OF TECHNICAL DOCUMENTATION

3.1 GENERAL

3.1.1 Technical documentation on construction, conversion, modernization and repair of the ships, manufacture of the materials and products, repair of the products as well as software applications used for designing are approved by the River Register to check compliance with the requirements of the Rules.

3.1.2 Technical documentation shall be submitted to the Head Office (see 1.3) or Branch Office (see 1.4) in the geographical boundaries of which the design organization operates. Technical documentation shall be submitted in the form of originals or copies signed (confirmed) by the organization which is the developer of technical documentation.

3.1.3 If documentation has engineering solutions providing the same level of safety which would be provided by compliance with the requirements of the Rules (equivalents), the organization developing technical documentation submits a list of these solutions with their contents and technical justification to the River Register.

3.1.4 Documentation shall be submitted for review in the scope which allows to ensure that the requirements of the Rules are met. For the standard list of technical documentation submitted for review to the River Register, see Appendix 8.

3.1.5 The design organization upon agreement with the River Register may select one of the following ways of technical documentation submission to the River Register for approval:

1. in two stages: first, documentation in scope of technical design and then detailed documentation shall be submitted;
2. in one stage: technical documentation shall be submitted in the scope which includes all the required data, provides the possibility to determine compliance of the designed ship or products with the requirements of the Rules and provides technical supervision during manufacture of the main structural assemblies (detailed design).

3.1.6 Documentation shall be submitted for review in two copies. One copy - in paper media, second copy - in electronic media (hereinafter the River Register copy) attaching paper design document list drawn up according to 3.1.7.1.

Detailed documentation (see 3.3) shall be submitted for review in one copy.

3.1.7 The following requirements shall be applied to the submitted documents:

1. documents in paper media shall:
   have the required signatures (at least of the developer and approver);
   be made in a legible manner;
   be free of erasures, postscripts, crossed out words and other corrections which were not specified;
   be free of damages, the presence of which does not allow ambiguous interpretation of the document contents;
2. documents in paper media shall:
   be in PDF (PDF/A);
   have built-in fonts used during designing;
   have a separate page for each drawing;
   have the drawing name or its name in the list of documents in the file names.
3.1.8 The period of validity of approval of technical documentation and software applications is six years. Upon expiry of this period or if the interval between the dates of approval of technical documentation and start of ship construction, manufacture of the materials and/or products exceeds three years, technical documentation shall be subject to reapproval in order to consider the changes in the Rules entered during the specified period.

Approval of technical documentation for repair, conversion or modernization of the ships as well as for repair of the products is performed without time limitation.

3.1.9 Validity of approval of technical documentation shall expire in the following cases:

1. if the interval between the dates of approval of technical documentation and start of the ship construction, manufacture of the materials and/or products exceeds three years;
2. amendment of the requirements prescribed by the Rules with respect to the ships, materials and products to be installed on the ships;
3. amendment of the previously approved technical documentation without approval by the River Register.

3.1.10 Production processes of construction and repair of the ships, manufacture of the materials and products shall be subject to approval by the River Register if the Rules establish the requirements with respect to process operations or production processes.

3.1.11 The production process shall specify the following: a list of operations, equipment, materials (in the cases prescribed by the Rules), control/test methods, instruments and correction methods (in the cases prescribed by the Rules).

The production process of assembly and welding of the ship structures and hull shall include the following:

1. description of the welding techniques and characteristics of the used welding equipment, production accessories and welding consumables during construction or repair of the hull;
2. block and section plans of construction or repair of the hull;
3. principal assembly and welding procedure of the type panels, two- and three-dimensional sections and blocks as well as hulls on slipway specifying the sequence of assembly-welding works, welding methods and conditions;
4. guidelines for welding procedures.

3.1.12 Approval of technical documentation by the River Register shall be drawn up by stamping the drawings or documents with numbers and dates of a conclusion letter.

The stamp samples shall be approved by the Head Office.

3.1.13 Approval of technical documentation by the River Register structural unit shall be valid for all River Register Branch Offices. This approval can be cancelled or changed only by the Branch Office which approved the specified technical documentation or by the higher (as to subordination) River Register Branch Office.

Technical documentation approved by one of the River Register Branch Offices shall be accepted by other Branch Offices for technical supervision without additional approval if by conditions of works during technical supervision of the River Register in a specific organization, correction or entering changes in the specified technical documentation is not required.

3.1.14 Changes entered by the developers in technical documentation previously approved by the River Register shall be approved by the River Register structural unit which reviewed technical documentation except for the cases specified in 3.1.13.

3.1.15 Changes entered in technical documentation during construction, conversion, modernization and repair of the ship, manufacture, repair of the product or manufacture of the material in the production process, shall be approved by the River Register Branch Office which approved the specified documentation or Branch Office which performed technical supervision. The Branch
Office which performs technical supervision may submit critical decisions for review and approval to the River Register Branch Office which approved the specified documentation.

The changes approved only for a specific item, do not apply to the next items without preliminary review and approval by the River Register.

Permission to deviate from technical design, detailed documentation, technical documentation on the materials or products, production process, shall be drawn up with a permission map for deviation (Appendix 9) with a reference to the Branch Office letter or approved document of the River Register.

3.1.16 During review of technical documentation, the River Register does not check correctness of computing operations used during calculations, including programs approved by the River Register. The River Register reviews the end results of calculations. The calculations shall be made according to the guidelines of the Rules or methods approved by the River Register.

In specific cases the River Register additionally examines reliability of the end results of calculations.

3.2 TECHNICAL DESIGNS OF THE SHIPS

3.2.1 Technical designs of the ships shall be submitted for review by the Head Office or Branch Office with an accompanying letter and a full list of documents submitted for review.

3.2.2 Designs can be submitted in separate parts (hull, machinery and electrical) upon agreement with the River Register. The first part of the documentation shall be submitted with the specification and general arrangement plans.

If according to the results of reviewing other parts of documentation remarks requiring corrections of the previously approved part are made, this part shall be corrected and approved by the River Register.

3.2.3 For the new types of ships, for which the requirements are not available or not fully covered in the Rules, the River Register may request additional documents and data as deemed necessary by the River Register.

3.2.4 The time for review of technical designs submitted for review in the scope prescribed by the Rules shall not exceed 30 working days.

3.2.5 For each reviewed design or entered changes the River Register shall draw up a written opinion.

If the River Register refuses to approve the design, the Register shall specify the grounds of refusal and its remarks in the reporting letter.

The reporting letter on design approval shall specify ship class, navigation area and freeboard depth as well as the list of approved documents and stamps on them. If required, restrictions on wind and wave conditions, type of carried cargo, etc. shall be specified. Then remarks (if any) subject to elimination during correction of the design or during development of the working drawings shall be specified.

The list of approved documents and stamps on them shall be specified in the reporting letter on approval of changes or additions entered in the documentation of the technical design approved by the River Register.

3.2.6 Approval of technical designs by the River Register submitted in paper media shall be drawn up by stamping the drawings or documents (see 3.1.12).

3.2.7 The River Register shall send the set of approved technical designs in paper media with the conclusion to the developer.

3.2.8 Technical designs on construction of a ship with expired approval (see 3.1.8, 3.1.9.1) shall be subject to correction in order to consider the changes in the Rules entered since design approval. The design submitted for review shall include an explanatory note with analysis of the design compliance with the Rules (changes) introduced after previous review of the design. In case of design non-compliance with the requirements of the Rules, the grounds of practicability on bring-
ing the design in compliance with the Rules or substantiating maintaining separate technical solutions on the initial design shall be specified in the same document.

It is allowed to include drawings from the set of detailed documentation in the designs submitted for re-approval. A notice on cancelling or restricting the use of the previously approved working drawings shall be submitted with new drawings of detailed documentation.

3.2.9 The procedure of review and approval of technical designs shall be also applied to technical documentation submitted to the River Register in one stage.

3.2.10 The Head Office reviews the designs approved by the Branch Office by the way of control. In this case at request of the Head Office, the Branch Office sends a copy of the approved design for check review, after which the design together with the conclusion is returned to the Branch Office by the Head Office. The Branch Office shall inform the design organization on the Head Office conclusion in case of remarks and provide control over elimination of the remarks.

3.3 DETAILED DOCUMENTATION

3.3.1 The conditions of the detailed documentation review (place, time, procedure and method of document preparation) shall be determined by the design organization upon agreement with the Branch Office.

3.3.2 Detailed documentation is prepared according to the technical design approved by the River Register considering the requirements of the Rules and national standards, if their use is mandatory according to the Rules.

3.3.3 Approval of the detailed documentation and changes entered in the specified documentation shall be drawn up in the form of a reporting letter. The approved detailed documentation shall be stamped (see 3.1.12). The stamp on approval shall be put on the first page of the document after elimination of all the remarks of the Branch Office.

3.3.4 The designer signs all the copies of the detailed documentation approved by the Branch Office.

3.3.5 After repeated approval of the technical design (see 3.2.8, 3.3.7), the detailed documentation shall be corrected.

The detailed documentation issued under a new number shall be approved by putting a stamp on it and the corrected documentation with the same number shall be approved by putting a stamp on the notice on change.

3.3.6 If approval of the detailed documentation, newly developed or corrected by results of re-approval of the technical design, the developer shall issue a list of materials of the detailed design approved by the Branch Office. Marks on the date of approval of each document shall be put on the list.

3.3.7 Anonymized documentation developed according to national standards is subject to approval by the Branch Office as part of the detailed documentation.

3.4 TECHNICAL DOCUMENTATION ON THE MATERIALS AND PRODUCTS

3.4.1 The River Register reviews and approves technical documentation on manufacture of the products and materials, repair of the products included in the Nomenclature. If the designer (developer of technical documentation) takes decisions in the technical documentation submitted for review and these decisions do not comply with separate requirements of the Rules, then grounds confirming that the taken decisions are of same efficiency as the decisions prescribed by the Rules from the point of view of safety shall be submitted for review by the River Register as part of technical documentation.

3.4.2 Technical documentation on manufacture of the products shall be submitted for review by the River Register according to 3.1.6.

For the standard list of the submitted documentation, see Section 5 of Appendix 8. Technical conditions or documents replacing
them (hereinafter technical conditions) shall include the following:

- description of the product characteristics;
- requirements of environmental protection;
- acceptance rules;
- operating instructions.

The "Description of the product characteristics" section includes the main parameters and characteristics (properties) of the product, scope of application, requirements to the materials, completeness and marking.

The "Requirements of environmental protection" section includes the requirements on product recycling.

The "Acceptance rules" section includes the product control procedure by the manufacturer's quality control departments and the scope of the submitted batches.

The "Operating instructions" section includes instructions on product installation at place of its operation/use and operating conditions, if such requirements are prescribed by the Rules as well as the parameters and characteristics of the product subject to operation inspection established by the manufacturer.

The submitted test program specifies the test procedure, the necessity of which is prescribed by the Rules, as well as test conditions and instruments.

3.4.3 If the materials and products (their parts) for the ships are designed and manufactured according to the requirements of national standards (see 2.1.5), then the documents subject to approval are the documents specified in Appendix 8: calculations, general arrangement drawings and drawings of critical parts, assembly drawings, schematic diagrams, test programs, etc.

3.4.4 Technical documentation on the assemblies or units, which include the components specified in the Nomenclature and delivered by the contractors (generators, reduction gears, prime movers of generators, compressors, pumps, deck machinery, automation systems, etc.) shall be approved after approval of technical documentation on the components.

The River Register approves technical documentation on the assembled product in case of availability of non-approved technical documentation on the materials and components, if the results of the functional, mechanical and climatic tests of these components as part of the assembled products and their electromagnetic compatibility tests (for electrical equipment) are recognized by the respective requirements of the Rules.

3.4.5 If the products are not developed as standard products, and they are developed for a specific ship, technical documentation on them is reviewed by the River Register as part of the ship's technical documentation.

3.4.6 Technical documentation on manufacture of the materials shall include data on the method of manufacture, chemical composition, mechanical and technological properties, scope and procedure of control and acceptance, drawing up the test results and marking procedure.

Test types, methods of control and rules of acceptance are established according to Part X of RCCS.

The test program shall be submitted together with technical documentation.

3.4.7 Review of technical documentation submitted in the scope prescribed by the Rules for one type of material or product shall not exceed 15 working days.

3.4.8 According to results of reviewing technical documentation (changes in the previously approved technical documentation) on the materials or products the River Register draws up a reporting letter. The reporting letter on approval of technical documentation or changes in the documentation includes a list of approved documents and stamps put on them (3.1.12).

3.4.9 The River Register shall send the set of approved technical documentation in paper media with the reporting letter to the developer.

3.5 SOFTWARE APPLICATIONS

3.5.1 Software application in this chapter means a set of connected program, graph and
text modules intended for solving the set calculation task using a computer.

3.5.2 Software applications intended for calculations according to the requirements of the Rules shall be subject to approval by the River Register.

The River Register takes into consideration software products used to ease computation, the possibilities of which are limited by calculation techniques or an application used to determine auxiliary values when developing technical documentation without approval.

3.5.3 In order to receive the software application approval certificate, the following materials shall be submitted to the River Register:

1. distribution disk or application demo;
2. user manual which includes requirements to computer configuration, information on the authors, description of input and output forms;
3. detailed description of the calculation methods implemented in the application with submission of all the used equations, their applications, specifying empirical coefficients, methods of solving computational tasks and in justified cases — convergence criteria, restrictions on scope of application, etc.;
   This description shall include correspondence analysis of the calculation method implemented in the application as well as accepted assumptions to the requirements of the Rules and references to literary sources;
4. test/check examples of calculations with a complete list of source data and explanation of features of their selection, all output forms and interpretation of calculation results.

Reliability of calculations made using the specified application may be checked by making calculations on initial data of the test task issued by the River Register and further comparison of summary data with the calculation results made using a reference application or results of full-scale and/or model experiments.

Test examples shall cover the whole range of possible use of the main parameters.

Information on recognition of this application by other classification societies or other competent organizations may be also submitted to the River Register. In these cases upon agreement with the River Register, the scope of the submitted materials may be reduced.

If the application considers the requirements of the Rules, it is necessary to mention this circumstance and provide a reference to the year of publication of the Rules.

Documentation shall have a number, name and shall be registered according to the established procedure.

3.5.4 Upon satisfactory results of review and check of the submitted application according to the requirements of these Rules, the River Register shall issue a software application approval certificate (Form ÐÐ-8.4).

3.5.5 If calculations included in technical documentation and made using software application with an approval certificate are submitted to the River Register, a reference to the number of Certificate issued by the River Register shall be given in the respective place.

3.5.6 If changes affecting approval are entered in the program modules of the application by its developer, the software application approval certificate may be cancelled by the River Register irrespective of its validity.
4 TECHNICAL SUPERVISION
DURING CONSTRUCTION AND REPAIR OF SHIPS

4.1 GENERAL REQUIREMENTS

4.1.1 The procedure of check tests of the items under technical supervision, types of inspections and tests are specified in the List (see 2.3.1).

4.1.2 Prior to installation of the engines and other technical facilities, devices, systems, equipment and supply the surveyor checks if the specified items have documents specified in 2.2.6.

4.1.3 Upon completion of hull works, installation of the engines and other technical facilities, devices, systems, equipment and supply the surveyor performs technical supervision during mooring and running trials per program developed according to the requirements of the Rules and design documentation of the ship approved by the River Register.

4.1.4 The program of mooring and running trials considers the requirements of technical documentation on the products as well as manufacturer's test programs for the products installed on the ship.

In case there are test methods approved by the River Register, the program of mooring and running trials shall include references to these methods.

4.1.5 The program of mooring and test trials shall be approved by the same Branch Office of the River Register which reviewed the materials of technical design.

4.1.6 The program of mooring and running trials includes the following sections:

1. preparation for trials;
2. mooring trials;
3. running trials;
4. inspection;
5. check sailing, check trials.

The surveyor participates in ship trials at all trial stages. During preparation for trials the surveyor checks the complete set of construction documents (manufacturer's acceptance certificates, test reports, construction book, quality control department's documents, etc.) and operating documents on the components.

4.1.7 Equipment control during trials is performed according to operating rules and operating manual.

4.1.8 The surveyor is not allowed to control equipment on his own or to interfere with the actions of the acceptance board (trial crew) assigned for trials. If the personnel's actions may lead to an emergency or damage of equipment, the surveyor may request to stop such actions through the representatives of the quality control department and person responsible for trials (responsible inspector).

4.1.9 During trials of the items under technical supervision all the works which interfere with trials or create a risk for the participants of the trials shall be stopped, the production areas near the item of trial shall be freed from foreign objects, lighting and ventilation shall be provided.

4.1.10 Mooring and running trials shall be performed according to the schedule approved by the surveyor.

4.1.11 If the trial results of the items under technical supervision do not comply with the
requirements of the Rules or approved documentation, they shall be subject to repeated trials after elimination of the causes which led to unsatisfactory results.

The methods of elimination of the defects and the scope of repeated trials shall be approved by the surveyor.

4.1.12 The possibility of interruption of the item trials in the modes which require continuous operation shall be considered in the test program and the matter of continuing the trials and their conditions (increase of length and scope) shall be approved by the surveyor considering the causes which led to stop of the trials.

4.1.13 During repeated forced interruption of one of the modes of continuous operation, the trials shall be stopped until elimination of the causes which led to interruption with further repeating of trials in full scope. Time of the trials shall be approved by the surveyor.

4.1.14 The trials of the items shall be interrupted in the following cases:

.1 in case of detection of faults or defects, elimination of which requires longer interruption than that specified in the program;
.2 in case of emergency state of the item;
.3 in case of deterioration of weather conditions which pose a threat to safety of the ship.

4.1.15 The decision on trial termination depending on the causes, requiring to stop the trials shall be taken by the ship constructor or customer. When detecting the cases specified in 4.1.14 the surveyor may request the person responsible for trials (responsible inspector) to stop the trials.

Irrespective of the person taking the decision to stop the trials, the item under technical supervision shall be subject to repeated trials, the length and scope of which shall be approved by the surveyor.

4.1.16 During termination of the item trials, a report shall be prepared specifying the causes of terminating the trials as well as requirements and measures on their elimination subject to performance before repeated trials.

4.1.17 Upon completion of the trials, an acceptance certificate with protocols and tables of acceptance tests shall be submitted to the surveyor for signing.

4.1.18 In case of ship construction in two or more shipbuilding organizations, the River Register documents shall be prepared by the surveyor who performed technical supervision during outfitting and trials of the ship.

The surveyor who performed technical supervision at initial stages of ship construction shall prepare a report on the carried out works with the list of the carried out works as per the List (see 2.3.5) and shall send it together with the certificates on the products, datasheets and files on the installed equipment to the Branch Office performing technical supervision during outfitting of the ship. The report shall include the required information to fill in the Certificates of seaworthiness and other documents of the River Register. It is not allowed to use the River Register forms to prepare a report.

4.1.19 Upon completion of the ship construction, availability of the fixed marking nameplates including the following information shall be checked:

.1 name, location and identification of the ship constructor;
.2 serial/hull number;
.3 year of ship construction;
.4 type of ship and its main parameters;
.5 project number (code);
.6 tonnage or passenger capacity;
.7 maximum capacity of main engines (for self-propelled ships);
.8 maximum speed (for self-propelled ships).

4.2 MOORING TRIALS

4.2.1 Mooring trials are performed to check the following:

.1 quality of the carried out hull works, location, complete set and quality of installation, adjustment and serviceability of the engines, devices, systems, equipment and supply as well as compliance of their parameters with
the requirements of the Rules and approved technical documentation;

2. readiness of the ship, its main and auxiliary engines, devices, equipment and supply for running trials.

4.2.2 Prior to start of mooring trials, the following shall be submitted to the surveyor:

1. documents certifying completion of installation and other works;
2. mooring trial program;
3. mooring trial plan subject to approval by the surveyor;
4. specification;
5. list of replacements equivalent to the requirements of the Rules (see 3.1.3), a permission map to deviate (see 3.1.15);
6. files and datasheets on ship machinery;
7. documents for devices;
8. description of items under technical supervision and maintenance instructions;
9. test procedures (including simulation with diagrams of simulators).

4.2.3 The date and time of mooring trials shall be determined by the ship constructor as approved by the surveyor.

4.2.4 Machinery, devices, equipment and systems which do not require running modes shall be checked and tested during mooring trials.

4.3 RUNNING TRIALS

4.3.1 Running trials shall be performed for the following:

1. to check the main parameters of the main engines and power plant as well as their compliance with the specifications;
2. to check operation of the power plant at maneuvering at ahead and astern running;
3. to check reversing properties of the main engines;
4. to check serviceability of the main engines and power plant under conditions close to operating conditions;
5. to check characteristics of manoeuvrability and controllability of the ship;
6. to check automation equipment under conditions close to operating conditions;
7. final check of the items except those which shall be subject to inspection and further check tests;
8. to check serviceability of deck machinery, devices, apparatuses, navigation, radio- and electrical equipment under conditions close to operating conditions;
9. to measure torsional vibration parameters of the system (engine - shafting - propeller) and vibration parameters of hull structures and technical facilities;
10. to confirm the possibility of assigning the River Register class to the ship prescribed by the project according to its purpose.

4.3.2 Prior to start of running trials, the following shall be submitted to the surveyor:

1. quality control department's documents certifying completion of mooring trials;
2. running trial program approved by the River Register;
3. running trial plan approved by the surveyor;
4. trial procedures;
5. information on the ship stability and floodability;
6. heeling test report and stability calculations (for the lead ship);
7. documents specified in 4.2.2.4, 4.2.2.5, 4.2.2.7 and 4.2.2.8.

4.3.3 After submission of the documents specified in 4.3.2 to the surveyor, as well as upon completion of mooring trials and elimination of the detected defects, a notice specifying the assigned date of running trials shall be sent to the surveyor.

The notice shall specify readiness of the ship for running trials and information on the quantity of participants of the trials, availability of collective and personal life-saving appliances and ship stores.

4.3.4 Upon satisfactory results of mooring trials, the surveyor shall confirm the possibility of ship sailing for running trials in writing.

4.3.6 The area of running trials and restrictions on weather conditions shall be approved by the surveyor for compliance with the conditions prescribed by the requirements of the
Rules and approved technical documentation. The area of running trials shall be safe, suitable for performance of the test program in full and to obtain reliable test results.

4.3.7 During running trials, operation of all the technical facilities, devices, systems and equipment shall be checked. The detected defects shall be eliminated and repeated trials shall be performed, if necessary.

4.3.8 The test results shall be recorded in the protocols and books specifying the values of the controlled parameters required to evaluate proper operation of technical facilities, devices, systems and other equipment.

4.3.9 Upon completion of running trials, the surveyor shall submit all the remarks detected during running trials to the organization in writing.

4.4 INSPECTION AND CHECK SAILING

4.4.1 Upon completion of running trials or trials in running mode without ship motion using simulation, elimination of remarks and meeting the surveyor’s requirements (see 4.3.9), the organization together with the surveyor shall prepare a list of items subject to inspection specifying the scope of works. The list shall be prepared considering the results of mooring and running trials as well as technical supervision of same type items.

4.4.2 During inspection, separate assemblies of the items under technical supervision shall be dismantled to determine their condition and necessity of check tests after inspection.

4.4.3 The inspection results shall be drawn up with a report with the following information:

- a list of the items under technical supervision subject to inspection;
- description of detected defects;
- causes of defects;
- a list of measures to eliminate the defects.

The surveyor shall sign the report only for the items under technical supervision of the River Register.

4.4.4 Prior to check sailing all the defects detected during mooring and running trials and detected violations of the Rules shall be eliminated.

4.4.5 Necessity of check sailing shall be approved by the surveyor. Check sailing is required in the following cases:

- Item under technical supervision was subject to inspection and check tests can not be performed without check sailing;
- Parameters describing proper operation of the item under technical supervision may be confirmed only during check sailing;
- According to results of mooring and running trials and/or inspection, complete replacement of the item or replacement of assemblies the serviceability of which was confirmed only during check sailing was required;
- The simulation devices do not allow to obtain the required modes or if such devices are not available.

4.4.6 Satisfactory results of mooring and running trials as well as check sailing shall be the ground for drawing up the River Register documents on the constructed ship.

4.4.7 If the ship is delivered to the customer by railway or other transport, the Branch Office which performed technical supervision during construction, shall assign register number to the ship, draw up a set of the River Register documents and send it to the Branch Office’s address in the area of operation of which the ship shall be operated. The report of initial survey shall specify the requirement on ship submission for occasional survey of the River Register Branch Office for registration.

The Branch Office in the area of operation of which the ship arrived, performs occasional survey with check test of the ship and its components in running mode, specifies the date of the next survey and registers the ship for classification of the Branch Office.
4.5 PECULIARITIES OF TECHNICAL SUPERVISION DURING TESTS OF PROTOTYPE SHIPS

4.5.1 Tests of the prototype ship are performed according to an extended program, compared to that of ships of a series, which includes checking the characteristics and determination of the parameters which shall be used for the ships of a series without such checks.

4.5.2 The trial program for the prototype ship include:
- 1. performing inclining test according to Part II of RCCS;
- 2. determining maneuvering capabilities;
- 3. measuring vibration parameters of the hull structures and separate items of ship equipment;
- 4. checking strength and seaworthiness at rolling (see 4.5.4);
- 5. measuring torsional vibration parameters of the system (engine-shafting-propeller);
- 6. running trials under conditions maximally close to operating conditions;
- 7. tests of the power plant in the scope larger than that for the ships of a series;
- 8. inspection in the scope larger than that for the ships of a series;
- 9. check sailing meeting the conditions of running trials.

4.5.3 Trials of prototype ships including pushed convoys in order to determine maneuvering capabilities as regards controllability and inertial properties shall be performed according to the procedure approved by the River Register.

4.5.4 Trials of prototype ships and ships of new structural types as well as ships with main dimension ratios outside the limits prescribed by the Rules shall be performed under design wind and wave conditions considering the following:
- 1. testing the ship and coupling strength with voltage measurement according to a specially developed program;
- 2. checking controllability at wind;
- 3. evaluating roll parameters;
- 4. general monitoring of the ship condition (wettability, operation of propellers and ship equipment at roll).

The specified tests are performed according to the program and within the terms approved by the River Register.

4.5.5 Upon completion of the prototype ship trials, the developer of the ship design shall determine the list of measures to be performed on the following ships of a series. This list shall be approved by the River Register.

4.5.6 In case of use of new materials, type specimens of products and equipment depending on the ship purpose, operational tests shall be provided according to the program approved by the River Register.

Operational test reports shall be submitted to the Branch Office within the approved terms after completion of the tests.

4.5.7 The necessity of performing operational tests shall not be an obstacle for drawing up and issue of the River Register documents for the ship.

4.6 PECULIARITIES OF TECHNICAL SUPERVISION DURING SIMULATION TESTS

4.6.1 The simulation tests shall be performed during construction of the ship series according to the procedure developed considering PД3Р.0202.

4.6.2 Expediency and methods of simulation tests shall be determined by the shipbuilding organization, designer and customer.

4.6.3 Simulation devices, methods of their fastening and their impact (vibration, etc.) shall not adversely affect the tested item or ship structures.

Adjustment of simulation devices and comparative tests shall be performed on the serial and prototype ships.

4.6.4 The requirements of this chapter do not apply to prototype ships and type specimens of items under technical supervision.
The purpose of joint simulation and full-scale tests on the prototype ships and standard items is evaluating the possibility of replacement of full-scale tests with simulation tests of the next serial items.

4.6.5 During simulation tests, all the control parameters of the tested item prescribed by the Rules shall be checked.

If simulation tests allow to determine only some of the parameters, other parameters shall be determined during full-scale tests.

4.6.6 In order to justify use of simulation methods, comparative tests (full-scale in open water and simulation) shall be performed on one ship with further analysis of their results, development and approval of operating program (procedure) of simulation tests for the ships of this series.

4.6.7 Comparative tests shall be performed according to the program (procedure) approved by the River Register.

4.6.8 The program (procedure) of comparative tests includes the following:
- 1. explanatory part which includes theoretical justification of the accepted simulation method of tests, diagrams (drawings) of simulation devices and their connections with the tested items, diagrams of training courses, information on quantity of the ships on which comparative tests are performed;
- 2. instructions on checking installation quality and requirements to tests in mooring mode;
- 3. instructions on performing simulation tests including instructions on control and measurement of the parameters as well as on providing values of the controlled parameters;
- 4. instructions on comparison procedure and on the required comparability of the parameters obtained during practical simulation and full-scale tests.

4.6.9 According to results of comparative tests on at least two ships, a document shall be drawn up and signed by the surveyor. The document shall include values of comparable parameters, information on test reproducibility and conclusion on possibility to perform simulation tests on the next ships of a series.

4.6.10 Simulation tests shall be performed according to the program (procedure) prepared by results of comparative tests and approved by the River Register.

4.6.11 The program (procedure) of simulation tests includes the following:
- 1. general provisions;
- 2. requirements to technical condition of the item submitted for tests;
- 3. requirements to technical condition of simulation device or other support device or equipment;
- 4. guidelines for preparation to tests and their performance including instructions on control and measurement of parameters. Values of the parameters which shall be obtained using simulation device shall be also specified;
- 5. diagrams of simulation devices and training courses;
- 6. instructions on control comparative tests and their intervals.

4.6.12 In case of use of simulation methods during tests of ship machinery and equipment after inspection the same simulation methods which were used to check items in running mode shall be used.

4.6.13 Check comparative tests using a complete program of full-scale tests shall be performed on serial ships tested using simulation methods in order to confirm reliability and stability of the results of simulation tests within terms approved by the River Register or on the ships with previously assigned hull number (e.g., each third, fifth, tenth, etc.)

The intervals (frequency) of comparative check tests shall be established by the shipbuilding organization considering stability of manufacture and installation quality of the items under technical supervision and reproducibility of full-scale and simulation tests.
4.7 PECULIARITIES OF TECHNICAL SUPERVISION DURING CONVERSION, MODERNIZATION AND REPAIR OF THE SHIPS

4.7.1 The River Register performs technical supervision during conversion, modernization and repair of the ships in service.

4.7.2 Technical supervision during conversion, modernization and repair of the ships is performed according to the approved technical documentation.

Technical documentation shall be submitted for approval for those parts of the hull, ship machinery and equipment which are subject to conversion, modernization, recovery or repair.

4.7.3 Technical documentation on repair shall be developed in the following cases:

The organization has no detailed or design documentation on the repaired ship, detailed or operating documentation on the repaired items under technical supervision

Impossibility to perform repair works on available technical documentation with respect to functionality of process equipment or technologies (production, control and test) which exist in the organization.

4.7.4 Technical supervision during conversion, modernization and repair of the ships is performed on a contract basis.

4.7.5 At technical supervision during repair of the ships the requirements of these Rules shall be met as regards the following:

.1 Nomenclature;
.2 procedure of design documentation approval (see 3 of these Rules);
.3 scope of technical supervision (type of inspections and trials, including mooring and running trials);
.4 use of materials and welding;
.5 scope of technical documentation submitted for review by the River Register.

4.7.6 Scope and methods of repair determined by the ship repair organization shall be approved by the surveyor.

4.7.7 Fault detection of the ship components shall be conducted by the ship owner considering the requirements of the Rules or standards specially developed for the ships of this project and related to determination of technical condition (see Appendices 2 to 4 to RSSS).

4.7.8 The results of check tests of scope and quality of the works carried out during technical supervision during conversion, modernization and repair of the ships, remarks and requirements of the surveyor shall be drawn up in the form of the documents prescribed by these Rules.
5 HULL AND HULL EQUIPMENT

5.1 GENERAL REQUIREMENTS

5.1.1 This section establishes requirements on technical supervision during manufacture of metal, reinforced concrete and plastic hulls as well as superstructures and wheelhouses irrespective of their participation in global bending of the hull.

5.1.2 Procedure and scope of inspections and tests of hull structures shall be determined according to the List (see 2.3.1) developed considering the peculiarities of production processes, methods of hull and superstructure construction, welding methods, control methods accepted in this shipbuilding organization.

5.1.3 At technical supervision of construction quality of hull structures the following shall be checked:

.1 availability of the certificates on flat steel, strip bar, profile iron, bar iron, pipes, cast and forged products, documents on welding consumables;

.2 compliance of data specified in the certificates and other documents on the materials, requirements of the Rules and technical documentation approved by the River Register as regards checked structure;

.3 compliance of the steel grade, material grade and cast number specified for the parts with the certificate data. If cast number for the parts is not available or replaced with a symbol, it shall be determined by the documents according to the procedure applicable in the organization;

.4 compliance of the material grades with the drawing requirements.

5.1.4 Visual examination is required to check the following:

.1 compliance of the structure of the item under technical supervision with the drawings and technical documentation, alignment, mating and connection of parts, assemblies and other components, quality of machining and established structural requirements;

.2 meeting the requirements of the Rules related to the item under technical supervision;

.3 absence of visible defects and deviations from the product shape, quality of removal of temporary mounting parts and facilities;

.4 compliance of the welded joint type and parameters of the completed weld with the requirements of the drawing and welding table, absence of external defects.

5.1.5 The following structural parameters are subject to random checks for compliance with the values specified in the drawings:

.1 thickness of parts made of sheet material;

.2 dimensions of parts of welded and rolled beams, knees, stiffeners, foundation components, coamings, shelves;

.3 distance between framing beams;

.4 distance between welded joints and beams, ends of knees;

.5 spaces between weld joints;

.6 dimensions of cutouts, distance between them, distance from the part and support edges, spherical radii;

.7 beam cuts, noses, gaps at ends;

.8 values of thickness variation, shifts of members and parts;

.9 straightness of members, angles of connecting to blades and beams;

.10 values of residual deformation parameters (bulges, dents, corrugations, ribbing
of panels and other construction welding deformations) which shall be within limits specified in production documentation (Appendix 8);

1.1 dimensions of weld structural components (weld width, shape and height of strengthening, weld leg, length and pitch of intermittent welds);

1.2 dimensions of structural components of rivet joints (width of laps and angle bar faces, pitch of rivet joint, distance between rows of rivets and from rivet axis to the plate edge, dimensions of the rivet components).

5.1.6 When checking quality of welding operations, the surveyor shall refer to the requirements of Part X of RCCS.

5.1.7 At periodical inspections of the organization welding industry (see 2.3.5) the surveyor shall check the following:

1. quality of welding consumables;

2. welding methods;

3. qualification of welders and specialists of non-destructive testing (see 2.8.2.2);

4. preparation of connections for assembly and welding, quality of tacks of the welded joints and welds;

5. meeting the technology including protection against bad weather conditions;

6. methods and scope of quality control of the welded joints.

5.1.8 During technical control according to the List, make sure that the welds have no defect in the form of: cracks in the weld and weld area, unfilled craters, preparation not filled with metal, shifts and narrowing of welds, slag, metal (tungsten), oxide and flux inclusions on the weld face, holes, pores, cavities, low spots between beads, saddles, piling and ripple, undercuts, not smooth transition of the weld to the base metal, irregular shape of the weld.

5.1.9 The surveyor shall check quality of the welds made by the organization personnel using non-destructive testing, if it is prescribed by the Rules. The following shall be checked:

1. availability of the approved monitoring diagram of the welds;

2. compliance of the control method approved by the River Register;

3. compliance of the quantity of the tested areas of the welds and their location with the monitoring diagram considering additional and check tests.

4. test results according to the documents of the organization.

5.1.10 Radiographs and gammagrams, reports on ultrasonic testing shall be subject to random checks. The welds shall be opened to determine the types of defect.

5.1.11 Hull tightness tests shall be performed according to the test patterns approved by the River Register and developed according to Appendix 10.

5.1.12 At technical supervision during hull tightness tests the following shall be checked:

1. preparation of a room (compartment) for testing;

2. methods and conditions of trials;

3. coverage of the structures and welds by the tests;

4. sequence and procedure of process operations and functional inspection by the organization;

5. accuracy of tightness estimation;

6. quality of elimination of unsound spots.

5.2 TECHNICAL SUPERVISION DURING MANUFACTURE OF ASSEMBLIES, SECTIONS AND BLOCKS

5.2.1 During manufacture of structural parts, assemblies, sections and blocks, it is necessary to perform functional inspection and stage-by-stage control established by the production processes and standards.

5.2.2 Test benches, jig plates, beds and other equipment prior to assembly shall be preliminary calibrated to provide permitted accuracy of the overall dimensions of the assemblies, sections and blocks, smoothness of their outlines according to the drawings and ordinates removed from mold loft.

5.2.3 During construction of the serial ship hulls, technical supervision at this stage in-
cludes periodic examinations of the manufactured sections and separate assemblies. Their tests are performed at the following stages of hull construction: as part of blocks, sections, hull parts in pre-slipway positions or as part of the hull on the slipway.

5.2.4 The following shall be performed at technical supervision during construction of sections:

.1 material test according to 5.1.3;
.2 external examination of sections according to 5.1.4, components of welded structures according to 5.1.8;
.3 checking dimensions according to 5.1.5;
.4 flaw detection of the welds according to 5.1.9;
.5 checking the conditions and results of the tightness tests according to 5.1.11 and 5.1.12.

5.2.5 Completely ready sections and separate assemblies shall be supplied to the places of block formation accepted by the organization’s quality control department and after the surveyor’s inspection if prescribed by the List.

5.2.6 Blocks shall be submitted for inspection according to the List after completion of the assembly-welding and fitting works as well as tightness tests.

5.2.7 At technical supervision during construction of blocks, make sure that:

.1 Quality of installation of sections included in the blocks provides continuity of the hull. Coupling of the longitudinal members determining global strength is carefully checked;
.2 Use of bottom-hole parts and assemblies improves the quality of intersection connections;
.3 Allowances in the sections, bottom-hole parts and assemblies are within tolerances established by technical documentation, cuts in the places of intersection connections allowing to make high quality butt welds;
.4 Field connections on the hull plating are welded first on the inside and then after removing weld root — on the outside of the hull;
.5 Deformation parameters do not exceed values specified in Appendix 11.

5.3 TECHNICAL SUPERVISION DURING CONSTRUCTION OF THE METAL HULL ON THE SLIPWAY

5.3.1 Sections and assemblies shall be supplied to the slipway completely ready and accepted by the shipyard’s quality control department and inspected by the surveyor if prescribed by the List.

Sections and blocks shall be checked for compliance with the approved technical documentation. The necessity and procedure of installing temporary reinforcements and parts, the values of allowances on mounting edges to provide proper quality of the slipway assembly by the River Register shall not be determined.

5.3.2 At technical supervision during the slipway assembly the surveyor shall check the following:

.1 proper installation of sections and blocks relative to the slipway base lines and previously installed sections and blocks;
.2 proper coupling of sections by plating and by members and preparation of intersection connections for welding;
.3 dimensions and quality of welds;
.4 values of welding deformations of the hull, superstructures and quality of deformation flattening (see Appendix 11).

5.3.3 If the sections or blocks were inspected and tested during their manufacture, the scope of technical supervision shall include inspection to make sure that there are no damages in the result of transportation and installation.

5.3.4 Hull spaces shall be submitted for inspections and tests according to the List after completion of all the works on assembly, welding, riveting and flattening as well as installation of all the saturating parts connected directly to the hull structures. The structures adjoining to the checked space, shall be finally welded at a distance of at least 1 m from this space.
5.3.5 During detection of cracks in the hull structures the surveyor shall notify the organization and check the structure condition. During detection of cracks, measures shall be taken on detection and elimination of the crack causes. Hull works in the areas specified by the surveyor shall be stopped. The damaged structures shall be removed from the hull or shall be corrected with complete removal of cracks according to the technology approved by the Branch Office.

5.3.6 When analyzing the results using non-destructive testing, straining ties and areas subject to vibration as well as quality of fillet and T-butt welds, welding of which is prescribed by full penetration shall be checked. Tightness tests of the welds shall be combined with tightness tests of the hull according to the diagram approved by the Branch Office. Tightness test results of the welds performed prior to hull testing, shall be checked according to the organization's documents.

5.3.7 At technical supervision during construction of the hull on the slipway, the surveyor shall check sequence of hull formation as well as tests of the hull position on the slipway and keeping slipway log by the organization.

5.4 TECHNICAL SUPERVISION DURING CONSTRUCTION OF REINFORCED-CONCRETE SHIPS

5.4.1 During technical supervision of a ship under construction, the following shall be checked:
.1 quality of the materials used for hull construction according to the certificates and laboratory analysis data;
.2 quality of the reinforced steel billets, proper manufacture of reinforcing cages and fabrics, installation and attachment of fittings with embedments and line ups;
.3 proper dosage of the concrete components, quality of concrete preparation, its laying and vibration compaction;
.4 compliance with temperature and moisture conditions, concrete hardening time as well as concrete strength before removal of the sections from the matrices;
.5 compliance of sections with the design requirements after their removal from the matrices and drawing up datasheets or logs of sections;
.6 readiness of the slipway, its leveling and markings;
.7 proper section installation on the slipway, installation, welding and grinding of bar joints, installation of embedments and line ups in field joints, preparation of the section edges for concreting;
.8 proper concreting of bar joints, concrete quality, compliance with temperature and moisture conditions at its hardening;
.9 compliance of the hull components with the design prior to its shift from the slipway position. The hull shall be inspected outside and inside and the dimensions of these components shall be checked. Prior to shift, concrete strength of bar joints shall be checked.

5.4.2 During manufacture of solid reinforced-concrete hull, proper installation of the formwork and thickness of the protective layer, obtaining the required temperature and moisture conditions at curing of concrete and time of formwork removal shall be checked.
At intervals in concreting, readiness of the surfaces of the previously laid concrete shall be checked.

5.4.3 At technical supervision during tests, the reinforced-concrete ship hull shall be checked according to the test patterns approved by the Branch Office and developed according to the methods and scope of tests as per GOCT 5 R.0276.

5.5 TECHNICAL SUPERVISION DURING CONSTRUCTION OF PLASTIC HULL SHIPS

5.5.1 At technical supervision during construction of the ship, the following shall be checked:
.1 results of the material laboratory analysis prior to their use. The main parameters shall comply with technical documentation on manufacture of these materials;
.2 quality of the equipment working surface;
.3 compliance of the equipment with detailed drawings and molding shapes

5.5.2 When preparing to formation of hull structures, the surveyor evaluates the following:
.1 quality of preparing and applying release agents;
.2 quality of preparing the binding materials and proper cutting of reinforcing materials.

5.5.3 During formation of the hull structures, the following shall be checked:
.1 proper laying of fiberglass, warp direction and quantity of layers, gaps between coupled panels;
.2 uniform impregnation and sealing of the reinforcing material;
.3 absence of foreign inclusions;
.4 process allowances for physical tests.

5.5.4 After formation of the hull structures, their holding period shall be checked according to technical documentation:

5.5.5 When inspecting the ready assemblies and sections, absence of the following shall be checked:
.1 unacceptable deviation of the section dimensions from those specified in the drawings;
.2 external and internal defects;
.3 unacceptable deviation from the given thicknesses, straightness and thickness variation.

5.5.6 Temperature and relative air humidity shall be reported during manufacture of the sections, blocks of the hulls and superstructures.

5.5.7 The surveyor shall check physical and mechanical properties of the hull structure material, determined using a destructive method according to the requirements of the Rules (by results of laboratory tests of dry samples).

5.5.8 The surveyor shall make sure that the hulls made of fiberglass are repaired using the same materials as for construction. The hull repair procedure shall be approved by the Branch Office.

5.6 TECHNICAL SUPERVISION DURING MANUFACTURE OF STRUCTURAL FIRE PROTECTION

5.6.1 At technical supervision during manufacture of fire protection structures on the ship under construction, the following shall be checked:
.1 certificates for materials;
.2 insulation thickness and dimensions of air gaps, quality of insulation fastening to metal base, compliance with the technology of applying insulating materials when forming fire bulkheads and decks;
.3 transition pieces of the electrical route pipes and ventilation ducts through fire divisions;
.4 equipment of dangerous spaces;
.5 equipment of liquid fuel and lubricant storage facility;
.6 compliance with the requirements related to the ship purpose.

5.6.2 During technical supervision of manufactured fire doors and other closures, the following shall be checked:
.1 serviceability and density of closures;
.2 their opening and closing by one person;
.3 operation of the closure of self-closing doors when controlled from local and remote (if any) stations;
.4 closures of ventilation ducts, ring spaces around smoke pipes, skylights of the machinery, boiler and pump rooms.

5.6.3 Quality of materials used for internal insulation and equipment shall be checked by the surveyor on the documents on the materials and visual inspection for compliance with the approved design documentation.
5.7 TECHNICAL SUPERVISION DURING MANUFACTURE OF EQUIPMENT OF SPACES, CLOSURES, FENCINGS, LADDERS AND COMPONENTS OF DEVICES CONNECTED TO THE UNDERWATER PART OF THE HULL

5.7.1 During technical supervision of corridors, exits, doors and ladders, compliance with the drawings and Rules shall be checked:
.1 passages intended for quick escape of people to lifeboat and liferaft embarkation areas;
.2 type and dimensions of doors;
.3 direction of door opening;
.4 length of dead-ends in corridors;
.5 width of exits from halls, accommodation and service spaces;
.6 width of main corridors in the area of accommodation spaces for passengers and the crew;
.7 width of inclined ladders and dimensions of the platforms.

5.7.2 Upon completion of the closure installation the surveyor shall check the following:
.1 compliance of device and closure structures with the drawings;
.2 contact of seal gaskets with bead edges;
.3 easy and free (smooth) opening, closing, shifting and battening of the closures;
.4 compliance of the coamings height with the drawing and requirements of the Rules;
.5 quality of welds in places of closure connection with the hull, superstructures and wheelhouses;
.6 fastening of removable boards for glasses;
.7 tightness test results.

5.7.3 During technical supervision of manufactured guard rails, bulwark and catwalks, the following shall be checked:
.1 quality of welded joints of bulwark and catwalks;
.2 compliance of the distance from the deck to the foot line of guard rails and distance between other guard rails with the requirements of the Rules;
.3 compliance of the bulwark and guard rails height with the requirements of the Rules.

5.7.4 Upon completion of the foil arrangement installation the following shall be checked:
.1 compliance of foil angles of attack with the design;
.2 fastening of the foil arrangement to the hull;
.3 availability and efficiency of the arresters preventing loosening of nuts.

5.7.5 Upon completion of the hovercraft flexible skirt installation the following shall be checked:
.1 installation and fastening of the flexible skirt;
.2 availability and efficiency of the arresters preventing loosening of nuts.

5.8 CHECKING HULL READINESS FOR LAUNCHING

5.8.1 The hull shall be launched according to the production process approved by the River Register (see 3.1.10).

5.8.2 Prior to approval for launching, the surveyor checks the documents of the organization and River Register drawn up in the process of technical supervision confirming stage-by-stage control and tests:
.1 hull structures;
.2 hull structure tightness;
.3 weld joints;
.4 installation of stern tubes, propeller shafts and propellers, rudders, nozzles, dampers, and thrusters if these operations are performed when the ship is afloat;
.5 bottom and side valves;
.6 tightness of joints between the navigation equipment and the hull;
.7 installation and fastening of hovercraft foil arrangement and flexible skirts;
.8 installation of the thruster;
9. Installation and reliability of manhole covers in the inner bottom plating and tanks, closures of openings in watertight bulkheads;
10. Plugging of temporary openings in the hull;
11. Application of load line and draught marks;
12. Main dimensions and hull shape with the dimension tables attached;
13. Completeness and quality of application of paint coatings to the underwater part of the hull (see 5.8.6 and 5.8.7).

5.8.3 Upon satisfactory results of the tests specified in 5.8.2, the surveyor shall draw up an approval for ship launching by making a record in the Notice and in the protocol on the ship readiness for launching.

5.8.4 According to results of inspection of all the ship compartments after launching, the quality control department shall draw up a report and submit it to the surveyor.

5.8.5 The ship's bottom shall be submitted for inspection in the dock or on the slipway, if:
1. The ship's bottom is damaged during launching;
2. Leakage is detected in the underwater hull;
3. Defects are detected or there are grounds to suspect inadmissible defects in the bottom which appeared during launching, outfitting or trials of the ship.

5.8.6 Diagrams of coating, painting and cementing, quality control of their use on inland navigation ships including performance of technical documentation shall not be selected by the River Register.

5.8.7 For river-sea navigation ships, the River Register performs technical supervision of painting of the underwater hull, cargo spaces and ballast tanks of dry cargo ships and tankers. During technical supervision the surveyor checks compliance of the used coating materials with the painting list approved by the River Register, availability of the documents (see 2.2.6.3) on coating materials (for interior spaces) and compliance with the application method on the hull structures.
6 POWER INSTALLATION AND SYSTEMS

6.1 GENERAL REQUIREMENTS

6.1.1 This Section establishes requirements for technical supervision during manufacture, installation and testing of the following products subject to technical supervision by the River Register according to Section 4 of the Nomenclature: main and auxiliary internal combustion engines, reduction gears and reverse reduction gears, disengaging couplings and flexible couplings, compressors, pumps, fans, separators, deck machinery, shafts, propellers, systems and piping, boilers, heat exchangers and refrigerating equipment.

6.1.2 Scope and procedure of checks and tests of the products specified in para 6.1.1 is determined by the List developed by the organization upon the Nomenclature and Rules requirements taking into account specifics of manufacture, assembly, installation, and control methods and procedures, adopted by organization in accordance with the Branch Office.

6.1.3 All materials, including forgings and castings, associated equipment and items, used in manufacture of products specified in para 6.1.1 and their parts or intended for assembling the set, should be provided with certificates or other documentation verifying the material, product and technological process compliance with the requirements of technical specification approved by the River Register. In case specified by the Nomenclature parts and items shall be stamped.

6.1.4 Technical supervision during manufacturing and installation of parts includes conformance inspection of the measurement results in all measure points and sections, specified in detailed documentation and installation and operating instructions to the product and results of non-destructive testing of parts as prescribed by the Rules, documentation agreed with the River Register. Linear and angular dimensions, mounting clearances, form deviation, roughness, hardness and material structure are subject to measurement.

6.1.5 Technical supervision of rectification of castings, forgings and welding constructions surface defects shall be based on requirements of technical documentation, agreed with the River Register and requirements of Part X of RCCS. Parts and items after defects rectification are subject to non-destructive control, if so required by Rules and technical specification.

6.1.6 In technical supervision during product and their components manufacturing, the Surveyor shall:

.1 verify the quality of material and heat treatment as well as availability of the associated equipment through the documentation;

.2 control hydraulic and atmospheric tests of the products;

.3 ensure the random visual inspection and the quality control of the processing, dimension compliance with detailed drawings, technology compliance and use of flaw detection prescribed by process documentation;

.4 verify the compliance of manufactured parts, assemblies and items under technical supervision to the technical documentation requirements;

.5 check for marking as per agreed technical documentation.
6.1.7 Products being subjected to a hydraulic test in accordance with the Rules requirements, shall be preliminary heat treated and machined.

For product hydraulic test residual deformations, sweating and leakage are considered as rejection sign.

6.1.8 Results of hydraulic test are to be recorded in the test log indicating the following information:

.1 description of the item;
.2 manufacturing number;
.3 drawing number;
.4 working pressure;
.5 hydraulic test pressure;
.6 test results and data on permitted defect rectifications;
.7 testing date.

Reliability of this information shall be certified by the signature of the representative from organization's QC service.

6.1.9 Tested items and parts shall be stamped in plain view with the detail number, mark of the manufacturer's QC service, working and test pressure values.

Ship machinery safety valves being hydraulically tested shall be adjusted as per Rules, air tested and sealed by organization's QC service.

6.1.10 Technical supervision of repair of the items specified in para 6.1.1 shall be provided by the organization approved for works of such type, granting the technical documents for repair agreed with the River Register.

6.1.11 Parts and hinged units replaced during repair are subject to the same tests as new ship machinery during manufacturing.

6.1.12 Once ship machinery is repaired, the River Register ensures the technical supervision of testing of parts and assembly units subjected to the same test types as new ship machinery during manufacturing.

6.1.13 Engines thoroughly repaired are to be verified for compliance to standards for emissions according to the test program developed in accordance with Appendix 12.

6.1.14 Upon satisfactory results of tests and checks, the River Register issues documents on products, as provided in Rules.

**General requirements to bench tests procedure**

6.1.15 After product manufacturing and acceptance by manufacturer's QC service, in cases stipulated by the Rules and agreed with technical documents, bench tests are executed in the presence of the Surveyor according to program approved by the River Register.

6.1.16 Prior to start product testing, the Surveyor shall be provided with the following:

.1 organization document on bench readiness for testing;
.2 arrangement of the equipment and instrumentation, as well as bench specification;
.3 documents on instrumentation checkout and calibration of bench or standard devices;
.4 document from organization's QC service on accomplishment of factory tests providing results of controlled parameters;
.5 technical documentation on manufacturing and delivery of the product, as well as associated equipment in case of its installation on the bench with the product subjected to the testing;
.6 description and maintenance instruction, drawings, results of parts and mounting dimensions measurement;
.7 completed logbook (datasheet) for the item under test;
.8 test program (when it is an integral part of the agreed technical documents).

6.1.17 Continuity of test modes can be disrupted only once not more than for 15 minutes due to failure while forced shutdown of the item under test. Once all the deficiencies are rectified, the item shall be tested again, from the mode where the forced shutdown occurred.

In cases of forced shutdown exceeding 15 minutes, or repeated tested item shutdown, or replacement of tested item components, the test is considered failed. It can be restarted only after analysis and removal of all
causes and defects, interrupting continuous operation of the item under test.

6.1.18 After bench tests, product units and parts shall be subject to inspection. Scope of the inspection and analysis shall be determined on the results of checks or tests and adjusted on the basis of detected defects nature.

6.1.19 In case of inspection with product partial dismantling it shall be concluded by control tests carried out in the presence of the Surveyor. Control tests shall be carried out in mode of rated load or expected working load.

Technical parameters got while control testing, shall be recorded in the product supporting documentation (file, datasheet, operating guidance, etc.)

6.2 TECHNICAL SUPERVISION DURING MANUFACTURE

Internal combustion engines

6.2.1 Technical supervision during manufacture of internal combustion engine parts and units involves checking of their conformance to the requirements of the Rules and agreed technical documentation in regard to the following:

1. structures, materials, chemical and heat treatment, mechanical and physical and chemical surface properties;
2. size, shape, location and roughness of base mating surfaces, axes straightness, mating parts setting
3. quality of welding;, threaded and other joints, fixation and locking of connecting parts;
4. adhesive uniformity and strength of antifriction, antiwear and other coatings;
5. presence of defects, their nature and repair;
6. flaw detection of forged and cast steel parts, welded joints;
7. hydrostatic tests (see 6.2.2);
8. availability of technological base, lugs and openings, final machining allowances;
9. deviation from the profile and contact area in gearings;
10. crankshafts static and dynamic balancing;
11. determination of harmful substances emissions in exhaust gases.

6.2.2 Parts, pipelines and units of internal combustion engines operating under excessive pressure shall undergo hydraulic test according to the requirements of Table 2.3.2 after final machining and before protective coating is applied.

1. Air coolers of turbochargers shall undergo hydraulic test only from the water side.

Notes: 1. $p$ — working pressure, MPa.
2. These hydraulic test norms do not apply to fuel pumps with plunger controlling edge.

6.2.3 The engine is to be assembled from parts and units, accepted by organization's QC service. Prior to assembling they are subject to inspection by the Surveyor.

6.2.4 In the course of technical supervision of the engine assembly, the following shall be checked;
.1 base frame positioning as per technical documentation;
.2 alignment of main bearings soles;
.3 fitting of main bearing inserts by soles and of journal-and-thrust bearing;
.4 crankshaft laying with check of journals fit to the bearings, shaft line, journals beat and crankshaft deflections;
.5 installation and fastening of cylinder block, mating surfaces fitting;
.6 tightening load of threaded joints;
.7 deflections (again) after anchor ties tightening and flywheel installation;
.8 installation and alignment of gas distribution drives, camshaft and hinged units;
.9 installation of cylinder and piston group parts;
.10 installation of assembled cylinder heads;
.11 installation and alignment of inhalers;
.12 installation of engine set;
.13 parts locking.

6.2.5 After assembling, running-in and adjustment, the Surveyor shall ensure the technical supervision of engine bench test performance according to the program agreed with the River Register.

6.2.6 In the course of technical supervision of bench test performance, the Surveyor shall base on requirements of 6.1.15 – 6.1.19 with regard to the following:
.1 main engines intended for operation with fixed pitch propeller shall be tested by propeller characteristic;
.2 engines intended for generators drive, pumps, compressors shall be tested by load characteristic;
.3 new design solutions as for the engine – transmission – propeller system shall be tested according to the program which takes into account those solutions;
.4 bench engines shall be tested along with all standard devices, apparatus and automatic control, general alarm system and protection devices;
.5 bench test duration shall be specified in accordance with Table 6.2.6.5. In this case, the following shall be considered:

<table>
<thead>
<tr>
<th>Mode No.</th>

| Astern running mode | 7 not standardized | 1.0 | 1.0 | 0.5 | 0.5 |
| Minimum steady rotation speed mode | 8 not standardized | 0.5 | 0.5 | 0.25 | 0.25 |

| Total test time | 14 | 12 | 7 | 3.75 |

Note: Modes 7 and 8 shall be applied only if the engine design provides for running at these modes.

.6 systems of control, regulation, alarm and protection, locking and cutoff, starting reversing engine characteristics, regulators functioning shall be tested before activate engine's mode;

.7 testings of automated control system shall be based on individual program agreed upon with the River Register;
operation of the engine shall be tested in all modes specified by program methodology, work process parameters and characteristics specified in technical documentation and test program are to be recorded;

work process parameters shall be measured at least twice under engine steady operating conditions;

measuring torsional vibration parameters (in cases specified in para 6.1.1 Part IV RCCS).

6.2.7 Engine testings to ensure the compliance of their specifics concerning harmful substances emissions and opacity in exhaust gases with the standardized values are to be performed as per approved test program, developed in accordance with Appendix 12. Engine type and model as basic engine of the family for testing shall be chosen by the manufacturer.

During manufacture of one family series engines, their parameters and rated values concerning harmful substances emissions and opacity in exhaust gases shall be admitted based on the testing results of a family basic engine.

If the engine design was modified so that the changes introduced effect the content of harmful substances and opacity in exhaust gases shall be admitted based on the testing results of a family basic engine.

When performing engine testings after the overhaul to ensure the compliance of their specifics concerning harmful substances emissions and opacity in exhaust gases the maximum allowed values of their specifics shall be in accordance with the requirements of 6.2.3 and 6.2.6 of the Rules for Prevention of Pollution from Ships.

6.2.8 During technical supervision it shall be taken into account that after bench tests envisaged by test program, depending on check results specified in para 6.2.6, assembly units and engine parts are subjected to the inspection with visual and dimensional examination in the scope agreed with the Surveyor.

6.2.9 If at engine inspection it was partially dismantled, engine control tests shall be carried out with technical supervised by the River Register Surveyor check of working process parameters and engine efficiency, as well as of its arrangements and systems given below:

starting devices;

reversing unit;

alarm and protection system, safety devices;

automated control system;

rotation speed control system.

6.2.10 The Surveyor ensures that in case of unsatisfactory check results, after full elimination by manufacturer of defects affecting the performance of this unit or system, the repeated engine operation checks are carried out in accordance with 6.2.8.

6.2.11 The manufacturer shall provide along with engine the following documents:

technical file;

assembly and sub-assembly engine drawings in scope specified by technical specification;

hinged units files provided by manufacturers;

technical datasheet and operating and maintenance instructions containing detailed description of engine units and special-purpose tool;

spares list;

instrumentation datasheets;

post-assembly engine acceptance certificate issued by the organization;

engine bench test report (checking test);

post-test engine inspection certificate issued by the organization;

technical datasheet of harmful substance emissions and opacity in exhaust engine gases (prepared as per ГОСТ 31967);

record book of engine parameters for recording of all changes in configuration and adjustments (may be integral part of the data-sheet or engine file). The record book shall contain the description of all changes related to design characteristics of the engine, including adjustments, replacement of components or design changes of engine components allowing the evaluation of the emission level.
6.2.12 Accomplished tests and supporting documents checking shall be accompanied by the issuing of certificate (PP-8.1 form). This certificate shall contain the information on values of harmful substances and exhaust gases opacity, got while basic engine of the family testing (see 6.2.7).

Shafting

6.2.13 In technical supervision during shafting manufacturing the following shall be checked:
- conformity of material quality to the requirements of approved technical documentation, heat treatment mode and flaw detection results;
- work surface roughness, size and shape;
- shaft radial run-out, axial run-out of flange faces and thrust collar, external and internal surfaces concentricity or hollow shafts wall thickness;
- section shape and key slot preparation, key slot position about an axis of the shaft and cone;
- assembly and alignment keeping at shaft connections, interference fit and gaps of connection;
- surface for facing with sufficient clearance to ensure the interference as per drawings.

6.2.14 The completely finished shafts are subject to visual inspection. The following shall be determined by the Surveyor:
- surface defects parameters do not exceed the norms set by the drawing technical requirements;
- shaft journals shall be free from chippings, scratches, notches or burrs;
- shaft threads shall be clean, without burrs or strips;
- fillets shall be made smoothly, seams shall be free from sharp edges and burrs.

Upon satisfactory results of checks, flaw detection and measurements, shafts shall be stamped by the River Register, if prescribed by the Nomenclature.

6.2.15 During the manufacture and after facing final processing, the Surveyor shall verify the following:
- compliance of material properties to the requirements of technical documentation;
- flaw detection results;
- the absence of defects on facing external surfaces;
- sizes ensuring guaranteed interference fit while facing fitting on the shaft;
- results of hydraulic test for facing tightness or welded shells before fitting on the shaft (see 6.2.16).

6.2.16 The Surveyor shall verify that propeller shaft and stern tube facings are hydraulically tested by pressure not less than 0,2 MPa.

6.2.17 After fitting the facing on the propeller shaft and final processing, the Surveyor shall control the results of the following checks performed by the manufacturer:
- absence of defects on facing external surfaces;
- work surfaces size, shape, roughness and radial run-out;
- quality of facing welds, welded on shaft, by the leak test results (by air or oil) under pressure of 0,2 MPa and/or using liquid penetrant method;
- quality of sealings of shafting ends.

6.2.18 Water insulation of the shaft shall be verified for absence of saggings, blistering or entrapped air.

6.2.19 Finally manufactured couplings, connecting bolts, main bearings and thrust bearings, stern units, sealings and glands are to be verified by the Surveyor before their installation. Final control of flange half-couplings by the external and end surfaces shall be performed after their fitting on the shaft.

Gears, disengaging and elastic couplings

6.2.20 In the course of technical supervision during manufacturing of parts and assemblies of main engines gears and disengaging couplings, the Surveyor shall verify the following:
- treated shaft journals, surfaces for facing, teeth cutting parameters, gear rings, surfaces or sealing and connections, keyways, threads, deviation from the profile, radial run-out, end surfaces squareness to the shaft axis,
axial run-out, chemical and heat treatment, protective coatings comply with the requirements of technical documentation approved by the River Register.

.2 Critical parts were subject to flaw detection.
.3 Fitting in connections were carried out with required interference fit (clearance).
.4 Finally assembled and treated gear-wheels, pinions, shafts with couplings and half-couplings assemblies as per 4.3.2 Part IV RCCS shall be statically and/or dynamically balanced.

6.2.21 After execution of welding works and heat treatment, while inspecting finally treated parts of the gear boxes and couplings, the Surveyor shall control:
.1 welds, including flaw detection methods;
.2 treated bearing surfaces of foundations and flange connections of individual hull parts;
.3 boring of the soles for bearings and sealings;
.4 alignment of soles borings for bearings of each shaft;
.5 quality and reliability of connections of individual gear box parts or coupling;
.6 mutual alignment of in gear shaft axis.

Gear box is subject to the tightness test, and hydraulic coupling case – to the hydraulic test.

6.2.22 When assembling gears and couplings, the Surveyor shall control:
.1 fitting of bearing by soles, standard shaft or false shaft journals, clearances of journal and thrust bearings;
.2 centre-to-centre spacing and mutual alignment of shaft axis;
.3 gear backlashes and tooth contact;
.4 quality of coupling assembling, hinged units and systems serving gear;
.5 alignment of gear with drive motor and loading device;
.6 quality of coupling drive and driven parts assembling.

6.2.23 For bench tests, gears and disengaging couplings shall be equipped in accordance with the approved technical documentation. During bench testings, provisions 6.1.15 – 6.1.19 shall be taken into account.

6.2.24 When testings are completed, gears and disengaging couplings are subject to inspection and to control tests, where the following shall be verified:
.1 reversing provided by transmission design;
.2 disconnection of the transmission from the prime mover or driven load;
.3 alarm and protection systems, safety devices;
.4 automated control system;
.5 smoothness of changing of the prime mover rotation speed within minimum steady to the rated one.

**Propellers**

6.2.25 In the course of technical supervision during propellers and their parts manufacturing, the Surveyor shall control:
.1 design parameters and size compliance with the technical documentation approved by the River Register;
.2 quality of the material for blanks, forgings and castings intended for propellers and their parts manufacturing (through the documentation furnished);
.3 results of flaw detection, carried out in accordance with the technical documentation;
.4 absence of internal or surface defects as per technical documentation for propellers approved by the River Register;
.5 interchangeability and difference in weight between standard and spare blades of detachable-blade propellers;
.6 results of static and/or dynamic balancing of propellers and water-jet propeller rotors after machining and fully assembled.

6.2.26 The scope of the technical supervision of the specially designed propellers parts (for example, rotating-blade, columns, paddle wheels), as well as types, sequence of tests and checks carried out during the technical supervision of their manufacturing, shall be determined by the River Register.
Compressors, pumps, fans and separators

6.2.27 In the course of technical supervision during manufacturing of parts and assemblies of compressors, pumps, fans and separators, the Surveyor shall verify their compliance with the Rules and approved technical documentation. This verification shall be based on provisions 6.1.6 and other requirements of these Rules.

6.2.28 In the course of technical supervision during hydraulic tests of compressors, pumps, fans and separators parts, operating under excessive pressure, to be carried out after final machining and before protective coating, results of these tests shall be checked by the Surveyor as well. The correct choice of the hydraulic test pressure determined by the formula given below (MPa), shall be checked:

\[ p_{\text{test}} = (1.5 + 0.1k) \cdot p, \quad (6.2.28) \]

where \( k \) — coefficient adopted from Table 6.2.28;

\[ p \] — working pressure, MPa.

In all cases the test pressure shall be admitted not below the pressure corresponding to full opening of safety valve but not below 0.4 MPa for cooled chambers of parts and sealings of different types and not below 0.2 MPa in other cases.

In case the working pressure given in Table 6.2.28 is exceeded, test pressure shall be approved by the River Register.

6.2.29 Parts and units of pumps, fans, filled with oil products or their vapours under hydrostatic or atmospheric pressure, shall undergo tightness test. In welded structures it is sufficient to test only tightness of welds.

6.2.30 In the course of technical supervision during the assembling and installation of the compressors, pumps, fans and separators, the Surveyor shall verify the following:

.1 Shafts shall be placed in bearings, fitted by soles and journals;

.2 Required clearances in bearings and sealings, between operating elements and housings shall be maintained;

.3 Shaft shall be aligned with the prime mover;

.4 Required contact in gear meshes shall be provided;

.5 Protective and safety devices shall be adjusted.

6.2.31 After assembling, running-in and adjustment, the Surveyor shall ensure the technical supervision of bench test performance (see 6.1.15 – 6.1.19), where compressors, pumps, fans and separators serviceability shall be checked and all parameters specified by the technical documentation shall be recorded, as well as following devices shall be tested in operation:

.1 automation equipment;

.2 safety devices.

6.2.32 Safety devices shall be tested in operation and sealed by the manufacturer's QC service.

Boilers, heat exchangers and pressure vessels

6.2.33 Technical supervision of the boilers, heat exchangers and pressure vessels, their parts and units manufacturing and of process operations performing shall be carried out by the Surveyor in accordance with the technical documentation approved by the River Register.

6.2.34 Soundness of plates, forgings and castings, designed for parts and units of boilers, heat exchangers and pressure vessels shall
be determined by their surfaces visual inspection.

6.2.35 Scantling of parts before assembling of items under technical supervision shall be checked for compliance with those specified by the drawings and drawing technical requirements.

6.2.36 In the course of technical supervision during assembling of parts and units of items under supervision, the compliance of gaps between the members and tolerances specified in the technical documentation approved by the River Register, shall be checked. Align mated elements by creating excessive push-up load or cold shock straightening is not allowed.

6.2.37 Before welding, bevel and gaps are to be verified on their compliance with the drawings approved by the River Register. The bevel surface shall be free from cracks, delaminations or other defects.

6.2.38 Welding operations shall be carried out with welding consumables specified in the technical documentation approved by the River Register.

6.2.39 Welded joints quality control shall be performed after heat treatment (if applicable).

Methods and scope of quality control of the butt welded joints shall be specified in the technical documentation.

6.2.40 Fittings of boilers, heat exchangers and pressure vessels are subject to the hydraulic strength test (see 6.2.28) before installation at their standard places.

6.2.41 Parts and units of boilers, heat exchangers and pressure vessels are subject to the hydraulic strength test by a test pressure as per standards of ГОCT 22161, before being assembled.

Hydraulic test by a test pressure shall be carried out in the presence of the Surveyor when meeting the following requirements:

1. All assembly, welding and welds control operations are finished and accepted by the manufacturer's QC service (confirmed by the document on part or unit readiness for hydraulic test issued by the manufacturer's QC service);

2. Components of the item under technical supervision are not insulated or coated with other protective coating;

3. Part or unit was subject to the Surveyor examination.

6.2.42 Assembled boilers, heat exchangers and pressure vessels without fittings and insulation or other protective coatings shall be subject to internal survey and hydraulic strength test by a test pressure as per standards of ГОCT 22161.

**Refrigerating plants**

6.2.43 Technical supervision during manufacturing of the refrigerating equipment for transport, refrigerated and catching vessels shall be carried out as per approved technical documentation.

6.2.44 Technical supervision during manufacturing of the refrigerating equipment specified in 6.2.43 includes the following:

1. verification of technical documents;

2. verification of parts, units and assembling parts;

3. verification of welded and soldered joints quality;

4. technical supervision during hydraulic strength testing;

5. technical supervision during pneumatic tightness testing;

6. technical supervision during vacuum leakage testing;

7. technical supervision during bench testing.

6.2.45 Technical supervision during manufacturing of the refrigerating equipment shall be based on the applicable provisions of 6.2.1 to 6.2.39 and requirements of technical documentation approved by the River Register.

6.2.46 Testings as per 6.2.44.4 to 6.2.44.6 shall be based on the provisions 6.2.47 to 6.2.51.

6.2.47 The units operating under pressure of the refrigerant shall be hydraulically tested...
by a test pressure equal to at least 1.5\(p\), where \(p\) is the design pressure taken in accordance with 6.2.47, with the exception of reciprocating compressor crank cases for which a test pressure shall be not less than the design pressure.

The units operating under pressure of the liquid coolant or water shall be hydraulically tested by a test pressure of at least 1.5 of the working pressure but not less than 0.4 MPa.

**To be used at medium condensation points instead of R22 which is not permitted for newly built refrigerating plants since 01.01.2020.**

6.2.48 The units operating under pressure of the refrigerant shall undergo pneumatic leakage tests by a test pressure equal to at least the design pressure taken in accordance with 6.2.47 with the exception of reciprocating compressor crank cases for which a test pressure shall be not less than 0.8 times the design pressure.

6.2.49 The equipment operating under pressure below the atmospheric pressure shall undergo vacuum leakage tests at residual pressure not exceeding 0.8 kPa.

6.2.50 Fittings in assembly and automation devices with stopping arrangements in addition to the above tests shall undergo pneumatic closing-tightness tests by a test pressure equal to the design pressure taken in accordance with 6.2.47.

6.2.51 Compressors, refrigerant, liquid coolant and cooling water pumps, heat exchangers and other equipment, vessels operating under the refrigerant pressure, piping and fittings rated for 1.0 MPa and over, devices of automation, control and protection systems as well as devices for measuring and registration of temperature within refrigerating spaces after assembling shall be tested in accordance with the requirements of 6.2.28.

6.2.52 Technical supervision during bench testings and refrigerating equipment inspection shall be based on requirements of 6.1.15 – 6.1.19, taking into account the following:

1. The bench for compressor testing shall ensure compressor operation with full refrigeration cycle using specified refrigerant, oil and keeping of the refrigerant nominal parameters and environmental conditions (cooling water temperature +32°C, ambient temperature +50°C);
2. Compressor type specimen testings shall be carried out at the rated power and idle run to determine refrigerating capacity, volume flow, power and oil consumption;
3. Compressors with incorporated motors shall be tested in regard to their starting characteristics, temperature and insulation resistance;
4. Standard compressor test time shall be at least 500 h, 150 h of which shall accrue to the operation at maximum pressure difference and other 150 h – at maximum power;
5. Refrigerant pumps shall be tested using specified refrigerant;
6. Refrigerant pump test time shall be sufficient to determine its specified characteristics, but not less than 8 h;
7. Heat exchangers (type specimens) operating under refrigerant pressure, shall undergo bench thermotechnical tests (the temperature of refrigerant measurement) using specified refrigerant and taking into account item structure and designation. Bench equipment shall ensure the item operation with full refrigeration cycle.

### Systems

6.2.53 Fittings of the piping shall be produced in accordance with the requirements of 10.3 and 10.4 of Part IV RCCS as per technical documentation approved by the River Register.
6.2.54 In the course of technical supervision during piping fitting manufacturing, the Surveyor shall control the following:

1. compliance of material to the requirements of technical documentation;
2. quality of finishing and lapping of the working and sealing surfaces;
3. compliance of the springs, spool pieces, diaphragms used in fittings to the technical documentation requirements;
4. results of hydraulic tests (see 6.2.57);
5. adequate operation of local and remote drives of fittings;
6. control, safety and measuring fittings as well as self-acting valves. The given fittings shall be checked in operation on bench to confirm their performance characteristics, specified in the technical documentation.

6.2.55 Checking of the hydraulic pressure results is designed to ensure the correctness of the test pressure chosen that, in case of fittings intended for a design pressure exceeding 0.1 MPa, shall be determined by the procedure specified in 6.2.28 relevant to testings of compressor components, pumps, fans operating under excessive pressure, and in the other cases shall be:

1. at least 0.2 MPa – for fittings intended for a design pressure of 0.1 MPa and less, as well as for vacuum conditions;
2. at least 0.3 MPa – for outboard valve box and ice box fittings;
3. equal to the design pressure – for fittings assembled and being tested on leak tightness.

6.2.56 Type specimens of valves shall be additionally examined for at least 3 h under conditions of vibration, temperature and pressure limits, other special modes depending on fittings designation (checks for fire-resistance, noninflammability of inflammable mixture vapours, preventing the accidental admission of water, reliability at hydraulic impact, hydraulic resistance).

6.2.57 During manufacturing of pipelines of Classes I and II (see 10.1.2 of Part IV RCCS) and all steam, feeding, compressed air and fuel system pipelines with a design pressure over 0.35 MPa regardless of their class, the Surveyor shall carry out the technical supervision of pipelines hydraulic testings performed prior to insulation and application of coating, results of these tests shall be checked by the Surveyor as well. The correct choice of the test pressure that is considered to be of 1.5 of the design pressure, is also subject to the control.

The test excessive pressure of the pipelines of cargo pumping system intended for carriage of hazardous goods in bulk (except liquefied gases) shall be at least 1 MPa.

The test pressure for liquefied gas pipelines from the reservoirs to the pressure reducing valves shall be at least 2.5 MPa.

6.2.58 During manufacturing of the firefighting system pipelines and fittings, the Surveyor shall realize the technical supervision of hydraulic testings of such items, including checking of the results of hydraulic tests by test pressure corresponding to the Table 6.2.58.

When using the Table 6.2.58, the following shall be considered:

Assembled fittings shall undergo leakage test in closed position by pressure not less than 1.25p.

Valves of carbon dioxide reservoirs shall undergo tightness test by the maximal breakdown pressure of safety diaphragm.

Onboard systems shall be tested in the assembly after all installation operations have been finished.

6.2.59 The Surveyor shall control the recording in logbook of the hydraulic test results (see 6.1.8) with the indication of test pressure, numbers of certificates for pipes and data on welds testings.

6.2.60 Where it is impossible to carry out hydraulic tests of the pipelines prior to their installation onboard due to technical reasons, it is allowed to test separate pipe lengths, in particular, assembly joints.

6.2.61 Small bore pipes (less than 15 mm) of any class are not subject to testing by a test pressure.
### Test pressure during hydraulic testings of fire-fighting system pipelines and fittings

**Notes:**
1. *p* — maximal working pressure in the system, for carbon dioxide system — design pressure in a bottle or reservoir, MPa.
2. Pipelines stated in 2.1 tested in the workshop by hydraulic pressure of 1.5p, may be tested on a ship by air with pressure of 1p.

### Internal combustion engines, gears, disengaging and elastic couplings

**6.3.3** Installation and assembling of main engines, gear components and shafting components shall be carried out after accomplishment of all hull operations and testing for tightness of compartments and double-bottom tanks in the engine room area and the shaft line, including completion of foundation manufacturing.

**6.3.4** During onboard installation of the main engine in dismantled condition, checks and technical supervision shall be carried out as per requirements of 6.2 including foundation preparation and base frame installation.

**6.3.5** The installation of items shall be carried out in accordance with the approved technical documentation depending on their type and construction.

**6.3.6** In the course of technical supervision during installation of gears and couplings, the following shall be checked:
1. Security of attachment of gearing cases to ship foundations;
2. Quality of installation of units and components used in torque transfer, on shafts.

**6.3.7** Technical supervision during installation and testing of items driven by main engine shall be carried out at the same time as pair of mechanisms, boilers, pipelines and fittings.

### 6.2.62 The organization's QC service stamp confirming conducted hydraulic test shall be impressed on the side of one of pipe flanges or enclosure.

### 6.2.63 Silencers and spark arresters of exhaust systems and boiler flues shall be tested as per program approved by the River Register.
technical supervision during installation and testing of main engines.

6.3.8 Once the installation operations are completed, items are subject to the inspection to check the quality of installation and its compliance with the detailed drawings approved by the River Register.

Shafting

6.3.9 The onboard installation of stern gear and shafting shall be carried out after completion of hull operations, including all operations related to foundations for main engines and shafting bearings, tests of compartments and tanks in the area of shafting and engine room, determination of the shafting theoretical axis.

6.3.10 Prior to stern gear and shafting installation all fixed loads that can cause deformation of the hull due to heavy weight, shall be placed and installed in their respective places, and change of hull position in the area of shafting and engine room shall not exceed ±3 mm relative to its position recorded at the beginning of operations.

6.3.11 In the course of technical supervision during installation of stern gear, the following shall be checked:

1. quality of the punching of shafting theoretical axis;
2. sizes, deviation from the shape and roughness of seatings and horn end faces, bosses, welded pad of after peak bulkhead, seatings of stern gear and bearing bushes;
3. compliance of mating surfaces setting with the drawing requirements;
4. forces for components pressing-in, security of their attachment and locking.

After installation, internal diameters are subject to the control measurement and stern tube bearings – to the inspection.

If stern tube was installed after watertightness test of the hull, corresponding hull compartment shall be tested again.

6.3.12 Prior to shafting installation the following shall be checked:

1. bearings foundations and bearing surface finish – deviations from flatness, roughness, thickness of foundation bearing plates;
2. shafts (propeller shaft, thrust shaft, tunnel shaft), bearings, couplings and stern gear through the visual examination and its documentation;
3. quality of propeller and half-coupling fitting to the propeller shaft;
4. clearances in sterntube and strut bearings by results of propeller shaft and bearing necks measurement.

6.3.13 After propeller shaft installation the following shall be checked:

1. clearances in bearings;
2. propeller shaft position in stern gear in axial direction;
3. quality of installation of stern seals or other stern gear sealings and gland packing laying.

6.3.14 Prior to propeller installation the following shall be checked:

1. availability of documentation and stamps;
2. surface soundness (by visual examination);
3. quality of preparation of hub bore mounting surface, tapered hub bore fitting-on;
4. keys fitting into keyed connection.

6.3.15 In the course of technical supervision during the installation of propeller or water-jet propeller rotors, the following shall be checked:

1. propeller axial shift in relation to the shaft;
2. pressing force and interference fit of connection;
3. uniformity and tight fitting of fairing nut to the hub and security of its locking;
4. tightening force and locking of the fastening elements of detachable blades;
5. clearances between the propeller blade and the nozzle or in the flow path of waterjet.

6.3.16 Prior to shafting installation and alignment the following shall be checked:

1. diameters of shaft journal and internal borings of bearing inserts by results of control measurement to determine clearances in bearings;
.2 quality of rolling bearings installation on shafts;
.3 shaft laying into bearings and bearings installation on foundation;
.4 shafts mutual alignment relative to each other by control marks when connecting in the shop;
.5 finish of fastening bolts and holes in the foundation and bearings.

6.3.17 Shafting shall be aligned in such a way as to prevent the exceeding of permissible values of shaft stress and bearing load at any ship loading condition and allowable wastage of shafts and bearings in operation.

6.3.18 The holes for flange connections bolts shall be treated jointly for both flanges of connected shafts by their actual dimensions, and bolt heads and nuts are to be checked for adequate contact with the flanges surface.

6.3.19 In the course of technical supervision during shafting installation and after assembling of all connections and securing of bearings, the following shall be checked:
.1 shaft position in the bearings and fitting of support inserts to the shaft journals
.2 clearances in the thrust bearing between the collar and segments, axial clearances between thrust collar and shafting fillets or bearing insert ends
.3 fitting of chocks to the support branches of bearing bodies
.4 finish of holes for templet bolts in the foundation and bearings
.5 security of attachment and locking of bolts
.6 crankshaft deflections of the main engine after its connection to the shafting

6.3.20 Final control of the shafting alignment shall be performed with the ship afloat after chocks fitting to the bearings, at displacement of at least 85% of the lightship displacement.

The Surveyor shall check the provided results of alignment parameters measurement (fractures and misalignment of the shaft axis), entered into the tables, indicating as well design and allowable values of these parameters.

6.3.21 Installation, assembling and control of fitting of the shaft turning gear, tachometer transmitter, shafting brake, devices for reducing power are to be performed as per technical documentation requirements approved by the River Register.

6.3.22 The Surveyor shall check the parameters of the main engine crankshaft alignment with the shafting or reduction gear simultaneously with or after shafting alignment. Measured values of parameters shall not exceed those specified in the manufacturer's technical documentation on installation of such items. Deviations in frame straightness and crankshaft deflections shall not exceed the norms determined by the manufacturer of the engine.

6.3.23 The Surveyor is to verify that in the process of alignment of engine crankshaft and electric generators at their rigid connection (at main units on electric ships), allowances specified in the technical documentation of the generator manufacturer are kept, and in the process of alignment of propulsion electric motor armature shaft and thrust shaft are kept allowances determined by the propulsion electric motor manufacturer.

Compressors, pumps, fans and separators

6.3.24 The technical supervision during installation of compressors, pumps, fans and separators shall be performed as per approved technical documentation. Scope of technical supervision is to be determined taking into account type, designation and design of the item under technical supervision.

Boilers, heat exchangers and pressure vessels

6.3.25 Installation of boilers, heat exchangers and pressure vessels shall be carried out in accordance with the requirements of technical documentation on installation approved by the River Register. Prior to start the installation, it is important to ensure that assembly and welding of ship foundations are completed and items have a document issued by the QC service and confirming their applicability.
6.3.26 The Surveyor shall perform the internal survey of the boiler with standard valves and instruments after completion of the assembling, boiler installation on the foundation and fixing, but prior to application of insulation, shell and lining.

Heat exchangers internal survey shall to be performed by the manufacturer's QC service.

Pressure vessels internal survey shall to be performed by the Surveyor.

If the boiler is fully assembled (with insulation, shell and lining) and provided with supporting documents, only accessible parts are subject to internal survey.

6.3.27 During boiler internal survey, the Surveyor shall verify the following:

1. Boiler components and welds shall be free from damages and defects.
2. Hot-water, waterwall and down-take pipes shall not be deformed but free from plugs (verify by the means of master balls).
3. Water level indicators shall be installed relative to heating surface as per Rules requirements.
4. Drums and headers internal equipment shall correspond to the drawing and is fixed.
5. Fittings and instruments installed on the boiler shall correspond to the drawings.
6. Instruments shall be provided with documents on calibration by metrological organization.
7. Boiler drums and headers as well as superheaters headers shall be protected against direct heat flow.

6.3.28 Hydraulic leak test of boiler (with all pipelines, fittings and instruments) shall be carried out under test pressure as per standards of ГОСТ 22161, in the presence of the Surveyor after boiler installation on the ship.

Main steam piping, feeding pressure piping, blow-off pipes, water gauge instruments and all fittings are subject to the hydraulic test with the boiler.

If the boiler is fully assembled (with insulation, shell and lining) and provided with supporting documents confirming hydraulic tests performance, the boiler hydraulic test on board the ship is not required.

Onboard hydraulic test of the steam piping is obligatory.

6.3.29 Tested boiler shall be kept under test pressure for at least 5 to 10 min. During keeping under test pressure, the purge pump shall be disconnected and pressure in the boiler shall not decrease. Then, the pressure is decreasing to the working value and maintained constant to the completion of the examination.

6.3.30 The boiler shall be considered as having passed the test if no leaks or sweating of welds, leakage in pipe expanded connection, fitting connecting flanges, instrument connections as well as no local bulges, residual deformation or signs of any connection damage are detected.

6.3.31 Technical supervision during hydraulic leak tests, air test and outer survey of the pressure vessels with all fittings and system piping which contains the pressure vessels, shall be performed after onboard installation of the system. The hydraulic test shall be performed under a test pressure equal to 1.5 of operating pressure in the system.

6.3.32 After hydraulic test, pressure vessels are subject to air test (ГОСТ 22161) for working pressure to check the tightness of connections.

After testing and adjustment in accordance with the requirements of the Rules, safety valves shall be stamped by the manufacturer's QC service.

6.3.33 After onboard installation, the Surveyor performs technical supervision for boiler steam sample, taking into account the following:

1. Test duration is 4 to 8 h at steam working pressure.
2. Boiler steam is not consumed, all boiler valves are closed except blow-down valve of superheater header.
3. Water level in the boiler is maintained in a working range.
4. Boiler insulation and shell are removed in such a way as to ensure meeting the requirements of 6.3.34.
If the boiler is fully assembled (with insulation, shell and lining) and provided with manufacturer supporting documents on results the boiler steam sample, boiler steam sample after its onboard installation is not required.

After steam sample, the boiler is subject to mooring and running trials. Waste-heat boilers are tested during the operation of engines at mooring and running trials.

6.3.34 In the course of technical supervision during boiler steam sample the following shall be checked:

.1 tightness of welding, riveted, threaded and expanded joints of the boiler, flange connections of fittings and steam pipelines
.2 tightness of the boiler and boiler flues shell
.3 presence and sizes of expansion clearances in the holes of boiler support on the foundation allowing thermal expansion of the boiler and clearances in the arrangements preventing displacement of the boiler
.4 presence and parameters of thermal distortion of the boiler components

When the results of boiler test in steam are satisfactory and defects detected in the course of testing are eliminated, insulation and shell installation is to be carried out.

Refrigerating plants

6.3.35 Technical supervision during installation and testing of the refrigerating plant on transport, refrigerated and catching vessels shall be based on the applicable provisions of 6.3.1 to 6.3.33 taking into account the following:

.1 Components and equipment of the refrigerating plant supplied to the shipyard are subject to the Surveyor’s check by certificates or documents of refrigerating equipment manufacturer;
.2 Equipment and items manufactured by the shipyard, are subject to the check and testing prior to installation as per 6.2.44 to 6.2.53.

6.3.36 After completion of assembly-welding works on the hull but prior to insulation installation, leak testing of the refrigerating plant room is subject to the technical supervision, taking into account the following:

.1 Test (excess) air pressure during leak testing is taken equal to 2 kPa;
.2 compressed air pressure drop for 1 h shall not exceed 25 % of the initial test pressure, i.e. 1 h after the pressure in the tested room shall be not less than 1.5 kPa.

6.3.37 In the course of technical supervision during the refrigerating plants installation, the Surveyor shall check the following:

.1 meeting the requirements of the Rules on the control stations equipment and places of maintenance, arrangement of the passes, escape and emergency routes as well as their closures;
.2 compliance of the refrigerant equipment arrangement (including control, monitoring, alarm and protection devices) with the requirements of the approved technical documentation
.3 proper installation of pipelines and their reliable protection against damages;
.4 fastening of the refrigerating equipment;
.5 alignment of the refrigerating plant units;
.6 quality of the insulation installation, including the type (brand) of insulating material, thickness and security of insulation attachment, quality of the insulation of installation assemblies in the area of framing, pipes passages, hatches and doors.

6.3.38 In the course of technical supervision during refrigerating plant systems manufacturing and installation, the Surveyor shall check:

.1 quality of welded butt-joints of the refrigerant pipelines – using one of non-destructive testing methods.

Overlapped joint weld, on the backing rings and other which can not be checked by the non-destructive testing, shall be tested by the hydraulic pressure equal to 1.5 of the working pressure;

.2 operation of isolation valves and refrigerant system pipelines after leakage testing of the system by stage-by-stage connection of
the system sections depending on the group of refrigeration consumers and pressure rise in these sections to 1.1 of working pressure;
3. penetrations of air cooling systems and ventilation ducts through watertight and fire protection structures;
4. arrangement of ventilation inlets and outlets, flame-breaking fittings on the ends of air channels and fans of non-sparking type in the explosion-hazardous spaces;
5. gas and air tightness of air channels before and after insulation operations;
6. insulation of air channels.

6.3.39 The refrigerant system shall be tested for leakage by the gaseous atmosphere test pressure equal to a working pressure (see 9.3.2 Part IV RCCS) for 18 h, after completion of installation. Total pressure drop caused by adsorption or leakage during the testing shall not exceed 2% of the initial test pressure.

In such testing shall be used dry air, carbon dioxide or nitrogen with the temperature of water vapor saturation up to 45°C.

After leak test, the pressure is to be relieved by sequential valves opening on the emergency drainage station to check the emergency drainage system of the refrigerant.

6.3.40 After passing the leakage tests the refrigerant system shall be drained and undergo vacuum leakage tests at residual pressure not exceeding 1 kPa.

6.3.41 In the course of technical supervision during the leak test of the refrigerant system it should be taken into account that all tests shall be performed for 12 h after vacuuming to the residual pressure up to 1 kPa.

The system is considered as passed the test if total pressure rise (due to steam-gas desorption and inrush of air in the course of testing) do not exceed 25% of the initial residual pressure.

When the leak testing is completed, the quality of drainage of the refrigerant system is to be checked.

The absolute water content after drainage according to the laboratory analysis data shall not exceed 0.15 g/m³.

6.3.42 Coolant and cooling water systems are subject to the leak test (see 6.2.48), being kept under working pressure for at least 1 hour.

6.3.43 Safety valves designed for refrigerating plant shall be checked and tested in the testing laboratory prior to their onboard installation, taking into account the following:
1. Valve is to be adjusted to blow at 1.1 to 1.2 of working pressure;
2. Valve is to be closed after actuation at a pressure of at least 0.85 of working pressure;
3. Valve trim tightness shall be checked by the immersing with secondary rise of pressure to the designed value after its closing upon actuation.

Systems

6.3.44 In the course of technical supervision during installation of systems and piping the following shall be checked:
1. complete set and compliance of the system's components with the requirements of the approved technical documentation;
2. quality of system's components cleaning and processing, corrosion-resistant coatings;
3. fact of performance and results of hydraulic tests of fittings, pipings, devices prior to their onboard installation;
4. proper arrangement and installation of pipings, fittings, instruments and automation equipment, compliance of the pipe bending radiiuses with those specified by drawings;
5. completion of the assembling, welding and leak testing of hull structures as well as after installation of all the saturating welding parts;
6. reliable and proper installation of bottom and side valves and sacrificial protection components;
7. installation of standard gaskets, fasteners, security of pipes and compressors attachments;
8. availability and safety of maintenance and repair of pipelines and fittings;
9. availability of arrangements for draining or blow-down of the medium, absence of pos-
sible liquid stagnation areas, preventing of water hammers, presence of pipeline pitches;

.10 providing with insulation, housings, barriers, protection against mechanical damages;

.11 providing with identification plates on the fittings, identification pipelines painting, position indicators of shut-off devices, operation of local and remote drives, their accessibility;

.12 arrangement and structure of branch suctions and inlets;

.13 safety of precautions against compartment flooding, hazardous and toxic gases and vapors penetration into accommodation and service spaces;

.14 availability of grounding and (random) grounding check of electrically conductive plastic pipelines.

When the assembling is completed, the systems shall undergo hydraulic strength and leak tests (see 6.2.57) on board the ship or air test, if such alternative is provided by the Rules.

6.3.45 In the course of technical supervision during testing of systems metallic piping, the test pressure shall be taken considering provisions 6.2.57.

6.3.46 All pipelines after assembly shall undergo leak tests in operating conditions, except:

.1 heating coils in tanks and oil and gas fuel lines that shall be tested by 1.5 \( p \), but not less than 0.4 MPa

.2 liquefied gas pipelines that shall be leak tested (by air, haloids etc) by a test pressure chosen depending on the working pressure.

6.3.47 In case where hydraulic tests of assembled piping systems are carried out on board, leak tests and strength tests of them may be combined.

6.3.48 Testing of air, overflow and sounding pipes shall be carried out together with the tanks they are connected with.

6.3.49 Plastic pipelines making part of ship's systems that ensure the main purpose of the ship, its survivability and floodability, shall be tested after installation by hydraulic pressure at least 1.5 times exceeding the design system pressure.

6.3.50 Plastic pipelines not stated in 6.3.46 shall undergo leak test by the working pressure.

6.4 MOORING TRIALS

General requirements

6.4.1 The purpose of the mooring trials is to check the quality of installation and the adjustment of the items stated in 6.1.1, compliance of their parameters and characteristics with the specification and to state if the ship is ready for running trials.

6.4.2 Prior to start the mooring trials, all operations related to installation, running-in and adjustment of ship machinery, equipment and systems shall be completed and accepted by the manufacturer's QC service (organization responsible for conversion, modernization and repair). Items are subject to the mooring trials after preparation to their direct application together with systems and devices serving these items or containing them.

6.4.3 The mooring trials of the items in operation as intended shall be carried out only on the standard equipment in modes and scopes specified by the test program methodology approved by the River Register.

6.4.4 Prior to start the mooring trials, the Surveyor shall verify that all operations related to installation, running-in and adjustment of ship machinery and systems components are completed.

For general provisions on technical supervision during mooring trials see 4.2.

6.4.5 In the course of the mooring trials the Surveyor performs the technical supervision on functional check of manual, remote and automatic control, locking devices, alarm system, protection, means of communication between the wheelhouse, the engine room and control stations.

6.4.6 In the course of technical supervision during the mooring trials, the recording of all
6.4.7 If operation of components of ship machinery was forcibly interrupted during the functional checking, continuation of the mode, increase of its duration or recurrence shall be approved by the Surveyor considering the causes which led to the interruption.

**Internal combustion engines**

6.4.8 In the course of technical supervision during the engine trial, the following shall be checked:

1. operational readiness of units and systems serving engines;
2. engine starting and reversing characteristics as per Rules, adequacy of air receivers or battery capacity;
3. automatic control systems of rotation frequency and operation of limit switches;
4. engine parameters as per technical documentation.

6.4.9 Load modes and duration of mooring trials of main and auxiliary engines shall correspond to the Table 6.4.9. Duration of mooring trials of prototype ships engine at 100% mode increases twice compared to that established in the Table 6.4.9.

</table>

6.4.10 Parameters shall be measured at steady engine thermal state at least twice at each mode after completion of all transient processes.

**Shafting, gears, disengaging and elastic couplings**

6.4.11 Shafting, gears and couplings shall be tested while operating together with the main engine. In the course of technical supervision the Surveyor shall check:

1. temperature of journal and thrust bearings;
2. absence of hits in stern gear, gears and couplings, bearings;
3. vibration of engines, bearings and foundations;
4. effectiveness of the stern gear seals;
5. water supply to the sterntube.

**Compressors, pumps, fans and separators**

6.4.12 Compressors, pumps, fans and separators shall be tested together with units and systems they make part of.

In the course of technical supervision during these tests the following shall be checked:

1. possibility of control from a local, remote, emergency and secondary stations;
2. adequate operation of automation, alarm and protection means, possibility of controlling of the drive;
3. specified items parameters as per technical documentation;
4. efficiency of safety, relief, disengaging and breaking devices;
5. tightness of connections and pipelines;
6. forces on the handles of manual drives.

**Systems**

6.4.13 In the course of technical supervision during the testing of compressed air system and its serving compressors, the Surveyor shall check the following:

1. actuation of safety, reducing and starting quick closing valves and readings of press-gauges;
2. duration of air receivers filling by the compressed air to required working pressure;
3. timeliness of automatic activation and deactivation of compressors, duration of their automatic purging during starting;
6.4.14 During the testing of the fuel system the following shall be checked:

1. operation stability of fuel priming pumps in the specified mode and remote disconnection possibility;
2. duration of daily service tanks filling;
3. alarm actuation of the minimum permissible fuel level in the tank;
4. technical condition and working efficiency of the electric equipment;
5. adequate operation of devices for remote closing of valves of daily service tanks and main tanks, as well as overflow pipes;
6. stable engine operation at their transferring from heavy fuel to diesel and back;
7. adequate operation of the heavy fuel preparation system (separators, filters, heaters, automatic maintaining of preset fuel temperature).

6.4.15 In the course of technical supervision during the testing of oil system, the Surveyor shall check in operation the system of remote control from the wheelhouse of engine oil circulation, thermostats and oil transfer pumps, system of main engines oil circulation with the hand pump and the mechanically-driven pump (from the local control station or from the central control station).

6.4.16 During the testing of the cooling system the following shall be checked:

1. water temperature at the inlet and outlet of coolers and engines;
2. water supply for cooling compressors of exhaust gas pipe and stern unit;
3. adequate operation of the device for automatic control of the cooling water temperature;
4. possibility to switch the inner cooling circuit over to overboard water or standby;
5. alarm actuation of the minimum water flow in the inner cooling cycle expansion tank.

6.4.17 During the testing of the ship system in operation the following shall be checked:

1. capability of being operated as prescribed by technical documents;
2. proper operation of fittings, their drives, safety and relief valves;
3. tightness of connections;
4. accuracy of readings of standard instruments and automation equipment;
5. absence of abnormal vibrations, heating, noise;
6. meeting special requirements due to system purpose and covered by the Rules.

Boilers, heat exchangers and pressure vessels

6.4.18 During mooring trials steam boilers, heat exchangers and pressure vessels shall be checked as per program approved by the River Register.

6.4.19 Readiness of the steam boiler for mooring trial shall be confirmed by the document of the shipyard's QC service.

6.4.20 During mooring trials of the steam boiler the following shall be checked:

1. operation of the fuel system, including oil-fuel priming pump, filters, fittings, fuel heaters, filling of daily fuel service tank;
2. operation of nozzles and quality of burning (visually);
3. operation of the feed and condensate system: feeding pump, filters, fittings, quality of condensate in the hot well and observation tanks, and water treating quality;
4. operation of fans, gate valves, air channel density;
5. tightness of the boiler and boiler flues casing;
6. operation of automation equipment;
7. operation of electrical equipment;
8. amplitude and vibration frequency of the boiler and its components.

6.4.21 The boiler is to be tested in all modes provided in the operating manual and test program. Tests of self-contained boilers during mooring trials are final.
6.4.22 Results of tests in steam of the boiler and steam piping shall be recorded in the report of initial survey of the ship.

6.4.23 Visual inspection of boilers with fittings, equipment, pumps, filters, heat exchangers, pipings and other system components shall be carried out in steam under working pressure.

6.4.24 During visual inspection of the boiler, the following shall be checked:

1. water level in the boiler by purging sight glass channels with steam and water, and purging of control cocks;
2. proper appliance of mark on the cock plug of the boiler pressure gauge;
3. serviceability of water level indicators;
4. seal or stamp (indicating the calibration period) on the pressure gauges and red line on the pressure gauge scale;
5. serviceability of remote drives of steam pipeline shut-off valves, fuel and lock valves;
6. actuation of blow-down and scum valves of the boiler;
7. safety valves adjustment, herewith, firstly on the boiler with superheater shall be activated the superheater safety valve and when pressure continue to rise – saturated steam safety valves installed on the boiler. The adjustment of safety valves shall be checked under manual boiler control;
8. serviceability of manual drives of safety valves actuation from the boiler room and outside;
9. serviceability of feeding devices (pumps, pipelines and fittings);
10. proper operation of boiler’s automation equipment, emergency alarm and protection;
11. constancy of boiler performance while switching from automatic control to manual and back;
12. absence of leakage, steaming and buckling in the flame sections accessible for examination, condition of furnace brickwork, serviceability of furnace door locking devices;
13. overall condition of fuel storage and their air pipes, pipelines, fuel pumps, nozzles;
14. quality of boiler and steam pipes insulation.

When the results of safety valves adjustment are satisfactory, one of valves installed directly on the boiler shall be stamped by a representative of the shipyard’s QC service.

6.4.25 Heat exchangers in operation shall be checked together with serviced systems, piping and devices to check the quality of their installation and operational reliability. The following shall be checked:

1. operation on specified parameters of the working medium;
2. serviceability of fittings, instruments and control devices;
3. adjustment of safety and alarm and protection devices;
4. fastening and design of arrangements compensating thermal expansion.

6.4.26 To check the quality of installation of the pressure vessels and their applicability as intended, they shall be tested as a part of ship systems under working pressure. The following shall be checked

1. serviceability of fittings, instruments and control devices
2. adjustment of safety devices, sealing of safety valves;
3. functioning of arrangements for moisture removal from the vessel;
4. seal or stamp on the pressure gauges (indicating the calibration period) and red line on the pressure gauge scale indicating permissible pressure.

Refrigerating plants

6.4.27 Testings of refrigerating plant in operation purposes to verify its operational efficiency on board, as well as plant reliability and safety.

6.4.28 The refrigerating plant in operation shall be tested in the presence of the Surveyor as per program approved by the River Register. All items of the refrigerating plant shall be checked both in automatic and emergency manual operation.
6.4.29 In the course of technical supervision during refrigerating plant testing the following shall be checked:

1. proper operation of the main and standby refrigerating equipment (compressors, separators, apparatuses, systems, heating controllers, instruments, shut-off and control valves, warning alarm and protection systems, remote control), and serviceability of electrical and automation equipment, systems servicing the refrigerating plant room and refrigerated spaces

2. possibility to achieve the lowest specified temperature in the cooled spaces and time required for that

3. possibility to maintain the specified temperature in the cooled spaces for 24 h connecting at regular intervals standby equipment under condition of its continuous operation for 10 to 12 h. In this case the refrigerating capacity of lead ships shall be determined as well

4. insulation efficiency by mean heat transfer coefficient and dynamic of air temperature change when the refrigerating plant (of lead ships) is not in operation during 24 h

6.4.30 In the case of refrigerating plant testing at a boiling and condensing temperature of the refrigerant different from designed ones by more than 1 °C (boiling temperature) or than 2 °C (condensing temperature), the refrigerating capacity shall be re-evaluated for design conditions.

6.4.31 The refrigerating capacity and mean heat transfer coefficient are considered to be confirmed if their difference from the designed values do not exceed 5 %.

6.4.32 The processed results of the refrigerating plant tests shall be submitted to the Surveyor for drawing up the River Register documents.

The conclusion about compliance of the plant characteristics and its equipment with specification shall be attached to the test report documentation for the plant in operation.

6.5 RUNNING TRIALS

6.5.1 Running trials are intended for complete functional check of the power plant and systems in operating conditions.

6.5.2 Running trials shall be performed after eliminating defects detected during mooring trials as per the program approved by the River Register. The running trials program provides for checking all the parameters prescribed by the vessel’s specification and technical documentation for ship machinery or similar technical documentation.

6.5.3 Load modes and operation period of the main engines in these modes during running trials shall comply with those in Table 6.5.3. Running trials duration for engines of the lead ships at 100 % mode increases twice compared to that established in the Table 6.5.3.

During running trials, diesel generators shall be checked in operation as intended.

6.5.4 Boilers, heat exchangers, compressors, pumps, fans, separators, pressure vessels, refrigerating plants, general systems and systems of the ship’s power plant shall be checked in operation during running trials as intended.

6.5.5 After running trials, steam boilers shall be submitted for internal survey.
The Surveyor shall be submitted the measurement results of flame tubes performed by the shipyard’s QC service after mooring and running trials, to compare them with the measurement results obtained when manufacturing the boiler in the shop, or specified in the technical documentation.

6.5.6 Deck machinery shall be tested together with their devices in modes provided by the test program approved by the River Register.

6.5.7 In cases provided by the Rules, during running trials they measure torsional vibration parameters of the shafting as per the separate program approved by the River Register.

Measurements shall be performed in propeller characteristic modes from minimum stable to maximum rotation frequency.

If a prohibited zone of rotation frequencies was found, numerical values of its boundaries shall be fixed in the ship datasheet, and prohibited zones on tachometer scales shall be marked according to 6.4.3 Part IV of RCSS. Availability of prohibited zones shall be fixed in the Certificate (PP-1.0 form) issued on board the ship.

6.5.8 In case of failure of boilers, heat exchangers and pressure vessels during technical supervision of their functional check during mooring trials, after remedying them, they perform technical supervision of boilers as per 6.4.18 to 6.4.25, heat exchangers and pressure vessels – as per 6.4.26 to 6.4.28. During running trials, waste heat boilers shall be tested as per 6.4.21 to 6.4.24.

6.5.9 In case of failure of refrigerating plants during technical supervision of their functional check during mooring trials, after remedying them, they perform technical supervision of refrigerating plants as per 6.3.44 to 6.3.49 during running trials. When testing, all the circuits of refrigerating plants shall be used. Refrigerating plant elements shall be checked both in automatic and emergency (manual) mode.
7 SHIP ARRANGEMENTS AND OUTFIT

7.1 GENERAL REQUIREMENTS

7.1.1 This section contains the requirements for the technical supervision during manufacture of ship arrangements, equipment and outfit and during installation and testing of the above items onboard according to the Nomenclature.

7.1.2 Materials to be used for manufacture of items shall comply with the requirements of Part V and Part X of RCCS.

7.1.3 The technical supervision during manufacture and testing of steering engines, steerable thrusters, transverse thrusters and deck machinery (windlasses, capstans, and anchor, mooring, towing and boat winches) shall consider the applicable requirements set out in 6 of these Rules.

7.1.4 When conducting the technical supervision during manufacture of deck machinery, cargo handling gears and their assemblies, follow 6 of these Rules.

7.2 TECHNICAL SUPERVISION DURING MANUFACTURE

General requirements

7.2.1 The technical supervision during manufacture of arrangements, equipment and outfit includes the following:

.1 verification of technical documents;
.2 check of materials;
.3 visual inspection of items;
.4 validation of measurements;
.5 check of nondestructive testing;
.6 tests.

Rudder and steering gear

7.2.2 When parts of rudder and steering gear, transverse thrusters and steerable thrusters are visually inspected, the following shall be checked in addition to the list in 7.2.1:

.1 assemblage of rudder (nozzle), quality of key slots;
.2 protection of internal cavities of items from corrosion or their fill-up;
.3 quality of machining of holes for tight fit bolts;
.4 installation of plugs and drain plugs on hollow structures of rudders and steerable nozzles after filling them up with inert mass.

Anchor arrangement

7.2.3 When anchors are inspected, the following shall be checked in addition to the list in 7.2.1:

.1 documents on drop tests;
.2 quality of welding of welded anchors;
.3 curvature of anchor shank;
.4 weight of anchor.

7.2.4 The technical supervision during manufacture of anchor chains and their component parts includes the following:

.1 check of documents on materials to be used;
.2 check of documents on accessories (for chains);
.3 visual inspection for compliance of dimensions (for chains);
.4 review of test results;
.5 check of marking;
.6 branding.
Coupling arrangement

7.2.5 For type approval, standard samples of coupling equipment shall be bench-tested by test load with strain-gauging of critical parts as per the program agreed upon with the River Register.

Values of test load and permissible stresses in the coupling equipment parts are specified in Part V of RCCS.

7.2.6 When conducting the technical supervision during manufacture of series-produced coupling equipment, check the following:
   .1 compliance of workmanship of main parts and coupling equipment as a whole with technical documentation for manufacture;
   .2 kinematics and interaction of all parts, opening of lock under design load and strength of lock under bench test with test load (without strain-gauging).

Load-handling device

7.2.7 When conducting the technical supervision during manufacture of cargo handling gears to be installed on ships to be classified by the River Register, check the following:
   .1 quality of parent and welding materials used to manufacture metal structures and compliance of the same with technical documentation agreed upon with the River Register;
   .2 availability of necessary documents for component parts as per the Nomenclature;
   .3 workmanship of parts and assemblies and quality of assemblage of cargo handling gear according to the List;
   .4 correctness of bench testing of assembled removable parts of cargo handling gear as per 7.2.9 to 7.2.11 as per the program agreed upon with the River Register.

7.2.8 Tested cargo handling gears shall be branded according to 6.17 Part V of RCCS.

7.2.9 All newly manufactured removable parts of cargo handling gears (blocks, hooks, chains, turnbuckles, rope sockets, etc.) shall be tested with test load under supervision of person competent for conducting this type of tests. This test shall be performed on the properly calibrated machine or by suspending a load of specified weight to parts under test according to Table 7.2.9.

The proof load shall be applied statically. The time of keeping the upper structure under the load is at least 5 min.

<table>
<thead>
<tr>
<th>Removable parts</th>
<th>Load weight $m_{SWL}$ (t) corresponding to permissible load SWL</th>
<th>Test load weight $m_{test}$ (t)</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
</tbody>
</table>

On completion of test, all parts shall be visually inspected for absence of defects or residual deformations. Blocks shall be disassembled for visual inspection of axes and sheaves.

All removable parts shall be submitted for visual inspection and tests with corrosion-resistant coat applied (except for paint coat).

Tested parts shall be branded according to the Nomenclature.

7.2.10 If removable parts of cargo handling gear are jointed in an assembly, test shall be applied to this assembly.

When this takes place, removable parts shall not be tested individually.

7.2.11 Standard samples of removable parts shall be tested with limit load equal to double test load within time specified by the manufacturer in the testing program.

Removable parts of cranes with lifting capacity of 100 t are not tested with limit load if
calculations and results of testing with test load have confirmed their strength.

Quantity of parts from a batch subject to this test shall be determined upon agreement with the River Register.

Sleeves and compression clamps for terminating wire ropes and thimbles shall be tested together with terminated rope.

A part is considered to have passed the test if it is not broken under limit load.

Parts tested with limit load shall not be repaired and used for the purpose specified.

Tests with limit load shall be witnessed by the surveyor. Test results shall be recorded in the report (see 2.3.12).

Hydrofoil system

7.2.12 When conducting technical supervision during manufacture of hydrofoil system, check the following in addition to the list in 7.2.1:

1. assemblage of hydrofoil system;
2. protection of internal cavities of items from corrosion or their fill-up;
3. fitting of plugs and drain plugs on hollow structures of hydrofoil system.

Deck machinery

7.2.13 When conducting the technical supervision during manufacture of deck machinery parts operated under excessive pressure, check results of hydraulic tests performed after final machining before application of protective coats. Hydraulic test pressure $p_{\text{test}}$ (MPa) for such tests shall be determined in accordance with the requirements of 6.2.28 imposed to test pressure for hydraulic tests of parts of compressors, pumps and fans operated under overpressure.

7.2.14 Parts and assemblies of deck machinery (bodies of reduction gears, trays, etc.) to be filled with petroleum products or their vapours under hydrostatic or atmospheric pressure shall be subject to tightness testing with dye penetrant method. In welded structures it is sufficient to test only tightness of welds.

7.2.15 After assembled, adjusted and run in and before installed onboard, deck machinery shall be bench-tested under load according to the program agreed upon with the River Register (according to Part V of RCCS).

Bench tests may be replaced with onboard tests.

Hydraulic drives

7.2.16 The elements of hydraulic drives being under load shall be strength-checked for the application of forces corresponding to the working pressure, here, the equivalent stresses in the elements shall not exceed 0.4 of the yield point of the element.

Life-saving appliances

7.2.17 The technical supervision during manufacture lifeboats, liferafts, life-saving apparatuses, lifebuoys and lifejackets shall be conducted in accordance with the requirements of 7.2.1.

Standard samples of life-saving appliances shall be tested according to the testing program agreed upon with the River Register and guidelines stated in Appendix 13.

Signal means

7.2.18 Standard samples of pyrotechnic signal means shall be tested according to the testing program agreed upon with the River Register and guidelines stated in Appendix 14.

7.2.19 When conducting the technical supervision for navigation lights, check the following in addition to the list in 7.2.1:

1. interchangeability of parts;
2. degree of protection (see Appendix 15);
3. insulation breakdown strength (see Appendix 15);
4. insulation resistance (see Appendix 15).

7.2.20 Bench tests of standard samples of lights, except for those mentioned in 7.2.18, shall be performed as per the agreed testing program developed according to Appendix 15 and shall include the following:

1. functional tests;
.2 vibration survival, vibration resistance and on impact tests;
.3 operation check at high and low ambient temperatures;
.4 check for corrosion resistance;
.5 check for heat resistance;
.6 check for moisture resistance;
.7 operation check under roll and pitch;
.8 check of degree of protection from contact with current carrying parts;
.9 lighting tests.

Ropes

7.2.21 The technical supervision during manufacture of wire, synthetic and natural fiber ropes consists in:
.1 check of materials to be used for manufacture of products as per accompanying documentation;
.2 review of results of tests performed as per the agreed testing program;
.3 visual inspection and measurement.

7.3 TECHNICAL SUPERVISION DURING ONBOARD INSTALLATION AND TESTS

Rudder and steering gear

7.3.1 On completion of installation of rudder and steering gear and thrusters, the surveyor shall check the following:
.1 certificates for chains and ropes, reports on hydraulic test of hydraulic system;
.2 reliable installation and fastening of main steering drive on ship’s foundation;
.3 correct application of gauge-marks of rudder (nozzle) midposition, correct graduation of rudder (nozzle) position indicator at quadrant;
.4 drive alignment;
.5 quality of installation of rudder stock bearings;
.6 correct fit of steering drive support surfaces to gaskets, gaskets to foundation support parts and heads of foundation bolts and nuts to drive surfaces and foundation flanges;
.7 tightness of joints of hydraulic system pipelines of rudder and steering gear and thrusters;
.8 ease of turn of rudder blade or steerable nozzle with drive disconnected;
.9 mounting connections of rudder stock with rudder blade or steerable nozzle, availability of River Register brand on rudder stock if provided for by the Nomenclature;
.10 installation of side stops of steering drive;
.11 sealing gland of rudder stock and impermeability of seal of tapered joints;
.12 installation and fastening of stand-by steering drive;
.13 clearances in hinges and bearings;
.14 clearances that regulate rudder or nozzle movement in axial direction (upwards) depending on steering drive design;
.15 availability of locking devices that eliminate loosening of moving parts of gear;
.16 rudder or steerable nozzle angles to contact with turn limiter on hull and size of contact surface area;
.17 compliance of indications of rudder indicators with position of rudders or nozzles.

7.3.2 During harbour acceptance trials of rudder and steering gear, the following shall be checked:
.1 operability of gear with drive from power source by continuous rudder or nozzle deflection from hard over to hard over during 30 minutes;
.2 possibility of gear operation from emergency power source during 15 minutes;
.3 time of rudder or nozzle deflection from hard over to hard over and from mid-position to port and starboard separately with power supplied from main and emergency power sources. When main engine is used as a drive for hydraulic pump of steering gear, time of rudder deflection shall be measured in slow and full speed modes;
.4 reliability of switching from main drive to standby one and back at least three times and at different positions of rudder or nozzle;
.5 operability of gear with stand-by drive by deflecting rudder or nozzle from hard over to hard over, time of turn from 20° at a side to 20° at another side and number of people required for this operation;
operability of steering engine limiters and quadrant turn angle;
7 operability of communication means of control positions and rudder indicators;
8 temperature of steering engine bearings, reduction gears and other parts;
9 rudder or nozzle deflection by means of tiller (steering tackles).

7.3.3 When conducting the technical supervision during harbour acceptance trials of transverse thruster, check the following:
1 operation of thruster during 30 minutes;
2 thrust of thruster by method of direct measurements in alternate operation to starboard and port side (on lead ships);
3 correct operation of signalling system in wheelhouse.

7.3.4 Running trials of rudder and steering gear of lead ships shall be performed simultaneously with check of maneuvering capabilities of loaded and light ship at design draughts and of tug boats and pushboats without convoys and with convoys.

7.3.5 During running trials of rudder and steering gear of ships mentioned in 7.3.4, the following shall be checked:
1 no-failure rudder (nozzle) deflection from hard over to hard over and from any arbitrary position to a side or along centreline at full, mean and slow speeds ahead and astern;
2 no-failure operation of gear in ship seaworthiness test modes;
3 time of rudder or nozzle deflection from hard over to hard over and from centreline to each side at full and slow speed ahead (for electric power drive with power supply from main and emergency power sources);
4 operability of test lamps, limit switches and overload alarm;
5 indications of rudder indicators and their compliance with rudder blade or nozzle positions;
6 force applied to hand drive wheel;
7 force applied to water-jet propeller reversing handle;
8 reliability and ease of changeover from main drive to standby one and back at different ship speeds and different deflection angles of rudders or nozzles.

7.3.6 Rudder and steering gear on series-produced ships shall be tested in accordance with 7.3.5.1 and 7.3.5.3 to 7.3.5.5.

Anchor arrangement

7.3.7 On completion of installation of anchor arrangement, the surveyor shall check the following:
1 installation and fastening of windlass or anchor capstans on ship foundation;
2 installation and fastening of anchor arrangement stoppers on ship foundation;
3 mounting of anchor chains — i.e. assembly of coupling links;
4 equipment of chain lockers;
5 installation of devices for fastening and unfastening of bitter ends of anchor chains;
6 assembled anchor chains and anchors for compliance with drawings, including availability of brands and compliance of assemblies and parts as per certificates;
7 sizes of welds of foundations for elements of anchor arrangements;
8 absence of angular misalignments of anchor chain in plan view;
9 installation of remote control system equipment.

7.3.8 During harbour acceptance trials, anchor arrangement shall be checked in operation by alternately hauling out several shots of each chain and hauling them in by means of electric power drive and hand drive.
The following shall be checked during trials:
1 correctness of running of chain links on sprocket wheels, through stoppers and anchor hawses;
2 operability of stoppers and belt brakes of windlass, capstan or anchor winch (two or three break operations while chain or rope is hauled out);
3 free run-out and run-in of chain and anchor from/to hawsehole and contact of anchor flukes with ship side;
reliability and rapidity of anchor release when sprocket wheels are disengaged from windlass shaft;

tightness of closed hawse and chain pipes;

no-failure operation of remote anchor release device;

compliance of anchor chain hauling speed with mechanism ratings;

self-stowage of all hauled anchor chain in chain locker.

During running trials on lead ships and convoys, anchor arrangement capability of providing safe anchorage and safe operation in navigation areas specified in the preliminary specifications.

The following shall be checked:

sufficiency of holding power of anchors to hold a single ship or a pushboat with convoy on current;

operability of anchor arrangement when hoisting anchors from design anchorage depths.

Operation of anchor arrangements on series-produced ships shall be checked at maximum depths of test area, as well as on river under current conditions.

When bow anchor arrangement is tested, the following shall be checked:

operability of belt brakes with dead drive by breaking an anchor chain or an anchor cable being hauled out;

operability of deck stoppers;

capability of hauling in each anchor by means of windlass with lifting it off the ground and hoisting speed;

capability of releasing both anchors by means of windlass with drive operating in all design operating modes;

capability of simultaneous hoisting of two hanging anchors and hoisting speed;

no-failure operation of remote anchor release device from wheelhouse;

operability of hand drive of windlass or anchor winch;

correct run of anchor chain links on windlass sprockets, through stoppers and hawses during all types of tests and correct run of anchor cable through cable layer.

When stern anchor arrangement is tested, the following shall be checked:

reliability of anchor release with anchor; arrangement drive disabled by brake;

capability of anchor release, lift-off from ground and hauling in by means of anchor handling gear and hauling speed;

operability of deck stoppers.

Towing and coupling arrangements

On completion of installation of towing arrangement, the surveyor shall check the following:

installation and fastening of towing winches on foundation;

compliance of type, diameter or circumference and length of towing rope with drawing or list;

adjustment of mechanical lock of towing hook;

correct installation of towing rope limiters;

operability of remote towing rope release device at all possible angles of deviation from centreline;

arrangement and design of guide rollers and blocks, no slipping off of rope or friction of rope against hull structures.

During harbour acceptance trials of towing arrangement, the following shall be checked:

movability of towing hook with rope attached to it;

capability of free release of towing rope from hook;

correct operation of remote rope release device from wheelhouse;

correct operation of towing winch during rope hauling in/out;

operability of towing winch mechanisms and brakes.

During harbour acceptance trials of lead tugboats and pushboats with convoy, the following shall be checked:
.1 operability of towing winch;
.2 no-failure operation of brakes and cable layers;
.3 capability of free movement of rope on towing arches and efficiency of rope stopping on limiters.

7.3.16 On completion of installation of coupling arrangement, the surveyor shall check the following:
.1 availability of coupling equipment;
.2 safe attachment of coupling equipment to foundation;
.3 availability of ship hull reinforcement at coupling equipment location.

7.3.17 During harbour acceptance trials of coupling arrangement, the following shall be checked:
.1 correct operation of luffing mechanism;
.2 correct operation of claws and locking hooks;
.3 operability of head cams by turning them with a winch and returning them with springs;
.4 correct operation of pressure shanks for two-locked couplings;
.5 correct operation of winch when lock is lifted and lowered throughout height of stop;
.6 correct operation of lock holder and release;
.7 correct operation of lock key and rope coupling sea-securing device;
.8 tensioning of ropes with tensioning station;
.9 operability of rope shortening device.

On completion of operability check of mechanisms, test convoys shall be checked during running trials by direct measurement of stresses or forces that occur in coupling and uncoupling shall be performed, and operation of devices preventing spontaneous unlocking shall be checked. Unlocking shall be performed from local and remote control posts.

Test coupling and uncoupling of coupling arrangement of pushboats and bow locks of nonself-propelled ships may be performed on benches that simulate aft end of barge.

Strength characteristics of coupling arrangement on lead ships and arrangement.

7.3.18 On completion of installation of mooring arrangement, the following shall be checked:
.1 installation and fastening of mooring capstans or winches and other equipment of mooring arrangement on foundations;
.2 positional relationship and height of installation of mooring arrangement components and availability of free areas and approaches to them;
.3 compliance of type, circumference and length of mooring ropes with drawing instructions (list of supply);
.4 quality of mounting of hydraulic system pipelines and pumps.

7.3.19 On completion of installation and testing of cargo handling gear, preliminary tests of all units idling shall be performed. If results of preliminary tests are satisfactory, cargo handling gear with appropriate documentation shall be submitted to the surveyor for final trials.

7.3.20 Before onboard testing of cargo handling gear, the surveyor shall check the following documents:
.1 notification on acceptance and readiness of gear for testing;
.2 data sheet or certificate (for cranes);
.3 testing program;
.4 certificates for chains, ropes, removable parts of cargo handling gear, materials of critical parts of machines, metal parts of cranes, spars and welding materials;
.5 reports of quality test of welded joints and information on certification of welders who performed critical welding;
.6 data sheets for mechanisms and units;
.7 specification for cargo handling gear;
.8 drawings and diagrams.

7.3.21 Before tests begin, the surveyor shall visually inspect the cargo handling gear to check the following:
.1 safe fastening of units to foundations and foundations to deck;
.2 correct assemblage of cargo handling gear;
.3 convenience of location of control posts;
.4 safe stowage of rope on drum;
.5 availability of safety devices, safety guards and fences.

7.3.22 Cargo handling gear installed onboard shall undergo static and dynamic tests with test load.

Dynamometer shall not be used instead of test load.

Luffing cranes shall lift a test load with maximum and minimum overhangs. If luffing cranes have variable outreach-dependent lifting capacity, they shall lift a test load at maximum and minimum overhangs for each fixed lifting capacity.

Lifting capacity limiter shall be off for testing with test load.

7.3.23 For static test of crane, a test load weighing 125% of nominal capacity shall be used. Here, crane beam shall be in a position corresponding to least crane stability, and load shall be lifted to height of 100 to 200 mm. Test load shall be retained by crane in fixed position for at least 10 minutes.

For dynamic test of crane, a test load weighing 110% of nominal capacity shall be used. All motions shall be performed at full speed.

Luffing during tests shall be carried in all range of possible outreach values between two permissible extreme positions of beam.

Reliable operation of brakes of cargo winches of beams and cranes shall be checked by quickly lowering a test load by about 3 m and abruptly braking it. This test shall be performed in at least two positions of beam.

Test load hanging with dead winch drive shall be checked too.

7.3.24 After tested with test load, crane shall be tested with a load equal to lifting capacity with hoisting, turning, luffing and travelling mechanisms operating at maximum speed. When this takes place, abrupt braking shall be applied to test operation of brakes of hoisting, turning, luffing and travelling mechanisms.

Operation of limit switches and outreach indicators shall also be checked.

If crane is capable of making different simultaneous motions (hoisting, luffing, turning and travelling), all permissible combinations of motions shall be checked.

Lifting capacity limiters shall be checked in operation by lifting a load corresponding to limiter setting.

7.3.25 While crane is tested, condition of steel structures, beams, mechanisms, critical parts and fastenings shall be monitored.

Special attention shall be paid to crane stability, uniform contact bottom parts of all supports with base and fastening and operation of counterbalance weight and braking device.

Ensure that at least 1.5 rope coils remains on winch drum at lowermost working position of load-handling device.

7.3.26 When testing travelling cranes, ensure that travelling roller do not separate from rails.

7.3.27 After tests, all metal structures, units and parts of cargo handling gear shall be visually inspected by the surveyor to detect possible defects.

If defects are detected, their causes shall be eliminated, defects shall be remedied by methods agreed upon with the River Register, and retests shall be performed.

7.3.28 If results of cargo handling gear tests are positive, the River Register documents shall be drawn up.

Boat handling gear and life-saving appliances

7.3.29 After installed onboard, each boat handling gear shall be tested with a boat being lowered and lifted. The load shall be in accordance with Part V of RCCS.

7.3.30 Before boat handling gear tests with test load begin, assembled launching arrangements shall be inspected. The surveyor shall check the following:
.1 quality of mounting and complete set of launching arrangements;
.2 availability of brands and markings of items, assemblies and parts and their compliance with submitted certificates;
.3 tightening of fastening screws, close fit of bed frame feet to foundations, quality of welds of foundations and reinforcements under foundations;
.4 reliable attachment of ends of boat falls on winch drums and of bitter ends of boat falls;
.5 boat davit outreach;
.6 possibility of observing the boat being lifted and lowered from winch control post;
.7 correct operation of hand drive of boat davit winches and screw drive of collapsible boat davits.

7.3.31 When boat handling gear is tested, the following shall be checked:
.1 reliable operation of winch hand brake with boat being lowered. Braking shall be smooth, but effective;
.2 smooth motion of travelling rollers along guides of rolling-down boats;
.3 run of falls on sheaves and guide rollers and in places closed by housings;
.4 boat lowering speed;
.5 uniform coiling of rope on winch drum;
.6 necessary length of falls for lowering a boat at each side to level of lowest ballasted ship waterline at 15° heel to any side;
.7 rope capacity of winch drum (sufficient elevation of winch drum shoulder at end faces over top row of completely stowed rope);
.8 boat lowering time.

7.3.32 Swinging arms of boat davits shall be tested by swinging out and swinging in arms and boat davits and lowering and lifting a boat with cargo equal to weight of complete set of outfit and launching team several times (not less than three times). The following shall be checked:
.1 smooth movement of arms of boat davits;
.2 smooth movement of travelling rollers on guides of roll-down boat davits;
.3 force applied to hand drive handle;
.4 automatic cut-off (blocking) of power supply of electric drive when hand drive is activated (hand drive handle is attached);
.5 availability and adjustment of limit switches.

7.3.33 Mechanically driven life-boats and motor boats shall be tested underway to check drive and (or) motor in operation. If radio equipment, navigation equipment, floodlights, sprinkling system and compressed air system (on tanker boats) are available, they shall be tested for intended use.

7.3.34 When liferafts are installed, compliance of type, quantity, holding capacity, location, brands and markings of liferafts with requirements of agreed technical documentation and availability of River Register certificates shall be checked.

7.3.35 The surveyor shall check compliance of quantity, location and fastening of life-saving devices on vessel with requirements of technical documentation agreed upon with the River Register, availability of River Register certificates and manufacturer documents, as well as operability and completeness of life-saving devices.

7.3.36 Lifejackets shall be visually inspected and checked for compliance with manufacturer documents and River Register certificates.

7.3.37 Outfit items of life-boats shall be checked for compliance with documentation agreed upon with the River Register and with requirements of Part V of RCCS. Outfit items of life-boats shall also be checked for completeness and proper location inside boat and availability of manufacturer documents.

7.3.38 During the technical supervision for signal means of ships under construction, the following checks shall be performed:
.1 compliances of signal means with documentation agreed upon with the River Register;
.2 installation of signal means on ships.
7.3.39 Check of compliance of signal means with agreed technical documentation shall include check of data sheets and certificates, check of signal means and comparison of accompanying documents with markings and brands applied to signal means.

7.3.40 Check of installation of signal means on ships shall include visual inspection and check measurements (checks) to ascertain the following:

1. Correct location of stationary signal means in vertical and horizontal planes and with reference to ship centreline;
2. Correct installation and fastening of signal means;
3. Ease of dismounting of signal means and replacement of replaceable parts;
4. Correct wiring of electric cables and protective earthing of signal means;
5. Effective protection against radio interference created by electrical signal means;
6. Quality of mounting of compressed air, vapour or other agent piping for actuating acoustical signal means;
7. Operability of structures and safety of devices and appliances for actuating pyrotechnic signal means and their storage locations.

7.3.41 When conducting the technical supervision for fire protection, navigation and emergency outfit and pyrotechnic and acoustical signal means, check the following:

1. Availability of documents on outfit items and their validity;
2. Complete set of outfit according to the design and Rules;
3. Location and fastening of outfit items on ship according to the design.

7.3.42 In addition to requirements of 7.3.41.1, installation of onboard fire extinguishers and availability of certificate of compliance of fire extinguishers with fire safety regulations (Federal law No. 123-ФЗ dated 02.07.2008).
8 ELECTRIC EQUIPMENT

8.1 GENERAL REQUIREMENTS

8.1.1 This section covers requirements to technical supervision during manufacture, onboard installation and testing of electric equipment stated in the Nomenclature.

8.1.2 Technical supervision of electric equipment by the River Register provides:

.1 approval of technical documentation, test program for electric equipment;
.2 technical supervision during manufacture and tests of electric equipment;
.3 technical supervision during installation and tests of on-board electric equipment.

8.1.3 Technical supervision of electric process and household equipment shall be limited to the following checks:

.1 insulation condition and resistance;
.2 using distribution systems;
.3 for serviceability of points of connection to power sources;
.4 explosion-proofness level of electric equipment during arrangement in explosion-hazardous spaces and areas;
.5 types, brands and cross-sections of the cables used;
.6 earthing.

8.1.4 All types of electric equipment, installation works, valves and material, which become unavailable for check after their fitting and completion of works, shall be submitted to the Surveyor at the stage of works when checks provided by the Rules are possible.

8.2 TECHNICAL SUPERVISION DURING MANUFACTURE

8.2.1 Technical supervision during manufacture of electric equipment includes:

.1 checking for availability of the approved technical documentation and test program;
.2 monitoring of the used materials to meet the requirements of 2.4 Part VI RCCS;
.3 item inspection;
.4 supervision during tests.

8.2.2 During inspection, the following shall be checked:

.1 the documents for materials used during manufacture;
.2 technical condition of components included in the survey item;
.3 installation quality of the item electric circuit;
.4 strength of connection and fastening of assemblies, live parts, welded, soldered, screwed or other structural and contact joints;
.5 presence of corrosion-resistant coatings;
.6 availability of necessary markings and inscriptions;
.8 technical condition of contact and protection terminations of cables and wires;
.9 serviceability of structures providing electric safety.

8.2.3 Type specimens shall be tested as per the approved test program, developed in accordance with Appendix 15. Test types shall be established by Part VI RCCS.
8.2.4 Type specimens of cable items shall be tested on flame retardence as per the procedure given in Appendix 16.

8.2.5 Serial items shall be tested as per 1 to 3 Appendix 15.

8.3 TECHNICAL SUPERVISION DURING ONBOARD INSTALLATION

8.3.1 When surveying foundations and other support structures for fitting electric and electronic equipment, the following shall be checked:

1. quality of the performed works, absence of sharp edges and other defects causing damages of the electric / electronic equipment to be fitted;
2. possible access for maintenance of electric and electronic equipment;
3. compliance of the position of electric / electronic equipment with the requirements of the Rules (fitting on the shell plating of the ship, walls of fuel, oil, water tanks, pressure vessels is not permitted) and the approved technical documentation;
4. remote location of electric/electronic equipment and its energized parts from the hull plating, deck and platform platings;
5. remote location of electric/electronic equipment from combustible materials, heat sources, emissions of gas, steam and water as well as pipelines, tanks, valves and other fittings which may accommodate damages of electrical equipment or cause combustion of nearby materials.

8.3.2 When surveying electrical propulsion systems, the following shall be checked:

1. absence of flange or thread connections of pipelines, valves and other fittings above electric machinery of electric propulsion installation;
2. arrangement of water coolers, their pipelines, availability of valves in water mains, of quick-release valves.

8.3.3 When surveying cable network, the following shall be checked:

1. removal of cable routes from potential places of oil and oil products;
2. proper structure of the cable support devices;
3. sufficient and periodical cable fastenings on support structures;
4. separate laying of cables with various purposes and voltages;
5. compliance of structures and methods of fitting pipes, compensators and methods of fastening cables, channels, conduits, risers, sleeves, bus line carcasses, pull cable boxes, specific sealing structures and other devices for laying cables through bulkheads and decks with the technical documentation requirements;
6. proper cable laying in explosion-hazardous spaces and areas and fire-hazardous spaces;
7. marking, terminations in cable conductors and wires.

8.3.4 When surveying storage batteries, the following shall be checked:

1. compliance of the battery room (locker) and arrangement of storage batteries with the Rules requirements;
2. secure attachment of batteries;
3. absence of trapped zones in the deck-head of battery rooms;
4. availability of autonomous ventilation in the battery room;
5. serviceability of blocking preventing from charging batteries prior to activating ventilation of an accumulator room;
6. explosion protection measures.

8.3.5 Technical supervision during on-board installation of Domestic, household and engineering electric equipment includes the following checks:

1. compliance of the electromagnetic interference level (as per supporting documents) with the requirements of 2.7 Part VI of the Rules. In case of no information presentation on the electromagnetic interference level, no electromagnetic interference influence, caused by the equipment, should be confirmed. The requirement applies to the equipped fitted in spaces for operation with radio communication aids, navigation aids, and to control systems of technical facilities including electronic components;
Electric Equipment

8.3.6 The Surveyor shall verify that after fitting at standard places, all the electric equipment as per the protection degree, completion, quantity, electric protection, cable network, arrangement in spaces and areas of the ship, easy maintenance, controllers and regulators, fencings, fire and explosion safety measures, electric shock protection, protective grounding and other characteristics and parameters complies with its purpose and ensures safe navigation of the ship.

8.3.7 The fitted electric equipment shall be inspected after laying, fixing and connecting all cables to the equipment.

8.3.8 When checking the installation of electric equipment for oil tankers, meeting the requirements of the Rules for the equipment of these ships shall be additionally controlled.

8.4 MOORING TRIALS

8.4.1 During mooring trials, all consumers shall be supplied from standard power sources.

When standard power consumers do not ensure the required load for ship's generators during mooring trials, specific loading appliances shall be used.

8.4.2 Parameters checked during mooring trials of the electrical propulsion system for the built ship, see Appendix 17.

8.4.3 During mooring trials of electrical propulsion system, the following shall be checked:

1. proper operation of the installation for starting and reversing in all reversal variants provided by the design documentation;

2. serviceability of starting aids for diesel generators, backup excitors, fans, coolers and lubricators;

3. possible unit control from local and remote stations;

4. sparking degree under brushes at load and reverses;

5. serviceability of protectors, alarms and blocking;

6. insulation resistance of electric machines, cable network and auxiliary units of electric propulsion system in cold and hot states;

7. proper readings of the propeller shaft revolution frequency indicators in the engine room and in the wheelhouse.

8.4.4 Generators of the ship's electric power plant shall be tested in all modes together with the main switchboard.

The following shall be tested:

1. serviceability of generators as per the test program;

2. stable parallel work at different loads and generator load transfer;

3. serviceability of voltage regulators and distributors of active and reactive loads between generators;

4. adjustment of automatic generator protectors;

5. sparking degree under the generator brushes;

6. insulation resistance;

7. serviceability of automatic synchronizers and load dividers.

8.4.5 During functional test of batteries, the following shall be checked:

1. electrolyte density and filling level in storage batteries;

2. insulation resistance;

3. operation of the charging device and battery in case of discharge;

4. actuation of automatic protectors (reverse-current protection, etc.);

5. battery discharge capacity in operation as intended and voltage of its clamps;

6. efficient ventilation of the room / locker (on board the prototype ships).
8.4.6 When testing power distribution devices, the following shall be checked:

1. serviceability of devices at the load conditions in all modes in load combinations / variants specified by the ship design;
2. possible control transfer from the main stations (consoles) to local ones and their uninterruptible operation in case of such control;
3. compliance of the set control element positions with actual operating modes for the controlled item;
4. adjustment of automatic protectors (by inspection of the actuation set points and by random tests of automates, except for short-circuit protection), interlockings and alarms;
5. readings of instruments and recorders;
6. insulation resistance.

8.4.7 When testing electric drives, they reveal characteristics of each electric drive and its compliance with its purpose.

In addition to these tests, the following shall be checked:

1. serviceability of the drive at the load conditions during the time determined by the test program (using instruments, if necessary);
2. possible control of the drive from the remote and local stations and deactivation by means of emergency switches;
3. proper operation of limit switches, brakes, lockings, control devices, automatic protectors and alarms;
4. compliance of heat protection settings with currents of the protected electric motors;
5. insulation resistance of electric motors and equipment in cold and hot conditions.

8.4.8 When testing control and alarm devices, the following shall be checked:

1. coordinated action of setters and actuators;
2. serviceability of alarms, devices, equipment;
3. actuation of general and fire alarm;
4. insulation resistance.

8.4.9 During tests of emergency electrical propulsion system, the following shall be checked:

1. reliable automatic start of emergency diesel generator;
2. reliable automatic connection of emergency generator to emergency switchboard busbars;
3. uninterruptible connection of consumers to the emergency power source supply (diesel generator or storage battery);
4. uninterruptible connection of consumers to the emergency short-term power source supply (if any);
5. parameter values of emergency diesel generator by measuring voltage, revolution frequency and current during operation of all emergency consumers.

8.4.10 Proper operation of interlocking arrangements for the electric drive of the boat winch when activating the manual drive and limit switches.

8.4.11 Serviceability of main and emergency lighting torches shall be checked.

8.4.12 Serviceability of navigation lights and their malfunction alarms shall be checked.

8.5 RUNNING TRIALS

8.5.1 During running trials, they check the operation of the ship's electrical propulsion system in all modes provided by the program, at actual loads and underway conditions, as well as proper operation of electric equipment. When developing the program, the duration of tests and checks of electric equipment shall be determined with regard to the time set in the corresponding sections of these Rules.

8.5.2 When testing ship's power plant, the following shall be checked:

1. sufficient power of generators for power supply of consumers in accordance with load mode table for all ship's operating modes, except for standby one;
2. uninterruptible activation of the emergency power source in case of no voltage of the main switchboard and no power from its necessary consumers;
.3 uninterruptible activation of the emergency short-term power source (if any) when commissioning the emergency diesel generator.

8.5.3 When testing electrical propulsion systems, the following shall be made:

.1 tests specified in 8.4.3.1, 8.4.3.4 and 8.4.3.5;
.2 measurement result analysis of the reverse length in different ship speeds.

8.5.4 Electric drives of pumps, compressors, separators, fans and other ship machinery shall be checked as intended in order to check the reliable (uninterruptible) operation, activation/deactivation, switching to the reserve set (if any), actions of remote consoles to activate/deactivate the electric drive, automatic activation of reserve electric drives as per the signals from the adjustable parameters of working medium on automated installations.

When checking the operating electric equipment, absence of loads, inadmissible temperature increases of hulls, shells, panels, bearings shall be checked. In addition, parameters of its own vibration and vibration caused by operation of main engines and other ship machinery or propellers shall be checked.

8.5.5 Electric drives of steering gears, their power supply systems (main and backup supply lines), control systems, rudder position indication system, electric drive operation / stop alarm system, shall be checked during the steering gear operation in all provided modes.

8.5.6 Steering gear drives shall be checked both during operation of two (if any) electric units of the steering drive, and of each power unit individually from all provided remote and local control stations when supplying electric drives of power units and control system from the main and backup supply line.

In this case, cycle of putting the rudder from side to side, provided in 7 of these Rules, shall be performed at least 5 times for each unit from each station and for each power supply line.

8.5.7 Electric drives of anchor and mooring arrangements, boat winches shall be checked during tests of the above arrangements, during the ship mooring/unmooring, unberthing, whilst at berth or at anchor.

8.5.8 During running trials, they measure insulation resistance of electric equipment both during its operation by means of boards for measuring insulation resistance, and by means of portable megger immediately after decommissioning with the equipment temperature set during operation.

8.5.9 Sparking degree of electric machines with collectors and contact rings shall be checked.

8.5.10 After running trials, they establish the inspection scope to open bearings of electric machines not heated during running trials in excess of the technical documentation norm.

8.5.11 When opening the electric machine, the following shall be checked:

.1 technical condition of stator winding support structures;
.2 location of winding wedges;
.3 technical condition and location of poles with their windings;
.4 secure attachment of rotating parts.
9 RADIO COMMUNICATION AIDS AND NAVIGATION EQUIPMENT

9.1 GENERAL REQUIREMENTS

9.1.1 This Section establishes requirements to technical supervision of the River Register during manufacture, on-board installation and tests of radio communication aids and navigation equipment in accordance with the Nomenclature.

9.1.2 Technical supervision of radio arrangements and navigation equipment by the River Register provides:
- approval of technical documentation, test program;
- technical supervision during manufacture and tests;
- technical supervision during installation and tests.

9.1.3 The River Register does not perform technical supervision during navigation equipment manufacture, but during mooring and running trials, checks the navigation outfit availability on board the ship in accordance with standards specified in Table 10.2.2. Part V RCCS.

9.2 TECHNICAL SUPERVISION DURING MANUFACTURE

9.2.1 Technical supervision of radio arrangements and navigation equipment by the River Register includes:
- checking for availability of the approved technical documentation and test program;
- checking documents for components (if components are prescribed by the approved documentation);
- item inspection;
- supervision during tests.

9.2.2 When examining the item, the Surveyor:
- shall verify the documents for materials used during manufacture;
- shall examine the inside and the outside of the item;
- shall inspect the proper operation of the item;
- shall check the availability of necessary markings and inscriptions.

9.2.3 Type specimens of radio communication aids and navigation equipment shall be tested as per the approved test program developed in accordance with 1 to 3, 6 to 14 of Appendix 15.

Type specimens of portable radio equipment used in Global Maritime Distress and Safety System (GMDSS) shall be additionally tested for compliance with 16 of Appendix 15 with buoyancy requirements. The tests shall be also performed for compliance with 17 of Appendix 15.

9.2.4 Serial items shall be tested as per 1 to 3 Appendix 15.

9.3 TECHNICAL SUPERVISION DURING ONBOARD INSTALLATION AND TESTS

9.3.1 When controlling the arrangement of equipment and devices, the following shall be checked:
- the availability of documents confirming the compliance of the item with the requirements of Rules;
- placement, installation of items as per approved documentation;
.3 easy arrangement, maintenance and repair of transmitters, receivers, indicators, control consoles, starters, converters, etc.;

.4 complete set of operating documents.

9.3.2 When checking installation, the following shall be verified:

.1 secure attachment of valves;
.2 secure attachment of antennas;
.3 antenna location relative to metallic parts of the ship;
.4 laying, fastening and cable penetrations through the watertight decks and bulkheads;
.5 compliance with brand drawings and cable cross-sections;
.6 condition of external cable coverings;
.7 excessive length of the cable before the entry of equipment;
.8 continuity of screening of power cable network and radio cables;
.9 hull grounding of cable network shells, radio equipment cases;
.10 insulation resistance of antennas (except for antennas with DC short-circuit structure), cable network and power supply sources;
.11 availability of fencings for live and rotating equipment parts;
.12 fitting of protective devices near the transmitter entries;
.13 resistance value of the protective grounding.

9.3.3 After installation and adjustment, radio communication aids and navigation equipment shall be subject to mooring and running trials as per the programs approved by the River Register. The equipment shall be supplied from the ship's main.

9.3.4 When testing radio communication aids, the following shall be checked:

.1 parameters and serviceability as per the approved test program in accordance with functional purpose of the radio station, with regard to the operating instructions;
.2 quality of reception and availability of interference in all the receiver bands;
.3 effective radio signal reception against interference caused by ship's electric equipment.

9.3.5 When testing public address and broadcasting devices, the following shall be checked:

.1 proper remote control of the public address device (start, deactivation, switching broadcasting lines, reset of programs and activation of forced broadcasting) from any command microphone stations regardless of the control element position for all the rest command microphone stations;
.2 transmission quality of service orders from command microphone stations to all accommodation and public spaces, as well as to open decks;
.3 available priority of service orders over broadcasting or audio recording if there is no additional command public address device for this purpose;
.4 operation of visual alarms in each microphone station, that is activated when starting the command public address device;
.5 remained serviceability of broadcasting line in case of short-circuit in loudspeaker branches;
.6 absence of plug adapters in loudspeaker branches;
.7 no clutter from electric equipment and radio communication aids.

9.3.6 When testing emergency position-indicating radio beacon, the following shall be checked:

.1 availability of applicable documents confirming the emergency position-indicating radio beacon registration in international coordination and calculation centre of the COSPAS-SARSAT system and compliance of entries in registration documents on the item model and number, name of the radio beacon, as well as available information on the expiry date of storage battery shelf life and date of the next due shore-based maintenance (not exceeding the established date during the check) in the radio beacon marking;
.2 availability of documents on testing laboratory checks.

9.3.7 When testing the navigation equipment, it is checked as per the approved test program in accordance with its purpose with regard to the operating instructions.
10 MATERIALS

10.1 GENERAL REQUIREMENTS

10.1.1 This Section establishes requirements to technical supervision during manufacture and installation of mechanisms listed in Section 9 of the Nomenclature.

10.2 TECHNICAL SUPERVISION DURING MANUFACTURE

10.2.1 Technical supervision during manufacture of the materials includes:
   .1 checking for availability of the approved technical documentation and test program;
   .2 supervision during tests;
   .3 survey during type approval;
   .4 survey during manufacture, as prescribed by the Nomenclature.

10.2.2 In case of technical supervision during materials, the Surveyor shall check the acceptance tests performed by the technical control bodies in the scope specified in the technical documentation.

10.2.3 In case of the type approval, the materials shall be tested in the Surveyor’s presence in accordance with the test program. The type specimen tests may be combined with tests in order to obtain the Recognition Certificate.

10.2.4 When surveying metals and alloys, forgings and castings, the Surveyor shall check:
   .1 documents of the performed tests prescribed by the Rules and agreed technical documentation;
   .2 company’s documents on the performed acceptance prescribed by the agreed technical documentation;
   .3 documents confirming the production manufacture as per the agreed process (as prescribed by the Rules);
   .4 inspection of defect absence on the surface;
   .5 presence of defects, their nature and repair;
   .6 marking.
11 EQUIPMENT FOR PREVENTION OF ENVIRONMENT POLLUTION FROM SHIPS

11.1 GENERAL REQUIREMENTS

11.1.1 This Section establishes requirements to technical supervision during equipment manufacture and tests for prevention of environment pollution from ships, as well as during on-board installation and tests listed in accordance with the Nomenclature.

11.1.2 Equipment, parts and units shall be manufactured and installed in accordance with the technical documentation approved by the River Register, specified in Appendix 8.

11.1.3 Equipment shall have a nameplate with its purpose, manufacturer’s name, type and model, serial number and year of manufacture.

11.2 TECHNICAL SUPERVISION DURING MANUFACTURE

11.2.1 Technical supervision during manufacture of equipment for prevention of environment pollution from ships includes:

.1 checking for availability of the approved technical documentation and test program;

.2 inspection of material and components, verification of supporting documents;

.3 checking for compliance of the manufactured parts and units with the technical documentation approved by the River Register;

.4 check of welding operations;

.5 hydraulic tests;

.6 check of equipment in operation.

11.2.2 Elements of systems included in the equipment shall be subject to hydraulic tests in accordance with the requirements 6 of these Rules.

11.2.3 A type specimen of the equipment shall be subject to bench tests as per the program approved by the River Register.

When replacing the bench tests with on-board tests, they shall be performed as per the program-procedure approved by the River Register.

Scope of acceptance tests for serial items shall be established when drawing up and approving the test program with regard to the standard specimen test results.

11.2.4 Proper installation of pipelines, valves and cables shall be checked by visual inspection. Tightness of valve and pipeline connections shall be checked during hydraulic test.

11.2.5 Actuation of safety devices of the filtering equipment and sewage treatment plant shall be tested under pressure not exceeding 1.1 of the operating pressure.

11.2.6 Prior to commencing installation of the incinerator lining, they inspect walls for absence of bulges, saggings and roughnesses exceeding 10 mm per 1 m.

After installation, proper lining of the incinerator shall be checked. The brickwork surface shall be flat. Separate ledge steps shall not exceed 3 mm, and roughness shall not exceed 10 mm per 1 m. Lining or its separate parts shall not shift.

The air hole diameter deviation from the set dimensions shall not exceed ±5 mm, and misalignment of the air hole and nozzle axes shall not exceed 2 mm.
After the final assembly, leak tests of the incinerator casing by air shall be performed (if provided by the technical documentation). Pressure and possible air leaks shall be in conformity with technical documentation approved by the River Register.

**11.3 TECHNICAL SUPERVISION DURING ONBOARD INSTALLATION AND TESTS**

**11.3.1** When checking the equipment installation, the Surveyor controls the compliance of the performed works with the requirements of the technical documentation approved by the River Register.

**11.3.2** Settling tanks, isolated ballast tanks, sewage and oily waters collecting tanks shall be checked for compliance with the operating documentation approved by the river Register, and shall be subject to tightness tests during the hull formation.

Structures, equipment and systems shall be considered to have passed the tests, if no leaks or sweating of welds, leakage in pipe expanded connection, as well as in fitting connecting flanges, and instrument connections are detected.

**11.3.3** When checking the installation of hoses included in ship's outfit and used for pumping oil, oil-containing and sewage water, it is necessary to check the marking allowing to identify items, as well as the manufacturer's documents, specifying the following:

- the type of liquid allowed for hose pumping;
- the date of manufacturing;
- the working pressure;
- the date of tests and the test pressure.

**11.3.4** Upon completion of installation works and hydraulic tests, the equipment shall be checked in operation, as per the program approved by the River Register, drawn up with regard to the requirements in Appendix 18.
NOMENCLATURE OF ITEMS
OF THE REGISTER TECHNICAL SUPERVISION

1 This Nomenclature (Table A1.1) establishes the list of items, whose technical supervision during manufacture, installation and tests is performed by the River Register as per the Rules, stamping these items in cases prescribed by this Nomenclature, as well as performing the applied forms of technical supervision. Numbers of Sections in Table A1.1, except for Section 11, repeat numbers of the RCCS corresponding parts.

2 The following symbols are used in this Nomenclature:

- P — technical supervision carried out by the River Register;
- OP — technical supervision carried out by the River Register and company's personnel;
- OT — technical supervision in the form of type approval;
- ПД — technical supervision in the form of recognised documentation;
- К — branding. During technical supervision in the form OP (supervision is performed by the Register and the company's personnel), stamping is not necessary.

### 3 Fire protection

#### 3.1 Structural fire protection:
- **1.** Bulkheads and inner decks
- **2.** Fire doors
- **3.** Fire dampers
- **4.** Fire-resisting divisions
- **5.** Penetrations in fire-resisting divisions of A, B and C classes
- **6.** Alarm and control systems for fire doors
- **7.** Flame arresters
- **8.** Spark arresters of exhaust systems and flues

#### 3.2 Fire-fighting equipment and fire-extinguishing systems

#### 3.2.1 Fire extinguishing, water-spraying and inert gas systems

#### 3.2.2 Items and valves for fire extinguishing, water-spraying and inert gas systems:
- **1.** Storage reservoirs for fire-extinguishing medium
- **2.** Pneumohydraulic tanks
- **3.** Pressure vessels and apparatuses of fire extinguishing systems
- **4.** Carbon dioxide, compressed air and nitrogen cylinders
- **5.** Fire-extinguishing system pumps
- **6.** Valves of fire extinguishing, water-spraying and inert gas systems
- **7.** Steam generators
- **8.** Aerosol generators
- **9.** Monoblock pumps
- **10.** Steam generator
- **11.** Gas analyzers
- **12.** Nozzles for water-spraying and water fog systems
- **13.** Nozzles of dual-purpose type (spray/jet type)
- **14.** Portable foam set

#### 3.2.3 Safety devices in venting systems to prevent the passage of flame into the cargo tanks of tankers

#### 3.3 Units for domestic purpose, domestic units and fire extinguishing systems

#### 3.3.1 Gaseous fuel systems used for domestic purposes
- **1.** Equipment for gaseous fuel systems, used for domestic purposes, except for that stated in 2.3.3

#### 3.3.2 Water extinguishing system for exhaust ducts from a galley range
- **1.** Equipment for systems of automatic or manual fire extinguishing for exhaust ducts from a galley range

#### 3.3.3 Domestic heaters working on oil fuel, liquid gas or solid fuel:
- **1.** Galley ovens
- **2.** Domestic liquefied gas units
- **3.** Heaters and stoves regulated by the Rules

#### 3.4 Fire alarm
- **1.** Fire detection and fire alarm systems, fire smothering system release warning system, including:

#### 6.1 Electric propulsion plant:
- .1 Electric propulsion motors
- .2 Main and emergency power sources:
  - .1 Generators
  - .2 Accumulators and batteries
- .3 Power and lighting transformers, electric energy converters:
  - .1 Transformers
  - .2 Rotary and static frequency converters (rectifiers, inverters, frequency converters, soft starters)
  - .3 Electrical machinery amplifiers
- .4 Switchboards (main and emergency switchboards, monitoring, control and alarm panels):
  - .1 Protection, control and commutation facilities (circuit-breakers, disconnectors, relays, switches, fuse links, etc.)
  - .2 Reactors, condenser units for power factor increasing
  - .4 Cases of switchboards and electric cabinets
- .5 AC/DC motors of 0.5 kW and over:
  - .1 Ship critical technical equipment
  - .2 Ship non-critical technical equipment
- .6 Starting equipment of electric motors
- .7 Main lighting of spaces and places of essential services, escape routes and emergency lighting:
  - .1 Fixed lamps
  - .2 Fittings of lighting networks (switches, sockets, junction/branching boxes)
  - .3 Light evacuation indicators (photoluminous and electric)
  - .4 Safe electric lamps (manual torchlights), battery torchlights
  - .5 Floodlights
- .68 Electrical machine telegraphs, rudder / CPP blade position indicators, propeller shaft tachometers
- .6.9 Service telephone system
- .6.10 General alarm system (devices and contactors of light and sound signals)
- .6.11 Alarm system of watertight doors
- .6.12 Electric equipment in explosive spaces and areas (explosion-proof)
- .6.13 Cable network:
  - .1 Cables
  - .2 Wires
  - .3 Cable penetration seals
- .6.14 Lightening conductors and groundings, cathodic protection; hull grounding devices for oil tankers
- .6.15 Electric heaters of fuel and oil

#### 11 Equipment for prevention of pollution from ships

11.1 Systems, equipment and arrangements for prevention of pollution by oil:

| .1 pumping, delivery and discharge systems of oil-containing water, including automatic monitoring, recording and control systems of oil discharge for oil tanker | — | ПД | | P | P | P |
| .2 automatic monitoring and control system for ballast and washing water discharge | — | ПД | | P | P | P |
| .3 collecting tanks, settling tanks | — | ПД | | P | | |
| .4 filtering equipment, including oil filtration equipment | P | P | P | P | P |
| .5 alarm devices | P | P | P | P | P |
| .6 device for automatic interruption of oil-containing water discharge | P | P | P | P | P |
| .7 detectors of the oil-water phase division boundary in settling tanks | P | P | P | P | P |

11.2 Emergency oil spill localization pack

| .1 floating boom barrier | P | P | P | P |
| .2 floating anchor buoy; | P | P | P | P |
| .3 anchor chains and towing ropes | — | ПД | | P | P | P |
| .4 sorbent | P | ОТ | | P | P | P |
| .5 device for sorbent supply | P | ОТ | | P | P | P |
| .6 oil and waste sorbent collecting device | — | ПД | | P | P | P |

11.3 Systems, equipment and devices for prevention of sewage pollution:

| .1 pumping, delivery and discharge system for sewage | — | ПД | | P | P | P |
| .2 collecting tanks. | — | ПД | | P | P | P |
| .3 sewage treatment plant | P | P | P | P | P | P |

11.4 Equipment and arrangements for prevention of pollution by garbage:

| .1 garbage containers | — | ПД | | P | P | P |
| .2 incinerators | P | P | P | P | P | P |
| .3 garbage treatment plants | — | ПД | | P | P | P |

11.5 Monitoring equipment and devices of harmful substances, exhaust gases opacity and for reducing prevention of air pollution from ships:

| .1 cleaning systems designed for reducing the content of harmful substance in exhaust gases | — | ПД | | P | P | P |
FORM OF NOTICE ON SURVEYOR INVITATION

To Surveyor
Branch Office
of the Russian River Register

Notice No. _______________________
dated "____" ___________ 20 ___

_______________________________________
(organization name)
Ship, hull No.  
Project No.  

This notice submits to you the following for check test:

_______________________________________
(production description, content of the work to be submitted)

The operations were performed in accordance with drawings No. _____, specification No. ,
test program No. , technical documentation No. 

The operations stated in 2.9.1 RTSC, were performed by welders
(full name; Welder Approval Test Certificate No.)

_______________________________________
The submitted production meets the requirements of drawings, technical documentation, processes and fully completed.

Representative of QC service
(signature) (full name)

Conclusion on verification results

_______________________________________
_______________________________________

Surveyor of
Branch Office of the River Register

(signature) (full name)

“____” ___________ 20 ___

Conclusion on verification results read and understood:

Representative of QC service
(signature) (full name)

“____” ___________ 20 ___
APPENDIX 3
(mandatory)

LIST OF ITEM CHECK INSPECTIONS AND PROCESS OPERATIONS TO BE SUBMITTED TO THE BRANCH OFFICE (FORM)

<table>
<thead>
<tr>
<th>Description of item under technical supervision</th>
<th>Documents submitted by QC service, confirming the item compliance with the project, standards or technical documentation</th>
<th>Procedure of the item monitoring by the auditor</th>
<th>Drawing up a conclusion by the Surveyor and branding</th>

<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

Notes:
1. The list shall be drawn up as per the requirements of the Rules, with regard to the Nomenclature, forms and technical supervision methods of this company.
2. Repairable non-replaced parts shall not be stamped by the River Register.
3. Stamp of the River Register:
The Standard List of the item check tests and process operations (Table A4.1) was prepared as per items under technical supervision and does not establish sequence of their submitting to the Surveyor. Sequence of submitting to the Surveyor shall be determined in each particular case with regard to manufacture, assembly, installation and items under technical supervision and the ship as a whole.

The list is to be specified as per the scope of works on construction, modernization, conversion or repair of the ship.

Appendix 7

For welded joints made by fillet welding electrodes.

1 According to Fig. A7.1-1 to A7.1-8: $P_{1d}$ — butt joints in horizontal position; $P_{1v}$ — butt joints in vertical position; $P_{1h-v}$ — horizontal butt joints in vertical plane; $P_{10}$ — butt joints in overhead position; $P_{2h}$ — angular joints in horizontal position; $P_{2v}$ — angular joints in vertical position; $P_{20}$ — angular joints in overhead position.

2 May be supplemented by dye-penetrant or magnetic particle methods.

3 The River Register determines test assembly areas from which test specimens shall be machined.

4 The test assembly diameter is determined proceeding from the structure type.

5 For obtaining weld approval in piping constructions.

Note: $t$ — sample thickness.

<sup>1</sup> May be supplemented by dye-penetrant or magnetic particle methods.

<sup>2</sup> River Register determines sections of samples for cutting sample manufacture material.

**Notes:**

1. t — thickness of the test assembly, D — diameter of the test assembly.
2. To be chosen according to the welding procedure and the availability of automatic welding equipment.
STANDARD LIST OF TECHNICAL DOCUMENTATION SUBMITTED TO THE RIVER REGISTER FOR APPROVAL

This Appendix determines the lists of technical documentation submitted to the River Register for approval.

The specified lists are generic and determined by design organization (manufacturer) on agreement with the River Register depending on the design features of ships and ships' elements.

The operating documentation for the ship machinery construction items, electrical, radio and navigation equipment is submitted with due regard to the Nomenclature. The documentation scope is determined by the design organization on agreement with the Branch office.

The documentation marked with * and all the operating documents shall be stamped APPROVED. The documentation not marked with * in Sections 1 to 5 of this Appendix shall be stamped TAKEN INTO CONSIDERATION.

1 Technical design

1.1 The technical design of a ship shall include the following general design documents:

.1 list of technical design documents;
.2 explanatory note to the design;
.3* specification including Section for prevention of pollution from ships;
.4* list of equivalents to the requirements of the Rules (if admitted) with substantiation;
.5* program and method of acceptance trials for the prototype ship of the series (submitted after approval of engineering design);
.6* loading, unloading and ballasting instructions for a cargo ship (submitted after clarifying the mass loads while detailed designing);
.7* stability and floodability data (submitted after clarifying the mass loads while detailed designing);
.8* general arrangement plan indicating the technical means, devices and equipment:
   side view;
   inboard profile specifying the watertight bulkheads, decks, platforms and other elements;
   plans of decks, holds, bridges, platforms and other elements;
.9* general arrangement plan of equipment in wheelhouse;
.10 arrangement plan of explosion and fire hazardous areas and rooms (if any);
.11 lines drawing of a ship's hull;
.12 calculations of mass loads and centre of gravity position, trim and initial stability for various loading conditions;
.13 static and dynamic stability diagrams with table of heeling and capsizing moments and heel angles for various loading conditions (calculation of stability diagram arms may be omitted) stability assessment for various loading conditions initial data tables when calculating by means of software applications;
.14 calculation of ships floodability in accordance with the requirements of 4.2 Part I RCCS, initial data tables when calculating by means of software applications;
.15 freeboard calculations;
calculations of ship maneuverability including maneuverability table;
.17 calculations of gross tonnage;
.18 list of materials, components and equipment to be delivered with documents specified in 2.2.6.

1.2 The technical design shall contain the following hull documentation:
.1* midship section and hull cross-sections with the main framing members;
.2* design drawing of hull and superstructures engaged in global bending, with framing table;
.3* shell expansion for ships with sophisticated hull shape;
.4 calculations for selection of design and dimensions of the hull members, initial data tables for calculating by means of software applications;
.5 calculations of global and local vibration;
.6 calculation of strength and stability of hull members (for single-hull steel ships and catamarans over 50 m in length, ships with hull made of light alloys, hydrofoils, hovercraft and ships with plastic hull);
.7 initial data table for calculating by means of software applications;
.8 calculations of hull strength (for ships with reinforced-concrete hull);
.9 calculations of transverse ship strength (for undecked cargo ships and ships with ratio \(B/H\) exceeding the prescribed value);
.10 calculation of superstructure strength (for passenger ships with large window cut-outs);
.11 general view of ship hatchway cover with strength calculations of hatchway covers and main drive components;
.12 calculation of hull global strength at the end of the ship’s service life;
.13 calculation of icebreakers’ ice strength.

1.3 The engineering design shall contain the following documentation for equipment and room insulation:
.1 data on the used finishing, structural and insulation materials indicating their installation places, burning quality, quantity of combustible materials per 1 m² of each room floor area;
.2* room insulation and furnishing diagram.

1.4 The technical design shall contain the following documentation for ship arrangements:
.1* arrangement plan of signal means and navigation lights;
.2 selection of device elements and outfit items according to the Rules, or calculations substantiating the selection of these elements;
.3* general arrangement plan of new-type devices.

1.5 The technical design shall contain the following documentation for power unit and systems:
.1* arrangement plan of the main and auxiliary engines and equipment in the machinery spaces and central control station rooms with indication of the passages and escape routes according to 1.9 Part IV RCCS;
.2* shafting with stern-tube, propeller (steering thruster), shafts and couplings;
.3 calculation of shafting (including torsional vibrations), propeller and selection of shafting elements according to the Rules;
.4* schematic diagrams (indicating operating parameters, diameter, pipe wall thickness, pipe materials, valves and fittings) of cooling, oil, fuel supply, start air, gas exhaust (may be shown on the general view of room), steam pipeline, feed and condensate systems.

1.6 The technical design shall contain the following documentation for ship’s systems:
.1* schematic diagrams (indicating operating parameters, diameter, pipe wall thickness, pipe materials, valves and fittings) of ventilation, fire-fighting, drainage, ballast, bilge oily water removal, oil heating systems; hydraulic pneumatic actuator system of auxiliary technical means and deck mechanisms; liquefied gas domestic facility; air, overflow and measuring pipelines; compressed air system; oily water pumping, delivery and discharge system;
.2 calculation of ship's ventilation, firefighting, bilge, ballast, compressed and start air systems;
.3 calculation of tanks capacity of the oily water pumping, delivery and discharge systems.

1.7 The engineering design shall contain the following documentation for refrigerating plant:
.1* general arrangement plan of refrigerating plant;
.2* schematic diagrams of coolant, coolant fluid, ventilation, air cooling and cooling water systems, and control, monitoring, alarm and protection systems;
.3 main calculations for refrigerating plant.

1.8 The technical design shall contain the following documentation for oil tankers (in addition to the documents stated in 1.5 and 1.6 of this Appendix):
.1* arrangement plan of equipment in pump room;
.2* schematic diagrams of cargo handling, stripping, inert gas and vent systems.

1.9 The technical design shall contain the following documentation for automation:
.1* arrangement plan of the main remote control and automation means (control stations and consoles);
.2* schematic diagrams and organizational charts of the remote control, automation and warning alarm systems of the main ship's technical means and systems with indication of the power supply sources;
.3* schematic diagrams of fluid level alarm of the oily and sewage waters pumping, delivery and discharge systems.

1.10 The technical design shall contain the following documentation for electrical equipment:
.1* circuit diagrams of electrical power distribution from main and emergency sources: power mains, lighting (to section switchboards);
.2* circuit diagrams of main and emergency switchboards, control desks and switchboards of non-standard design;
.3* circuit diagrams of electric drives for ship equipment stated in 5.3.1, 7.5 to 7.10 and 4.2 Table 4.5.2 Part VI RCCS;
.4* circuit diagrams of main and emergency lighting mains;
.5* circuit diagrams of navigation and signal lights;
.6* circuit diagrams of general and fire alarms;
.7* circuit diagrams of the main current, excitation, control, monitoring, signal, protection and interlock of electric propulsion plant;
.8* earthing diagram for ships with non-conductive hulls;
.9* diagram of lightening conductors (may be shown on ship's general view);
.10 calculation of the required power plant capacity to ensure all ship's operation modes, substantiation for selection of generator quantity and capacity as well as calculation of capacity of emergency power supply sources;
.11 calculation of cable cross-sections with indication of their grades, currents and protection degree;
.12 calculation of short-circuit currents and voltage changes;
.13 calculation of dynamic and thermal capacity at short circuit (at nominal power of generator or parallel operating generators over 100 kW) for buses, communication and protection hardware of the main distribution switchboard and cables of essential devices;
.14 lightning protection calculation;
.15 list of measures to ensure electrostatic and galvanic sparking safety (for oil tankers).

1.11 The technical design shall contain the following documentation for communication and navigational equipment
.1* electric block diagram of navigational equipment, radio communication means, public address system, voice communication means, onboard internal communication equipment, receivers of broadcasting station signals (audio and video broadcasting stations) and broadcasting satellite service;
.2* drawings (not less than two views) showing arrangement of equipment in rooms
intended for the installation of radio and navigational equipment;

.3* arrangement drawings of antennas (three views) may be shown on ship’s general view;

.4 calculation of MF/HF antenna parameters and radio range;

.5* arrangement drawing of the main/steering (reserve) marine compass.

1.12 The technical design shall contain the following documentation for equipment for prevention of pollution from ships:

.1* plans of arrangement of equipment and devices for the prevention of pollution from ships;

.2* calculations of the navigation autonomy due to ecological safety conditions;

.3* schematic diagrams of oily and sewage waters pumping, delivery and discharge systems including collecting tanks and standard discharge connections;

.4 technical description and operation principle of water supply and discharge systems;

.5* onboard test program of the equipment;

.6* diagram of sealing stop fittings of overboard discharge system for oil-containing and sewage water;

.7* diagram of collection system for leaking fuel and oil;

.8* for oil tankers (except for documents stated in 1.12.1 to 1.12.7) the following documents shall be submitted:

- calculations of the capacity of cargo, settling and pure ballast tanks;
- the diagram of location of all tanks on board of a ship;
- the diagram of compartments subdivision and emergency stability calculations;
- the diagram of emergency oil pumping;
- the diagram of location discharge outlets;
- the diagram of oil residues pumping system to the settling tank;
- operating manual for tanks intended for pure ballast (if applicable);
- operating manual for the automatic monitoring control system for ballast and washing water discharge;

.9 operating manual for emergency oil spill localisation pack.

2 Technical documentation for ship conversion, modernization, re-classification and repair

2.1 The technical documentation shall be submitted for those parts of hull, ship’s technical means and equipment which subject to conversion, modernization, restoration or repair.

If the characteristics of strength, stability, manoeuvrability, etc. are changed due to ship conversion, the correspondent calculations or substantiations shall be submitted.

2.2 When changing the hull design, converting or modernizing a ship, the technical documentation in a scope specified for the ship under construction (see 1) shall be submitted to the River Register.

2.3 In order to re-classify a ship, the following documentation shall be submitted to the River Register:

.1 explanatory note with substantiations for re-classification;

.2 analysis of ship compliance with the RCCS requirements for a new class for all ship elements;

.3* list of equivalents to the Rules requirements for a new class, with substantiations;

.4 analysis for compliance with the requirements of international normative documents (for ships engaged on international voyages). The following documents shall be submitted for reference:

- .5* supplement to specification;
- .6* test program;
- .7* instruction on loading and unloading or related supplement;
- .8* stability and floodability data or related supplement;
- .9 global and local strength calculations;
- .10 additional calculations for selection of reinforcements and hull scantlings;
- .11 freeboard calculation and load line drawing;
- .12 substantiations confirming the capability to operate the main engines, propulsion
and steering unit and ship's power plant without degradation of their technical characteristics determined by the delivery documentation and the Rules;

.13 technical documentation for ship reclassification related to hull reinforcement, further equipment and outfit including general arrangement drawings;

.14 calculations of ship maneuverability including maneuverability table;

.15 special standard values of residual thicknesses and local residual deformations that differ from those prescribed by the RSSS;

.16 technical documentation from the list specified in 1.12 when such a documentation is required due to installation of new equipment for prevention of pollution from ships, the availability of which prescribed by the RSSS, if an inland navigation ship is reclassified to О-ПИ, М-ПИ or М-СП class.

3 Project of ship passage outside the specified navigation area

3.1 The ship passage project includes:

.1 explanatory note with indication of passage area and conditions, description of measures for ensuring the passage safety (including organizational measures);

.2 calculation of strength, stability and freeboard required by the Rules for passage area and conditions;

.3 drawings of hull and superstructure reinforcements;

.4* drawings and diagrams of opening covers in hull and superstructures as well as installation of structures to improve seakeeping (rakes, protection of superstructures, wheelhouses and other technical solutions for ship conversion);

.5* drawings of towing and/or pushing arrangements, arrangement plan of towing bitt;

.6* arrangement drawings of navigation lights and daytime signals of the towed ship;

.7 description of power plant, electrical, radio and navigation equipment;

.8 description of steering, anchor, mooring arrangements, fire protection, life-saving appliances and signal means;

.9* list of emergency outfit and its arrangement plan;

.10* guidance to the master of the passed ship or tugboat including the specified weather limits, instructions on ship ballasting, consumption of ship's stores and damage control in case of emergency.

4 Technical documentation for preparing a ship for transportation of bulky and/or heavyweight cargoes

4.1 The documentation shall include:

.1* arrangement plans of the transported cargo with indication of dimensions, centre of gravity coordinates and weight of each cargo unit, fastening methods and means (distance bars, stops, lashes, etc.);

.2* arrangement plans of navigation lights and lightening conductor, if they are subjected to alterations;

.3* reinforcement drawings — bulkheads and partial bulkheads, trusses, web girders, support structures distributing the load from cargo; leveling platings, arrangements for prevention of cargo shift when rolling and mooring;

.4 additional calculations of global and local strength of a ship and specific loads on support structures with regard to load distribution irregularity when handling and transporting the cargo. When determining the local loads from the concentrated cargoes inertial loads due to rolling are considered;

.5 calculations of anchoring strength and related forces with regard to inertia forces when rolling and mooring. The anchoring may be omitted, if friction force exceeds shearing forces. Based on the strength calculations the permissible pressure limit on support surface of the cargo or along the leveling platings is determined;

.6* additional guidance on handling the equipment developed on basis of the strength and stability calculation results indicating the capability and requirement of ballasting as well as indicating the sequence, method and
diagram of handling with drawings of additional structures;
7* additional stability data drawn up based on calculation of stability, floodability and trimming. When checking the emergency stability, the requirements of Part II RCCS shall be met;
8* guidance to the master for ensuring the cargo transportation safety including organizational measures, transportation route, specified weather limits.

5 Technical documentation
5.1 The technical documentation for internal combustion engines and reduction gears shall include:
1* specifications;
2* general view drawings and essential component drawings;
3* schematic diagrams of fuel, lubricating, cooling, starting, electric equipment, remote control, automation, gas control alarm and protection systems;
4* programs of bench tests and test to verify engine exhaust gas compliance with normative values of harmful substances and opacity;
5* strength calculations of essential engine components, calculations of crankcase ventilation arrangement and safety valves, data on the maximum and average specific pressures in bearings (main, crankpin, thrust bearings), strength calculation of shafts and reduction gear tooth, calculation of reduction gear bearings, calculation of torsional vibrations in links of the planned torsional system;
6 technical data sheet of emissions (not applicable to reduction gears).

5.2 The technical documentation for the retrofitted engines shall include:
1* specifications for the retrofitted engine;
2* general view drawing of the converted engine with all assemblies and components included in conversion work scope;
3* test program;
4 copy of specifications developed and issued by the Manufacturer of basic engine to be retrofitted;
5 technical data sheet of emissions.

5.3 The technical documentation for steam and water boilers shall include:
1* specifications;
2* assembly drawing with longitudinal and transverse sections in scale not less than 1:10 and connections in scale of not less than 1:2;
3 calculation of boiler strength in accordance with the Strength Calculation Manual for Boilers, Heat Exchangers and Pressure Vessels;
4 calculation of safety valve cross-sections;
5* assembly and welding procedures;
6* schematic diagrams of warning alarm and protection automation;
7* program of testing a specimen and serial item.

5.4 The technical documentation for cargo handling gears shall include:
1* specifications;
2* general view drawings of cargo handling gear, bearing metal structures, machinery;
3 kinematic diagram;
4* schematic diagrams of electrical equipment;
5 diagrams of safety arrangements and means (describing their operation principle);
6 calculation of forces and stresses in components of the cargo handling gears;
7* program of testing a specimen and serial item.

5.5 The technical documentation for coupling equipment shall include:
1* specifications;
2* bench test program;
3* assembly drawings of lock and tensioning station;
4* essential component drawings;
5 calculation of components strength.

5.6 The technical documentation for deck machinery and ship auxiliary equipment shall include:
1* specifications;
Appendix 8

.2 general arrangement drawings;
.3 assembly drawings of essential components;
.4* schematic diagrams of control, gas control alarm automation and protection;
.5* calculations agreed in the Rules;
.6* program of testing a specimen and serial item.

5.7 The technical documentation for steerable and fixed propellers shall include:
.1* specifications;
.2 general arrangement drawings;
.3 assembly drawings of essential components;
.4* schematic diagrams of electrical equipment, hydraulic, lubricating, alarm and protection systems, kinematic diagram (if they are not presented in specifications);
.5* calculation of input (primary) and output shafts, gear drives, calculation and selection of bearings;
.6* program of testing a specimen and serial item.

5.8 The technical documentation for gear and hydraulic drives shall include:
.1* specifications;
.2* general view drawings with sections;
.3kinematic diagram;
.4calculations agreed in the Rules;
.5schematic diagram of control, gas control alarm automation and protection;
.6* program of testing a specimen and serial item.

5.9 The technical documentation for electrical equipment shall include:
.1* specifications;
.2* electric schematic diagrams, diagrams of automation, gas control alarm and protection;
.3 calculations agreed in the Rules;
.4* program of testing a specimen and serial item.

5.10 The technical documentation for communication and navigation equipment shall include:
.1* specifications;
.2* program of testing a specimen and serial item;
.3 diagrams.

5.11 The technical documentation for equipment for prevention of pollution from ships shall include:

For filtering equipment:
.1 technical description and operation principle of separator or filter, operating and maintenance manual;
.2* specifications;
.3* general arrangement drawings with sections (separator or filter design with main dimensions, used materials and coatings);
.4* assembly drawings of pumps and other devices being a part of filtering equipment;
.5* drawings of welded joints (in casings, base frame and other parts) containing welding data;
.6* diagrams of maintenance systems within the filtering installation;
.7* principal electrical circuit of the installation as well as control, adjustment, monitoring, alarm and safety diagram;
.8* program of testing a specimen and serial item;
.9 list of the essential elements with mechanical characteristics of the material and test hydraulic pressure;

For alarm device:
.10* technical description indicating the operation principle and technical parameters, operating manual, reliability data;
.11* specifications;
.12* general arrangement drawings;
.13* specification indicating used materials and assembling parts;
.14* principal and function diagrams;
.15* program of testing a specimen and serial item;

For automatic monitoring and control systems for ballast and washing water discharge:
.16* technical description indicating the operation principle and technical parameters, operating manual, and reliability data;
.17* specifications;
.18* general arrangement drawings;
specification indicating used materials and assembling parts;

principal and function diagrams;
drawings of fittings for emergency shut-off the discharge;

For sewage treatment plant:
technical description and operating manual;
specifications;
general arrangement drawings with sections (the design, the main dimensions, used materials and coatings);
principal electrical circuit;
control, adjustment, monitoring, alarm and safety diagram;
program of testing a specimen and serial item;

For incinerator:
technical description and operating manual;
specifications;
general arrangement drawings with sections (the design, the main dimensions, used materials and coatings);
general drawing arrangement of atomisers;
drawings of loading unit;
diagram of fuel system within the installation;
principal electrical circuit;
control, adjustment, monitoring, alarm and safety diagram;
program of testing a specimen and serial item;

For garbage container (removable):
technical description;
specifications;
general arrangement drawings with sections (the design, the main dimensions, used materials and coatings);

For garbage treatment plant:
technical description and operating manual;
specifications;
general arrangement drawings with sections (the design, the main dimensions, used materials and coatings);
principal electrical circuit.

Operating documentation for a ship to be agreed with the Branch Office

The following drawings and documents for hull and superstructure are submitted to the Branch office for approval:

midship section and cross-sections;
design drawing of hull with framing table;
design drawing of superstructures;

Note: Hereinafter the "superstructures" means superstructures and wheelhouses engaged in global bending of a ship.

shell expansion of hull and inner sides;
deck and inner bottom plating;
diagram book of standard assemblies and structures for hull and superstructure;
welding table;
diagram of welds radiographic inspection;

stems, keels, propeller brackets, stern-tubes, sleeves, fixed nozzles;
two-dimensional sections of decks, platforms, bottom sides, longitudinal and transverse watertight bulkheads, inner sides and double bottom plating, except for identical sections within the area of cylindrical section;
three-dimensional sections of double bottom, extremities of ship and superstructures, except for identical sections of the double bottom and double sides within the area of cylindrical section;
blocks of ship hull;
foundations under the main engines, thrust bearing, coupling equipment, cargo cranes;
cargo, deck, escape hatches and skylights and their covers, watertight doors, windows, scuttles and other hull fittings according to the Nomenclature;
bulwarks and guard rails, metal fender bars, pushing stops, coupling girders;
arrangement plan of manholes, ladders, external exits indicating the coaming height and overall dimensions;
arrangement plan of bottom inlets and scuppers;
fire-proof bulkheads and doors;
.19 guidance and diagram of hull tightness test;
.20 assembly and welding procedures for manufacturing standard and sophisticated assemblies, sections, blocks, procedure for hull assembly on slipway;
.21 hull and superstructure blocking plan;
.22 load line and draught scales;
.23 diagram of process cut-outs and openings;
.24 welding and welding-in procedure of thick-walled and forged items (brackets, stems, stern-tubes, thrusters' pipes).

For the reinforced-concrete hull, the following drawings are submitted additionally:
.25 section connections;
.26 reinforcement of monolithic areas of sections;
.27 reinforcement of ship hull in areas of cut-outs, installation sites of ship machineries, devices and hull fittings;
.28 installation drawings of embedments.

6.2 For the steering gear and thruster, the following documentation (drawings) shall be submitted to the Branch office for approval:
.1 general arrangement plan of steering gear;
.2 rudder, rudder stock, quadrant, main and reserve rudder drives, steerable nozzle, damper on waterjet-propelled ships, installation of rudder, nozzle, rudder shaft tube, mainpiece, rudder stock bearings, tiller, rudder angle limiters and nozzles;
.3 general arrangement plan of thruster.

6.3 For the anchor arrangement, the following documentation (drawings) shall be submitted to the Branch office for approval:
.1 general arrangement plan of anchoring arrangement;
.2 senhouse slip fastening;
.3 anchor hawses;
.4 remote-controlled anchor release device.

6.4 For the life-saving appliances, the following documentation (drawings) shall be submitted to the Branch office for approval:
.1 general arrangement plan of boat appliance;
.2 davits, their fastenings and tackles;
.3 lifeboats and their securing in the stowing for voyage;
.4 life-saving buoyancy aids (liferafts, benches, etc.) and their arrangement plans.

6.5 For the mooring and towing arrangements, the following documentation (drawings) shall be submitted to the Branch office for approval:
.1 general arrangement plan of mooring and towing arrangements, towing hook, arches, towing rope frame limiters, bitts, hawses;
.2 remote and local towing rope release device.

6.6 For the coupling arrangement, the following documentation (drawings) shall be submitted to the Branch office for approval:
.1 general arrangement plan of coupling arrangement;
.2 installation of coupling arrangement;
.3 installation drawings of release drives.

6.7 For the hydrofoil system, the following documentation shall be submitted to the Branch office for approval:
.1 drawings of bearing planes, stays, brackets, stabilizers, flaps;
.2 assembly drawings;
.3 installation diagram of hydrofoil system.

6.8 For the bending arrangements, the following documentation (drawings) shall be submitted to the Branch office for approval:
.1 general arrangement plan of bending arrangement;
.2 hydraulic cylinders, rotating frame, pump station, thrust metal structures;
.3 design of arrangement components connecting to ship hull (foundations, hull reinforcement).

6.9 For the cargo hatch covers, the following documentation shall be submitted to the Branch office for approval:
.1 general arrangement plan of hatchway cover;
.2 design drawings of hatchway cover;
For the cargo handing gears, the following documentation shall be submitted to the Branch office for approval:

1. general view drawing of cargo handing gear;
2. drawing of control cabin with equipment;
3. drawings of assemblies and components: of metal structures (derrick, gauge head, foundation of thrust-rotating arrangement, stay of fixed units, levers and tie rods of counterbalances, guy ropes of gauge head, etc.), gear assemblies (lifting, locking, turning, change in radius and transfer), lifting capacity limiter assembly, radius indicator, hook assembly, attachments of guy and cargo ropes, attachments of slip ring unit, installation of limit switches, units, hooks, fencings;
4. process documentation for installation.

For the systems, the following documentation shall be submitted to the Branch office for approval:

1. installation drawings (indicating the operating pressure and hydraulic test pressure) of cooling, lubrication, fuel supply, air supply, vent, steam pipeline, feed and condensate systems of the power plant;
2. drawings of equipment of the system units and ship machineries being a part of the systems (at aggregate design method, except for panels);
3. installation drawings (indicating the operating pressure and hydraulic test pressure) of ship’s ventilation, fire-fighting, drainage, ballast, bilge, oily water discharge, cargo heating systems; hydraulic pneumatic actuators of ship auxiliary equipment and deck machinery; liquefied gas domestic facility; air, overflow and measuring pipelines, compressed air systems;
4. installation drawings of refrigerator machine, refrigerant, air cooling and cooling water systems of the ships fitted with refrigerating plant;
5. installation drawings of cargo handling, stripping, vent systems of the tankers;
6. calculation of steam piping (if available) for thermal expansion including summary table of stresses and safety factors for all the piping sections;
7. assembly drawing of collecting tanks indicating their capacity;
8. assembly drawings of discharge connections with the indication of materials used and hydraulic test pressure.

For the shafting and propellers, the following documentation (drawings) shall be submitted to the Branch office for approval:

1. shafting with stern-tube and propeller;
2. thrust, intermediate and propeller shafts of the shafting;
3. thrust and main bearings;
4. couplings with bolts;
5. stern-tube;
6. propeller shaft lining;
7. propeller;
8. input (primary) and output shafts, gearing, propeller of steerable thruster.

For the power plant, the following documentation shall be submitted to the Branch office for approval:

1. assembly drawings for installation of the main and auxiliary engines, steam and water boilers on the foundations;
2. drawings of silencers and spark arresters.

For automation, the following documentation shall be submitted to the Branch office for approval:

1. schematic diagrams and assembly drawings of remote control systems (with engines, thrusters, pitch changing mechanism, etc.);
2. assembly drawings of control stations and consoles.

For the electrical equipment, the following documentation shall be submitted to the Branch office for approval:

1. electric schematic diagrams of joints and connections, as well as assembly drawings of the main and emergency switchboards, control consoles, section power and light switchboards, monitoring, control and alarm switchboards and panels;
.2 Circuit diagrams of electric drives for ship equipment stated in 5.3.1, 7.5 to 7.10 and 4.2 Table 4.5.1 Part VI RCCS;
.3 Circuit diagrams of electric machines, propulsion plant, ship power plant generators, power mains; lighting, communication and alarm, monitoring, protection, locking and navigation light mains;
.4 Drawings of cable routes throughout all ship rooms and spaces via watertight bulkheads, decks and platforms;
.5 Arrangement and installation drawings of electrical equipment in all ship rooms and spaces with fastenings and earthing units;
.6 Earthing drawings for ships with non-conductive hulls.

6.16 For the communication and navigation equipment, the following documentation shall be submitted to the Branch office for approval:
.1 Arrangement and fastening drawings of antennas, design of antenna leads and their guards;
.2 Arrangement and installation drawings of equipment in all ship rooms and spaces with fastenings and earthing units;
.3 Drawings of routing and fastening cable routes throughout all ship rooms and spaces with fastenings;
.4 Diagrams and drawings of devices for protection of radio signal reception against interference;
.5 Drawings of echosounder trunks, arrangement and fastening of echosounder vibrators and cable routing;
.6 Installation drawing of the main / steering (reserve) marine compass.

6.17 In addition to the documents specified in 6.1 to 6.16, the following documentation shall be submitted to the Branch office for approval:
.1 Specification for ship’s and hull parts, arrangements, engines, shafting, boilers, power plant and ship systems, electrical and radio equipment;
.2 Program (for serial ships) and acceptance trials procedure;
.3 General view and arrangement of ship rooms;
.4 Fire control (general arrangement) plans indicating the following: arrangement of control stations; arrangement of fire-retarding and fire-resistant structures; arrangement of rooms protected by the fixed fire-extinguishing systems, indicating the location of devices and fittings to monitor their operation; arrangement of fire-fighting and emergency appliances; means of access to different compartments, rooms, on decks indicating the escape routes, corridors and doors; arrangement of fire hydrants; diagram of ventilation system including the central fan control system with indication of its location, and fans;
.5 Installation diagram of navigation lights;
.6 List of outfit regulated by the Rules;
.7 Docking plan;
.8 Assembly and welding procedures of ship structures and hull (developed by the Constructor and approved by the Branch office which carries out technical supervision during construction);
.9 Program and procedure of comparative and simulation ship trials;
.10 Summary of the River Register remarks elimination on technical design (without stamping);
.11 List of operating design materials approved by the Branch office.

Note: The deviation permit shall be agreed with the surveyor only for those structures documentation of which are agreed with the River Register.

Permitted

Chief Engineer
HULL TIGHTNESS TESTING

1 GENERAL PROVISIONS

1.1 Scope of application

1.1.1 This Appendix specifies the procedures and norms of tightness testing (capability of a structure not to pass water or other fluids) of metal hulls of the inland and river-sea navigation ships classified by the River Register.

1.1.2 The Appendix applies to the ships under construction and in service.

1.2 General requirements

1.2.1 The tightness testing which scope includes process exposure on the hull by test mediums with assessing the tightness of structures based on changes of test medium parameters or by detecting places of its penetration are carried out on all the hull structures, equipment, devices and hull fittings which may contact with water or other fluids under operating conditions and in emergency cases stipulated by the calculations and which shall not pass it keeping their serviceability.

1.2.2 In order to carry out the tightness testing, the compartments and hull structures are divided into 2 groups:

.1 group "a": compartments and tanks which during operation are temporary or permanently filled with fluid as well as forepeak, afterpeak, hollow rudders, nozzles, hollow elements of foil arrangements, air boxes, watertight compartments of the motorboats without inner bottom;

.2 group "b": compartments and structures of hull, superstructures and wheelhouses not included in group "a", but according to the operating conditions shall be watertight including dry compartments of floating docks and thruster rooms which shall meet the tightness requirements.

1.2.3 The testing of hull, its compartments and separate structures shall be carried out according to the tightness testing diagram and table developed in accordance with this Appendix and agreed with the Branch office. The tightness testing diagram and table include the design documents defining the Nomenclature, arrangement, test methods and norms of compartments covered by the tightness requirements. When developing these documents provision shall be made to ensure the strength of hull structures and slipway sites according to the conditions of hull flooding testing.

When testing ship hull in floating dock the dock stability is assessed additionally.

1.2.4 All hull members including the inside parts which provide floating of a ship after launching from a slipway as well as structures inaccessible for inspection and defect elimination afloat, shall be tested on the slipway or in dock before ship launching.

Watertight hull structures accessible for inspection over the entire contour when ship is afloat (except for double bottom plating and watertight structures inside the double-bottom space) may be tested afloat, if they were not tested on slipway or in dock.

1.2.5 When performing assembly and welding operations providing the watertight of the hull structures, fittings and equipment
previously subjected to tightness testing, the local and global strength are checked.

Testing conditions and rejection parameters are agreed with the surveyor.

1.2.6 Before tightness testing the quality of welded and riveted joints are checked in accordance with 8 Part X RCCS — for welded joints, OST 5.9367 — for riveted joints of steel structures, OST 5.1031 — for riveted joints made of aluminum alloys.

1.2.7 The surface of tested structures and joints shall be cleaned, and the control surface of the structures shall be dry.

1.2.8 The structures and joints to be subjected to tightness testing shall not be painted, paved and covered with special coatings until completion of testing, except for cases specified in 1.2.9.

1.2.9 Before tightness testing the structures including intersectional connections may be fully primed and painted at the manufacture site meeting the following conditions:

.1 main plates making part of the tight contour shall be at least 12 mm thick, and framing webs restricting the tested contour and welding to the main plates — at least 8 mm thick;

.2 before painting (pavement or applying the special coatings) all the intersectional connections of structures making part of the tight contour are carefully inspected;

.3 before priming and painting butt and tee joints related to the structures of group "a" and located below the waterline are subjected to tightness testing by wetting with petrol or blowing with compressed air;

.4 double-sided welds of tee joints without continuous fusion are subjected to tightness testing by wetting with petrol or blowing with compressed air after the final formation of weld from one side or by applying an air pressure to the closed contour after the welding from both sides;

.5 all operations on the structures related to installation, assembly, welding, leveling, riveting of the hull structures and fittings as well as installation, assembly, welding and riveting of all the saturating parts shall be completed. At the same time, all assembly-welding operations on the structures creating the tested contour from the side of adjacent hull structures shall be completed.

1.2.10 The structures tested and adopted on section of preliminary assembly may be primed and painted, except for section of 30 to 40 mm wide adjacent to the mounting edges. The specified sections may be primed only in case of applying the prime not affecting the welding quality.

1.2.11 The tightness testing of field joints made on slipway is carried out by wetting with petrol or blowing with compressed air before its priming.

1.2.12 The structures not subjected to tightness testing after their assembly which are designed to be located outdoor during the extended period of time may be primed with one layer, except for the intersectional welded connections and sections of 30 to 40 mm wide from each weld side.

1.2.13 If the shipyard provides stable manufacture quality of the hull structures, upon agreement with the Branch office the flooding testing of ships in a series may be replaced by air pressure testing which conditions are specified in note 1, Table A10.4.1.

Prior to make a decision to carry out tightness testing of the structures by applying an air pressure, verification calculation of the tested structure strength shall be made.

If the design strength is insufficient to perceive the excessive pressure equal to 30 kPa, the air pressure may be reduced to 20 kPa upon agreement with the Branch office.

Other test methods may be used observing the requirements given in 3.7 of this Appendix.

2 TEST CATEGORIES

2.1 General

2.1.1 The test categories are determined by the scope and methods of tightness testing of the hull structures as well as hull fittings,
equipment and devices depending on the structure purpose and process sequence of its formation. The testing is divided into 3 categories: preliminary, main and verification.

2.1.2 Local tightness testing includes the tightness testing of an eliminating point of penetration defect.

2.1.3 General tightness testing includes the tightness testing of the entire structure using the methods specified for items' group to which this structure refers.

2.2 Preliminary testing

2.2.1 The preliminary tightness testing of intersectional connections of the hull structures are carried out while manufacturing the hull sections and blocks in order to decrease the test scope on the slipway.

The scope and methods of the preliminary structure testing are determined by the shipyard in accordance with the adopted construction technique.

2.2.2 The preliminary testing of the structures which will further be assembled and welded (except for assembly and welding along the mounting edges) are taken as the main testing, if the methods and norms of this testing comply with the methods and norms of the main testing.

2.2.3 Technical supervision for the preliminary testing is carried out by the surveyor by way of performing a sampling inspection.

2.3 Main testing

2.3.1 The main tightness testing is carried out by flooding in accordance with the testing diagram and table (design documents determining the nomenclature, arrangement, methods and norms of testing the compartments and structures covered by the tightness requirements) agreed with the Branch office.

2.3.2 Before the main tightness testing the assembly and welding as well as straightening operations of the structures included in the watertight contour to be tested shall be completed.

2.3.3 Technical supervision for the main testing is carried out according to Table A10.4.1.

2.4 Verification testing

2.4.1 The verification tightness testing of the compartments and structures of group "a" designed to store liquids is carried out by applying an excessive air pressure of 20 kPa upon completion of installation workmanship from both sides of the tested structures in accordance with testing diagram and table agreed with the Branch office.

2.4.2 The verification testing of tankers' tanks and cargo holds by flooding under pressure is carried out while checking the standard pumps and systems during the mooring and running trials.

2.4.3 Technical supervision for the verification testing is carried out by sample inspections. The verification testing is carried out witnessed by the surveyor.

3 TEST METHODS

3.1 Flooding testing

3.1.1 Hydrostatic pressure (head) during the flooding tightness testing is specified in accordance with the requirements given in Section 4 of this Appendix and determined in the testing diagrams and tables (see 1.3.3).

3.1.2 When checking the compartments and structures for which the testing head exceeds the structure height, in order to create the required head in the tested structure the head funneled pipe or rubber hose of at least 25 mm in diameter is installed. The standard air and measuring pipes may be used.

The pressure corresponding to the specified hydrostatic pressure may be created by means of low-duty booster pumps with diameter of delivery branch of less than 1.25 diameter of the head pipe.

3.1.3 When testing the structures using the head pipe, air-cushions in the upper parts of the tested structures are not allowed. To meet this condition openings of 8 to 10 mm in di-
ameter for air discharge are provided. Upon completion of the testing these openings are welded up and subjected to tightness testing by wetting with petrol or blowing with compressed air.

3.1.4 For testing the process fresh water without pollutants is used. Sea water may be used for testing of all the structures except for fresh water tanks, if the following conditions are met:

1. sea water shall not contain oil contaminates and other pollutants;
2. upon completion of testing and discharge of water the structure surfaces shall be washed with fresh water;
3. time of sea water in the structures shall not exceed two days from the moment of flooding.

3.1.5 The tested structures are inspected 1 hour after the test pressure is established.

3.1.6 Upon completion of testing the water from structures is removed. If pumping arrangements or standard openings are not provided, the water may be removed via the preliminary drilled and temporary plugged openings. Quantity, dimensions, locations of the openings are determined by the technical documentation approved by the surveyor. After discharging the water these openings are welded up and subjected to tightness testing witnessed by the surveyor.

3.1.7 In the event of environmental temperature below 0 °C the testing is carried out using the pre-heated water in the pre-heated structure. The water temperature is selected so that during testing the external surfaces of the tested structure have positive temperature, are not moisten and provide ingress of water through the leakinesses without freezing.

3.1.8 The structures are considered watertight if the tested surface is free from leaks in a form of jet, runs, drops and moisture.

3.2 Testing by water jet under pressure

3.2.1 The tightness testing by water jet under pressure is carried out using an applicator with a nozzle of at least 12 mm in diameter.

3.2.2 The water pressure in the hose shall provide the water jet of at least 10 m high.

3.2.3 The water jet is directed perpendicularly to the tested surface or into the connection when testing the closings. A distance from the nozzle to the tested section shall not exceed 1.5 m, and applicator travel speed along the tested connection shall not exceed 0.2 m/s.

3.2.4 Welded joints may be watered from any side, and riveted joints — only from the side opposite to caulking. If the welded and riveted joints are located vertically, they are watered from bottom to top.

3.2.5 Testing by water jet under pressure is carried out when the ambient temperature is above 0°C.

When the temperature is below 0°C, the testing may be carried out using the water heated to the temperature of plus 40 to 70°C. The tested structure sections are pre-heated to the temperature above 0°C.

3.2.6 The structures are considered watertight if the tested surface is free from leaks in a form of jet, runs, drops and moisture.

3.2.7 Structures and arrangements for closing openings which are not subjected to tightness requirements of the Rules are tested by divergent water jet.

3.3 Air pressure testing

3.3.1 The testing is carried out by applying the excessive air pressure of 30 kPa.

3.3.2 The tested structure shall be provided with two pressure gauges with a scale factor not more than 2 kPa as well as with a safety valve.

The liquid differential pressure gauges may be used.

The connections for pressure gauges, safety valves and air hoses are arranged on the opening covers, temporary plugs or in other places accessible for maintenance.

3.3.3 In order to stabilize the air pressure before testing, the time when the structure is
Appendix 10

under pressure starts 15 min after the end of supplying air to the compartment.

3.3.4 During air pressure testing of welded joints and other connections using a brush or compressed air the polymeric foaming agents are applied in order to detect the air leakage points based on occurrence of firm bubbles and foam envelopes as well as change of colour. If the polymeric foaming agents are not available, small structures may be tested using foaming agents in the form of soap emulsions.

3.3.5 Welded joints and structures tested at ambient temperatures below 0°C are dried by heating up to complete removal of water before wetting with an antifreezing foaming agent.

3.3.6 The defective points are marked on the structure with a chalk.

3.3.7 Leakinesses of overlap welds are detected using the polymeric foaming agents by supplying the compressed air under the excessive pressure of 50 kPa into the gap between contacting places via a nozzle screwed into the opening of lining or welded reinforcing pad.

3.3.8 The structure is considered watertight, if when wetting the joints and other connections with foaming agent the air bubbles or foam envelopes do not occur, and the pressure drop after conditioning for 1.0 hour does not exceed 5%, and for the structures intended for storage of diesel fuel and/or other light oil products — 1%.

3.3.9 Upon completion of testing the polymeric foaming agents are removed from the structure surface using water or a wet cloth.

3.4 Testing by wetting with kerosene

3.4.1 The tightness testing by wetting with kerosene is carried out in order to monitor the welded joints (except for overlap welds).

3.4.2 When testing by wetting with kerosene, the monitored side of the welded joint is covered with a chalk solution. The welds are wetted with kerosene from the opposite side when the chalk solution is dried. The kerosene is applied by a paint brush or a pad.

If the chalk solution is water-based, after the applying on the welded joints it is dried. Upon completion of testing, the chalk covering is removed by a cloth.

3.4.3 At ambient temperature below 0 °C the monitored welded joints are heated up to positive temperature and dried.

The chalk solution is antifreeze-based and keeps the white colour.

3.4.4 The hold time when testing butt and single-sided angle or tee joints with kerosene is determined depending on the thickness of joint’s plate or leg and its space position according to Table A10.3.4.4.

<table>
<thead>
<tr>
<th>Thickness of joint’s plate or leg (mm)</th>
<th>Hold time (min.) at joint’s position</th>
</tr>
</thead>
<tbody>
<tr>
<td>low</td>
<td>vertical and horizontal</td>
</tr>
<tr>
<td>&lt;6</td>
<td>40</td>
</tr>
<tr>
<td>6-24</td>
<td>60</td>
</tr>
<tr>
<td>&gt;24</td>
<td>90</td>
</tr>
</tbody>
</table>

When testing the angle and tee joints with double sided welds as well as at negative ambient temperature, the hold time is doubled.

3.4.5 The structure is considered watertight, if on the monitored surface covered with chalk solution the kerosene marks do not occur.

3.5 Testing by blowing with compressed air jet

3.5.1 The testing by blowing with compressed air jet is used as an auxiliary method for local testing: testing of welding points of separate elements and parts, eliminating defective welded joints as well as doors, comings and other elements located inside the hull and superstructures.

3.5.2 When testing by blowing with compressed air jet, the hose pressure shall be 390 to 490 kPa.

The jet is directed perpendicularly to the tested surface. The hose end is fitted with a nipple of 10 to 20 mm in diameter and is lo-
cated at a distance of not more than 100 mm from the tested joint’s surface. The travel speed of the hose nozzle shall be not more than 0.02 m/s. The foaming agents (see 3.3.4 of this Appendix) are applied from a side opposite to blowing proactively (if the polymeric foaming agents are used) or synchronously (if the soap solutions are used).

3.5.3 The structure tightness assessment shall be performed in accordance with 3.3.8 of this Appendix.

3.6 Testing by divergent water jet

3.6.1 The tightness testing by divergent water jet is used to check the tightness of decks, platforms, doors and hatch covers. The divergent water jet is a descending jet branch released from the applicator upwards by the angle to the horizon.

3.6.2 When testing by divergent water jet, the requirements specified in 3.2.4 to 3.2.6 of this Appendix shall be met.

3.7 Testing by other methods

3.7.1 The methods of hull tightness testing other than those specified in 3.1 to 3.6 (e.g. luminescent method, air pressure using the leak seekers, vacuum method) may be used after experimental tests under supervision of the River Register. When selecting the test method, its application shall be specified: main and/or replacing, hull structures, types of connections and main parameters of welded joints, thicknesses of welded parts as well as methods of applied welding.

3.7.2 The procedure specification for method other than those specified in 3.1 to 3.5 shall be agreed with the Branch office.

4 METHODS AND NORMS OF TIGHTNESS TESTING

4.1 The tightness test methods and norms are given in Table A10.4.1.

<table>

</tr>
</tbody>
</table>

Notes: 1. If the flooding testing on the slipway or in dock is impracticable, it is carried out after launching. Before launching all the cargo compartments are tested by applying air pressure. One central and two side compartments determined upon agreement with the surveyor are tested by flooding. These compartments are tested simultaneously. The mutual position of the tested compartments shall correspond to the most severe load conditions. If during testing the structure defects or tightness breaks are detected, all compartments shall be tested.

2. The testing by water jet under pressure may be replaced by testing the welded joint by wetting with kerosene (except for overlap welds) or by blowing with compressed air jet. The plate surfaces are carefully inspected. No defects and metal integrity loss are permitted.

3. Methods and norms of the tightness testing during repair and special surveys of ships shall comply with the requirements specified in this Table. Fuel and water tanks are tested by flooding up to the top of air pipe, and cargo compartments and cofferdams of tankers — up to the upper edge of the expansion trunks and hatches. The scope of testing during repair is specified depending on the nature of repair and shall be agreed with the surveyor.
PERMISSIBLE WELDING DEFORMATIONS OF SHELL AND HULL FRAMING AND DEVIATIONS DURING SHIP’S HULL ASSEMBLY

1. Sag values of cambers, ribbing, dents and "boxes" (angular camber) of the hull structures’ shell shall not exceed the values specified in Table A11.1. Sag values of cambers, "boxes" and ribbing of the bottom shell of 4 to 7 mm thick for high-speed craft within spacing shall not exceed 3 mm.

2. Local deformations of the hull framing structures (sags, skewness, wall cambers) shall not exceed the values specified in Table A11.2.

Welding deformations of hull structures outside the limits specified in this Appendix shall be eliminated. The applied correction methods and technique shall comply with the manufacturing procedure of this structure.

3. The permissible deviations during hull assembly are given in Table A11.3.

INSPECTION OF ENGINES FOR COMPLIANCE WITH MAXIMUM PERMISSIBLE HARMFUL SUBSTANCE EMISSION AND EXHAUST GASES OPACITY

1 Requirements to fuels and lubricants

1.1 While testing the engine shall operate on fuel and lubricants specified in technical documentation of the engine manufacturer. The specifications of fuel and lubricant used for testing shall be specified in the Test Report.

2 Atmospheric conditions during measurements

2.1 At the testing site, the following parameters shall be measured: atmospheric air temperature at the engine inlet $T_a$, $\text{K}$, atmospheric (barometric) air pressure $p_0$, kPa, considered as sum of partial pressures of dry air and water vapours in atmospheric air as well as relative and absolute air humidity used for calculation of partial pressure of dry atmospheric air.

2.2 Based on the measurement results the design coefficient (atmospheric factor) $F$ is calculated by the formulae:

for naturally aspirated engines, engines supercharged by a PTO supercharger or engines with combined supercharging:

$$F = \left(\frac{99}{p_{dry}}\right)^{0.7} \left(\frac{T_a}{298}\right)^{1.5}; \quad (A12.2.2-1)$$

for engines supercharged by free turbocharger:

$$F = \left(\frac{99}{p_{dry}}\right)^{0.5} \left(\frac{T_a}{298}\right)^{1.5} \quad (A12.2.2-2)$$

where $p_{dry}$ — partial pressure of dry atmospheric air, kPa, calculated by the formula:

$$p_{dry} = p_0 - p_{H_2O} \quad (A12.2.2-3)$$

$\rho_{H_2O}$ — partial pressure of water vapours in atmospheric air at $T_a$, kPa.

2.3 The testing results are considered reliable if during testing $F$ remains within the limits set for engines during:

- onboard testing $0.93 - 1.07$
- bench testing $0.98 - 1.02$

3 Measurement of exhaust gas composition

3.1 The exhaust gas composition is measured for engine operation modes specified in Table A12.3.1 depending on its application. The measurement shall be started with nominal power mode and then the load shall be gradually decreased to the minimum.

3.2 Before measurement the gas analyzers are heated and calibrated in accordance with the manufacturer instruction.

3.3 The gas analyzer indications are read for each mode three times with an interval of not less than 1 minute. The first reading is made not earlier than 2 minutes after the establishing the temperature condition of the engine in the test mode. The results of three sequential readings shall not differ more than by $\pm 3.5\%$. The measurement result is taken as arithmetic mean of three readings. If an event recorder is provided the measurement result is taken as arithmetic mean of continuous recording during 1 minute, if during the entire time of recording the deviations from initial value is not more than $\pm 3.5\%$.

#### 3.4 Simultaneously with measuring the exhaust gas composition the values of engine parameters required for determining the regulated parameters are recorded.

#### 3.5 Upon the engine testing results the Engine Test Report is drawn up in order to confirm the compliance of the engine to the technical regulations of harmful substances emissions and opacity in exhaust engine gases (TOCT P 52408).

#### 4 Processing of measurement results

**4.1** Hourly fuel mass flow is measured for each test mode by methods providing the accuracy of ±5%.

**4.2** The exhaust gas flow $V_{\text{exh}}$ is measured by any direct method followed by reducing to normal atmospheric conditions or is calculated according to the measured values of air and fuel flow for each test mode by the formula specified in 6.2.5 RPPS.

**5 Measurement of exhaust gas opacity by optical method**

**5.1** The exhaust gas opacity is measured in the engine operation modes which are the same for measurement of exhaust gas composition.

The installation diagram of the optical-type smoke density indicator is given in Fig. A12.5.1.

**5.2** Before measuring the smoke density indicator is heated and calibrated according to the reference light filter included in the device set in accordance with the manufacturer instruction.

**5.3** The opacity parameters are measured for each engine operation mode at least three times with an interval between the following measurements of at least 1 minute. After each measurement the zero position of the smoke density indicator arrow is checked and set to the zero position, if required. The measure-
5.4 The measurement results are included in the Test Report.

6 Measurement of exhaust gas opacity by filtration method

6.1 The installation diagram of filtration-type smoke density indicator is given in Fig. A12.6.1.

Before measuring the smoke density indicator is heated and calibrated according to the reflectance standard included in the device set in accordance with the manufacturer instruction.

6.2 A sample is collected in accordance with operation instruction developed by the manufacturer of the smoke density indicator. The sample is passed through a filter which then is removed from the smoke density indicator and replaced with a new one through which a new sample is passed in order to recheck the result and receive its mean value. No moistened or non-standard filters are permitted.

Fig. A12.6.1. Installation diagram of filtration-type smoke density indicator:
1 — straight section of exhaust engine pipeline; 2 — gas sampling probe; 3 — sampling line; 4 — cooler; 5 — smoke density indicator; EG — exhaust gases
6.3 The opacity for each engine operation mode is measured at least three times with an interval between two following measurements of at least 1 minute. After each measurement the zero position of the smoke density indicator arrow is checked and set to the zero position, if required. The measurements are considered valid, if deviations between two last readings as per scale FSN do not exceed \( \pm 0.2 \) FSN, and the results of three measurements do not form a steadily decreasing or increasing sequence. If these conditions are met, the measurement series can be continued until receiving three sequence parameters meeting the specified conditions. The measurement result is taken as arithmetic mean of three readings.

6.4 The measurement results are included in the Test Report.
GUIDELINES FOR TESTING OF TYPE SPECIMENS OF LIFE-SAVING APPLIANCES

1 Lifeboats

1.1 Testing of type specimens of lifeboats includes:
   .1 main dimensions checking;
   .2 lifeboat weight determining;
   .3 freeboard height determining;
   .4 lifeboat strength testing;
   .5 lifeboat tightness testing;
   .6 lifeboat stability testing;
   .7 accommodation capacity checking;
   .8 lifeboat floodability testing;
   .9 removable air boxes testing;
   .10 floodability testing of lifeboat buoyant material;
   .11 strength testing of lifeboat handling gear;
   .12 strength testing of plugging and fastening the handling gear (for plastic lifeboats);
   .13 checking of lifeboat engine operation;
   .14 fire testing (for lifeboats of oil tankers).

1.2 The main dimensions are checked and lifeboat weight is determined as follows:
   .1 in order to measure, a lifeboat is positioned horizontally on level in longitudinal and transverse directions.

   During measurement the following parameters are determined: compliance of thwart height and distance between transverse thwarts, dimensions $L$, $B$, $H$ of lifeboat hull and distance $A$ to the design documentation. Here:

   $L$ — distance between projections on the base plane of intersections of external shell surface and stem and sternframe (transom) at level of lower gunwale edge, m;

   $B$ — maximum width between the external shell surfaces;

   $H$ — side height in the middle of lifeboat from BL to the gunwale edge, m;

   $A$ — distance between axial lines of lifting hooks, m;

   .2 weight of lifeboat fully completed with ship equipment and outfit is determined by weighing. The weighing may be performed using dynamometers secured on the lifeboat hooks.

   1.3 The freeboard height is measured amidships on both sides of the lifeboat in light and fully loaded conditions on still water.

   The outfit and persons weight may be replaced by equivalent load weight. Weight of one person is taken equal to 75 kg, and position of centre of gravity — at a height of 0.3 m above a thwart.

   1.4 The lifeboat hull is subjected to strength testing taking into account the following guidelines:

   .1 lifeboat is hanged by handling gear and loaded with a load distributed at seats for persons with weight determined by the formula, kg,

   $$G_{load} = 0.25G_h + 1.25\left(G_p + G_o\right)$$

   where $G_h$ — weight of lifeboat hull, kg;

   $G_p$ — weight of people, kg;

   $G_o$ — weight of outfit, kg.

   At the same time the keel, keelsons, sheerstrake, bulwark are inspected. The lifeboat is deemed to have passed the testing, if it is free from cracks and other damages.
plastic lifeboat are additionally tested by impact and drop. The lifeboat with a load of weight equal to persons and outfit weight is hanged by lifeboat hooks on slings of 6 m long at a distance of 0.5 m from the lifeboat gunwale to the vertical surface (e.g. concrete walls). The lifeboat is deflected from the vertical surface by 2.5 m and suddenly release. The lifeboat in the same loading condition is dropped from a height of 2.5 m from the lower keel edge to the water surface. Water depth in the test site shall not be less than two side heights of the lifeboat amidships. The lifeboat is deemed to have passed the testing, if it is free from residual deformations, cracks and other damages. The lifeboat not having passed the testing, after eliminating the defects, is allowed to undergo the strength testing again.

1.5 The lifeboat having passed the strength testing is subjected to tightness testing using one of the following methods:

- on keel-blocks — by flooding the hull up to the level corresponding to the draught of the lifeboat fully completed with persons or ballast replacing them and outfit. The lifeboat is deemed to have passed the testing, if during 2 hours after flooding the external surface is free from leakages and drops;
- afloat — at draught corresponding to displacement of the lifeboat fully completed with persons and outfit. The lifeboat floating for 2 hours on even keel and in upright position shall be free from leakages. However, for wooden lifeboats the flooding up to the level of 20 mm from the lower keelson edge is permitted.

The lifeboat not having passed the tightness testing, after eliminating the leakages, is tested again.

In order to test the above water part, the lifeboat on keel-blocks or afloat is alternatively sloped on right and left side so that water achieves the gunwale level. The hold time on each side is 30 minutes. The lifeboat is deemed to have passed the testing, if the monitored surface is free from leakages.

1.6 Stability testing procedure

1.1 The testing is carried out afloat with a load corresponding to the weight of permitted number of persons and outfit. The load is arranged on the places for persons and outfit. Centre of gravity of the load simulating persons is positioned at a height of 0.3 m from thwarts and secured to prevent the offset at heel. The lifeboat shall not have a heel. In order to incline, the load with a weight of 4 to 5% of total water displacement is moved from side to side. When inclining the moment statically inclining the lifeboat by 10° from zero position is determined and compared with the specified in the design documentation.

1.3 The sufficiency of freeboard height is checked. It shall be at least 100 mm when the lifeboat is loaded with 50% of the number of persons permitted to accommodate seated to one side of the centreline.

1.7 Testing by accommodating persons is carried out on the site protected from current, waves and wind. The testing may be carried out at current of less than 0.1 km/h, ripple and wind up to 3 m/s (hereinafter referred to as the calm water).

Persons 75 kg each (in average) are taking seats in lifejackets. The number of persons shall correspond to the design capacity of the lifeboat. The testing results determine if the persons obstruct each other when paddling and if each person is capable to stand up and take the provided outfit.

1.8 During floodability testing the lifeboat with ballast simulating the persons, and outfit is flooded up to the upper gunwale edge. At the same time the freeboard height is measured (it shall be at least 20 mm) and the lifeboat is checked for a heel.

If the lifeboat has not passed the testing, the capacity of air boxes or floating material is increased or number of persons permitted to accommodate is reduced.

1.9 The tightness testing of removable air boxes is carried out using one of the following methods:
.1 An air box is weighted and fully submerged in water so that the water layer above its surface comprises at least 100 mm. After 2 hours the air box is recovered and weighted. If the box weight is not changed, it is deemed to have passed the testing;

.2 Air box is submerged into a tank containing hot water with a temperature of 60 to 70°C so that the water layer above its surface comprises at least 100 mm, and the box is turned over in the water for 10 to 15 minutes. If the box is untight, the heated air will expand and come out, and bubbles will show the defect point;

.3 Compressed air through a nipple soldered to one of the angles of the tested box is pressurized into the air box up to it reaches the excessive pressure of 0.0196 MPa. If pressure drop measured after 20 minutes does not exceed 1% of the specified (excessive) pressure, the box is deemed to have passed the test.

The box capacity is determined using one of the following methods:

- careful calculation performed according to the results of measuring the box dimensions
- filling the box with water the volume of which is measured in the calibrated vessel
- submerging the box into the tank fitted with fixed scale graduated in volume units

Before testing the load required for holding the box in fully submerged condition is lowered. According to the water level in the tank with lowered load a zero mark is installed. The box with the load is submerged into the tank to a depth of 100 mm from water level. The water level is marked as per scale and volume of the air box is determined.

1.10 The buoyancy testing of lifeboat buoyant material is carried out on a specimen. Before submerging the specimen, the weight which specimen is capable to support is determined. Then the specimen is submerged in water so that the water layer above the surface is at least 100 mm, and it is conditioned for 24 hours. After that, the weight which the specimen is capable to support is determined again.

The specimen is deemed to have passed the test, if the difference between load weights in the beginning and at the end of test does not exceed 10% of load weight in the beginning of test, and upon test completion the specimen is free from damages, shrinkage, blistering or other changes of mechanical properties.

1.11 Strength testing of lifeboat handling gear:

.1 Before installing on the lifeboat each lifeboat hook (or replacing device) as well as hangers and fastenings shall be tested with load of a weight equal to \( G_\mu \), kg, for 10 minutes

\[
G_p = 2 \left( G_h + G_p + G_o \right) / n
\]

where \( G_h \) — weight of lifeboat hull, kg;
\( G_p \) — weight of people, kg;
\( G_o \) — weight of outfit, kg;
\( n \) — number of hooks.

During testing the release of lifeboat with onboard handling gear is checked after its launching both in light and design loaded condition.

The handling gear is deemed to have passed the test, if after unloading the components are free from cracks, tears and residual deformations. The absence of deformations is determined by measuring the distance between three points marked on the component surface with a centre punch.

.2 The gear as a whole is tested simultaneously with strength testing of the lifeboat.

1.12 When checking the strength of plugging and fastening the handling gear the plastic lifeboat overloaded by 50% and hanged by hooks is lowered with speed of 0.6 m/s and then hard braked. The structure is inspected for integrity, and the lifeboat hull is inspected for cracks and deformations.

1.13 Check of engined lifeboat operation

.1 Lifeboat afloat is loaded with load corresponding to the weight of permitted number of persons and outfit. The engine start is checked (including manual start). The start time shall be not more than 2 minutes.

The lifeboat manoeuvrability is checked for 2 hours and within this time the fuel consumption is determined;
.2 the capability of engined lifeboat to tow a liferaft with the maximum capacity in loaded condition with speed of at least 3.7 km/h is checked;

.3 the lifeboat engine operation for at least 5 minutes when it is flooded up to the crankshaft axis is checked. As a result of this test the engine shall not be damaged.

1.14 The lifeboats of oil tankers are additionally tested by fire.

The water area with an extend exceeding the lifeboat dimensions in plan view is filled with kerosene which quantity when ignited is sufficient to cover the lifeboat with fire for 8 minutes. During the fire testing the temperature in several points inside the lifeboat is measured (it shall not exceed 60° C). At the same time, the space inside the lifeboat is checked for smoke and harmful gases in air by analyzing the collected samples.

After the fire testing, the lifeboat is subjected to tightness testing.

2 Liferafts

2.1 Testing of type specimens of liferafts includes:

.1 weighting;
.2 drop testing;
.3 jump testing;
.4 towing testing;
.5 afloat testing;
.6 accommodation capacity testing;
.7 stability testing;
.8 flooding testing;
.9 special testing of inflatable liferafts;
.10 testing of hydrostatic release device of liferaft.

2.2 The liferaft fully completed and packed in container or case is subjected to weighting.

2.3 During the drop testing the liferaft packed in case or container with outfit is dropped from a height of 10 m to water. A free end of painter is laid out simulating the real falling conditions. After dropping the liferaft is remained afloat for 20 minutes and checked for positive buoyancy. After lifting the liferaft is inspected. If the liferaft is inflat-

able, it is inflated up to the operating pressure in order to inspect it. The liferaft is deemed to have passed the test, if it and its outfit are free from damages which would result in deg-
radation in performance.

2.4 When testing by jumping the testers with a weight of not less than 75 kg and wearing shoes with flat sole jump at least 5 times from a height of at least 4.5 m to the liferaft full operational and afloat. The jump testing may be replaced by dropping a load with equal weight onto the liferaft.

The liferaft is deemed to have passed the test, if it is free from breaks and damages.

2.5 During towing testing the liferaft full operational in fully loaded condition is towed by a towing rope secured on the liferaft's towing eye to a distance of at least 100 m at a speed of 5.5 km/h on calm water.

The liferaft is deemed to have passed the test, if it and towing arrangements are free from damages.

2.6 Afloat testing

.1 liferaft with a load corresponding to the weight of design number of persons and outfit is brought to an anchor in water area. The liferaft is remained afloat for 3 days. If the liferaft is inflatable, it may be additionally pumped by hand-bellows once a day.

The liferaft shall maintain its form and be free from damages;

.2 the afloat testing defines that the lif-
eraft at design load is capable to move on calm water to a distance of at least 30 m by means of paddles included in the outfit.

2.7 Accommodation capacity testing

.1 design number of persons 75 kg each (in average) dressed in the lifejackets are ac-
accommodated on the liferaft.

The testing determines whether the lif-
eraft has enough place for all the persons tak-
ing into account a space overhead under the canopy and whether the persons are capable to use the outfit inside the liferaft.

During testing the possibility of ease and quick (for 1 minute) closing/opening entries
in canopy (from outside and inside) is checked.

If the canopy is removable two testers install the canopy for 5 minutes and check the possibility to open and close the entries;

.2 the liferaft with raised canopy is checked for possibility of water ingress into the under-canopy space when entries are closed. For this purpose, the entries are tested by divergent water jet directed perpendicularly to the entry surface for 5 minutes. As result, no significant water accumulation inside the liferaft shall be observed.

2.8 Stability testing

.1 The design number of persons are accommodated at one side of the operational liferaft situated on calm water. The testing determines whether the freeboard remains positive and whether there is a risk of downflooding the liferaft.

.2 In order to check the liferaft stability during boarding, two testers dressed in life-jackets climb onto the liferaft from water on their own. Then they raise from water the third person who simulating a loss of consciousness. The results show whether the liferaft is stable and whether there is a risk of its capsizing.

2.9 During flooding testing the operational liferaft situated on calm water and completed with outfit and design number of persons (or ballast simulating the design load) is completely flooded. It is determined whether the liferaft is afloat and whether there are significant hull deformations.

2.10 Special testing of inflatable liferaft design:

.1 the liferaft is inflated using the gas inflation system at ambient temperature from 18 to 20°C.

The liferaft is deemed to have passed the test, if the operating pressure is achieved for not more than one minute and the liferaft is free from joint deformation, cracking or any other damages;

.2 the liferaft packed and completed with outfit shall be conditioned for at least 24 hours in the cold chamber with a temperature of minus 30°C. After that, the liferaft is inflated using the gas inflation system.

The liferaft is deemed to have passed the test, if the operating pressure is achieved for not more than 3 minutes and the liferaft is free from joint deformation, cracking or any other damages;

.3 the liferaft packed and completed with outfit is conditioned for at least 8 hours in the chamber with a temperature of plus 50°C. After that, the liferaft is inflated using the gas inflation system.

The liferaft is deemed to have passed the test, if the operating pressure is achieved for not more than one minute and the liferaft is free from joint deformation, cracking or any other damages;

.4 the liferaft is tested by pressure. For this purpose, the inflatable compartment (buoyant chamber) of the liferaft is inflated with compressed air up to pressure two times higher than the operating pressure. The safety valves are in non-operation condition.

The liferaft is deemed to have passed the test, if within 10 min the pressure is not decreased more than by 5% and it is free from any damages;

.5 the liferaft is subjected to buoyancy testing. During buoyancy testing it is stated that the liferaft one buoyancy compartment of which is not inflated is capable to support the design number of persons 75 kg each (in average) sitting in normal position providing the positive freeboard along the entire perimeter.

2.11 Testing of hydrostatic release gear of liferaft:

.1 during temperature testing the hydrostatic release gears are placed into a chamber with a temperature of minus 30°C and conditioned for 8 hours. Then the gears are placed into a chamber with a temperature of plus 50°C for 8 hours. This procedure is repeated 10 times. At the end of testing one hydrostatic release gear shall be taken from the chamber with temperature of minus 30°C and activated in water with a temperature of 0°C. The other hydrostatic release gear shall be taken from
3 Life-saving buoyancy aids

3.1 Testing of type specimens of life-saving buoyancy aids includes:
   .1 dimensions and form determining;
   .2 strength testing;
   .3 tightness testing of metal aid case or air boxes;
   .4 stability testing;
   .5 buoyancy testing.

3.2 Dimensions $L$, $B$, $H$ and form of an aid are checked for compliance with the technical documentation. Here:

$L$ — design length of aid measured between its end points in the centreline, m;

$B$ — design width of aid measured between its end points in the midship plane, m;

$H$ — design height of aid measured between its end points in the centreline, m.

3.3 The strength of the aid shall be checked by dropping it from a height of 10 m into the water. The aid is deemed to have passed the test, if it is free from cracks, dents and breaks.

3.4 The casing of metal aid or air boxes are subjected to tightness testing using one of the following methods:

   sequential blowing of compressed air into each compartment up to the excessive pressure of 0.0196 MPa. If on the expiry of 30 minutes the pressure drop according to the installed pressure gauge does not exceed 1% of the excessive one, the compartment is considered tight;

   flooding each compartment up to a height of 3 m above its upper horizontal tangent to the compartment. For this purpose, a hose or tube fitted with a nozzle at the lower end for screwing into the compartment and with a glass tube at the upper end is vertically inserted into each compartment. If within 1 hour the water level in glass tube is not dropped, the compartment is considered tight.

3.5 During stability testing the steel or cast iron plumbs with a weight of 14.5 kg are hanged on one of the long aid sides on each sag of lifeline.
If the upper surface of the loaded aid is not covered with water, the aid is considered to be stable.

3.6 During buoyancy testing the aid subjected to strength and tightness testings is fully submerged in the water and conditioned for 24 hours. Upon expiry of the stated time, a load with a weight corresponding to the weight of design number of persons (14.5 kg per each person) is placed on the aid. The load shall be above the water. The aid is deemed to have passed the test, if it is afloat for 1 hour.

4 Lifebuoys

4.1 Testing of type specimens of lifebuoys includes:
.1 measuring and weighting;
.2 heat resistance testing;
.3 frost resistance testing;
.4 fire resistance testing;
.5 oil product resistance testing;
.6 strength testing;
.7 buoyancy testing.

4.2 When measuring, weighting and inspecting it is stated that internal diameter, weight of a lifebuoy and outfit provided comply with the requirements of technical documentation.

4.3 During heat resistance testing the lifebuoy is placed into a chamber with a temperature of plus 50°C and conditioned for 8 hours. The lifebuoy is deemed to have passed the test, if it is free from damages and form changes, and the linear contraction does not exceed 2% of initial dimensions.

4.4 During frost resistance testing the lifebuoy is placed into the cold chamber with a temperature of minus 30°C and conditioned for 8 hours. The lifebuoy is deemed to have passed the test, if it is free from damages and form changes, and the linear contraction does not exceed 2% of initial dimensions.

4.5 During fire resistance testing the fireproof vessel with a size of 300 × 350× 60 mm is filled with water up to the mark of 10 mm and with gasoline — up to the mark of 40 mm. The gasoline is ignited and left to burn for 30 seconds. After that, the lifebuoy is hanged at a height of 250 to 500 mm above the upper edge of the vessel and left for 2 seconds. The lifebuoy is deemed to have passed the test, if after removing from flame it does not burn or melt.

4.6 During oil product resistance testing the lifebuoy is fully submerged into diesel fuel to a depth of 100 mm for 24 hours at room temperature. After the testing the lifebuoy shall be free from any damages.

4.7 The lifebuoy is subjected to strength testing after the heat, frost and fire resistance testings:

*Strength testing*

.1 The lifebuoy is dropped 4 times from a height of 10 m onto the water or from a height of 5 m onto the concrete floor. The lifebuoy is deemed to have passed the test, if after the testing it is free from breaks on shell joints and cloths and there is no form changes, and for the lifebuoy with self-igniting buoy — degradation in performance of alarm device;

.2 The strength of lifebuoy subjected to strength testing by dropping as well as strength of fastening the ends and lifeline to the lifebuoy are checked by sequence hanging a load with a weight of 75 kg for 10 minutes to each section of the lifeline. The lifebuoy is deemed to have passed the test, if there is no sliding of the lifeline and offset of its bead, destruction of lifeline end fastenings as well as breaks of shell joints and cloth;

.3 The strength of lifebuoy is additionally tested by hanging it for 20 min with secured load with a weight of 90 kg. The lifebuoy and load are hanged on the opposite sides on tapes of 50 mm wide. The lifebuoy is deemed to have passed the test, if after the testing it is free from breaks, cracks or residual deformation.

4.8 The buoyancy testing is carried out after the strength testing. The lifebuoy with hinged load made of steel or cast iron with a
weight of 14.5 kg is submerged into the water for 24 hours. The load shall not be secured to the lifeline. The lifebuoy is deemed to have passed the test, if during this time it remains afloat. For the lifebuoy with self-igniting buoy, at the same time the alarm device is checked for capability to continuously flash for 2 hours with light intensity of at least 2 cd.

5 Lifejackets

5.1 Testing of type specimens of lifejackets includes:
   .1 heat and frost resistance testing;
   .2 fire resistance testing;
   .3 oil product resistance testing;
   .4 strength testing;
   .5 buoyancy testing;
   .6 stability and convenience testing of lifejacket for adult;
   .7 stability and convenience testing of infant life jacket;
   .8 additional testing of inflatable lifejacket.

5.2 The lifejacket is subjected to heat and frost resistance testings in accordance with 4.3 and 4.4. The lifejacket is deemed to have passed the tests, if the shell and inside buoyant material are free from damages (e.g. shrinkage, bulging and cracking).

5.3 The lifejacket is subjected to fire testing in accordance with 4.5. The lifejacket is deemed to have passed the test, if it does not sustain the combustion and does not melt after its removing from the flame.

5.4 The lifejacket is subjected to oil product resistance testing in accordance with 4.6. The lifejacket is deemed to have passed the test, if after the testing its shell and buoyant material are free from damages, bulging and cracking.

5.5 The strength testing of lifejacket is divided into two types: strength testing by applying a force to belt; and strength testing by applying a force along the lifejacket.

During strength testing by applying a force to belt, the lifejacket is submerged into the water for 2 minutes. Then, a force of at least 320 kg for adult lifejacket (Fig. A13.5.5-1) and 240 kg for infant lifejacket is applied to the lifejacket part which secures it on person's body or to the lifting eye for 30 minutes. The specified force is transferred to the adult lifejacket via cylinder of 125 mm in diameter, to the infant lifejacket — via cylinder of 50 mm in diameter.

![Fig. A13.5.5-1. Strength testing of lifejacket by applying a force to belt:](image)

- **a)** vest-type lifejacket;
- **b)** collar-type lifejacket;
- \( P \) — test load

During strength testing by applying a force along the lifejacket, it is submerged into the water for 2 minutes. After that, it is removed from water and fastened as if it is dressed on a person. Then, a force of at least 90 kg for adult lifejacket and 70 kg for infant lifejacket is applied to the lifejacket’s shoulder part for 30 minutes. The specified force is transferred to the adult lifejacket via cylinder of 125 mm in diameter, to the infant lifejacket — via cylinder of 50 mm in diameter (Fig. A13.5.5-2).

The lifejacket is deemed to have passed the test, if after testing it is free from damages.

5.6 During buoyancy testing the lifejacket subjected to strength testing is submerged into the water for 20 minutes. Then a load is placed on the lifejacket so that the lifejacket still could keep it afloat, and weight of this load is measured. After that, the lifejacket is conditioned in submerged condition for
24 hours so that the water layer above its surface is at least 100 mm. At the end of testing a weight of load, which the lifejacket can keep afloat after being conditioned under water, is determined again. The difference between weights of the load in the beginning and at the end of testing shall not exceed 5% of load weight in the beginning of testing.

Then the adult lifejacket is loaded with a load made of steel or cast iron with a weight of 20 kg, the infant lifejacket — with a weight of 9 kg, and submerged into the water. The lifejacket is deemed to have passed the test, if it is free from damages and remains afloat with the specified load for 15 minutes.

5.7 The stability and convenience testing of the adult lifejacket is carried out by at least 6 test persons (including 1 to 2 women) dressed in casual clothes with different height and weight stated in Table A13.5.6

<table>
<thead>
<tr>
<th>Height (m)</th>
<th>Quantity (persons)</th>
<th>Weight (kg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.4-1.6</td>
<td>1</td>
<td>less than 60 more than 60</td>
</tr>
<tr>
<td>1.6-1.8</td>
<td>1</td>
<td>less than 70 more than 70</td>
</tr>
<tr>
<td>Over 1.8</td>
<td>1</td>
<td>less than 80 more than 80</td>
</tr>
</tbody>
</table>

.2 Test person dressed in a lifejacket shall swim 25 m and board a liferaft or rigid platform extended by 300 mm above the water surface.

.3 Test person dressed in a lifejacket shall make at least three smooth breast strokes and then relax with head down and partially filled lungs simulating the unconscious condition. From this position the lifejacket shall turn the test person on his back at an angle to the vertical for not more than 5 seconds and support the person’s head above the water so that the mouth is at a distance of at least 120 mm from the water surface.

.4 The test person dressed in a lifejacket shall jump feet-first from a height of 4.5 m into the water. The lifejacket when entering into the water shall not move, cause injuries or pain.

5.8 As far as practical, the infant lifejackets shall be subjected to the stability and convenience testing similar to those used for the adult lifejackets. The infant lifejackets are tested using test persons (dummies). The test persons shall be selected so that fully cover all dimensions. At least 6 test persons are required for each height and weight interval.

During testing for turning in water the test person’s mouth shall be above the water after at least 5 seconds.

The average distance from the mouth to the water surface shall be at least 90 mm. The mouth of a separate test person with a height of at least 1.27 m and weight of less than 23 kg shall be above the water of at least 50 mm, and the mouth of test person with a height of more than 1.27 m and weight of more than 23 kg — at least 75 mm.

During testing it shall be determined that the lifejacket does not move, injure, hinder movements inside and outside the water.

5.9 Additional testing of inflatable lifejacket

.1 After testing described in 5.2 to 5.4 the inflatable lifejacket is put in operating condition using the automatic inflation system, manually or orally;
.2 the strength of buoyant chambers of the inflatable lifejacket is checked by inflating the chambers manually using the additional pressure 1.25 times higher than operating pressure when safety valves are closed.

The inflatable lifejacket is deemed to have passed the test, if after holding the pressure for 30 minutes it is free from any damages;

.3 the lifejacket one buoyant chamber of which is not inflated is subjected to buoyancy, stability and convenience testing.

6 Immersion suits

6.1 Testing of type specimens of immersion suits includes:

.1 heat and frost resistance testing
.2 fire resistance testing
.3 strength testing
.4 buoyancy testing
.5 watertightness testing
.6 convenience testing

6.2 An immersion suit is subjected to heat and frost resistance testing in accordance with the requirements of 4.3 and 4.4. The immersion suit is deemed to have passed the test, if it is free from any damages, cracking and bulging.

6.3 The immersion suit is subjected to fire resistance testing in accordance with the requirements of 4.5. The immersion suit is deemed to have passed the test, if it does not sustain the combustion and does not melt after its removing from the flame.

6.4 The immersion suit is subjected to strength testing in accordance with 5.5. However, the applied load shall be 1350 N (if required, during testing the immersion suit may be cut for special arrangements). The immersion suit is deemed to have passed the test, if after the testing it is free from damages.

6.5 The immersion suit not requiring the lifejacket is subjected to buoyancy testing in accordance with 5.5. The immersion suit is deemed to have passed the test, if its buoyancy is not decreased by more than 5% after submerging it into water for 24 hours.

6.6 Watertightness testing:

.1 before testing a weight of test person dressed in the wetted immersion suit is determined. After 1 hour in water, the test person dressed in the immersion suit is weighted again. The immersion suit is deemed to have passed the test, if the weight of ingress water for this time does not exceed 200 g;

.2 the method specified in .1 determines the water quantity in the immersion suit after the test person jump into the water from a height of 4.5 m. The immersion suit is deemed to have passed the test, if during jumping it is not shifted and damaged, and the weight of ingress water does not exceed (500±50) g.

6.7 In order to test the convenience, the test men are selected in accordance with 5.7.

If the immersion suit requires to put on a lifejacket, it shall be put over the immersion suit:

Testing procedure

.1 the test person shall correctly put on the immersion suit without assistance for not more than 2 minutes;

.2 the test person shall steadily swim on calm water faceup. His mouth shall be not lower than 120 mm above the water surface. Then, the test person relaxes and down the head simulating the unconscious condition. From this position the immersion suit design shall turn the person on back faceup for 5 seconds;

.3 the test person dressed in an immersion suit shall jump from a height of 4.5 m and remain in water with a temperature of plus 5°C. for 1 hour. After that, the temperature of test person's body is measured. It shall not be decreased by more than 2°C.

7 Thermal protection aids

7.1 Testing of type specimens of the thermal protection aids includes:

.1 watertightness testing of material and thermal resistance testing of thermal protection aid;

.2 heat and frost resistance testing;

.3 oil product resistance testing;

.4 convenience testing.
7.2 During watertightness testing of material it shall be determined that the material used for manufacturing the thermal protection aid is capable to maintain its watertightness when affected by water column of a height of 2 m.

The testing shall determine that heat transfer coefficient of the thermal protection aid is not more than 7800 W/(m²·K).

7.3 The thermal protection aid is subjected to heat and frost resistance testing in accordance with 4.3 and 4.4. The aid is deemed to have passed the test, if during inspection it is free from damages.

7.4 Oil product resistance testing:

The thermal protection aid after closing of all openings is subjected to the oil product resistance testing in accordance with 4.6. The aid is deemed to have passed the test, if after cleaning its surfaces, after testing and inspecting, it is free from damages and the heat transfer coefficient does not exceed 7800 W/(m²·K).

7.5 In order to carry out the convenience testing the test persons are selected in accordance with the stability and convenience testings of the adult lifejacket.

The test persons located in a life-saving mean afloat unpack the thermal protection aid and put it on over the lifejacket without assistance.

If the test persons being in water and dressed in the thermal protection aid take it off for not more than 2 minutes without assistance, the aid is deemed to have passed the test.

8 Launching and evacuation arrangements

8.1 Testing of type specimens of the launching and evacuation arrangements includes:

.1 performance and strength testing of launching arrangement;
.2 heat, frost and fire resistance testing of marine evacuation chute;
.3 strength testing of marine evacuation chute;
.4 convenience testing of marine evacuation chute.

8.2 Performance and strength testing of launching arrangement

.1 Lifeboat and liferaft davits and lifeboat launching arrangements are tested by the test static load 1.5 times higher than their maximum operating load. The lifeboat completely swung overboard is overbalanced by making an arc of approximately 5° on either side from vertical in the planned longitudinal plane. The testing is first carried out when the ship is in upright position, and then — imitating the heel of 15° to one and another side.

Upon completion of this testing there shall be no significant deformation of arrangements or any other damages;

.2 The test static load 1.5 times higher than the operating load is applied to the winch drums with maximum permissible number of hoses. Such a load shall be maintained using the brakes. Then, this load is decreased by at least one full lap of drum axis. The test load 1.1 times higher than the operating load is decreased with maximum speed to a distance of 3 m and hard braked using the manual brakes. As result of testing, the brakes shall operate properly;

.3 The winch operation is checked using the manual drive, if it is provided by the winch design;

.4 The launching time of lifeboat completed with design number of persons and outfit is checked. The launching arrangement is deemed to have passed the test, if the launching time including the time for preparation and swung overboard does not exceed 5 minutes.

8.3 The marine evacuation chute is subjected to heat, frost and fire resistance testing in accordance with the guidelines of 4.3 to 4.5. The marine evacuation chute is deemed to have passed the test, if when activating it after testing there are no hull cracking, joint deformations and other defects.

8.4 Strength testing of marine evacuation chute:

.1 Buoyancy chambers of the marine evacuation chute when safety valves are closed are inflated with compressed air up to the
pressure 2 times higher than the operating pressure. The marine evacuation chute is deemed to have passed the test, if the pressure in its buoyancy chambers does not fall by more than 5% for 10 minutes and there is no damages of the structure;

.2 Ends of the marine evacuation chute inflated up to the operating pressure are installed on a rigid base at low height. The middle part of the chute is loaded with the distributed load with a weight up to 150 kg (1.47 kN). The marine evacuation chute is deemed to have passed the test, if it is not folded and deformed.

8.5 In order to carry out the convenience testing of the marine evacuation chute, the test persons are selected in accordance with 5.7. Here:

.1 The marine evacuation chute packed in container or case is installed at a height of its installation on board the ship. One test person activates it. Another test person fastens the end of the marine evacuation chute to a life-saving appliance (lifeboat or liferaft). The slope angle of the marine evacuation chute relative to horizon is visually fixed. It shall be within 30° to 35°.

The marine evacuation chute is deemed to have passed the test, if the actuation time does not exceed 5 minutes;

.2 The marine evacuation chute is installed in order to lower persons dressed in the lifejackets. The marine evacuation chute is deemed to have passed the test, if the surface of launchway is free from damages. It shall be shown that the pressure loss in any buoyant chamber of the marine evacuation chute does not restrict its application as an evacuation mean.
GUIDELINES FOR PYROTECHNIC SIGNAL MEANS TYPE SPECIMEN TESTING

1 Thermal stability and cold resistance test

1.1 Two specimens of each pyrotechnic signal mean shall undergo tests in accordance with Guidelines for lifebuoys on thermal stability and cold resistance (see 4.2, 4.3 Appendix 13). Signal means are considered as having passed tests if there is no any damages, cracking and blistering, and they operate normally when commissioned right after tests.

2 Strength test

2.1 Two specimens of each pyrotechnic signal mean are thrown on the concrete floor from height of 2 m. Signal means are considered as passed the test if there is no any damage, and they operate normally when commissioned.

3 Water resistance test

3.1 Two specimens of each pyrotechnic signal mean are immersed in water to a depth of 100 mm for 24 hours. Signal means are considered as passed the test if they operate normally when commissioned, and all instructive signs and figures on the housing are readily visible.

4 Operational tests

4.1 The tester performs without assistance manual start of two specimens of each pyrotechnic signal mean barehanded and gloved.

4.2 When firing rocket parachute flares the tester shall confirm visually that the rocket actuates on the height of about 300 m without damaging the parachute and its fixtures. He also shall document:
   - rocket burning period that should be not less than 40 s;
   - rocket lowering time from the trajectory apex.

   Then the rocket lowering speed shall be determined; it shall be not more than 5 m/s.

4.3 When road flares are actuated, the tester shall note the burning period at ambient temperature of one of road flares. It should be not less than 1 min. The second road flare shall be immersed in water to a depth of 100 mm after 30 s of burning. The road flare shall continue burning for min. 10 s.

4.4 The working efficiency of each pyrotechnic signal mean with air flow rate not less than 30 m/s is tested through laboratory tests with using fan. Pyrotechnic signal mean are considered as passed the test if they do not extinguish at that air flow speed.
1 INSULATION RESISTANCE

1.1 Equipment and electric cables insulation resistance as related to ship’s hull and also between phases/poles, measured during tests that are carried out after the ship’s construction, shall be not less than designated in the Table A15.1.1-1:

<table>
<thead>
<tr>
<th>Insulation resistance</th>

</tbody>
</table>

DC voltage provided by a megohm meter during insulation resistance measuring shall be not less than specified in Table A15.1.1-2.

1.2 Every electric circuit can be divided in various number of sections using installed consumers circuit-breaker.

In fire hazardous premises insulation resistance measurement shall be performed after premises ventilation with 10 air changes.

1.3 Measurement of insulation resistance is to be performed immediately after waterproof testing:

1.4 Insulation resistance data from megohm meter shall be fixated after applied voltage become steady voltage.

2 INSULATION DIELECTRIC STRENGTH

2.1 Equipment insulation dielectric strength except for separate types listed in 2.2-2.4 is tested within 1 min by applying listed in Table A15.2.1, alternating sinusoidal voltage of frequency 50 Hz in normal weather conditions.
2.2 Electrical machines/electromagnetic couplings windings connection insulation shall be tested in machine/coupling no-load condition. Tests are performed on heat machine/coupling with temperature close to the maximum temperature during heating test. Test voltage shall be equal to 1.3 of rated voltage. Test time is 3 min (for turbine generator – 5 min.) unless particular cases are specified.

2.3 During transformer windings insulation testing windings should withstand test voltage listed in Table A15.2.3.

Table A15.2.3

<table>
<thead>

</tr>
<tr>
<td>6001–10000</td>
</tr>
</tbody>
</table>

Transformer windings connection insulation shall be tested by applying to ends of one winding overfrequency doubled voltage with other windings open. The test time is at least 15 s.

For current transformers connecting insulation of secondary side shall withstand in open position test voltage that is induced in it during rated current flowing in primary for 1 minute.

Testing by throwing on an impact load (instantaneous rise and drop of voltage by disabling without an arc with vacuum circuit breaker) on rated voltage shall be provided by transformer actuation on rated voltage 5 times. Occurrences accompanying turn-to-turn short circuit (noise change, smoke appearance, winding insulation colour changing and other occurrences indicating transformer's non-satisfactory condition) shall not be found.

2.4 Test voltage for fuses designed for voltage lower than 500 V shall be 3000 V.

2.5 During cables testing every isolated conductor of precut cable shall withstand for 5 minutes without rupture applying single-phased alternating sinusoidal voltage with frequency of 50(60) Hz or DC voltage stated in Table A15.2.5. This test voltage for precut cable either after for water stored cable or without such storage, either with or without immersion in water.

Cable tests are considered as positive if no insulation rupture or surface flashovers are detected.

<td>1500</td>
</tr>
</tbody>
</table>

Notes: 1. Tables requirements apply to cables with rubber, PVC and polyethylene insulation or PVC enclosure.

2. Test voltage for cables which nominated voltage is not indicated in the Table shall be determined in technical documentation.

3. For cables with shielded conductors if they exceed 50% of all conductors, tested voltage can be lowered on 25% in comparison with voltage designated in the Table.

3 FUNCTIONAL TESTS

3.1 Every equipment specimen is subject to functional tests prior to separate tests types.

For tests performance it should be determined that equipment complete set, spares and insulation resistance are in accordance with technical documentation.
3.2 Equipment tests shall be performed for the nominal ratings covered by technical documentation, and in normal weather conditions.

3.3 During the test needed measurements and calibration are performed. Characteristics are determined both with rated power voltage and frequency, and with prolonged (instantaneous) (see 2.2.1 Part VI RCCS) deviations:
- with prolonged voltage deviations on +6% and -10% and frequency deviations on ±5 %;
- with instantaneous voltage deviations on +15 and -30 % and frequency on ±10 %.
Instantaneous voltage deviation duration - not more than 1.5 s, instantaneous frequency deviation – 5 s.

3.4 Equipment intended for supplying from batteries shall be tested with voltage deviation from rated value within +30 to -25% (for equipment supplied from battery attached to charger) and +20 to -25 % (for equipment not attached to the charger during charging).

3.5 Measurements results and characteristics matching to values specified in the technical documentation, and equipment working efficiency in given parameters are tested.

For equipment operated at the load calibration performed on reaching steady state working temperature.

4 OVERSPEED AND OVERLOAD TESTS

4.1 Overspeed test shall be performed after short overcurrent test, and for electrical machinery tested for stop under load current - after stop under load current tests. The test is performed at electrical machinery parts temperature close to steady temperature reached by the end of heating tests. The test time for all electrical machinery except for starter is 2 min (for starters — 20 sec).

4.2 Electrical machinery with series excitation shall be tested at rotation speed exceeded the biggest stated in the datasheet data by 20%, but not exceeded rated rotation speed more than 50%. Starters shall be tested at 120% of idle speed.

4.3 Electrical machinery with regulated rotation speed and with several rated rotation frequency shall be tested at rotation frequency exceeded the biggest stated value on rating plate by 20%. All other electrical machinery is tested at rotation frequency exceeded rated frequency speed by 20%.

4.4 Alternating current generators overcurrent test is performed at load power factor of 0.6 (\(\cos \varphi = 0.6\)) with current of 150% of rated during 120 s. Direct current generators test is performed with current of 150% of rated during 15 s. The tests are considered as successful if generator’s voltage does not reduce more than by 10%.

5 SHORT-CIRCUIT SURGE CURRENT RESISTANCE TESTS

5.1 Electrical machinery short-circuit surge current resistance tests shall be performed if the following conditions have been fulfilled:
- Short circuit mode shall be created by sudden simultaneous short circuit of all 3 phases (poles) while machinery runs idle at voltage of 105% of rated, and with automated voltage control devices engaged.
- Electrical machinery power during the test shall be not less than rated power.
- Length of conductors from electrical machinery to closing appliance shall be minimal, cross sectional area shall be maximal of all provided in technical documentation for the generator; conductors material shall be copper.

Short-circuit mode parameters shall be oscillographed.

Test result evaluation shall be performed by its detailed examination, especially examination of stator winding face parts, welds and other mechanical joints condition and fastening, and also on the results of insulation electric strength test performed after short-circuit current resistance test.

5.2 Electrical machinery above 1000 kW/A test results evaluation shall be performed in accordance with readings obtained from strain-gauging (deformations value determination on parts surface), stresses in active steel
fasteners and their parts fronts insulation, and as a result of vibration measurement of these parts. Stress limits norms shall be stated upon agreement with the River Register.

6 VIBRATION RESISTANCE TESTS

6.1 Vibration resistance tests of disabled equipment are performed within band of 2–80 Hz (Table A15.6.1). Tests shall be performed in three mutually perpendicular planes; one of them shall be working plane.

6.2 Tests on resonant frequencies detection is performed in same sub-band and amplitude as were used during vibration resistance tests (Table 15.6.5) for all sub-bands. Equipment shall be rigidly (without shock absorbers) attached direct to the test bench platform.

<table>

</tbody>
</table>

Resonant frequencies search shall be performed by smooth frequency shift within every range with constant amplitude. Smooth frequency shift time within the range shall be not less than 2 minutes. Detected resonant frequencies shall be recorded both for equipment in general and for separate assemblies or parts to take them into account in subsequent vibration resistance tests. Amplitude increasing under resonance greater than 5 times as compared to connection points vibration amplitude is unacceptable.

6.3 Equipment vibration resistance test is performed when equipment is disabled, in such range stated in Table A15.6.1 where resonance appears; if there is no resonance within the range of 16 to 31.5 Hz, use amplitude 0.35 mm. The method of fastening the equipment to the test bench platform shall be the same as used in operation. Tests are performed by short-term vibration.

Smooth frequency shift within the range shall be performed with constant amplitude within at least one minute. The test time shall be distributed evenly between test positions on the test bench, i.e. for every position shall be stated nearly same number of frequency shift cycles.

In case of unsatisfactory test results the tests on resonant frequencies detection and vibration resistance by vibration prolonged exposure shall be repeated.

Equipment is admitted for vibration resistance testing if no equipment part breaking or any other visible damages were detected during the tests.

6.4 Vibration resistance tests shall be performed when equipment is operable under electrical load (under voltage for equipment having no load). Load is stated in test load and method of each equipment. The method of fastening the equipment to the test bench platform shall be the same as used in operation.

6.5 Frequency bands and amplitudes during vibration resistance test are shown in Table A15.6.5. Test time is the time needed for checking in operation and appearance of resonance in all equipment and its parts, but not longer than 2 h on every resonating frequency (if any) or on a frequency where parameters stability are violated.

The test shall be performed by smooth frequency shift under constant amplitude within every range. Smooth frequency shift time within every range shall be not less than 2 minutes.

Note: For electrical equipment installed on engines and other elevated vibration sources test norms can be extended.
6.6 Equipment is considered to have passed the test if switch contact positions did not change, work instability was not detected, parameter values did not exceed permissible limits, no broken parts, conductive wires brake, moving parts jamming, fastenings loosening or insulation deterioration were detected.

Note: Tests required by this Section are for equipment of weight less than 200 kg. Equipment of weight more than 200 kg can be tested block by block.

7 IMPACT AND SHOCKPROOF TESTS

7.1 Impact tests are performed when equipment is disabled; shockproof tests are performed when equipment is operable in three mutually perpendicular planes; one of them shall be working plane. The method of fastening the equipment to the test bench platform shall be the same as used in operation.

7.2 Test parameters: impact test: min. 1000 impacts with 7g acceleration and frequency of 40 to 80 impacts per minute; shock-proof test: min. 20 impacts with 5g acceleration and frequency of 40 to 80 impacts per minute.

Equipment is considered to have passed the test if no mechanical damages and breakages, fastening and contacts loosening and other events disturbing apparatus, devices and equipment normal operation are detected.

7.3 Portable VHF equipment shall withstand additional impact tests performed by dropping it on the hard surface from height of 1 m.

The test surface shall consist of hard wood solid peace of thickness not less than 150 mm and weight of over 30 kg. The height of equipment lowest point relative to test surface at the moment of dropping shall be (1000+10) mm.

A set of six droppings to the test surface is performed: one dropping per each equipment side. Equipment operating check and inspection for the presence of external damages.

Equipment is considered to have passed the test if no remarks on equipment operation check or visible damages that can prevent its operation are detected.

Note: Tests required by p.p. 7.1 and 7.2 are for equipment of weight less than 200 kg. Equipment of weight more than 200 kg can be tested block by block.

8 TESTS ON ROLLING RESISTANCE AND LONG-TERM SLOPE RESISTANCE

8.1 Equipment is tested in two mutually transverse directions. The method of fastening the equipment to the test bench platform shall be the same as used in operation.

During roll resistance tests the limit tilt angle from the vertical line is $-22.5^\circ$, roll period is 4 s. Test time shall be sufficient for functional testing, but not more than 15 min in every position.

8.2 During long-term slope resistance tests equipment is kept sequentially in two mutually transverse directions with inclination at an angle of $\pm 22.5^\circ$, emergency equipment - at an angle of $\pm 30^\circ$. Test time shall be sufficient for functional testing, but not more than 15 min in every position.

8.3 Equipment is considered to have passed the test if no false alarms under the influence of rolling and long-term slopes or breakdowns were detected during operation check.

9 HEAT STABILITY TESTS

9.1 When equipment is enabled, the working temperature stated in 9.2, 9.3 is set in the chamber with temperature increase rate of $(3\pm0.5)$ °C/min. Relative humidity shall be not more than 20%. Working temperature shall be kept within 16 h. Then equipment operation check is performed at least three times (when heat balance is reached, at the end of test mode and after tests in cold state).

9.2 Equipment (except for electrical machinery and lamps), designed for installation in premises where ambient temperature does not exceed 40 °C shall be tested on heat stability with working ambient temperature of 40 °C.
9.3 Equipment installed on the open deck, in engine room and galley, and also radio and navigational equipment installed on the open deck and in the ship interior spaces, shall be tested on heat stability with working ambient temperature of 55 °C.

9.4 Check of equipment operation at limit voltage and frequency deviations shall be performed after heat stability tests at the end of holding regime.

Equipment is considered to have passed the test if no events disturbing its normal operation are detected, parameters did not exceed accepted values during the tests, and insulation dielectric strength tests and insulation resistance measurement on the hot item at the end of tests gave satisfactory results.

9.5 Heat stability test of electrical machinery and their components in steering control systems and power installation electrical control systems shall be performed on enabled (operated) electrical machinery. During the heat stability tests specimen temperature is raised to 55 °C within 30 minutes. After that this temperature is kept for 16 h. Then tests on equipment adequate operation are performed to confirm its datasheet specifications.

10 COLD RESISTANCE TESTS

10.1 Equipment intended for installation indoors shall be tested in chamber within 6 h at temperature of –10 °C; equipment intended for installation on the open deck shall be tested at the temperature of –40 °C. After that equipment shall be tested in operation at rated load.

10.2 Items check on limit voltage and frequency deviations are performed right after its switch to operation condition after cold chamber.

10.3 Temperature change speed shall be not more than (3±0,5) °C/min. Equipment is considered to have passed the test if no faults, breakages and parameters deviations are detected.

10.4 During cold resistance tests of electronic device in steering control systems and systems of power installation or its components control, the item should be shut down, cooled to –25 °C and kept on this temperature within 2 h. Then temperature shall be increased to –10 °C, and tests on equipment adequate operation are performed to confirm its datasheet specifications.

11 HUMIDITY RESISTANCE TESTS

11.1 Equipment intended for installation on ships shall be tested on humidity resistance at air relative humidity of (95±3) % and temperature of +25 °C for 5 days; equipment installed on ships navigated in tropical area - for 7 days. Equipment of all versions shall be tested fully assembled in regular casing, except for sealed equipment, which hatches shall be open during tests in chambers.

11.2 Equipment is considered to have passed the test if no insulation breakdowns or resistance drop below the value stated in Section 1 of this Appendix are detected, and item parameters deviations did not exceed accepted values when equipment was in test medium, or equipment was in operated mode not less than 2 h.

12 TESTS ON SALT (SEA FOG) INFLUENCE

12.1 All items installed on river-sea navigation ships shall be tested.

12.2 Equipment is tested in regular enclosure with covers and doors shut down, with plugged feed-through holes. All other holes (for example, ventilation holes) shall be open.

12.3 Tests are performed by cyclical spraying (15 minutes for each hour of testing) in chamber aqueous solution of salt (sea fog) at temperature of +(27±2) °C:

- solution composition (g/l): sodium chloride — 27, magnesium chloride — 6, calcium chloride — 1, potassium chloride — 1, distilled water — 1 l
- fog dispersity — 1 to 10 μm (up to 90 to 95 drops)
- solution water content — 2 to 3 g/m² (at the end of spraying).
12.4 Test time depending on installation location:
   - 7 days — for equipment installed on open decks;
   - 2 days — for equipment installed in the inside spaces.

12.5 Equipment operation shall be checked after tests. Equipment is considered to have passed the test if no corrosion, paint coatings softening and disruption, and events disturbing its normal operation are detected.

13 ENCLOSURE PROTECTION TESTS

13.1 Equipment shall be subject to bench tests depending on its enclosure protection type. These tests apply to items with voltage lower than 1000 V. Protection level testing methods for voltage over 1000 V are developed in accordance with Electrical Installations Code.

13.2 Equipment shall be checked for efficiency of protection from access to its dangerous parts or foreign solid bodies and water penetration inside the item. Equipment protection level depending on installation place is stated in 2.3.6 Part VI of RCCS, and designations and characteristics of equipment protection level are stated in Appendix 1 Part VI of RCCS.

13.3 This para determines method of equipment enclosures testing depending on equipment level of protection against foreign solid bodies penetration inside the enclosure. Protection level is designated with the first characteristic digit:

   .1 The IP protection level equipment has no protection for characteristic digit 0 and can be used on board ships if built in the enclosure with adequate protection level;

   .2 Equipment of type IP for protection level characteristic digit 1. Application of sphere with diameter of 50 mm to any holes in enclosure with force of 30 N for all items and 50 N for electrical machinery;

   .3 Equipment of type IP for protection level characteristic digit 2. Application of tracing probe in any possible position with force up to 30 N and application of sphere with diameter of 12.5 mm to any holes with same force;

   .4 Equipment of type IP for protection level characteristic digit 3. Application of test bar with diameter of 2.5 mm with force up to 3 N should not lead to penetration inside the enclosure through any hole;

   .5 Equipment of type IP for protection level characteristic digit 4. Application of test bar with diameter of 1.0 with force up to 1 N should not lead to penetration inside the enclosure through any hole;

   .6 Equipment of type IP for protection level characteristic digit 5. Inside the chamber shall be induced vacuum adequate for differential pressure $2 \times 10^3$ Pa. Equipment is blown with talc sifted through a sieve with square mesh clear spacing dimension of 75 μm, in an amount of 2 kg of talc for 1m$^3$ of chamber volume. The test is performed as long as it needs for pumping with vacuum pump air volume in chamber 80-120 times more than air volume in the enclosure, but not less than 2 h;

   .7 Equipment of type IP for protection level characteristic digit 6. Same as for characteristic digit 5.

13.4 Evaluation of test results of equipment with type IP on foreign solid bodies penetration inside the enclosure:

   .1 Results are considered as successful for first characteristic digits 1, 2, 3, 4 if probe fullest cross section does not penetrate through any of holes and does not contact with current-carrying and moving parts inside equipment enclosure.

   .2 Results are considered as successful for first characteristic digit 5 if amount of talc penetrated inside equipment enclosure did not affect on its satisfactory performance (equipment efficiency and parameters are checked).

   .3 Results are considered as successful for the first characteristic digit 6 if talc does not penetrate inside the equipment enclosure (full dust protection).

13.5 This para determines method of equipment enclosures testing depending on
equipment level of protection against water penetration inside the enclosure. Protection level is designated with the second characteristic digit:

.1 The IP protection level equipment has no protection for characteristic digit 0 and can be used on board ships if built in the enclosure with adequate protection level.

.2 Equipment of type IP for protection level characteristic digit 1 is tested on protection efficiency from simulated rainfall vertical falling drops penetration inside the equipment. Tested equipment is mounted in normal working position under the reservoir created uniform drops falling on all enclosure surface. Swivel table, where enclosure is mounted, shall have rotation speed of 1 RPM and maximum off-centre distance about 100 mm. Test time is 10 min.

.3 Equipment of type IP for protection level characteristic digit 2 is tested on protection efficiency from simulated rainfall drops penetration inside the equipment. Tested equipment is exposed to rain with intensity of 3 mm/min. Equipment is mounted in four fixed positions with 15° slope. Test time is 2.5 minutes in every position. Total test time is 10 min.

.4 Equipment of type IP for protection level characteristic digit 3 is tested on protection efficiency from spray penetration inside the equipment. Tested equipment is exposed to spray from all directions at an angle of ±60° to the vertical line, created by special device with water pressure in supply pipe not less than 0.1 MPa. Test time is 1 min per 1 m² of the calculated surface; minimum test time is 5 min.

.5 Equipment of type IP for protection level characteristic digit 4 is tested on protection efficiency from blanket spraying penetration inside the equipment. Tested equipment is exposed to spray from all directions at an angle of ±180° to the vertical line, created by special device with water pressure in supply pipe not less than 0.1 MPa. Test time is 1 min per 1 m² of the calculated surface; minimum test time is 5 min.

.6 Equipment of type IP for protection level characteristic digit 5 is tested on protection efficiency from water penetration inside the equipment. Tested equipment exposed to water jet spilling from all directions using hose with nozzle inner diameter 6.3 mm from the distance of 2.5-3.0 m. Water pressure shall be not less than 0.1 MPa to get water discharge 12.5 l/min. Test time is 3 min.

.7 Equipment of type IP for protection level characteristic digit 6 is tested on protection efficiency from water penetration inside the equipment. Tested equipment exposed to strong water jet spilling from all directions using hose with nozzle inner diameter 12.5 mm from the distance of 2.5-3.0 m. Water pressure is adjusted to get water discharge 100.5 l/min ±5%. Test time is 3 min.

.8 Equipment of type IP for protection level characteristic digit 7 is tested on protection efficiency from submergence. Equipment is fully immersed so that water height to the upper part is not less than 0.15 m. Test time is 30 min. Equipment is considered to have passed the test if no water penetrates the enclosure at the specified pressure and in specified time.

.9 Equipment of type IP for protection level characteristic digit 8 is tested on protection efficiency from submergence. Unless there is a standard for equipment, test conditions shall be tougher than conditions stated by previous para. It shall also be taken into account that in operating conditions enclosure will be immersed for indefinitely long time (upon agreement). Equipment is considered to have passed the test if no water penetrated equipment enclosure at noted pressure and time.

13.6 For evaluation of test results of equipment with type IP on water penetration inside the enclosure, the following shall be considered:

Water penetration inside the enclosure is acceptable:

for equipment of type IP with second characteristic digits 1, 2, 3, 4 in the form of separate merged together drops of size not more than 30 mm;

for equipment of type IP with second characteristic digits 5 and 6 - in the form of separate drops.
In any case, if definite quantity of water penetrate the enclosure, there must not be:
- equipment perturbation of the normal operation and safety;
- water storage on electrically insulating materials, where water may cause arc tracking;
- water ingestion on parts being under voltage;
- water storage close to cable inlets or water insertion inside cables.
For equipment of type IP with second characteristic digits 7 and 8 water penetration is not allowed.

Equipment is considered to have passed the test if technical characteristics and/or working efficiency and/or electrical safety correspond to given requirements.

13.7 Generally, equipment enclosure protection tests are performed without power supply. Separate types of electrical equipment (if specified by requirements or testing program) can be tested with power supply. Safety measures must be adopted during such tests.

14 ELECTROMAGNETIC COMPATIBILITY TESTS

14.1 General provisions

Check of stress level and field strengths of industrial radio interference created by equipment is performed in accordance with ГОСТ 30805.16.1.1 (СИСП16-1-1), using measuring receivers with quasi-peak detector.

For measuring the level of:
- radio interference voltage artificial network and measuring receiver with quasi-peak detector shall be used. Receiver's band width during measuring must be 200 Hz in frequency band of 10 to 150 kHz, and 9 kHz in frequency band of 150 kHz to 30 MHz;
- in case of intensive radio interference a receiver with the band width of 9 kHz in frequency bands of 150 kHz to 30 MHz and 156 to 165 MHz, and with the band width of 120 kHz in frequency bands of 30 to 156 MHz and 165 MHz to 2 GHz shall be used.

Equipment is divided on the following categories:
- portable;
- protected from direct effects of weather conditions;
- non-protected from direct effects of weather conditions;
- immersed or having constant contact with water;

Nomenclature of equipment electromagnetic compatibility tests is specified in Table A15.14.1.

3For motor telegraphs, blades and rudder blade position indicators, tachometers, telephone switchboards, light, signal and sound devices apparatus, closers.

14.2 Electromagnetic interferences measurement

14.2.1 During interferences measurement tested equipment shall operate in normal conditions, and position of control elements affected on interferences (both conducted and
radiated) must be as to determine maximum interference level created by tested equipment. If needed equipment has several power modes, for example, "operation", "availability" etc., then the mode creating the max level of interference must be determined, and all measurements shall be performed for this mode. Equipment antenna's terminals shall be connected to non-radiative dummy antenna.

Allowable levels of created electromagnetic interferences during tests are specified in Table 2.7.3-1, Part VI of RCCS.

14.2.2 Conducted interferences (all equipment categories except for portable).

During tests shall be measured any signals generated by equipment or appeared on its power supply connection ports (terminals), that can disturb normal operation of other equipment if being included in ship's power mains.

For interferences measurements measuring receiver with quasi-peak detector shall be used. During tests equipment shall be connected to a separate power supply using artificial network to provide specific impedance on power supply terminals for high frequencies and elimination of undesired effect of external interferences incoming from common power supply. Receiver's band width must be 200 Hz when measuring in frequency band of 10 to 150 kHz, and 9 kHz when measuring in frequency band of 150 kHz to 30 MHz.

Connection cables between tested equipment power supply terminals (AC and DC) and artificial network must be shielded, and their length shall not exceed 0.8 m. If tested equipment consists of several devices with individual ports for AC and DC, then power ports with similar voltage rate may be connected in parallel with artificial network.

During measurements performance all metering equipments and tested equipment shall be mounted on a grounded surface and connected to it. If grounded surface using is impossible, then equivalent earthing must be performed on tested equipment metal frame or enclosure.

Radio frequencies voltage on power supply terminals of tested equipment in the band of 10 kHz to 30 MHz shall not exceed limit values specified in Fig. A15.14.2.2

14.2.3 Interferences radiated by equipment enclosure port (all equipment categories except for submersible).

During the test any signals radiated by equipment are measured except for antenna radiations that threaten to disturb normal operation of other ship equipment, for example, radio receiving equipment.

Test methods

The receiver with quasi-peak detector shall be used for measurements. The receiver shall have the band width of 9 kHz in frequency bands of 150 kHz to 30 MHz and 156 to 165 MHz, and the band width of 120 kHz in frequency bands of 30 to 156 MHz and 165 MHz to 2 GHz.
For frequencies higher than 30 MHz electromagnetic field electric component strength $E$ shall be measured. Measuring antenna shall represent dipole radiator of resonant length or, as an alternative - shortened dipole or antenna with a big amplification factor. Measuring antenna sizes towards to tested equipment shall not exceed 20% of the distance to it. On frequencies higher than 80 MHz the possibility of change of antenna's centre position height relative to ground within 1 to 4 m shall be provided.

Premise for tests shall have metal grounded surface. Premise dimensions shall allow to take measurement from the distance of 3 m.

Tested equipment shall be presented as a complete package with all connecting interdevice cables and set on normal operative position.

If tested equipment consists of several devices, connecting cables (excluding antennas power supply) between main and other devices shall be of maximum length indicated in Manufacturer's specification, or not shorter than 20 m if there is no such data. Input and output connectors shall be connected to cable, which max length is determined by manufacturer, or not shorter than 20 m if there is no such data; connectors also shall be aligned to impedance of other equipment which they usually connected to.

Cables shall be gathered in coils settled at the distance of 30 to 40 cm from connectors that they are connected to. If this is impossible, explanatory inscription shall be made in protocol.

Measuring antenna shall be located at the distance of 3 m from tested equipment. Antenna's centre shall be higher than grounded surface for at least 1.5 m. To determine maximum interference level, the antenna measuring E-field shall be adjusted for height only. Also, it shall have rotation possibility for measuring horizontal and vertical polarization. The antenna shall stay parallel to the floor. It shall be possible to displace either antenna around testing equipment to determine maximum frequencies level, or rotation of equipment mounted in orthogonal planes of measuring antenna at the level of its midpoint to achieve the same effect.

For frequency band 156 to 165 MHz it is allowed to use a receiver with peak detector or spectrum analyzer.

Limit radiation standards in the band of 150 kHz to 2 GHz, measured at a distance of 3 m from tested equipment enclosure, are specified in Fig. A15.14.2.3.

**Fig. A15.14.2.3. Limiting levels of radiated interferences from equipment enclosure connectors:**

- $B^*$ — measuring receiver's band width

### 14.3 External electromagnetic interference stability tests

**14.3.1** For performance of these tests (unless other instructions are provided) tested equipment shall be submitted in its normal working package and shall operate under normal conditions.

Tests results are assessed by criteria A, B and C:

- A criteria — normal operation in accordance with established requirements;
- B criteria — temporary functional deterioration or temporary functional failure with subsequent recovery of normal operation without operator's intervention;
- C criteria — temporary functional deterioration or temporary functional failure which
requires operator's intervention or system reboot.

Conditions and types of electromagnetic interference stability tests are shown in Table 2.7.3-2 Part VI of RCCS, where is also shown radio and navigation equipment operating quality criteria.

If radio receiver is included in equipment composition, then conducted interferences stability tests shall exclude any narrow bands of received operating frequencies on which radio receiver responds (false responses).

Stability to conducted low frequency interferences (all equipment categories except for portable)

14.3.2 In this test harmonic components of the voltage in AC mains supply or voltage ripples in DC mains is imitated. These tests are not applied to battery-operated equipment.

Tests on voltage harmonic components stability is performed by overlaying of additional testing sinusoidal voltage within the band of 50 Hz to 10kHz on power supply voltage. Level of sinusoidal voltage applicable actual value contains:

10% of supply voltage within frequency band of 50 Hz to 750 Hz;
10% to 1% of supply voltage within frequency band of 750 Hz to 5 kHz;
1% of supply voltage within frequency band of 5 kHz to 10 kHz.

Tested equipment operation control is performed during and after tests.

Stability to conducted radio frequency interferences (all equipment categories except for portable)

14.3.3 In this test effect of disturbances, induced in supply circuit, control circuit and circuit of signal flow from supply source starting, engine ignition systems, operating echo sounders and ship transmitters on frequencies below 80 MHz are imitated.

Tested equipment is mounted on an insulating table situated on the height of 0.1 m over the surface. Additional equipment needed for tested equipment power supply, as well as signals needed for its normal operation and functionality check, shall be connected with cables. Cables shall be provided with relevant communication devices and isolating devices, situates at a distance of 0.1 - 0.3 m from tested equipment.

Tests are performed with using generator connected through communication and isolation circuits.

Vacant input terminals of generator's HF-signal for communication and isolation circuits are loaded with resistance of 50 Ohm. Test generator is adjusted for every communication and isolation circuit; additional equipment and tested equipment are shut off and replace with resistances of 15 Ohm each. Test generator signal level shall be adjusted so as to provide non-modulated voltage of needed level on tested equipment input terminals.

Tests are performed in cases of following test signal levels:

- active voltage value 3 V at variable frequency in the band of 150 kHz to 80 MHz (test severity level 2);
- active voltage value 10 V in points with frequencies of: 2; 3; 4; 6.2; 8.2; 12.6; 16.5; 18.8; 22; 25 MHz.

During tests amplitude modulation with frequency of 400 Hz ±10% at modulation depth of (80±10)%.

Frequency slew rate shall not exceed \(1.5 \times 10^{-3}\) dec/s to give an opportunity to detect any malfunctions of tested equipment.

The above said signals are superimposed on power lines, signal lines and control lines of tested equipment. Tested equipment operation control is performed during and after tests.

Immunity to conducted radiated radio frequency interferences (all equipment categories except for submersible)

14.3.4 In these tests the effect of the impact of radio transmitters operated on frequencies above 80 MHz (for example, ships' fixed and portable VHF radio transceivers) situated close to the equipment are imitated.

Tested equipment is mounted in suitable shielded room or anechoic chamber, which dimensions shall be comparable to tested
equipment dimensions. Tested equipment shall be mounted in uniform field area and be insulated from the floor by non-metal support.

If requirements to the cable type for tested equipment are not specified, then unshielded parallel conductors shall be used. These conductors expose to electromagnetic field at the distance of 1 m from tested equipment.

Tests are performed with radiating antenna arranged face towards all sides of tested equipment. If equipment can be used in various orientations (vertical and horizontal), tests shall be performed from various sides. At start tested equipment is arranged face, matching with calibration plane. Frequency variation rate shall be \(1.5 \times 10^{-3}\ \text{dec/s}\) — for frequency band of 80 MHz to 1 GHz and \(0.5 \times 10^{-3}\ \text{dec/s}\) — for frequency band of 1 to 2 GHz and be slow enough to allow detection of any malfunctions in tested equipment.

Tested equipment is placed in modulated electrical field of strength 10 V/m at frequency shift within the band of 80 MHz to 2 GHz. At modulation frequency of \((400 \pm 40)\,\text{Hz}\) modulation depth shall be \((80 \pm 10)\,\%\).

**Immunity to electrical fast transient from fast transient processes in AC power supply circuits (all categories of equipment except for portable)**

14.3.5 In these tests fast low-power transient process created by equipment which enabling is accompanied by arcing on contacts are imitated.

Pulsing voltage is applied to power circuits, control circuits and signals circuits with following parameters:
- rise time: 5 ns (at level 10% and 90% of amplitude);
- duration: 50 ns (at level 50% of amplitude);
- amplitude: 2 kV on AC power supply differential inputs;
- 1 kV on signal and control circuits inputs;
- repeat rate: 5 kHz;
- type: periodic short sequences of continuance 15 ms, repeated every 300 ms;
- duration: 3-5 min for every positive and negative polarity of impulses.

**Immunity to microsecond impulse interferences from fast transient processes in AC power supply circuits**

14.3.6 These tests shall imitate influence of high energy pulse spikes, created by thyristor switches in AC mains supply.

Tests shall be performed using combined test generator of microsecond impulse interferences, together with communication and isolation circuit.

Pulsing voltage is applied to tested equipment power circuits with following parameters:
- rise time: 1 ms (at a level of 10% and 90% of amplitude);
- duration: 50 ms (at level 50% of amplitude);
- amplitude: 1 kV line/earth, 0.5 kV line/line;
- repeat rate: 1 impulse per second;
- nature of the exposure: continuous;
- exposure duration: 5 min for every positive and negative polarity of impulses;
- number of fed pulses: not less than five of positive polarity and five of negative polarity for each event of interference.

**Immunity to short-term parameters variation in power circuit (all equipment categories except for portable)**

14.3.7 These tests imitate changes of voltage and frequency in power circuits due to big load changes. Changes are not applied to DC powered equipment.

Power circuit parameters changes shall be performed using programmable power supply.

Equipment shall stay serviceable at following power circuit parameters changes compared with rated values (tests are performed once per minute, five cycles within 10 minute):
- voltage: increase of relative rated value by \((20\pm1)\,\%\) for \((1.5\pm0.2)\,\text{s}\);
- frequency: increase of relative rated value by \((10\pm0.5)\,\%\) for \((5\pm0.5)\,\text{s}\), with overlaying of specified parameter changes;
voltage: decrease of relative rated value by \((20\pm1)\%\) for \((1.5\pm0.2)\ s\);

frequency: decrease of relative rated value by \((10\pm0.5)\%\) for \((5\pm0.5)\ s\), with overlaying of specified parameter changes.

Time of voltage and frequency rise and drop shall be \((0.2\pm0.1)\ s\) (at amplitude level of 10 to 90%).

**Immunity to power source malfunctions**

(All equipment categories except for portable)

14.3.8 These tests imitate short interruptions of ship's power supply due to change of one power supply on another or while activating current protection. These tests are not applied to batteries-operated equipment.

Equipment shall stay serviceable after each of three power supply voltage interruptions of duration 60 s. Software shall not be ruined, and operation data stored in system's digital memory shall not be lost.

**Immunity to electro-static discharge**

(All equipment categories except for submersible)

14.3.9 In these tests static electricity discharges are imitated, that can appear at human contact with equipment enclosure.

Tests shall be performed using electro-static discharge generator (with storage reservoir of capacity 150 pF and discharging resistance of 330 Ohm, connected to discharging generator ferrule). Tested equipment shall be mounted on an insulating plate laid over grounded metal plate. Grounded plate shall protrude beyond the equipment overall dimensions on at least 0.5 m for all sides. Discharges from generator shall be applied to equipment points and surfaces that are accessible for stuff during normal operation. During tests generator shall be placed perpendicular to the surface, and points of discharges application can be chosen so that 20 discharges per second were provided. Every position shall be subject to tests on 10 positive and 10 negative discharges with intervals between discharges at least 1 s to provide detection of any malfunction in equipment operation. Preferred method during tests performance is contact discharge. If contact discharge can not be used (in the presence of painted surfaces), air discharge shall be applied.

For discharges imitation on items located or mounted close to tested equipment shall be performed 10 positive and 10 negative single contact discharges applied to grounded plate from every side of equipment. Places of discharges application shall be at a distance of 0.1 m from tested equipment.

Following 10 discharges shall be applied to the centre of vertical edges of grounded coupling plane of size 0.5×0.5 m. These tests shall be performed for every side of equipment. Vertical coupling plane shall be located so that all four front sides of equipment are fully covered.

Equipment shall stay serviceable at discharge voltage test levels of 6 kV for contact discharge and 8 kV for air discharge.

**15 TEST ON SOLAR RADIATION EXPOSURE**

15.1 Tests shall be performed on equipment (item) that is intended for operation on the open deck and that will fully or partly be subject to continuous exposure of solar radiation during operation.

15.2 Tests shall be performed in special chamber at air temperature in the shade of \((55\pm2)\ °C\). Equipment shall be placed on a support and continually exposed to solar radiation imitator during 80 h in accordance with Table A17.1.

Radiation intensity with regard to reflections shall be \((1120\pm112)\ W/m^2\) for spectral distribution, stated in Table A15.15.2.

15.3 Equipment is considered to have passed the test if:

1. no deformation, cracking, layering, buckling, ungluing of parts made of plastic or other materials have occurred;

2. parameters and insulation resistance have remained normal;

3. no reduction of visibility or readability of inscriptions and signs on bars or other parts of the item have been detected.

### 16 EQUIPMENT TESTS ON IMMUNITY TO OIL EXPOSURE

16.1 Tested equipment is immersed in mineral oil on 3 h at temperature of (19±5) °C. Oil shall have following parameters:
- aniline point: (120±5) °C;
- point of ignition: at least 240 °C;
- viscosity: 10-25 centistokes at 99 °C.

16.2 After tests equipment shall be cleared from oil, also, operation control and equipment check shall be performed. Equipment is considered to have passed the test if there are no remarks on operation check, no such damage criterion as cracking, swelling, coatings dissolution or no changes or changes in mechanical characteristics.

### 17 FALL INTO WATER

17.1 During the tests shall be performed series of three drops. Each drop is performed with equipment starting position different from previous position.

The height of equipment lowest point relative to water surface at the moment of dropping shall be (20±1) m.

17.2 Equipment operating check and inspection for the presence of external damages and pressurization leakage.

17.3 Equipment is considered to have passed the test if there are no remarks on operation check, external damages and pressurization leakage.
GUIDELINES FOR CABLE ITEMS TESTING ON FLAME RETARDENCE

1 Tests shall be performed for checking insulated cable on wires on flame retardence.

2 Specimens are cable or wire sections of length (600±25) mm each. Before tests specimens shall stand the temperature of (23±5) °C and relative humidity of (50±20)% for at least 16 h. If cable or wire is covered with paint or varnish, then specimen shall stand the temperature of (60±2) °C for 4 h before tests.

3 Testing chamber consists of metal crate of length (450±25) mm, width (300±25) and height (1200±25) mm without the front side. Testing chamber bottom shall be protected with mineral insulation layer. Testing chamber shall be placed in premise without draughts and with removal systems of toxic gases emitted during burning.

4 Before tests burner shall be placed on the horizontal surface so that its flame was directed straight up, and its total length shall be 125 mm, and length of inner blue flame - 40 mm. Burning operation is tested by inserting of copper wire of diameter (0.710±0.025) mm and length at least 100 mm transversely to the flame at a distance higher than end of flame inner blue part on 10 mm, so that wire length was over the nozzle edge. Flame temperature shall be so that copper wire melt not faster than in 4 s and no slower than in 6 s.

5 The specimen is attached to two horizontal bearings with copper wire (Fig. A16.5-1) so that the distance between lower edge of upper bearing and upper edge of lower bearing was (550±5) mm. The lower end of the specimen shall be situated at a distance of about 50 mm from the chamber's bottom. The burner arrangement shall be so that the blue flame inner cone end was touching the specimen surface at a distance of about 75 mm higher than lower grip; the burner nozzle axis together with specimen vertical axis shall create angle of 45° (Fig. A16.5-2). Flame inner blue part shall be located at a distance of about 10 mm from the specimen.

Fig. A16.5-1. Specimen arrangement in the testing chamber:
1 — metal chamber; 2 — bearing bar and copper wire attachment; 3 — specimen; A — distance from the chamber's bottom to lower end of the specimen (about 50 mm)
After the burning is fully over, the specimen shall be carefully wiped with fabric.

If the specimen surface has no damages, after the wiping presence of soot is permissible on the specimen surface. Softening or any deformation of non-metal material shall be ignored. The distance between lower edge of upper bearing and specimen carbonized part beginning shall be measured with accuracy of up to 1 mm.

Burning part beginning shall be determined as follows. Cable surface is pressed with sharp object, for example - knife blade. Place, where specimen pliant surface changed on fragile (crumbly) counts as burning part beginning.

A cable or wire is considered to have passed the test if the specimen does not ignite, or appeared specimen burning fades away by itself at the end of test flame exposure and traces of fire do not reach upper end of the specimen.

Besides, if burning spreads down to the point located at a distance of more than 540 mm from lower edge of upper bearing, cable or wire count as failed the test.

If the specimen failed the test, two more tests shall be performed. If after two additional tests satisfactory results were gained, cable or wire count as passed the test.

---

6 The specimen shall be continuously exposed to flame for the time specified in Table A16.6. At the end of test burner shall be removed and burner's flame extinguished.

Table A16.6

<table>
<thead>
<tr>

VALUES OF PARAMETERS CHECKED DURING THE TEST ON BUILT SHIP ELECTRICAL PROPULSION SYSTEM

Parameters checked during ship electrical propulsion system testing, requirements to their values and measurement tolerances are shown in Table A17.1.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Accuracy of voltage maintenance by AC main unit automatic regulator, equal to the ratio of difference between idle voltage and voltage at rated load to sum of these voltages at load $\cos \varphi = (0.8\pm 5)%$ without changing voltage regulator setting knob</td>
<td>Tolerance 2.5%</td>
</tr>
<tr>
<td>2. Accuracy of voltage maintenance by AC emergency unit automatic regulator, equal to the ratio of difference between idle voltage and voltage at rated load to sum of these voltages at load $\cos \varphi = (0.8\pm 5)%$ without changing voltage regulator setting knob</td>
<td>Tolerance 3.5%</td>
</tr>
<tr>
<td>3. Operation of automated generator load and frequency regulation at sudden load change. Apply on generator operating in idle intermediate load containing 70% (another power level is permissible in accordance with 2.12.3.2 Part IV RCCS) of rated generator power, then make a pause of duration at least 10 s, after that make a load rise up to 100% of rated generator power. Make a pause again of duration at least 10 s, then make a load relief down to idle</td>
<td>Voltage shall not deviate from rated value more than on +15, –30 % and shall restore to previous value within 1.5 s with deviation not more than ±3 % of rated value. Frequency shall not deviate from rated value more than on 10 % and shall restore to previous value within 5 s with deviation not more than ±5 % of rated value max. 1%</td>
</tr>
<tr>
<td>4. Steady frequency oscillations (swing) of AC diesel-generator at loads from 25 to 100% of rated active power.</td>
<td>Not more than 20% from rated power of generator with greatest capacity, operating in parallel with other generators (meeting the requirements of 3.6.4, Part VI of RCCS shall be provided)</td>
</tr>
<tr>
<td>5. Non-uniformity of active load of generators, operated in parallel, that can be checked by watt-meters reading difference with maximum and minimum values of active power.</td>

METHOD OF ON BOARD TESTING OF SYSTEMS, EQUIPMENT AND DEVICES FOR PREVENTION OF ENVIRONMENT POLLUTION

1 General requirements

1.1 Performance checking of ecological safety equipment shall be made during the mooring and/or running tests according to the program approved by the River Register.

1.2 Testing shall be held using authorised equipment and devices. Measuring means used for tests shall be supplied with the documents testifying its periodical checking if required.

1.3 The survey units are admitted to tests provided that its assembling has been checked by the Surveyor and no remarks have been made which may obstruct the testing procedure.

2 Filtering equipment

2.1 Tests shall be carried out at the design capacity of the equipment.

2.2 Before tests equipment shall be filled with clean water until its appearance from the sampling; at that standard purge pump output is measured (in case of filtering equipment supply and installation without standard purge pump, the output of used ship pump shall not exceed rated flow capacity of equipment more than by half as much). Then oil products shall be pumped through the equipment filled with water for 5 minutes in order to pollute it by oil together with connected pipes.

2.3 On the next stage the oil-water mixture with oil concentration of 5,000 to 10,000 ppm\(^{-1}\) shall be charged into the equipment until the stabilised mode is established. The mode is considered as stabilised when a volume of oil-water mixture has been pumped through the equipment which is not less than the doubled capacity of tested equipment.

The minimal rated time \(t\) needed to pump the indicated quantity of oil-water mixture is calculated by the formula, in hours

\[
 t = \frac{2(V_s + V_f)}{Q}, \tag{A18.2.3}
\]

where \(V_s\) — separator (filter) volume, \(m^3\);

\(V_f\) — filter volume, \(m^3\);

\(Q\) — pump capacity, \(m^3/h\).

2.4 The tests mentioned in 2.3 shall be carried out for 30 min. Samples shall be taken both at the inlet and outlet of the equipment on the 10th, 20th and 30th minutes of the stabilised mode; the last sampling at the outlet on the 30th minute shall be accompanied by air grasp by opening the cock at the pump suction and gradually closing the oil and water valves.

2.5 Sampling procedure and the analysis of the samples shall be carried out in accordance with the test program agreed with the River Register.

2.6 Oil contents in the discharge shall not exceed the admissible normative values (see Appendix 2).

2.7 In order to check the operation of oil gauge and the presence of oil in the oil collector as well as automatic drain valve sensors...
pure oil products shall be pumped to tested equipment until the devices are actuated.

The checking may be performed by means of submerging sensitive elements of the gauges dismantled from the oil collector into the capacity containing pure oil products.

2.8 The following shall be checked during the tests:
   .1 joint tightness during operation of the equipment;
   .2 automatic operating mode;
   .3 manually controlled operating mode;
   .4 operation of pump units and service systems;
   .5 operation of automation, alarm and control means.

Checking may be carried out by means of inducing extreme parameter values directly near the system sensors.

3 Alarm device. Device for automatic interruption of oil-containing water discharge

3.1 Tests are performed on oil-containing water and clean water as per 2.2.

3.2 Performance tests shall be carried out in conjunction with tests of filtering equipment; sampling shall be made as per 2.4. The pressure in a sampling point for test conditions shall be the same as for working conditions.

3.3 Results of sample analysis shall not exceed the device error which shall be within limits of ±10% of the actual oil concentration.

Readings of the alarm device for excessive oil concentration in the discharge shall comply with data of Appendix 2 of RPPS.

3.4 The following shall be tested:
   .1 calibration of the oil contents-measuring device according to the manufacturer instructions;
   .2 operation of the alarm device. It shall be actuated automatically when exceeding the given value of oil contents or by other way specified in its Registration Certificate, and send visual and audible signals simultaneously with actuation of the adjusting elements to interrupt overboard discharge. The alarm device shall be actuated automatically in the event of any malfunction of the device;
   .3 operation of the discharge controlling device. The overboard discharge of oil-containing water shall be interrupted if the normative value is exceeded. The discharge shall be interrupted in the event of any malfunction of the system or switching off the system;
   .4 availability of a local indicator of position of the system overboard valve;
   .5 operation of manual control of the discharge.

4 Automatic monitoring and control systems for ballast and washing water discharge

4.1 Tests are carried out in the water. The following shall be tested:
   .1 operation of pumps, absence of leakage in the sampling system;
   .2 operation of remotely controlled sampling valves;
   .3 the flow intensity or pressure drop whatever is used, and the adequacy of working flow parameters of the system. This test is to be carried out separately for each sampling point and checked by measuring;
   .4 operation of the alarm in the event of malfunctions caused by conditions external to the discharge control system, e.g. absence of the medium in the sampling system, absence of the flowmeter signal, power supply break etc.;
   .5 indication of adequacy of values and synchronisation of simulated (imitated) input signals by means of its manual measuring when the discharge control system operates on water. For discharge control systems of category A the evidence shall be got that the discharge control device is in operation and the data are recorded;
   .6 the possibility of restoration the normal operation conditions after the instantaneous intensity of the discharge has been reduced lower than 30 litres per mile;
.7 availability of recording after override to manual control. For discharge control systems of category A the evidence shall be got that the discharge control device is in operation;

.8 impossibility of overboard discharge control when the system has been switched off – for control systems of category A;

.9 position of zero point and calibration of the measuring device according to the operating manual and manufacturer’s instructions when the system is in operation;

.10 the accuracy of any installed flowmeter, e.g. by means of pumping water in closed contour where the flow rate may be calculated on the basis of the level changing in the tank. The checking is held at flow rate corresponding to 50 % of the nominal flow rate;

.11 the system actuation time from the moment of changing oil concentration in the discharge till the moment of actuation of the signal for the discharge interruption which shall not exceed 20 sec.

4.2 The following shall be tested during the tests of automatic oil measuring device in the discharge:

.1 the flow rate, pressure drop or other equivalent parameter whatever is used;

.2 incorporated alarm devices;

.3 adequacy of readings for several oil concentrations (checking method shall be approved by the River Register).

4.3 The following shall be tested during tests of the oil discharge control section:

.1 all signals;

.2 adequacy of operation of signal processing device and a recorder;

.3 actuation of the device when the oil discharge rate or the total amount of discharged oil exceeds the stated norms;

.4 actuation of signal of overboard discharge interruption in conditions when the alarm has been actuated.

5 Detectors of the oil-water phase division boundary in settling tanks

5.1 For testing purposes the tank shall be filled with oily mixture.

5.2 The following shall be tested:

.1 the accuracy of the detection of oil-water phase division boundary by means of comparison of the device readings with the position of phase boundary known or measured by any other method. The device accuracy shall provide for the indication of oil-water phase division boundary within limits of ±25 mm from the actual;

.2 actuation time of the device.

6 Pumping, delivery and discharge systems for sewage

6.1 During tests of pumping and collection systems the operation of the remote control of an oil amount in the oil-containing mixture and the level alarm in the cargo, settling and collecting tanks shall be checked. An oil amount in the oil-containing mixture may be simulated according to method agreed by the Inspection-office.

6.2 The following shall be tested during tests of the delivery system:

.1 operation of manual start and stop devices of pumping means;

.2 conditions of remote stop of pumping means from the place of the discharge observation or effective telephone or radio communication between the place of observation and the control station of pumping means;

.3 delivery of oil-containing water and oil residues from collecting tanks to reception facilities;

.4 adequate operation of visual and audible warning alarm when the upper limit level in the cargo, settling and collecting tanks is reached.

7 Sewage treatment plant

7.1 Prior to testing the sewage treatment plant in operation the availability of valid resolution of the federal sanitary supervision body shall be checked.

When the resolution in addition to tests (see 7.2 of this Appendix) is not available, the installation shall be tested for sanitary workability. The procedure of those tests shall be
determined by a representative of the federal sanitary supervision body.

The resolution of the federal sanitary supervision body shall be attached to the documents issued by the River Register.

7.2 The plant tests shall be performed on water and check:
   .1 free flow to the installation;
   .2 operation of a grinder (macerator) for solid impurities, if any;
   .3 adequate operation of pump and air-blowing units;
   .4 conditions of actuation of level sensors located in the installation chambers;
   .5 operation of batchers for flocculant (coagulant) and disinfecting agent;
   .6 operation in manual and/or automatic operating mode;
   .7 operation of automation, alarm and control means (may be made by simulation method);
   .8 operation of electric drives and auxiliary facilities (by external examination);
   .9 operation of submersible pumps, if any;
   .10 operation of ventilation system of a separate space containing the installation, if any.

8 Sewage collecting tanks

8.1 Tests may be carried out on the outboard water.

8.2 The following shall be tested:
   .1 free flow of sewage;
   .2 the possibility of washing from the water fire main and steaming if steam-heating system is available;
   .3 draining by a pump or ejector with overboard discharge of water;
   .4 adequate operation of visual and audible warning alarm when the upper limit level in the sewage collecting tanks is reached.

9 Pumping, delivery and discharge systems for sewage

9.1 Performance tests are carried out in conjunction with the tests mentioned in 7 and 8 of the present Appendix proceeding from the contents of the ecological safety equipment installed in a ship.

9.2 The following shall be tested:
   .1 adequate operation of means for manual start-up of pumping equipment (pumps or ejectors);
   .2 delivery of sewage from collecting tanks to reception facilities.

10 Incinerators

10.1 Tests are carried out on the kinds of refuse stated in the documentation for the incinerator.

10.2 Water contents in oil residues and/or sewage slime, when the incinerator is intended for its burning, shall be not lower than listed in the documentation.

10.3 Tests are carried out at operating modes specified in the documentation for the incinerator. The sequence of modes, the period of operation at each mode and test sequence are determined by the program approved by the River Register.

10.4 During testing the following shall be checked:
   .1 adequate operation of ventilation system of a separate space containing the installation, if any;
   .2 conditions of blocking the feeding hopper lids, if any, to prevent from its simultaneous opening during loading;
   .3 conditions of blocking the fuel nozzle when it is in working position and air for burning is supplied into the furnace;
   .4 adequate operation of automatic shut-off devices for fuel supply to the burner in the event of stop of the air supply, flame failure or cut-off of electric power supply;
   .5 adequate operation of the incinerator in manual and automatic operating modes;
   .6 adequate operation of automation, alarm and control means;
   .7 condition of the space during the operation of the incinerator;
.8 absence of sparking from gas-discharging system to the ambient atmosphere.

11 Garbage treatment plants

11.1 Adequate operation of the following items shall be tested:
.1 ventilation system of a separate space containing the installation, if any;
.2 loading mechanisms;
.3 grinders for refuse. The size of grinded particles shall not exceed 25 mm;
.4 compacting devices for refuse which shall reduce its initial volume by 5;
.5 automation, alarm and control systems.

12 Hoses designed to pump the oil and oil-containing water

12.1 Hoses included into ship supply and used for pumping oil, oil-containing or sewage water are subjected to hydraulic tests by testing pressure equal to 1.5 of work pressure.
RUSSIAN RIVER REGISTER

RULES
FOR CLASSIFICATION
AND CONSTRUCTION OF SHIPS
(RCCS)

MOSCOW 2015
The Rules for Classification and Construction of Ships (RCCS) have been approved by the Order of Federal Autonomous Institution “Russian River Register” No. 35-п dated 09.09.2015 and brought into force since 19.07.2016 by the Order of Federal Autonomous Institution “Russian River Register” No. 27-п dated 11.07.2016.

The present re-edition of the Rules for Classification and Construction of Ships (RCCS) includes amendments and additions approved by the following Orders of the Federal Autonomous Institution “Russian River Register”:
- Order No. 32-п dated 20.07.2016, came into force since 23.07.2016;
- Order No. 42-п dated 09.08.2016;
- Order No. 50-п dated 09.09.2016 (Notice No. 1);
- Order No. 78-п dated 07.11.2016;
- Order No. 100-п dated 27.12.2016;
- Order No. 24-п dated 09.03.2017 (Notice No. 2), came into force since 15.03.2017;
- Order No. 38-п dated 11.04.2017 (Notice No. 3), came into force since 17.04.2017;
- Order No. 65-п dated 14.08.2017 (Notice No. 4), came into force since 20.08.2017;

It is strictly prohibited to make photocopy, store in a retrieval system, publish, perform in public, adapt, broadcast, transmit, record or reproduce the present edition in any form or by any means for sale purposes without the prior written permission of the Federal Autonomous Institution “Russian River Register”.

2 Instruction on determining the location of ship’s centre of gravity from experiment (instruction on inclining test of ships) .............. 276
3 Calculation of assumed heeling moment for bulk grain carriage ...... 290
4 Requirements for full-scale trials and experimental data to confirm stability of hovercraft .................. 294

5 Manoeuvrability calculations and fullscale manoeuvrability trials of inland and river-sea navigation ships. 295

Part III
FIRE PROTECTION

1 General provisions
1.1 Scope of application .......................... 316
1.2 Terms and definitions ........................ 316
1.3 Fire protection plans .......................... 320
1.4 Classification of explosion-hazardous zones and spaces ............. 320

2 Structural fire protection
2.1 Subdivision of materials due to combustibility, flame spreading and inflammability .......................... 322
2.2 Requirements for materials ................. 322
2.3 Use of combustible materials ............... 324
2.4 Ladders, trunks. Requirements for draught restriction and penetration of smoke and flame ................. 324
2.5 Fire-hazardous material storage, welding rooms and saunas .......... 325
2.6 Requirements for structural fire protection of various ship types ...... 327
2.7 Structural fire protection of M-CTII class ships ...................... 332

3 Fire-extinguishing systems
3.1 General provisions ........................... 339
3.2 Fire extinguishing stations .................. 343
3.3 Water extinguishing system .................. 344
3.4 Sprinkler system ............................. 348
3.5 Water-spraying system ...................... 350
3.6 Drenching and water screen system ......... 350
3.7 Foam extinguishing system .................. 351
3.8 Gas fire extinguishing system ................ 354
3.9 Aerosol fire extinguishing system ........... 356
3.10 Inert gas fire extinguishing system ....... 358
3.11 Additional requirements to passenger vessels .......................... 358
3.12 Additional requirements for fire extinguishing systems and fire protection of oil tankers and their tenders. 358
3.13 Fire extinguishing systems and stations of ships less than 25 m in length 360
3.14 Fixed local fire-extinguishing systems for machine spaces........... 361
3.15 Additional requirements for coastal ships.................................. 362

4 Additional fire safety requirements for domestic / general service equipment and systems
4.1 Location and equipment of galleys ........................................... 363
4.2 Structure of heating systems................................................... 363
4.3 Ship's domestic plants working on compressed / liquefied natural gas... 365
4.4 Lighting .................................................................................. 368

5 Fire alarm
5.1 General requirements ................................................................. 369

6 Fire protection outfit spare parts and tools
6.1 Fire protection outfit................................................................. 370
6.2 Spare parts and tools ................................................................. 374

7 Emergency escape breathing devices
7.1 General requirements ................................................................. 377
7.2 Location of the emergency escape breathing devices..................... 377

Part IV
POWER INSTALLATION AND SYSTEMS

1 General provisions
1.1 Scope of application................................................................. 380
1.2 Terms and definitions............................................................. 380
1.3 Operation in conditions of heel and trim.................................. 382
1.4 Control devices.................................................................. 382
1.5 Control stations................................................................. 383
1.6 Means of communication...................................................... 383
1.7 Instruments and alarms...................................................... 383
1.8 Machinery spaces .............................................................. 383
1.9 Arrangement of power installation components.......................... 384
1.10 Installation of engines, boilers and equipment........................... 386
1.11 Use of gasoline engines...................................................... 386
1.12 Ship’s speed................................................................. 387

2 Internal combustion engines
2.1 Scope of application and materials ............................................ 388
2.2 Testing of parts................................................................. 389
2.3 General technical requirements .............................................. 389
2.4 Frame................................................................. 389
2.5 Crankshaft................................................................. 390
2.6 Supercharging and air supply .............................................. 391
2.7 Fuel appliances.............................................................. 391
2.8 Lubrication................................................................. 392
2.9 Cooling................................................................. 392
2.10 Starting arrangements...................................................... 392
2.11 Gas exhaust.............................................................. 392
2.12 Control and adjustment...................................................... 393
2.13 Instruments ............................................................... 394
2.14 Gasoline engines............................................................ 394
2.15 Additional requirements to engines operating on various grades of fuel... 394

3 Shafting
3.1 General requirements, materials, testing.................................. 396
3.2 Shaft diameter calculation..................................................... 397
3.3 Corrosion protection ............................................................ 397
3.4 Holes and cut-outs in shafts................................................ 398
3.5 Shafting design................................................................. 398
3.6 Keyless connections of propellers and shafting couplings............. 400
3.7 Braking devices .................................................................. 402

4 Gears, disengaging and elastic couplings
4.1 General ................................................................. 403
4.2 Materials and welding...................................................... 403
4.3 General requirements...................................................... 404
4.4 Gearing ................................................................. 404
4.5 ?Tooth couplings............................................................ 405
4.6 Elastic couplings............................................................ 406
4.7 Disengaging couplings...................................................... 406

5 Propellers
5.1 General requirements...................................................... 408
5.2 Materials, testing and welding........................................... 408
5.3 Propeller designing........................................................... 409

### Part VII

#### RADIO COMMUNICATION EQUIPMENT

#### 1 General provisions

- 1.1 Scope of application ................................ 732
- 1.2 Terms and definitions ............................ 732
- 1.3 General requirements to radio equipment .............................................. 734

#### 2 Radio equipment

- 2.1 Radio equipment for ships of Ì, Î, Ð and Ë classes .................................. 736
- 2.2 Radio equipment for ships of M-СП, M-ПП and O-ПП classes .... 737

#### 3 Power sources

- 3.1 Power sources for radio equipment for ships of Ì, Î, Ð and Ë classes .. 741
- 3.2 Power sources for radio equipment for ships of M-СП, M-ПП and O-ПП classes .............................................. 741

#### 4 Arrangement of radio equipment and installation of cable network

- 4.1 General requirements ................................ 744
- 4.2 Radio room ........................................ 745
- 4.3 Arrangement of radio equipment in the radio room .......................... 746
- 4.4 Radio equipment room ................................ 746
- 4.5 Arrangement of radio equipment in wheelhouse ............................. 747
- 4.6 Power equipment room ........................... 748
- 4.7 Battery room ......................................... 748
- 4.8 Arrangement of public address and broadcasting equipment ............ 749
- 4.9 Arrangement of EPIRBs, radar transponders, AIS transmitters, VHF apparatuses .............................................. 749
- 4.10 Cable network installation .............................................. 750

#### 5 Antenna assemblies and grounding

- 5.1 General requirements ............................. 751
5.2 Antennas of INMARSAT ship earth station ........................................ 752
5.3 Antenna of VHF radiotelephone station ........................................ 753
5.4 Antenna cable leads and laying inside spaces .................................. 753
5.5 Grounding ........................................ 754

6 Requirements to radio equipment

6.1 General requirements .................................. 755
6.2 Technical requirements to radio communication means ...................... 758
6.3 MF/HF radio installation ................................ 759
6.4 VHF radiotelephone station ......................................... 763
6.5 Public address and broadcasting device ....................................... 764
6.6 Command public address device ........................................ 764
6.7 MF radio installation ........................................ 765
6.8 VHF radio installation ........................................ 765
6.9 Enhanced group calling receiver .................................... 768
6.10 NAVTEX receiver ........................................ 769
6.11 HF NBDP receiver for reception of maritime safety information .......... 770
6.12 INMARSAT ship earth station ........................................ 771
6.13 General requirements to EPIRBs........................................ 772
6.14 Satellite EPIRB of COSPAS SARSAT system ................................ 773
6.15 VHF EPIRB ........................................ 773
6.16 Ship's and life-saving appliance's radar transponder ......................... 774
6.17 Free floating emergency radio equipment release and activation arrangements ........................................ 774
6.18 Two-way VHF radiotelephone apparatus of life-saving appliances ....... 775
6.19 Man-portable two-way VHF radiotelephone apparatus for aircraft communication ........................................ 776
6.20 Stationary two-way VHF radiotelephone apparatus for aircraft communication ........................................ 777
6.21 GMDSS integrated radio communication system ................................ 778
6.22 Security alert system ........................................ 779
6.23 Ship's and life-saving appliance's automatic identification system transmitter ........................................ 779
6.24 Stationary two-way VHF radiotelephone apparatus for life-saving appliances ........................................ 780

Part VIII
NAVIGATIONAL EQUIPMENT

1 General requirements

1.1 Scope of application ........................................ 784
1.2 Terms and definitions ........................................ 784
1.3 Navigational equipment composition ........................................ 786

2 Location of navigational equipment

2.1 General requirements ........................................ 790
2.2 Radar location ........................................ 790
2.3 Magnetic compass location .................................. 792
2.4 Gyrocompass location .................................. 792
2.5 Autopilot and directional stabilizer location .................................. 793
2.6 Echo sounder location .................................. 793
2.7 Log location ........................................ 794
2.8 Location of the antennas and receivers of the radio navigation systems and GLONASS, GPS, GLONASS/GPS, GALILEO systems ........................................ 795
2.9 Rate-of-turn indicator location .................................. 795
2.10 Location of the electronic chart display and information system for inland navigation (Inland ECDIS) ........................................ 795
2.11 Ship path control system location .................................. 796
2.12 Automatic identification system location .................................. 796
2.13 Voyage data recorder location .................................. 796
2.14 External audio signal reception equipment location .................................. 796
2.15 Radar reflector location .................................. 797
2.16 Integrated navigational system location .................................. 797

3 Requirements to navigational equipment

3.1 General requirements ........................................ 798
3.2 Requirements to radar ........................................ 803
3.3 Requirements to magnetic compass .................................. 815
3.4 Requirements to gyrocompass .................................. 817
3.5 Remote heading transmitting device 818
3.6 Requirements to autopilot and directional stabilizer 818
3.7 Requirements to echo sounder 819
3.8 Requirements to log 820
3.9 Requirements to GNSS GLONASS/GPS receiver 821
3.10 Requirements to GPS receiver 822
3.11 Requirements to GLONASS receiver 824
3.12 Requirements to GALILEO receiver 825
3.13 Requirements to rate-of-turn indicator 827
3.14 Requirements to presentation of navigation-related information on shipborne navigation displays 828
3.15 Requirements to the electronic chart display and information system for inland navigation (inland ECDIS) 834
3.16 Requirements to electronic chart display and information system 839
3.17 Requirements to ship track control system 849
3.18 Requirements to shipboard automatic identification system equipment 851
3.19 Requirements to voyage data recorder 853
3.20 Requirements to simplified voyage data recorder 856
3.21 Requirements to radar reflector 857
3.22 Requirements to integrated navigation systems 858
3.23 Requirements to external audio signal reception equipment 858
3.24 Requirements to sea watch alarm system 858
3.25 Requirements to long range identification and tracking system equipment 859
3.26 Requirements to Electronic Chart Display Systems 861

2 General requirements
2.1 Fire water main system 869
2.2 Fire smothering systems 869
2.3 Equipment of protected spaces 870
2.4 Alarm systems 871
2.5 Fire outfit 871

3 Ships carrying dangerous goods in bulk or in containers
3.1 Cargo spaces 873
3.2 Ventilation 873
3.3 Engines and gas exhaust piping 874
3.4 Fuel tanks 874
3.5 Drainage system 874
3.6 Fire extinguishing system 874
3.7 Fire detection system 875
3.8 Additional fire safety requirements 875
3.9 Electrical equipment 875
3.10 Double side space 876
3.11 Emergency exit 876
3.12 Floodability 876
3.13 Scope of requirements depending on class of carried dangerous goods 877

4 Inland navigation ships carrying dangerous goods in bulk
4.1 General provisions 879
4.2 Materials 879
4.3 Protection against penetration of gases 880
4.4 Hold spaces and cargo tanks 881
4.5 Ventilation 882
4.6 Service and accommodation spaces 883
4.7 Cofferdams 884
4.8 Openings of cargo tanks 885
4.9 Stability and floodability 886
4.10 Machinery spaces 886
4.11 Tightness test 886
4.12 Pumps and pipelines 887
4.13 Residual dangerous goods tanks and settling tanks 888
4.14 Water spraying system 888
4.15 Engines and gas exhaust piping 889
4.16 Bilge and ballast pumps 889
4.17 Additional fire safety requirements 889
5 River-sea navigation ships carrying liquid dangerous goods in bulk

5.1 General provisions .......................... 895
5.2 Materials ........................................ 895
5.3 Side drain holes ................................ 896
5.4 Cargo tanks ...................................... 896
5.5 Ventilation in cargo area .................. 896
5.6 Accommodation, service and ma-
   chinery spaces and control stations .. 897
5.7 Access to spaces located in cargo area 897
5.8 Floodability ..................................... 898
5.9 Drain and ballast systems ............... 899
5.10 Cargo system .................................... 899
5.11 Gas-freeing system ......................... 900
5.12 Degassing of cargo tanks ............... 901
5.13 Cargo temperature control systems .. 901
5.14 Cargo tank atmosphere control ...... 901
5.15 Electrical equipment ....................... 902
5.16 Fire extinguishing system .............. 902
5.17 Personnel protection ....................... 903
5.18 Special requirements ...................... 904

6 River-sea navigation ships carrying liquefied gases in bulk

6.1 General provisions ......................... 912
6.2 Hull design ..................................... 912
6.3 Cargo tanks .................................... 912
6.4 Secondary barrier ............................ 918
6.5 Insulation of cargo tanks ............... 919
6.6 Fabrication and testing of cargo 
   tanks ............................................. 920
6.7 Strength calculations ....................... 922
6.8 Structural fire protection ............... 928
6.9 Floodability ..................................... 929
6.10 Control stations ................................ 930
6.11 Detection of dangerous cargo va-
   pours (gas) ..................................... 931
6.12 Arrangement of power installation 
   units and systems............................. 933
6.13 Hull structure heating system .......... 934
6.14 Pipelines, valves and fittings ......... 934
6.15 Cargo system .................................. 938
6.16 Pressure reduction system .............. 938
6.17 Additional pressure reduction sys-
   tem for liquid level adjustment .......... 940
6.18 Vacuum protection system .............. 941
6.19 Safety valve dimensions ................. 942
6.20 Cargo tank filling limits .................. 942
6.21 Gas-freeing system ......................... 943
6.22 Cargo pressure and temperature 
   regulation system ......................... 944
6.23 Bilge system for evacuating cargo 
   leaks and ballast system ................. 944
6.24 Ventilation system ......................... 944
6.25 Fire-fighting systems ..................... 946
6.26 Inert gas system ............................ 949
6.27 Tests of systems ............................ 950
6.28 Personnel protection ...................... 951
6.29 Electric equipment ......................... 953
6.30 Special requirements ...................... 956

Appendices

1 Dangerous liquid cargoes and special 
   technical requirements to inland navi-
   gation ships carrying such cargoes 965
2 Dangerous liquid cargoes and special 
   technical requirements to river-sea 
   navigation ships carrying such cargoes 976
3 Liquefied gases and special technical 
   requirements river-sea navigation 
   ships carrying such cargoes 996

Part X
MATERIALS AND WELDING

1 General provisions

1.1 Scope of application ...................... 1000
1.2 Terms and definitions ................. 1000
1.3 Marking ........................................ 1000

2 Steel and cast iron

2.1 General requirements ................. 1002
2.2 Hull structural steel .................... 1002
2.3 Steel for boilers and pressure vessels 1005
2.4 Steel pipes and tubes 1006
2.5 Steel for chain cables and accessories 1008
2.6 Steel forgings 1008
2.7 Steel castings 1011
2.8 Steel propeller castings 1013
2.9 High strength steel for welded structures 1014
2.10 Steel reinforcement 1014
2.11 Nodular graphite iron castings 1015
2.12 Grey iron castings 1016
2.13 Malleable cast iron 1017

3 Copper and copper-base alloys
3.1 Semi-manufactured products of copper and copper-base alloys 1018
3.2 Propeller castings 1018

4 Aluminium alloys
4.1 Wrought aluminium alloys 1020
4.2 Cast aluminium alloys 1021

5 Materials used for LNG carriers
5.1 General requirements 1023
5.2 Materials to be used at design temperatures of 0 °C and above 1024
5.3 Materials to be used at design temperatures of 0 to minus 55 °C 1024
5.4 Materials to be used at design temperatures of minus 55 to minus 165 °C 1025
5.5 Materials intended for pipes to be used at the design temperature of 0 to minus 165 °C 1026
5.6 Testing of insulation materials 1026

6 Non-metallic materials
6.1 General requirements 1028
6.2 Reinforced concrete 1028
6.3 Glass-reinforced plastics 1030
6.4 Laminated textiles 1031
6.5 Foam plastics 1032
6.6 Deck plating 1033
6.7 Plastic piping and fittings 1033
6.8 Adhesives 1033
6.9 Retro-reflecting materials for life-saving appliances 1033

7 Welding procedure requirements
7.1 General requirements 1035
7.2 Welding of ship hull and equipment 1036
7.3 Welding of ship machinery construction items 1038
7.4 Welding of steam boilers and pressure vessels 1039
7.5 Welding of ship pipelines 1040
7.6 Welding of castings and forgings 1040
7.7 Welding of clad steels 1041
7.8 Welding of high strength steel 1041
7.9 Welding of cast iron 1042
7.10 Brazing 1042
7.11 Welding of aluminium alloys 1042
7.12 Welding of copper alloys, heavy metals and other non-ferrous metals 1042

8 Inspection of welded joints
8.1 Inspection management 1043
8.2 Scope of non-destructive testing 1045
8.3 Assessment of weld quality 1047

9 Welding consumables
9.1 General provisions 1050
9.2 Welding consumables for hull structural steels 1050
9.3 Welding consumables for boiler steel 1052
9.4 Welding consumables for welding steel intended for manufacturing of the ship machinery 1052
9.5 Welding consumables for high strength steel 1052
9.6 Welding consumables for aluminium and aluminium alloys 1053
9.7 Groundings not-removed prior to welding 1053

Appendices
1. Test method of ship structural materials for non-combustibility 1054
2. Test method of ship structural materials for flame propagation 1058
3. Test method for testing deck coatings for ignitability 1061
4. Method of fire tests of textiles 1064
Contents

5 Method for testing fire-resistant structures ..................................................... 1068
6 Determination of corrosion resistance of welded joint in sea water ............... 1072
7 Determination of crack-resistance of welding joint ................................... 1074
8 Determination of effect of non-removed groundings on weldability ......... 1079
9 Method of determination of diffusible hydrogen contents in deposited metal . 1082
10 Testing methods of materials .............. 1087
11 Inspection and acceptance methods of materials ........................................... 1099
12 Testing methods for welded joints and welding consumables and estimation of their results ................................................................. 1111

Part XI
ADDITIONAL REQUIREMENTS
FOR SHIPS TO BE OPERATED ON EUROPEAN INLAND WATERWAYS

1 General provisions
1.1 Scope and application .................. 1126

2 Hull and hull equipment
2.1 Hull design ................................ 1127

3 Stability, Floodability, Freeboard, Maneuverability
3.1 Passenger ship stability ............... 1128
3.2 Stability of container ships ............ 1129
3.3 Requirements for damage trim and stability of passenger ships in case of flooded compartments .......... 1132
3.4 Load line ...................................... 1133
3.5 Freeboard and safety clearance ...... 1134
3.6 Maneuverability of ships............. 1136

4 Fire protection
4.1 Fire protection outfit standards ...... 1139

5 Power installation and systems
5.1 Power installation ......................... 1140
5.2 Systems ........................................ 1140

6 Ship arrangements and outfit
6.1 Steering gear .............................. 1141
6.2 Anchor arrangement ..................... 1141
6.3 Life-saving appliances ................. 1142
6.4 Special wheelhouse arrangements for radar steering by one person ....... 1142
6.5 Signal means ................................. 1144

7 Electric equipment
7.1 Rate-of-turn meter ....................... 1145

Part XII
REQUIREMENTS
FOR CNG-FUELED SHIPS

1 General provisions
1.1 Scope of application ..................... 1148
1.2 Terms and definitions ................... 1148
1.3 Informative instructions ................. 1149

2 Gas-fueled ship hull and superstructure
2.1 General requirements .................... 1150

3 CNG tanks
3.1 General requirements ..................... 1152

4 Equipment for CNG supply to consumers
4.1 General requirements ..................... 1154

5 CNG consumers
5.1 Main and auxiliary engines ............. 1158
5.2 Self-contained boilers ..................... 1159

6 Ventilation of spaces
6.1 Normally manned spaces ............... 1160
6.2 Occasionally manned and other spaces ..................................................... 1161

7 Gas control in spaces
7.1 General requirements ..................... 1162

8 Fire protection
8.1 General requirements ..................... 1163
Part XIII
EQUIPMENT OF PASSENGER SHIPS
FOR CARRYING ONBOARD DISABLED PERSONS

1 General provisions
1.1 Scope of application .................. 1168
1.2 Terms and definitions ................ 1168
1.3 Information support .................. 1168

2 Passages, doors, sills and coamings
2.1 Requirements to passages ............ 1169
2.2 Requirements to doors ............... 1169
2.3 Requirements to sills and coamings .1169

3 Ladders, gangways, ramps, lifts
3.1 Requirements to ladders .............. 1170
3.2 Requirements to stairs ............... 1170
3.3 Requirements to gangways ........... 1170
3.4 Requirements to ramps ............... 1170
3.5 Requirements to lifts ................ 1170

4 Guard rails and handrails
4.1 General requirements ................. 1172

5 Requirements to spaces
5.1 General requirements ................ 1173
5.2 Lavatories and toilet compartments .1173

6 Safety measures
6.1 General requirements ................ 1175

7 Alarm and communication systems
7.1 General requirements ................ 1176
Part 0

CLASSIFICATION
1.1 The present Part of the Rules for the Classification and Construction of Inland and Combined (River-Sea) Navigation Ships (here and in all other Parts — Rules) defines the basic terms and definitions applicable for all Parts of the Rules, general procedure of ship's class adjudication and composing of class formula, as well as contains information on the documents issued by Russian River Register (hereinafter — River Register) and on the areas and seasons of operation of the ships with the River Register class.

1.2 When performing its classification and survey activities the River Register is governed by the requirements of applicable international agreements of Russian Federation, Regulations on Classification and Survey of Ships, as well as the Rules specified in Clause 2 of Article 35 of Inland Water Transport Code of Russian Federation which contain the requirements for the ships and their components specified in 1.4, in regard to their designing, manufacturing, modernization, refitting and repair, as well as the requirements for products and materials intended for use onboard the ship.

1.3 The purpose of classification and survey of the ships is the performance of works (rendering services) on evaluation of compliance of ships, materials and products intended for installation onboard the ships, organizations, which design, manufacture, modernize, refit and repair the ships as well as products and materials for ships, with the Rules.

1.4 The requirements of the present Rules are applicable to the ships subject to official registration as well as to the products and materials for the ships except for small craft used for non-for-profit purposes. The requirements of the present Rules are applicable to passenger ships, tankers, pushboats, tugboats, ice breakers and industrial ships of overall length less than 20 m.

The requirements of the present Rules are not applicable to small craft, pleasure ships, sports sailing ships, military and border-security ships, ships with nuclear power units, floating drill rigs and other floating facilities. However, the River Register develops and issues corresponding regulations and other standards being part of the Rules for particular types of ships (small craft used for commercial purposes, pleasure and sports sailing ships, ekranoplans etc.) and other floating facilities (pontoon bridges etc.).

1.5 In order to verify the compliance with the requirements of the Rules the River Register approves the technical documentation on construction, repair, modernization and refitting of ships, manufacturing of products and materials for installation onboard the ships.

Ships, materials and products, which technical documentation is submitted to the River Register for approval after the Rules or amendments thereto have come into force, are to meet the requirements of those Rules and amendments. To ships under construction, materials and products, which technical documentation had been approved by River Register before the Rules came into force, the Rules’ version is applied which was in force at the moment of its approval unless otherwise stated in the Rules.

1.6 If the technical documentation contains equivalents to the Rules’ requirements, the organization developer of such technical
documentation shall provide to the River Register a list of the equivalents with their detailed description and technical evaluation.

1.7 If the ship with the River Register class does not comply with the requirements of the Rules, then the corresponding documents shall not be issued (confirmed, renewed or restored) for such ship or the already issued documents shall be withdrawn or suspended by the River Register as specified in 2.16 of the Rules for Supervision of Ships in Operation.
2 BASIC TERMS

2.1 The following terms and abbreviations related to the classification activity are used in the present Rules:

.1 River Register — FAI “Russian River Register” as organization in general or its particular structural subdivision (Head Office, Branch Offices) if otherwise specified;

.2 Head Office of River Register (Head Office) — part of River Register located at the legal (actual) address of River Register and executing inter alia such functions as arrangement and coordination of Branch Offices’ activity;

.3 Branch Office — standalone subdivision of the River Register specified in its Statute and executing part of River Register’s functions on the basis of the guidelines approved by the River Register and within the specified scope of activity;

.4 Expert — authorized person of River Register executing one or more of the following functions in accordance with the Rules:
   - consideration and approval of technical documentation;
   - technical supervision over construction, modernization, refitting, repair of ships and their components, manufacturing of materials and products intended for installation onboard the ships;
   - survey of the ships in service and the organizations which carry out works (render services) or manufacture products in accordance with the requirements of Rules;
   - issuance of the documents of the River Register;

.5 Regulations on Classification and Survey of Ships — regulatory legal act of the Ministry of Transport of Russian Federation which specifies the procedure of ships classification by organizations authorized to carry out classification and survey of ships;

.6 Rules of the River Register (Rules) — an integrated technical standard document(s) of the River Register. The Rules specify the requirements for ships, materials and products to be used on board the ships when designing and manufacturing (construction); the requirements for the procedures of technical supervision over construction, modernization, refitting and repair of ships, manufacturing, mounting, testing of materials and products to be installed onboard the ships as well as the requirements for the survey procedures applied to ships, their components and facilities in service.

2.2 The following terms and definitions are used in the Rules.

.1 Withdrawal of class — cancellation of the documents issued by the River Register for a ship and removal of this ship from the Register book of ships;

.2 Tugboat — self-propelled ship equipped with a towing gear and intended for towing of other ships and floating facilities;

.3 Light-ship displacement — ship displacement in tons without cargo, fuel, lubrication oil, ballast, fresh and boiler waters in the tanks, waste waters, ship’s stores, passengers, crew members and their belongings, but with water, fuel and oil in boilers, engines and pipelines;

.4 Renewal of class — issuance of Classification Certificate for a ship, which had a class before but its validity period has expired;
.5 Restoration of class — restoration of Classification Certificate for a ship the class of which was suspended;

.6 Random inspection — one of the River Register’s methods of technical supervision or survey. During the random inspection when performing the technical supervision the object’s compliance with the requirements of the Rules is examined on the basis of control inspection of particular parameters, dimensions, properties or characteristics of the object or on the basis of inspection of one or more samples from a batch as well as particular manufacturing operations, conditions or other parameters. During the random inspection when performing the technical supervision of a ship the compliance of ship’s components and ship’s technical facilities with the requirements of the Rules is examined on the basis of the random inspection of particular dimensions, properties, parameters and characteristics;

.7 High-speed ship — a ship capable to move at a maximum speed \( v \), \( \text{m/s} \), equal or more than \( v \geq 3.7V^{0.1667} \), where \( V \) — volume displacement of the ship at the design waterline draught, \( \text{m}^3 \). The definition is applicable for ships with \( V \geq 150 \text{ m}^3 \);

.8 Wave height — a characteristic of waves specified as height of wind waves the probability of which complies with that approved for water basins and sea areas of the given type;

.9 Skimming boat (skimmer) — a ship the basic mode of motion of which is skimming the water surface, when the supporting force is mainly composed of water reaction and the influence of buoyancy is negligible;

.10 Type ship — a ship of single construction or first ship in production batch built from a new project.

First ship built from the same project but by other organization is considered as first but not type ship;

.11 Cargo ship — a ship designed for transportation of cargos (dry cargo ship, tank ship, combined ship, refrigerating cargo ship etc.);

.12 Date of ship construction — the date of issuance of the River Register documents for the ship when the results of initial survey of the ship after construction are positive. For the ships built not under technical supervision of the River Register the date of ship construction is the date of issuance of the documents by a classification society which carried out technical supervision over ship construction. If such supervision was not carried out at all the date of ship construction is the date of issuance of the documents by the organization manufacturer of the ship;

.13 Deadweight — difference between ship displacement at freeboard mark drought and light-ship displacement;

.14 Flammable liquids — oil, oil products and other liquids equivalent to them (hereinafter – oil products) capable to create explosive and inflammable concentrations of vapor and with vapor flash point specified according to national standards;

.15 Products — ship’s technical facilities (engines, generators, compressors, pumps, deck machinery, steering engines etc.), boilers, components of ship facilities, electrical, radio, navigational and other equipment, components of ship’s technical facilities, boilers and equipment, appliances, consumables, fixtures and other objects which are subject to the requirements of the Rules;

.16 Domestic voyage — any voyage of the ship which is not international;

.17 Product quality — a combination of product’s properties specifying product’s capability to meet the requirements of the Rules in accordance with product’s designation;

.18 Classification — activities of the River Register including development and publication of the Rules, consideration and approval of technical documentation for construction, refitting, modernization and repair of ships, manufacturing of materials and products, survey of ships and organizations, technical supervision over manufacturing of

1 ГОСТ Р 53717, ГОСТ 26098, ГОСТ 4333, ГОСТ 12.1.044
materials and products, repair of products, construction, repair, modernization and refitting of ships with class assigning (issuance of corresponding documents), as well as confirmation, suspension, renewal, restoration and withdrawal of class on the basis of ship survey results in accordance with the Rules;

.19 Ship’s class — a combination of symbols assigned to the ship during classification which specifies the design features and conditions of operation of the ship in accordance with the Rules and safety requirements;

.20 Combined cargo ship — a ship designed for alternate bulk transportation of liquid cargos or bulk and/or other hard cargos. A separate cargo space is provided for each cargo type;

.21 Container carrier ship — special ship designed and equipped for transportation of cargos in containers;

.22 Icebreaker — special ship designed for breaking the ice cover and supporting the navigation;

.23 Small craft — a ship the overall length of which does not exceed 20 m and the total number of persons onboard does not exceed 12 persons;

.24 Engine room — a room or a number of rooms where the main an auxiliary components of the power plant as well as repair bays and workshops are located. The room is longitudinally limited by the transverse tight bulkheads, in transverse direction — by ship's sides and vertically — by ship's deck and bottom;

.25 Machinery spaces — spaces within the engine room where main and auxiliary engines as well as boilers, compressors, their systems and auxiliaries, pumps of ship's systems, electric power sources, distributing devices, electrical devices, power converters, fuel receiving stations, technical facilities and equipment of refrigerating installations, ventilation and air conditioning systems are located as well as other similar spaces and trunks leading to such spaces;

.26 International voyage — a voyage from the state under the flag of which the ship is sailing to the port outside the flag state or from the port of foreign state to the port of the flag state of the ship.

.27 Shelter area — a natural or artificial protected water area which may be used by a ship as a shelter when there is a danger to ship's safety;

.28 Multihull ship — a ship the supporting force of which is provided by at least two hulls joint with a special structure;

.29 Ship modernization — a combination of operations on changing the design of the ship or ship's component aimed at improvement of technical and operational characteristics of the ship and living and working conditions as well as fulfilment of the requirements of international agreements and treaties of Russian Federation in the area of inland water transport and merchant marine;

.30 Superstructure — a closed structure on the freeboard deck which extends from side to side of the ship or whose side walls are not set inboard of the ship's sides by more than 4% of the breadth (B);

.31 Liquid cargo ship — a ship designed for transportation of liquid cargos in bulk;

.32 Floating bridge — a bridge with floating piers;

.33 Dangerous goods — substances, materials and products containing such substances and materials with properties which may create a threat to life and health of people, cause damage to the environment, damage or destroy material values during transportation;

.34 Organization — legal body (irrespective of legal organizational form, property form and departmental identity) or individual businessman which is carrying out design, construction, repair, modernization and refitting of ships, manufacturing and repair of products and manufacturing of materials for installation onboard the ships as well as test laboratories which have recognition certificate confirming that the organization manufactures its products, performs works and/or renders services in accordance with the Rules. The results of organization’s activities are used by the River Register during classification process;
.35 Survey of ships — part of classification process consisting of the following:
check of availability of approved technical
documentation, certificates (specified by the
Rules) or conformity documents for materials
and component parts used or installed on-
board the ship during the period of time since
the last survey, documents of organization's
technical control service, ship owner's docu-
ments, certificates of previous surveys;

visual inspection, measurements, checks
during operation and test of the ship and its
components;

issuance of the documents specified in the
Rules;

.36 Survey of organizations —
part of classification process aimed at confir-
mation that the organization manufactures
products, performs works and/or renders services
which meet the requirements of the Rules;

.37 Ferry — a self-propelled or non-
self-propelled transport ship intended for
transportation of land vehicles, people and
cargoes from one cost to another;

.38 Passenger — an individual which
concluded a passenger carriage contract, or an
individual for transportation of which a con-
tract of affreightment is concluded;

.39 Passenger capacity — maxi-
mum number of passengers allowed for trans-
portation by the given passenger ship or crew
boat according to its specification and the
River Register documents;

.40 Passenger ship — a ship inten-
ted for transportation of more than 12
passengers;

.41 Reclassification of ship —
a procedure of assignment of a new class to a
ship on the basis of initial survey in the course
of which an evaluation of compliance of all
ship components and technical documenta-
tion (approved by the River Register) with the
requirements of the Rules (applicable to the
new class) is performed. After reclassification
the ship receives a new class as well as new
conditions and areas of navigation are as-
signed. Apart from that the freeboard and the
dates of the next regular and annual surveys
are specified;

.42 Refitting of ship — a com-
Bination of operations on changing ship's struc-
ture in order to change its functional purpose;

.43 Floating crane — a crane on a
floating platform intended for load handling;

.44 Confirmation of class — an
averment made on the basis of annual or
regular survey of the ship which confirms that
the ship with the River Register class fully or
to the extent considered by the River Register
as sufficient complies with those requirements
of the Rules which are applicable to the ship
in accordance with its employment, condi-
tions of operation and class formula. On the
basis of the above the ship is recognized as
able for navigation in the areas specified in
the Classification Certificate;

.45 Pontoon — a floating structure
intended for keeping afloat various facilities
using its own buoyancy. The pontoons may be
used as supports for floating cranes, floating
docks, traveling ship elevators etc.;

.46 Control stations — spaces
where the main navigational instruments, ship
control equipment, radio sets, broadcasting
centers and central fire-fighting stations are
located, accumulator rooms and plant rooms
for radio sets or for emergency lighting as well
as spaces for emergency power sources;

.47 Suspension of class — sus-
pension of validity of ship documents;
after damage of the ship without elimina-
tion of which the operation safety can not be
provided;
in case of presentation of the ship for sur-
vey within specified time limit;
when performing works on structural
changes of the ship without preliminary ap-
proval of the River Register;
when violating the navigation conditions
specified in the ship documents;
when failing to fulfill the requirements of
the Rules and the River Register.

.48 Pleasure ship — a ship in-
tended for recreation on water with total
number of people onboard not exceeding 18
persons including not more than 12 passengers;

.49 Crew boat — a ship intended for
transportation of not more than 12 crew
members and which is not a passenger, small or pleasure ship;

**.50 Deckhouse** — a decked structure on the freeboard deck or a superstructure deck whose side walls are set inboard of the ship's sides by more than 4% of the breadth (B). The deckhouse has doors, windows and other openings in the outside bulkheads. The deckhouses may be arranged in one or more tiers;

**.51 Fishing ship** — a ship intended and specially equipped for fishing and/or fish handling as well as for transportation of fish products;

**.52 Convoy** — self-propelled and non-self-propelled ships coupled with each other or floating structures towed or pushed by a ship (ships) forming part of the convoy;

**.53 Rapid ship** — a ship capable of sailing at a speed greater than km/h;

**.54 Sailing sport ship** — a ship built or refitted for sports activities and used for noncommercial purposes, the primary motive force of which is the wind force;

**.55 (shall be considered to have lost force);**

**.56 Ship** — a self-propelled or non-self-propelled floating facility used for navigation such as combined (river-sea) navigation ship, ferry, dredger, floating crane and other technical facilities alike;

**.57 Ship under construction** — a ship under construction from the moment of keel laying-down until the moment of obtaining of ship's documents issued by the River Register, which confirm ship's compliance with the Rules.

The moment (date) of keel laying-down is the moment of the beginning of construction, which can be specified as related to the present ship, or when the mass of assembled part of the hull is not less than 1 % from calculated mass of all the ship materials;

**.58 Ship in operation** — a ship, which is not a ship under construction;

**.59 Air-cushion ship (ACS)** — a ship, the mass (in whole or significant part) of which is maintained above the water (ground, ice etc.) in motion or at standstill by the excess air pressure forces created by the air constantly inflated under the hull into the cavity called air cushion;

**.60 Hydrofoil ship** — a ship, which is maintained above the water surface by hydrodynamic forces created by the hydrofoil wings when moving under operating conditions;

**.61 Bulk oil-carrying ship** — a cargo ship designed for oil and oil products storage and transportation in bulk. Oil stations (oil transfer, bunker and pollution control stations, as well as oil-containing water gathering and treatment stations) and oil-gathering ships are to be considered as bulk oil-carrying ship as regards to the Rules application;

**.62 Ship with dynamic principle of supporting** — a ship, the mass (or major part of the mass) of which is counterbalanced by non-bouyant forces under one of the operating conditions; or which is capable to operate at such speed when the ratio (speed coefficient) of maximal speed of the ship to the square root of product of free fall acceleration and ship length (at construction waterline) is not less than 0.9 (ACS, hydrofoil ship, air cavern ship, skimmer, ekranoplan etc.);

**.63 Combined navigation (river – sea) ship** — a ship, which is capable (according to technical characteristics) and allowed (according to established procedure) for operation at sea and on inland water ways;

**.64 Industrial ship** — a ship designed for maintenance of ships and water ways, port facilities, underwater mining etc. (dredgers, sludge carriers, multicats, bouy tenders and crew boats designed for navigation support, ecological monitoring and analysis of water environment, bottom soil and ambient air);

**.65 Ship owner** — a legal body or an individual which operates the ship on behalf of itself whether he owns the ship or uses her on other legal grounds;

**.66 Navigation** — an activity related to the use of ships on inland water ways for transportation of goods, passengers and their belongings, as well as postal items, towing of ships and other floating objects, exploration and extraction of minerals, construction activities, trackworks, hydraulic works, underwater technical operations and other similar works, piloting, icebreaker assistance, rescue operations, water objects protection activities, contamination and pollution prevention, lift-
ing of sunken property, monitoring activities, scientific activities, educational, training, sports activities, as well as for cultural and other purposes;

.67 Dry cargo ship — a ship designed for transportation of dry cargoes (general cargoes, containers, timber, cargoes in bulk, vehicles without passengers etc.);

.68 Tanker — a liquid cargo ship built or refitted for transportation of liquid or semiliquid cargoes, mainly crude oil and oil products;

.69 Technical documentation — design and technological documentation, as well as technical documentation for objects of technical supervision, which contains data required for checking the compliance with the Rules;

.70 Technical supervision — part of classification process, which includes step-by-step checks of Rules execution as well as attendance at the tests in the course of ships (or their components) construction, refitting, modernization and repair, manufacturing and repair of ship technical facilities and materials intended for installation onboard the ship. The list of objects, type and volume of technical supervision are specified by the Rules;

.71 Type technological process — a technological process intended for specified conditions and field of application without any reference to particular ship or other object of technical supervision;

.72 Pushboat — a ship designed for propelling other ships or other floating facilities by means of pushing;

.73 Requirements of River Register — requirements of the Rules and other regulatory documents of the River Register, as well as the requirements specified in written form including the documents issued by the River Register;

.74 Area with sea navigation conditions — an area of water ways of Russian Federation within which the navigation-hydrographic conditions of navigation safety provisions comply with the requirements of merchant navigation, and the matters arising from navigation safety are subject to the Merchant Shipping Code of Russian Federation;

.75 Ship class formula — a sequence of symbols and words specifying ship's class, which is specified by the Regulations on Classification and Survey of Ships and the Rules (see 2.2.19);

.76 Ship crew — command personnel, ship's company, as well as servicing staff onboard the passenger ship. Command personnel consists of the captain, dredger officer, their mates and assistants, engineers, electrical engineers, their assistants, radio engineers and medical officers. Ship's company consists of persons (which are not part of command personnel or servicing staff) who provide the following: ship navigation, maintenance, survivability and safety of operation, as well as maintenance of ship's technical facilities, systems and equipment;

.77 Floating object — a non-self-propelled floating facility, which is not a ship, including landing stage, floating (located on water surface) house, hotel, restaurant, pontoon, raft, pontoon bridge, floating pier and other similar technical facility;

.78 Special personnel — persons onboard the ship which are not passengers or ship crew.

Special personnel include:

.1 officers performing official duties within the scope of their official powers in the field of border monitoring, customs inspection, sanitary, transport, port control or any other state control or supervision;

.2 persons participating in the following activities: exploration and extraction of mineral resources, building, roadway, hydraulic or underwater works and similar, rescue operations, security of water objects, weighing of sunken property, investigation of transport accidents, scientific researches, pilotage and icebreaker assistance.

.3 persons which are transported to other ships in order to change the crew.

.79 Special purpose ship — a ship allowed for operation in sea areas with more than 12 persons of special personnel onboard.
3 SHIP’S CLASS AND CLASS FORMULA

3.1 The ship’s class is assigned to the ship during the initial survey. The class may be confirmed, suspended, renewed and restored for a period of time (specified by the River Register) or withdrawn during other types of surveys. Assignment, renewal and restoration of class are certified by issuance of Classification Certificate or by confirmation of Certificate’s validity period.

3.2 The ship’s class assignment is performed in accordance with ship’s design features and classification of water basins where the ship shall be operated.

3.3 Inland water basins are classed on categories "Ë", "Ð", "Î" and "Ì" due to their wind-and-wave conditions on the basis of the following:

- in the basins of "Ë", "Ð" and "Î" categories the waves of 1 percent probability with 0.6; 1.2 и 2.0 m height respectively have a total reoccurrence (probability) for not more than 4 percent of navigation time;
- in the basins of "Ì" category the waves of 3 percent probability with 3.0 m height have a total reoccurrence (probability) for not more than 4 percent of navigation time.

The sea areas are classed on "Î-ÏÐ", "Ì-ÏÐ" and "Ì-ÑÏ" categories depending on their wind-and-wave conditions and availability of shelter areas.

The list of inland water basins and sea areas where the ships are operated according to their categories, as well as the operating conditions of the ships are established by a federal body of executive power in the field of transport. These lists are given in Appendices 1 and 2 for reference.

3.4 The assignment of a class to the ship is certified by issuance of Classification Certificate where (as in other ship documents) the class formula is specified for the ship on the basis of initial survey results.

3.5 The main symbols in the class formula of inland navigation ships are letters "Ì", "P", "O" and "M", which determine the design features of a ship and the water basin category where the ship is allowed for operation.

The main symbols in the class formula for the ships operating in the sea areas are letter combinations "O-ÎP", "M-ÎP" and "M-ÇP", which determine the design features of the ship and her operating conditions in the sea areas.

3.6 Proceeding from the design features of the ship the main class symbol is added by the following supplementary symbols:

- the symbol ‡ for the ships built under technical supervision of the River Register or other Classification Society recognized by the River Register and authorized to perform classification and survey of ships, which is put in front of the main symbol, e.g. ‡Î.

---

the permissive wave height in meters with the accuracy to within nearest decimal point is put directly after the main class symbol, e.g. "‡Î2.0".

For high-speed ships: skimmers, ACS, hydrofoil ships, air cavern ships and ekranoplan the wave height restrictions are given as a fraction with a numerator being the wave height at displacement mode, and a denominator being the wave height in service mode followed by the ship type according to the movement principle, e.g. "‡Ð1.2/0.8 skimmer", «‡Î2.0/1.2 ACS», «‡Î2.0/1.5 hydrofoil ship», «‡Ð1.2/0.4 ekranoplan»;

for ships fitted with special ice strengthenings the wave height value is followed by the word "ëåä" (ice) in brackets and the value of thickness of finely broken winter ice, in cm, specified by the River Register when approving the ship design, e.g. "‡Î2.0 (ëåä 20)". Class formula of icebreakers includes the word "ледокол" (icebreaker);

for ships fitted with automation means according to the Rules the letter "A" is put after all symbols mentioned in para. 1 – 3 of the present Clause, e.g. "‡Î2.0 (лед 20) А".

3.7 The River Register may withdraw or change any symbol in the class formula in the event of change or violation of conditions being the basis for entering that symbol into the class formula.

3.8 Upon ship owner's application the River Register may perform ship re-classification. On the basis of such re-classification the main class symbol in the class formula of the ship, as well as ship's type and/or purpose, may be changed.

3.9 The works connected with preparing the ship for re-classification for higher class assignment and/or changing the ship's type and purpose shall be performed according to the technical documentation approved by the River Register and under the technical supervision of the latter. Calculations and tests shall be made according to the Rules' version, which was in force at the moment of development of the technical documentation for re-classification, and shall be directed towards the new operating conditions due to changes of external stresses, technical characteristics (draught, water displacement, freeboard etc.), the type of goods carried etc.

The works connected with preparing the ship for re-classification for lower class assignment shall be performed according to the technical documentation approved by the River Register and under the technical supervision of the latter provided that the type and purpose of the ship shall not changed. The volume of documentation shall be sufficient for confirmation of ship's components compliance with the Rules' requirements applied for the new class of the ship.

3.10 The River Register may assign a class to a ship which is built not under the technical supervision of the latter or built under technical supervision of other organization authorized to perform classification and survey of ships. In this case the River Register shall consider the technical documentation for the ship and perform the analysis of ship design compliance with the Rules' requirements, requests elimination of discrepancies detected and survey of defects for all components of the ship including component-by-component survey of hull structure. Upon completion of the above the River Register shall assign a class to the ship on the basis of initial survey.

3.11 A ship entry shall be made in the Ship Registry Book after assignment of the River Register's class.
4 DOCUMENTS OF THE RIVER REGISTER

4.1 When performing classification the River Register issues documents specified by the laws of Russian Federation and the Rules.

5 REQUIREMENTS FOR SHIPS

5.1 The requirements for ships (and their components) intended for operation in “I”, “II”, “III” water basins and “O-II”, “M-II”, ”M-CII” sea areas are given in the Parts I – XI of the Rules and Appendices 1 – 3.
6 List of Inland Water Basins According to their Category for Determination of Areas and Conditions of ... 31

6.1 Category "JI" is assigned to the following basins:

1. reservoirs:
   Voronezhskoe;
   Sayano-Shushenskoe — from Verkhny Enisey River to Shagonar City;

2. rivers:
   Aldan — from the upper reaches to the village of Ust-Maya;
   Amur — from the source to 978th km of Sredny Amur (Blagoveshensk City);
   Belaya — from the source to Yamalinsky Yar (1776th km of Belaya River);
   Volga — from the source to 278.3rd km of Volga River (river port of Tver City);
   Don — from the source to 2689th km of Don River and from the dam Tzymliansk Hydroelectric Power Station to Rostov-on-Don City — 3121st km of Don River (mouth of Aksay River);
   Don — from 3121st km of Don River (mouth of Aksay River) to Rostov-on-Don City — 3151st km of Don River (mouth of Koysug River);
   Enisey — from the source to Ust-Abakan village;
   Indigirka — from the source Druzhin village;
   Irtysh — from the source to Omsk village (mouth of Om River, 1833.5th km of Irtysh River);
   Iya — from the source to 180th km;
   Kama — from the source to Berezniki City;
   Kolyma — from the source to Zyryanka village;
   Lena — from the source to the mouth of Vitim River;
   Manych — from the dam of Veselovskoe reservoir to the mouth;
   Mezen — from the source to Mezen City;
   Ob — from the source to Kamen-on-Ob City;
   Oka (tributary of Angara River) — from the source to 330th km;

* N o t e : the symbol * marks the areas of inland waterways of Russian Federation where the navigating conditions and hydrographic characteristics of ships operation and safety navigation comply with the requirements of merchant shipping and are regulated by the Federal Law No. 81-ФЗ dated 30 April 1999 «Merchant Shipping Code of the Russian Federation» (Collection of Legislative Acts of the Russian Federation, 1999, No. 18, art. 2207; 2001, No. 22, art. 2125; 2003, No. 27, art. 2700; 2004, No. 15, art. 1519, No. 45, art. 4377; 2005, No. 52 (Part 1), art. 5581; 2006, No. 50, art. 5279; 2007, No. 46, art. 5557, No. 50, art. 6246; 2008, No. 29 (Part 1), art. 3418, No. 30 (Part 2), art. 3616, No. 49, art. 5748; 2009, No. 1, art. 30, No. 29, art. 3625; 2010, No. 27, art. 3425, No. 48, art. 6246; 2011, No. 23, art. 3253, No. 25, art. 3534, No. 30 (Part 1), art. 4590, 4596, No. 45, art. 6335, No. 48, art. 6728; 2012, No. 18, art. 2128, No. 25, art. 3268, No. 31, art. 4321; 2013, No. 30 (Part 1), art. 4058; 2014, No. 6, art. 566, No. 42, art. 5615, No. 48, art. 6659; 2015, No. 1 (Part 1), art. 89, No. 13, art. 1810, No. 29 (Part 1), art. 4339, 4356).
Oka (tributary of Volga River) – from the source to the mouth;
Olenyok – from the source to Ust-Olenyok village;
Petchora – from the source to Ust-Tsylma village;
Northern Dvina – from the source to the mouth of Pinega River;
Yana – from the source to Yansky village;
3 lakes, canals and rivers not specified in Items 6.2 – 6.4.

6.2 The «P» category is assigned to the following basins:
1 lakes:
Beloe;
Ilmen;
Kubenskoe;
Pskovskoe;
Teletske (from Artybash village to Azhin Cape);
Chudske;
Onega (during navigation period from May to September inclusively): within the water areas of Petrozavodskaya Guba bay, Kondopozhskaya Guba bay and Velikaya Guba bay, Kizhi skerries; Gulf of Bolshoe Onega to the north of parallel 62°10'00,0'' N including Gorskaya Guba bay, Bolshaya Lzhemskaya Guba bay, Unitskaya Guba bay, Zaonezhsy Gulf to the north of parallel 62°15' N, Povenetsky Gulf;
2 reservoirs:
Boguchanskoe;
Bureyskoe;
Veselovskoe;
Gorkovskoe;
Zeyskoe – from the dam to 65th km and upstream of 180th km;
Irktuskoe;
Krasnodarskoe;
Krasnoyarskoe – along Enisey River from the village of Ust-Abakan to the pier of Chernogorsk; along Derbino River from 30th km to the mouth; along Ezagash River from 20th km to the mouth; along Sisim River from 20th km to the mouth; along Syda River from 25th km to the mouth; along Tuba River from the village of Gorodok (22nd km) to the village of Nikolo-Petrovka (15th km);
Novosibirsk Reservoir – from the city of Kamen-na-Obi (497th km from the confluence of Biya and Katun River s) to the village of Maloyino (530th km from the confluence of Biya and Katun River s), from the upper approach channel of Novosibirsk lock to the 3rd km of Berd River;
Rybinsk Reservoir – from the city of Cherepovets (540th km of Nizhnyya Sheksna River) to the village of Vichelo;
Saratov Reservoir – from Syzransky bridge to the dam of Saratov Hydroelectric Power Station;
Sayano-Shushenskoe – from the city of Shagonsar to the dam of Sayano-Shushenskaya Hydroelectric Power Station;
Ust-Ilmenskoe;
Cheboksary Reservoir;
Sheksninskoe;
3 rivers:
Aldan — from the village of Ust-Maya to the mouth;
Amur – from 978th km of Sredny Amur (Blagoveschensk City) to the line connecting the mouth of Polovinka River and the Cape Kuklya (Nikolayevsk-on-Amur);
Anadyr — from the source to the zero kilometer, Cape Amerikanskaya Koshka;
Anadyr – from the zero kilometer, Cape Amerikanskaya Koshka, along the ship channel of Onemen Gulf to the line connecting Zaselelniya Cape and Alyumka isle and then going to the stream Promyslovya*;
Angara – from the dam of Irkutsk Hydroelectric Power Station to the village of Nizhnaya Barkhatovo; from the dam of Boguchanskaya Hydroelectric Power Station to the mouth;
Belaya – from Yamalinsky Yar (1776th km of Belaya River) to the mouth;
Velikaya (Bolshaya) – from the source to the influx into Anadyr River;
Volga – from the 278.3th km of the Volga River (river station of Tver City) to Koprino village (including Ivankovskoe and Uglich Reservoirs), from the dam of Rybinsk Hydroelectric Power Station to the mouth of
6 List of Inland Water Basins According to their Category for Determination of Areas and Conditions of ... 33

- Elnat River, from the dam of Gorkovskaya Hydroelectric Power Station to the mouth of Sura River, from the dam of Cheboksarskaya Hydroelectric Power Station to the village of Kamskoe Ustye, from the dam of Kuibyshevskaya Hydroelectric Power Station to Syzranksy bridge, from the dam of Saratov Hydroelectric Power Station to Uveksky bridge, from the dam of Volgogradskaya (Volzhskaya) Hydroelectric Power Station to the village of Streletskoe;
  - Volga – from the village of Streletskoe to the village of Krasnye Barrikady (0 km of Volga-Caspian canal)*;
  - Don – from Rostov-on-Don City (3151 km of Don River, mouth of Koysug River) to the meridian 039°12'00,0'' E including Azov-Donskoy maritime canal, outer roads No. 6 and the Kalancha arm to the halting point Dugino*;
  - Enisey – from the dam of Krasnoyarsk Hydroelectric Power Station to the city of Igarka;
  - Indigirka — from the village of Druzhina to Nemkov isle;
  - Irtysh – from Omsk City (mouth of Om River, 1833.5 km of Irtysh River) to the mouth;
  - Iya – from 180th to 45th km;
  - Kama – from the dam of Kama Hydroelectric Power Station to Chastye pier, from the dam of Vohtinsk Hydroelectric Power Station to the town of Ust-Belsk (1756 km of Kama River), from the dam of Nizhnekamsk Hydroelectric Power Station to the city of Chistopol;
  - Kanchalan – from the source to the influx into Anadyr River;
  - Kolyma – from the village of Zyryanka to the village of Chersky;
  - Kolyma – from the village of Chersky to the village of Mikhalkino*;
  - Lena – from the mouth of Vitim River to the village of Zhigansk;
  - Mezen – from Mezen City to the mouth of Bolshaya Chetsa River *;
  - Neva – from the source to the border of inland waterways: along Bolshaya Neva River – Blagoveshchensky bridge; along Malaya Neva River – along the lower border of Tuchkov bridge, along Malaya Nevka River along the lower border of Bolshoy Petrovsky bridge, along Bolshaya Nevka and Srednyya Nevka River s – to meridian 030°13'00,0'' E;
  - Ob – from the dam of Novosibirsk Hydroelectric Power Station to Yamsal bar along the Khamanelskaya Ob River and along the branch of Bolshaya Narechinskaya Ob to Nachalny isle;
  - Oka (Tributary of Angara River) — from 330th km to the village of Toporok;
  - Pechora – from the village of Ust-Tsylma to the city of Naryan-Mar;
  - Pechora – from Naryan-Mar City to Alekseevskiy isle including Vasilkovo Gulf *;
  - Svir;
  - Northern Dvina — from the mouth of Pinega River to the mouth of Uyma River;
  - Northern Dvina – from the mouth of Uyma River:
    - To Lapominka village along Korabelny arm including Maymaks and Kuznechikha Rivers*;
    - To Cape Knevaty along Murmansk arm*;
  - To the entrance into the branch between Nikolsky isle and Ugol isle along Nikolsky arm including the branch of Korytka and the water area of Severodvinsk City within the limits of Yagra isle shore in the north, mainland shore in the south, reinforced-concrete mole in the west and Bolshoy Chayachy isle and reinforced-concrete bridge across the branch of Korytka in the east*;
    - The mouth reach of Northern Dvina River:
      - Konetskdvorka branch (from Onishevka branch to Svinets isle),
      - Onishevka branch (from Kiselev isle to the front edge of Khop isle),
      - Rybolovka branch (front edge of Kego isle to Onishevka branch),
      - Perednya branch (from Onishevka branch to Chubola village),
      - Khabarka branch (front edge of Khabarka isle to Pustosh village),
      - Podborka branch (from Maymaks arm to Lapaminka village);
  - Selenga;
Tazovskaya Guba bay – from the mouth of Taz River to the parallel 68°00'00.0" N; 
Khatanga (with tributaries) – upstream of Novorybnaya village; 
Yana – from the village of Yansky to Udey village; 
.4 canals: 
Belomorsky entrance canal to the point 64°34'48.0" N, 035°14'00.0" E*; 
Volga-Baltic – from the Lake Onega to the dam of Sheksninskaya Hydroelectric Power Station including Sizminsky expansion; 
Volga-Don – from Volgograd City (lower approach canal of lock No. 1, 2588.6 km of the Volga River) to the lower border of oil-loading Pyatizhianskie roads (2701.6 km of the Volga River); 
Volga-Caspian canal – from the village of Krasnye Barrikady (0 km of the canal) to 146th km of the canal*; 
Moscow Canal – from the pier of Bolshaya Volga to the lock No. 7; 
.5 gulfs: 
Kaliningradsky (Vistula Lagoon) Gulf including the sea port and canal of Kaliningrad (except for the remote sea terminal Pionersky) to the line connecting the ends of the northern and southern moles of the port of Baltiysk*; 
Kanchalan*; 
Kurshsky Gulf to the line connecting the ends of the northern and southern moles of the entrance gate to the port of Klaipeda*; 
Onemen*. 
.6 The harbour of Vyborg merchant port*; 
.7 Yeysky firth to the east of the line connecting the northern edge of Yeyskaya spit and the southern edge of Yeyskaya Kosa isle; eastern edge of Yeyskaya Kosa isle with the basis of Glafirovskaya spit on the parallel 46°46'18.0" N*; 
.8 Nevskaya Guba – from the border of inland waterways to the dam along the line connecting Gorskaya village – Kronstadt City – Lomonosov City*. 

Notes. 1. The passenger ships operating in the Gorkovskoe Reservoir from the city of Yuryevets to the dam are to be of «O» class. 
2. The covers onboard the ships of «P» class navigating the Bureyskoe Reservoir, Amur River from the city of Khabarovsk to the city of Nikolsyevsk-on-Amur, in Onemen Gulf, Anadyr River throat, Kanchalan bay and Saratov Reservoir from the dam of Saratov Hydroelectric Power Station to Syzransky bridge shall meet the requirements specified for the «O» class ships. 
The open ships of «P» class are allowed to navigate the abovementioned part of Saratov Reservoir at the wind speed not exceeding 8 m/s. 
3. The ships of «P» class are allowed to navigate the Angara (100 – 145 km, 205 – 245 km, 260 – 290 km) and Ilim (50 – 110 km) directions of Ust-Ilimskoe Reservoir at the wave height \( h_{1\%} = 1.2 \) m and being fitted with the equipment according to the requirements specified in the Rules for the «O» class ships. 
4. The ships of «P» class are allowed to navigate the Sayano-Shushenskoe Reservoir from the city of Shagonar to the mouth of Bedelig River if they are fitted with the equipment required for the «O» class ships. 

6.3 The «O» category is assigned to the following basins: 
.1 lakes: 
Vygozero; 
Lake Ladoga during the navigation period from May to September inclusively; west area – to the west of the line connecting Cape Pesotsky Nos, western edge of Konevets isle and Cape Kurkiniemi, north area – to the north of the line connecting Zayachy isle, Nikonovsky isle and north-west edge of Valaam isle to Pitkyaranta City including 2 mile coastal area around the Valaam isle; south area – to the south of the line connecting Cape Moryn Nos, point with coordinates 032°30'00.0" E, 60°40'00.0" N and along the parallel 60°40'00.0" N to the shoreline; 
Note. The navigation in the Lake Ladoga in the «O» category areas is allowed to the ships with «O.2,0» class, in the west, north and south areas from May to September inclusively at the wave height \( h_{1\%} \leq 1.5 \) m. 
The ships navigating in Ladoga and Onega Lakes shall be fitted with collective life-saving equipment in accordance with the standards specified for the ships of «M» class.
Lake Onega during the navigation period from May to September inclusively:
areas to the west and north of the line connecting the mouth of Vytegra River and the crossing point of the line, connecting the mouth of Vytegra River and the south edge of Suysari isle, and the parallel 61°45'00,0'' N and then going across to the south edge of Rechnoy isle to the shoreline;
5 mile coastal area along the isles Bolshoy Klimentsky and Rechnoy and Peninsula Zaonezhye to the parallel 62°15'00,0'' N;
Teletskoe (from Cape Azhyn to the mouth of Chulysman River);
.2 reservoirs:
Bratsk Reservoir — along Angara River from N. Barkhatovo village to dam of Bratsk Hydroelectric Power Station;
along Oka River from the village of Toporok to the mouth; along Iya River from the 45th km to the mouth;
Volgograd Reservoir — from Uveksky bridge to the dam of Volgogradskaya (Volzhskaya) Hydroelectric Power Station;
Votkinsk Reservoir — from the pier Chastye to the dam of Votkinsk Hydroelectric Power Station;
Zeya Reservoir — from 65th to 180th km of the reservoir;
Kama Reservoir — from the city of Berezniki to the dam of Kama Hydroelectric Power Station;
Krasnoyarskoe — along Enisey River from the pier Chernogorsk to the dam of Krasnoyarsk Hydroelectric Power Station; along Tuba River from the village of Nikolayevsk-on-Amur City; along Mezen from the mouth of Bolshaya Chetsa River to the line crossing the perpendicular axis of the navigation pass in the point with coordinates 66°10'30,0'' N 043°58'31,8'' E;
Pechora — from Alekseevsky isle to the line connecting Cape Bolvansky Nos and the north edge of Lovetskaya isle;
Northern Dvina — along Korabelny arm from Lapominka village to the south edge of Mudugsky isle; along Murmansky arm from Cape Knevaty to Kumbysh isle; along Nikolai river from the south-east edge of Uglimin isle to the north edge of Yagra isle;
Nadymskaya Ob — from the village of Salmal to Obskaya Guba bay and Obskaya Guba bay to the line Novy Port – village of Yamburg;

Novosibirsk Reservoir — from the village of Maletino to the dam of Novosibirsk Hydroelectric Power Station;
Rybinsk Reservoir excluding its northern part from the city of Cherepovets (540th km of Nizhnyya Sheksna River) to the village of Vichelo;
Tsimlyansk Reservoir — from the lower border of oil-loading Pyatizbianskie roads (2701.6th km of the Volga River) to the dam of Tsimlyansk Hydroelectric Power Station;
.3 rivers:
Amur — from the line connecting the mouth of Polovinka River and Cape Kuklya (Nikolayevsk-on-Amur City) to the line connecting Astrakhanovka village and Subbotino village (Nikolayevsk-on-Amur City)*;
Anadyr — from the line connecting Cape Zaseleniya and Alyumka isle and then going along the stream Promyslovy along the ship channel to Nikolaya spit*;
Enisey — from Igarka City to Ust-Port*;
Kilyma — from Mikhalitino village to Cape Medvezhy*;
Len — from Zhigansk village to Cape Bykov;
Len — from Cape Bykov to the sea port of Tiksi City*;
Mezen — from the mouth of Bolshaya Chetsa River to the line crossing the perpendicular axis of the navigation pass in the point with coordinates 66°10’30,0’’ N 043°58’31,8’’ E*;
Pechora — from Alekseevsky isle to the line connecting Cape Bolvansky Nos and the north edge of Lovetskaya isle*;
Northern Dvina — along Korabelny arm from Lapominka village to the south edge of Mudugsky isle; along Murmansky arm from Cape Knevaty to Kumbysh isle; along Nikolai river from the south-east edge of Uglimin isle to the north edge of Yagra isle*;
Tazovskaya Guba bay – from parallel 68°00'00,0'' N to the line connecting Cape Povorotny and Antipayuta village;

Anabar – from Yuryung-Khaya to Cape Khorgo*;

river bars: Indigirka from Nemkov isle, Olenyok from the village of Ust-Olenyok, Yana from the village of Udey – to 5 m depth isobath curve;

Note. The ships of «Î» class are allowed to navigate the bars of Indigirka, Olenyok and Yana at the wave height $h_{3%} \leq 1.5$ m.

Taganrog Bay – area from meridian 039°12'00,0'' E to meridian 038°52'00,0'' E*;

transloading roads of the mouths (bars) of Indigirka, Olenyok and Yana Rivers*;

Sevastopol bay including all other bays being part of it – to the line connecting the northern and southern protecting moles*;

Balaklava bay – to the line connecting the eastern and western entrance capes*;

Donuzlav Lake *.

6.4 The «M» category is assigned to the following basins:

.1 lakes:

Baikal;

Ladoga (except for areas specified in the subparagraph 1 of paragraph 3 of the present Annex);

Onega (except for areas specified in the subparagraph 1 of paragraph 2 and subparagraph 1 of paragraph 3 of the present Annex);

.2 rivers:

Enisey – from Ust-Port to the northern edge of Brekhovskie isles*;

Obskaya Guba bay – from the line Novy Port – village of Yamburg to the line consequently connecting the point with coordinates 68°26'00,0'' N, 073°35'00,0'' E (Cape Kamenny); 68°25'00,0'' N, 073°48'00,0'' E; 69°04'00,0'' N, 073°52'00,0'' E (Cape Trek-lobugorny);

Tazovskaya Guba bay – from the line connecting Cape Povorotny and Antipayuta village to Obskaya Guba bay;

Khatanga Gulf – from the line connecting Cape Povorotny and Cape Bolshaya Korga to Cape Kosisty*.
7 LIST OF SEA NAVIGATION AREAS FOR DETERMINATION OF AREAS AND CONDITIONS OF NAVIGATIONS OF THE SHIPS WITH THE CLASS OF RUSSIAN RIVER REGISTER

7.1 In the present Section the navigation conditions shall be understood as operating restrictions specified for ships according to areas and seasons of navigation, as well as 3% probability wave height.

7.2 Constant operation in the sea areas is allowed for the cargo self-propelled and non-self-propelled ships, tugboats, passenger displacement self-propelled ships according to their class and limitations specified in the Table given below.

7.3 The navigation conditions for tugboats, ice-breakers, industrial ships, non-self-propelled passenger ships and ships with dynamic principle of supporting are specified as agreed upon with the River Register.

7.4 The passenger displacement self-propelled ships are allowed for operation in the sea when the value of 3% probability wave height in the class formula is equal to the specified one complying with the main class symbol.

For such ships the permissible distance between the shelter areas, which provide entrance and mooring at the wind of all directions, shall not exceed the distance passed by the ship within 12 hours at still water and sailing rate – 70% of the rated one.

The ship is allowed to leave the shelter area (port) and return to the route of navigation when the weather forecast for the next 12 hours specifies that the 3% probability wave height does not exceed the $h_{3\%}$ value reduced by 0.5 m. For the displacement ships of 30 m length and less the predicted wave height, irrespective of the class, can not exceed $0.2L^{0.75}$ value, where $L$ – overall length of the ship in meters.

7.5 The following abbreviations are used in the Table given below:
- ГС – for cargo self-propelled ships only;
- КН – except for cargo non-self-propelled towed ships and tugboats;
- КП – except for passenger self-propelled displacement ships;
- НБ – for cargo non-self-propelled towed ships and tugboats;
- ПБУ/БС – for floating drilling outfits/ships;
- ССН – for special purpose ships;
- СТФ – for industrial ships;
- РС – fishing ships;
- ТР – Technical Regulations on the safety of inland water transport objects of Russian Federation.

7.6 The «М-СП» class ships may be operated in the areas specified for operation of «М-ПП» and «О-ПП» class ships, the «М-ПП» class ships – in the areas specified for operation of «О-ПП» class ships.

7.7 The areas and seasons of navigation for roads (harbour) and port navigation are specified on the basis of special studies carried out by an organization having the Recognition Certificate of the River Register. Such studies shall be based on the update of long-term characteristics of sea in the area under consideration or evaluation of the maximal possible waves in protected water area taking into account the ice conditions.
7.8 The lists of water basins are given in the following Tables: for "M-СI" category - Table 7.8.1, for "M-II" category - Table 7.8.2, for "O-II" category - Table 7.8.3.

7.9 The areas and conditions of operation for the "M-СI 4.5" class training sailing ships and the "M-СI 4.5" class special purpose sailing ships are specified by the decision of the Head Office after consideration of justifications provided by an organization having the Recognition Certificate of the River Register or taking into account the areas and conditions of navigation specified by a classification organization recognized by the River Register and having an agreement on cooperation and mutual substitution concluded with the River Register.

1. The navigation areas in Taganrog Bay at the lines Azov – Taganrog – Yeysk are assigned to the passenger self-propelled displacement ships designed for navigation on inland waterways and re-classed for higher class, or built using components of other inland water ships which were previously in operation.

2. The operation of the passenger self-propelled displacement ships is allowed only when they are used for accommodation of special personnel in protected water areas.

3. Except for the passenger self-propelled displacement ships designed for navigation on inland waterways and re-classed for higher class, or built using components of other inland water ships which were previously in operation.
Part I

HULL AND HULL EQUIPMENT
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 The present part of the Rules applies to single-hull displacement ships and catamarans, hydrofoils craft and hovercraft classed by the Russian River Register (hereinafter referred to as the River Register) and establishes requirements to the structure and designing of hull, global and local strength, vibration strength, buckling strength of hull structural components, equipment of spaces, railings and handrails designed for crew and passengers protection, gangways, companionways, scuttles.

The requirements of the present part of the Rules apply to the designed ships and ships under construction if otherwise is stated in the corresponding clauses and chapters of the present part of the Rules.

1.1.2 The requirements of this part of the Rules apply to ship’s hulls made of steel, aluminum alloys, reinforced concrete and glass reinforced plastics.

1.1.3 Materials used for fabrication of hull structural components shall comply with requirements of Part X of the Rules.

1.2 TERMS AND DEFINITIONS

1.2.1 Terms related to the Rules general terminology and their definitions are stated in 2.1 and 2.2 Part 0 of the Rules.

1.2.2 The following terms are used in these Rules:

.1 Freeboard means the distance between the upper edge of the deck line and the upper edge of the maximum draught line measured vertically on the side amidships (for the definition of deck line, see 1.2.24 Part II of the Rules);

.2 Main ship dimensions:

- \( L \) — design waterline length, m;
- \( B \) — maximum design waterline breadth, m;
- \( H \) — depth, i.e. vertical distance measured in the midship plane from the base plane to the intersection line of moulded surfaces of the side and upper deck (or their extensions in case or rounded deck-to-side joint), m;
- \( T \) — moulded draught / draught to design waterline, m;
- \( D \) — ship displacement at the moulded draught, kN;
- \( V \) — volume displacement at the moulded draught, m³;
- \( \delta \) — block coefficient.

.3 Design waterline (DWL) means a waterline chosen as the basis for lines drawing, which corresponds to the full displacement of the ship obtained by preliminary calculation;

.4 Aft perpendicular means the intersection line of centre plane and vertical transverse plane passing through the aftmost point of the design waterline;

.5 Engine room — see 2.2.24 Part 0 of the Rules;

.6 Machinery spaces — see 2.2.25 Part 0 of the Rules;

.7 Fore perpendicular means the intersection line of centre plane and vertical transverse plane passing through the foremost point of the design waterline;

.8 Draught means the vertical distance between base plane and specified load waterline amidships;
.9 Compartment means a part of inner space of the hull limited by the bottom or inner bottom, sides or longitudinal bulkheads, deck (if available) or the upper edge of the side (when there is no deck), and two adjacent transverse watertight bulkheads or a peak bulkhead and an extremity;

.10 Bulkhead deck means the uppermost deck, up to which the transverse watertight bulkheads extend;

.11 Ship length parts:
   ship’s middle part is a part $0.5L$ long taking $0.25L$ forward of and abaft the midship;
   fore extremity is a part $0.15L$ long measured from the fore perpendicular towards the midship;
   aft extremity of a self-propelled ship means a part between the aft perpendicular and the aft bulkhead of the engine room or a part $0.15L$ long from the aft perpendicular towards the midship, whichever is less;
   aft extremity of a non-self-propelled ship means a part $0.15L$ long from the aft perpendicular towards the midship;
   transition areas mean parts between the middle part and extremities.

1.2.3 Definitions and explanations relating to the catamaran and hovercraft hulls are given in 4.1.2 and 6.1.7 to 6.1.9.
2 STRUCTURE AND STRENGTH OF STEEL HULL

2.1 GENERAL REQUIREMENTS

2.1.1 The present Section establishes requirements to strength and dimensions of main structural components of steel welded hulls.

2.1.2 This Section establishes requirement to ships operating in М-ПР, М, О-ПР, М, О, Р and Л water basins at the design wave heights shown in Table 2.1.2.

2.1.3 The requirements of 2.1.5 to 2.6 apply to ships with main dimensions ratios within the limits prescribed by Tables 2.1.3-1 and 2.1.3-2.

The requirements of this Section apply to ships given in Table 2.1.3-2 if their forward draught is not less than given in Table 2.1.3-3.

2.1.4 The requirements of this Section apply to the following ship types with length not exceeding 140 m:

1. self-propelled aft-engined one-decked ships with holds;
2. self-propelled aft-engined tankers;
3. non-self-propelled one-decked dry-cargo ships with holds;
4. non-self-propelled tankers;
5. self-propelled flush deck aft-engined ships and non-self-propelled flush deck ships;
6. passenger ships;
7. tugboats and pushboats;
8. industrial ships;
9. fishing vessels;
10. crew boats,
as well as ships of М-СП, М-ПР and О-ПР classes up to 140 m long, types of which are

</tr>
</tbody>
</table>

* The minimum permissible forward draught for intermediate ship lengths shall be determined by linear interpolation.

given in Table 2.1.3-2 (except for passenger ships and icebreakers of M-CIII class).

2.1.6 Where main dimension ratios are outside the limits prescribed by Tables 2.1.3-1 to 2.1.3-2 and where types of ships are not covered by 2.1.4, structures and scantlings shall be chosen according to the results of additional calculations, on the basis of which the applicability of the Rules or their equivalents may be proved.

The structural elements of hulls shall comply with the requirements of 2.2, the scantlings of the hull elements of all ships to the requirements of 2.3 to 2.6. Scantlings of ships with a length exceeding 50 m, moreover, shall be verified by calculation in accordance with the requirements of 2.2. Designer can also specify the scantlings of the hull elements based on the results of direct strength calculation and buckling strength verification of structural hull elements with due regard to their specified service life according to 2.2.83 and requirements to ships in service stipulated by the Rules.

2.1.7 The Instruction on Loading and Unloading proved by necessary strength, stability and trim calculations made for the most unfavorable loading cases during loading/unloading shall be prepared for all dry-cargo ships and tankers.

The Instruction on Loading and Unloading shall contain the following data:

.1 ship’s loading conditions in which her navigation may be allowed, including partial loading and permissible overloading under certain circumstances, with the indication of corresponding draught marks;
.2 conditions of ship’s loading, i.e. availability of ballast and possibility of simultaneous loading, unloading and ballasting, as well as monitoring methods;
.3 permissibility of performing cargo handling operations in wavy open water areas and the category of the respective water area basin permitted for cargo handling operations and the permissible wave height;
.4 procedure in case of emergency i.e. flooding of some holds or compartments of the ship;
.5 measures aimed at provision of goods safety in accordance with the rules and regulations on carriage of bulk cargoes;
.6 permissible longitudinal and transverse non-uniformity of the ship loading between holds and inside each hold;
.7 permissible values of specific loads both at uniform cargo distribution with due regard to non-uniformity as per .6 and also when carrying concentrated cargoes and heavyweights;
.8 permissible number of cargo layers and the order of loading and unloading operations;
.9 recommended cargo stowing and securing methods;
.10 distinctive features of loading and unloading of tankers: the order of tanks filling, permissible capacity of the cargo systems
with due regard to electrostatic sparking safety provisions, methods for monitoring cargo tank levels and ship draught, permissible cargo level differences between the tanks, drop of filling capacity at the initial stage and before the loading is finished, etc.;

1 the information on the possibility and procedure of accelerated loading and unloading depending on the type and the maximum capacity of the equipment and cargo systems, number of transverse and longitudinal bulkheads, etc.

2.1.8 Materials used for fabrication of hull structural components covered by the present Section of the Rules shall comply with requirements of Part X of the Rules.

2.1.9 High normal strength steels (see 2.2 Part X of the Rules) with yield point of 235 MPa and higher strength steels with yield point up to 390 MPa inclusively may be used.

Note: Rolled steel is used under the following conditions:

- steel of grades D, E, D27S, E27S, D32, E32, D36, E36, D40, D40S, E40, E40S (see 2.2 Part X of the Rules) of any thickness may be used without restrictions;
- steel of grades B, A27S, A32, A36, A40, A40S (see 2.2 Part X of the Rules) may be used for ships of all classes excepting the ice belt;
- steel of grade A may be used for:
  - ships of all classes with a length of 25 m and more excepting the ice belt, pushing and coupling arrangements, and structures participating in the global strength;
  - ships of all classes with a length less than 25 m excepting the ice belt and pushing and coupling arrangements.

2.1.10 Values of the cross-section moduli of hull framing girders calculated according to formulae given in 2.4 correspond to steel with \( R_{th} = 235 \) MPa. Where steel with higher strength is used for hull structures, the section moduli shall be reduced in proportion to the ratio 235/(\( k_{th} R_{th} \)), where \( k_{th} \) is coefficient determined by formula (2.2.67-3) and \( R_{th} \) — yield point of the used steel with higher strength.

2.1.11 When using tables of the present Section, intermediate values of parameters shall be determined by linear interpolation.

2.2 STRENGTH AND BUCKLING CALCULATIONS

Design loads at global bending

2.2.1 In order to calculate bending moments \( M_w \) and shear forces \( N_w \) on still water\(^1\), a load curve shall be integrated over not less than 21 equidistant ordinates. For ships of all types and purposes, the most unfavorable loading cases shall be considered.

2.2.2 Design loading conditions for dry cargo ships and tankers are as follows:

- lightship condition without ballast, with 10% and 100% of stores and fuel;
- lightship condition with ballast, with 10% and 100% of stores and fuel;
- fully loaded with cargo distributed in accordance with the Instruction of Loading and Unloading;
- in other unfavorable loading conditions, namely carriage of heavyweights, partial utilization of ship’s cargo capacity, etc.;
- during loading and unloading.

2.2.3 Design loading conditions for tugboats and pushboats are as follows:

- with 10% of stores and fuel with and without ballast;
- with 100% of stores and fuel with and without ballast.

2.2.4 Design loading conditions for passenger ships are as follows:

- lightship condition without cargo and passengers, with 10% and 100% of stores and fuel;
- fully loaded and with passengers, with 10% and 100% of stores and fuel;

2.2.5 Design loading cases for industrial ships:

- with 10% and 100% of stores and fuel, with and without ballast, in cruising condition;

---

\(^1\) Still water means the water area with current velocity less than 0.1 km/h and still surface (ripple is permissible) at wind speed up to 3 m/s.
2.2.6 Design loading conditions for other ships not stated in 2.2.2 to 2.2.5 are specified in technical documentation approved by the River Register with due regard to their purposes and design features.

2.2.7 Loading conditions (other than the loading condition as per 2.2.2.5), at which flooding of some spaces (see 4.2 and 4.3 Part II of the Rules) results in increase of bending moments, shall be considered.

2.2.8 For dry cargo ships, $M_{sw}$ and $F_{sw}$ shall be determined for the loading condition as in 2.2.2.3 with an assumption that 5% (7.5% is recommended for ships intended for local carriages of mineral building materials) of the total cargo taken on a ship have been carried from holds/cargo deck in the middle part of ship to holds/cargo deck in extremities (Figs. 2.2.1.8-1 and 2.2.1.8-2) or vice versa.

2.2.9 $M_{sw}$ and $F_{sw}$ at still water may be determined with due regard to hull flexibility. In this case calculations shall be made using a method approved by the River Register. Area moments of inertia of the ship hull corresponding to the design thickness, which are determined regardless of reduction of the hull girders, shall be used as rigidity factors.

2.2.10 Additional wave bending moment at the midship of the M, O, P and Λ ship classes shall be calculated as follows, kN·m:

![Cargo distribution according to the Instruction of Loading and Unloading](image1)

![Cargo distribution according to the Instruction of Loading and Unloading](image2)
where $M_w$ — bending moment due to waves

$k_p$ — coefficient considering the influence of wave vibration;

$M_i$ — bending moment due to the impact of waves to the fore extremity (impact bending moment), kN-m.

Wave bending moment is determined by the following formula, kN-m:

$$M_w = 0.255s k_\delta k_t k_w B L^2 h,$$

(2.2.10-2)

where $h$ — wave height obtained from Table 2.1.2, m;

$\varepsilon$ — coefficient obtained from Table 2.2.10-1;

### Parameters for determining components of additional wave moment

Coefficients $k_\delta$, $k_t$, $k_w$ are calculated by the formulae:

$$k_\delta = \exp\left[-1.6\left(1 - \delta\right)\right];$$  

(2.2.10-3)

$$k_t = \exp\left[-1.14T\delta\left[\eta h(2\delta + 1)\right]\right];$$  

(2.2.10-4)

$$k_w = \left[1 - \exp\left[-0.198B/(\eta h)\right]\right] \eta h/(0.198B);$$  

(2.2.10-5)

$\delta$ — block coefficient;

$\eta$ — coefficient obtained from Table 2.2.10-1.

The aforementioned coefficients may be obtained also from Tables 2.2.10-2 – 2.2.10-4, where $a$ and $b$ are calculated as follows:

$$a = 3T\delta/(2\delta + 1);$$  

(2.2.10-6)

$$b = \delta B.$$  

(2.2.10-7)

Values of $L$, $B$, $T$ and $\delta$ shall be determined at the ship’s trim corresponding to the design loading case used for calculating a bending moment on still water $M_{sw}$.

Coefficient $k_p$ shall be calculated by the formula:

$$k_p = \psi\left[1 + \omega_{th}^2/\left(\sigma^2\left[1-\omega_{th}^2/\sigma^2\right]^2 + \left(2k_p\omega_{th}/\sigma\right)^2\right]\right],$$

(2.2.10-8)

where $\omega_{th}$ — wave frequency observing from moving ship, s⁻¹;

$$\omega_{th} = \omega_{av} + 1.92 k_v v_{av}/L$$

(2.2.10-9)

$\omega_{av}$ — wave frequency, s⁻¹ determined as per Table 2.2.10-1;
\[ \sigma = k_s \sqrt{I/[1.2 + B/(3T)] DL^3}] ; \]  
(2.2.10-10)

\[ k_s = 0.0612 (1 - 0.047\sigma - 0.0077\sigma^2) \geq 0 \]  
(2.2.10-11)

(coefficient \( k_s \) shall be not less than zero);

\[ k_v = \text{coefficient determined by the formula:} \]
\[ k_v = 1 - 19.9h/L + 143(h/L)^2, \]  
(2.2.10-12)

\[ v_{sw} = \text{ship’s speed in still water for design loading case, km/h;} \]
\[ k_s = \text{coefficient equal, for the following ships, to:} \]
- cargo ships \( 123 \times 10^4 \)  
- passenger ships \( 117 \times 10^4 \)  
- tugboats and pushboats \( 104 \times 10^4 \)

\( I \) — area moment of inertia of the hull girder amidships, \( m^4 \) calculated using the design thicknesses and girder reduction coefficients equal to 1;

\( D \) — ship’s displacement corresponding to design loading condition, kN;

\( \psi \) — coefficient determined by the formulae:
- if \( 0 \leq \omega_{dh}/\sigma \leq 1.0 \)  
  \[ \psi = \cos \left[ 1.3 \left( \omega_{dh}/\sigma \right)^2 \right] \]  
  (2.2.10-13)
- if \( 1.0 < \omega_{dh}/\sigma \leq 1.4 \)  
  \[ \psi = 2.167 \omega_{dh}/\sigma - 1.9 \]  
  (2.2.10-14)

The impact bending moment is determined by the formula, kN-m:
\[ M_i = k_i \varphi_1 DL, \]  
(2.2.10-15)

where
\[ k_i = 5.3 \times 10^{-4} \varphi_0 \sigma v_0 \]  
(2.2.10-16)

\( \varphi_1 \) — coefficient equal to:
- \( \varphi_1 = 1 \) if \( T_f \leq T_f^0 \);
- \( \varphi_1 = 3 - 2T_f/T_f^0 \) if \( T_f^0 < T_f < 1.5T_f^0 \);
- \( \varphi_1 = 0 \) if \( T_f \geq 1.5T_f^0 \);

\( T_f \) — forward draught for design loading case, m;

\( T_f^0 \) — “threshold” forward draught, m, equal to:
\[ T_f^0 = \left( 0.68 + 0.21k_v v_{sw}/\sqrt{L} \right) \eta h \]  
(2.2.10-17)

\( \varphi_0 \) — coefficient equal to
\[ \varphi_0 = 1 - 1.03b_0 + b_0^2 - 0.417b_0^3 \]  
(2.2.10-18)

\[ b_0 = 4.32\sqrt{8(B/L)(T/L)} \]  
(2.2.10-19)

the value of \( v_0 \) is obtained by the formula
\[ v_0 = \left( 0.336 + 0.104 k_v v_{sw}/\sqrt{L} \right) v_1 + 0.024k_v v_{sw} \]  
(2.2.10-20)

the value of \( v_1 \) is taken from Table 2.2.10-1.

The value of the additional wave bending moment for the ships of P and L classes shall be taken constant within \( 0.5L \) in the middle part of the hull and shall go down linearly towards the ship’s extremities down to zero (see Fig. 2.2.10). For ships of M and O classes, boundaries of constant section of the distribution diagram shall be not less than \( 0.15L \) forward of and abaft the midship.

![Fig. 2.2.10 Distribution diagrams of additional wave moment and shear force](image)

The maximum value of the additional wave shear force \( N_{sw} \) is determined by the formula, kN:
\[ N_{sw} = 4M_{sw} / L. \]  
(2.2.10-21)

Distribution diagram of additional wave shear forces shall be taken in accordance with Fig. 2.2.10.

### 2.2.11 Additional wave bending moment

Additional wave bending moment of ships of Ì-ÑÏ, Ì-ÏÐ and Î-ÏÐ classes shall be determined using the following formula, kN-m:
\[ M_{aw} = 9.81k_0 k_1 k_2 k_3 \delta B L^2 h \]  
(2.2.11-1)

where \( k_0 \) — coefficient calculated by the formula:
\[ k_0 = 1.24 - 1.7B/L \leq 1.0 \]  
(2.2.11-2)
$k_1$ — coefficient depending on ship length $L$ determined as per Table 2.2.11;

<table>
<thead>
<tr>
<th>Ship class</th>
<th>Coefficient $k_1$, values* for ship length, m</th>
</tr>
</thead>
<tbody>

<tr>
<td>O-PIT</td>
<td>0.0154 0.0154 0.0114 0.0089</td>
</tr>
</tbody>
</table>

* $k_1$ values for intermediate ship lengths shall be determined by linear interpolation.

$k_2$ — coefficient depending on ship length $L$ and forward draught $T_f$ determined by the formula:

$$k_2 = 2 - 20 T_f / L \geq 1.0; \quad (2.2.11-3)$$

$k_3$ — coefficient taken, for ships of M-CHI 4.5 class, equal to 1.114 for ships 25 and 60 m long; 1.277 for ships 100 m long; 1.367 for ships 140 m long. The values of $k_3$ for intermediate lengths of ship shall be determined by linear interpolation. For ships of all other classes, $k_3 = 1.0$ regardless of their length.

$\delta$ — block coefficient;
$h$ — design wave height taken from Table 2.1.2.
$L$, $T_f$ and $\delta$ values shall be taken with due regard to the design loading case used for determining a bending moment on still water.

Additional wave bending moment is taken as constant within 0.3$L$ in the middle part of the hull and linearly reducing towards the fore and aft extremities down to zero (see Fig. 2.2.10).

2.2.12 Design bending moments for sagging and hogging, $kN\cdot m$ in the hull section under consideration shall be calculated by algebraical summing the values of bending moments in still water and the additional wave bending moment in this section:

$$M = M_{sw} + M_{aw} \quad (2.2.12-1)$$

For passenger ships of M-CHI class with length of 50 m and more, the bending moments in still water $M_{sw}$, $kN\cdot m$ shall be calculated as per 2.2.4 and taken, by the absolute value, not less than that determined by the formula:

$$M_{sw} = \pm k_{sw} \delta BL^2, \quad (2.2.12-2)$$

where $\delta$ — block coefficient;

$k_{sw}$ — coefficient determined by the formula:

$$k_{sw} = k_\sigma k_1 k_2 - 34.34 k_0 k_1 k_2 \geq 0; \quad (2.2.12-3)$$

$k_\sigma$ — coefficient taken from Table 2.2.12-1;

</tbody>
</table>

$k_1$ — coefficient taken from Table 2.2.11.

2.2.13 Design shear forces for sagging and hogging, $kN$ in at the hull section under consideration shall be calculated by summing the absolute values of shear force on still water and the additional wave shear force in this section:

$$N = | N_{sw} | + | N_{aw} | \quad (2.2.13)$$

2.2.14 Maximum design bending moments and shear forces shall be determined according to 2.2.12 and 2.2.13 in design loading cases as per 2.2.2 – 2.2.7.

2.2.15 For the design condition as per 2.2.2.5, if loading and unloading at waves are not required by design documentation approved by the River Register, $M_{sw}$ and $N_{sw}$ in
formulae (2.2.12) and (2.2.13) shall not be taken not less than 0.7 of the respective values determined as per 2.2.10 for the ship of I class. If the design documentation approved by the River Register requires cargo operations in non-sheltered waters, $M_{aw}$ and $N_{aw}$ are determined by the formulae (2.2.10-1) and (2.2.10-21) for ships operating in basin category comprising the water area in question.

Values of $M_{aw}$ and $N_{aw}$ during loading and unloading operations shall be calculated with due regard to the cargo distribution over the ship’s length as per 2.2.8.

Design local loads

2.2.16 Local load shall be calculated for the following loading cases of the ship:

.1 in fully loaded condition;
.2 in lightship condition or with ballast;
.3 during loading and unloading (for cargo ships);
.4 during water-tightness and gas-tightness tests of the hull;
.5 in case of flooding compartments according to 4.2 and 4.3 Part II of the Rules;
.6 in other unfavorable operational conditions of the ship.

2.2.17 Local strength of structures shall be verified for the loads that produce maximal stresses.

The strength of longitudinal girders is verified against summary stresses produced by global longitudinal bending of the ship and the local load.

2.2.18 The design local load shall be specified in the form of a pressure taken equal to the greatest value from those obtained by the formulae in 2.2.19 to 2.2.29 according to ship type, permissible loading conditions, and hull form. These formulae use the following symbols:

- $T_b$ — draught of a ship with ballast in the section under consideration, m;
- $h_b$ — height of a ballast tank up to the top of the air pipe, m;
- $h_{tr}$ — height of expansion trunk of tanker’s cargo tank, m;
- $h_{aw}$ — water head corresponding to over-pressure, for which the breathing valve in the gas outlet pipe is designed and calculated, m;
- $r$ — wave half-height, m (wave height is taken from Table 2.1.2 regardless of permissible wave height limit set to the ship). For ships of M-CTI 4.5 class, the design wave half-height in common case shall be equal to $r = 2.35$ m. If the specified design wave half-height exceeds this value, it is required also to calculate the modulus of cross-section of the girder by the formulae stated in 2.4;
- $p_c$ — cargo/fuel pressure calculated regardless of non-uniformity of its distribution, kPa;
- $H_{sec}$ — height of the ship’s hold in the section under consideration measured from the base plane, m;
- $\gamma_c$ — specific gravity of bulk or liquid cargo, kN/m³;
- $h_{db}$ — double bottom height, m.

2.2.19 Cargo pressure $p_c$ is calculated by the following formulae with due regard to non-uniformity of its distribution, kPa:

.1 for dry cargo ships

$$p_{ma} = k_{nu} \cdot p_c$$

(2.2.19.1)

where $k_{nu}$ — coefficient of cargo pressure non-uniformity, taken equal to 1.25 to calculate web framing and 1.50 to calculate ordinary framing and plates (except for ships carrying cargo loaded in heaps or stockpiles);

.2 for tankers

$$p_{ma} = p_c \pm \Delta p_{nu}$$

(2.2.19.2)

where $\Delta p_{nu}$ — permissible design non-uniformity of cargo pressure by holds for the loading cases provided in the Instruction on Loading and Unloading;

.3 for dry cargo ships carrying cargo loaded in heaps when calculating ordinary members and plates
\[ p_{nu} = \gamma_c \left[ \frac{(H_{\text{heap}} - h)}{(1.13 + 0.480 + 0.150^2) + h} \right], \]  

(2.2.19.3-1)

where \( H_{\text{heap}} \) — height of a heap, m, determined from the mass of cargo in a heap increased by 10% (by 15% for ships carrying mineral building materials on local voyages) in order to take the non-uniformity of loading into account;

\( \theta \) — natural slope angle of the bulk cargo, rad;

\( h \) — reduced height of a heap, m, calculated by the formula:

\[ h = H_{\text{heap}} - \tan \theta \left( L_{\text{heap}} + B_{\text{heap}} + \sqrt{L_{\text{heap}}^2 + R_{\text{heap}}^2} \right) / \delta. \]  

(2.2.19.3-2)

Here \( L_{\text{heap}}, B_{\text{heap}} \) — length and breadth of a section of the deck plating occupied by one heap of cargo, correspondingly, m.

If calculation according to formula (2.2.19.3-2) results in \( h < 0 \), then \( h \) shall be taken equal to zero.

.4 for dry cargo ships carrying bulk cargoes in stockpiles, when calculating ordinary framing and plates

\[ p_{nu} = \gamma_c \left[ \frac{(H_{\text{st}} - h_{\text{st}})}{(1.07 + 0.330) + h_{\text{st}}} \right], \]  

(2.2.19.4)

where \( h_{\text{st}} \) — height of the rectangular part of stockpile’s cross-section, in m;

\( H_{\text{st}} \) — overall height of the stockpile determined from the cargo mass increased by 10% to take the non-uniformity of loading into account (15% for ships carrying mineral building materials on local voyages), m;

.5 for dry cargo ships carrying bulk cargoes in heaps, when calculating web framing, the cargo pressure is considered non-uniformly distributed throughout the deck plating area. Inside a circle with its centre in the heap’s centre and with radius

\[ r_1 = (0.12 + 0.390) R_1, \]  

(2.2.19.5-1)

where \( R_1 \) — radius of the flared part of the heap, m, determined by the formula:

\[ R_1 = (H_{\text{heap}} - h) \cot \theta, \]  

(2.2.19.5-2)

the pressure is constant and equal to \( p_{nu} \) as calculated by formula (2.2.19.3-1).

Inside the ring \( r_1 \leq r_M \leq R_1 \) the pressure varies along the radius linearly

\[ p_M = p_p + (p_{nu} - p_p)(R_1 - r_M)/(R_1 - r_1), \]  

(2.2.19.5-3)

where \( r_M \) — distance between point \( M \), at which pressure \( p_M \) is calculated, and the centre of the heap, m;

\( p_p \) — constituent equal to

\[ p_p = \gamma_c h. \]  

(2.2.19.5-4)

At points of bearing rectangle with a radius-vector \( r_M > R_1 \), the pressure is determined by the formula

\[ p_M = p_p. \]  

(2.2.19.5-5)

.6 for dry cargo ships carrying bulk cargoes in stockpiles, when calculating web framing, the cargo pressure is considered uniformly distributed over the stockpile length and non-uniformly distributed in the transverse direction. In the middle part of plating under the stockpile, the pressure shall be considered constant and equal to \( p_{nu} \) as calculated by the formula (2.2.19.4).

The middle part is considered as an area where

\[ y_M \leq (0.037 + 0.1650) B_{\text{st}}, \]  

(2.2.19.6-1)

\( B_{\text{st}} \) — breadth of stockpile, m;

\( y_{\text{st}} \) — distance between the point where pressure is determined and longitudinal axis of the stockpile on the deck plating, m.

At the stockpile’s edges, pressure shall be considered distributed in the transverse direction linearly

\[ p_M = p_{nu} - (p_{nu} - \gamma c h_2) \times \]  

\[ \times \left[ 2y_M/B_{\text{st}} - (0.074 + 0.3290)/(0.926 - 0.3290) \right]; \]  

(2.2.19.6-2)

.7 for dry cargo ships carrying bulk cargoes in heaps, when calculating the web framing, the cargo pressure may be considered uniformly distributed throughout the deck plating, provided that the breadth of the heap is not less than the breadth of the cargo bunker. In this case, the pressure shall be calculated by formula (2.2.19.1), where non-uniformity coefficient shall be calculated as follows
\[ k_{nu} = \left(1.6 + 0.2 \frac{L_{hoop}}{B_{hoop}}\right) \left[1 - 0.77 \left(\frac{L_{hoop}}{B_{hoop}}\right)^{0.7}\right] \left[1.5 - (1.1 - \gamma_t h_t / p_t) + \gamma_t h_t / p_t\right], \]  
(2.2.19.7-1)

where \( K_r \) — coefficient:

\[ K_r = n_{tg} \frac{L_{hoop}}{B_{hoop}}^{\frac{1}{3}} \left[n_{i} I_{t}\right]; \]  
(2.2.19.7-2)

\( n_{tg} \) — number of girders of main direction (transverse girders) per heap;

\( n_{i} \) — number of intersecting members (longitudinal girders) in the grillage;

\( I_{t}, I_{i} \) — area moments of inertia, with respect to neutral axis, of girders of main direction and intersecting members, respectively;

\( h \) — reduced height calculated by formula (2.2.19.3-2).

The non-uniformity coefficient shall be not less than 1.25.

.8 for dry cargo ships carrying bulk cargoes in stockpiles, when calculating the web framing, the cargo pressure may be considered uniformly distributed throughout the deck plating, provided that the stockpile’s breadth is not less than the cargo bunker’s breadth. In this case, the pressure shall be calculated by formula (2.2.19.1), where non-uniformity coefficient shall be calculated as follows

\[ k_{nu} = 1.46 - 0.33 \gamma_t h_t / p_c, \]  
(2.2.19.8)

where \( h_t \) — height of the rectangular part of cross-section of the stockpile.

The non-uniformity coefficient shall be not less than 1.25.

2.2.20 Design load at the fore extremity of a ship is considered to be uniformly distributed on the bottom (according to rectangle law) and on the sides (according to a triangle or trapeze law) over the side’s height. For the bottom, the design load is taken as, kPa:

.1 for a wedge bow

\[ p = 9.81 \left(T_{\text{load}} + 2r\right); \]  
(2.2.20.1)

.2 for a spoon-shaped bow

\[ p = 9.81 \left(T_{\text{load}} + 2.5r\right); \]  
(2.2.20.2)

.3 for a sledge-shaped bow

\[ p = 9.81 \left(T_{\text{load}} + 3r\right). \]  
(2.2.20.3)

2.2.21 Design load in the aft extremity is considered to be uniformly distributed as stated in 2.2.20 for fore extremity, and the design load for the bottom is taken to be equal to, kPa:

\[ p = 9.81 \left(T_{\text{load}} + r\right). \]  
(2.2.21)

2.2.22 Pressure at the bottom in the ballast tanks area shall be taken equal to, kPa

\[ p = 9.81 \left(h_b - T_{\text{load}} + r\right), \]  
(2.2.22-1)

but not exceeding

\[ p = 9.81 h_b. \]  
(2.2.22-2)

2.2.23 Design load on the bottom and inner bottom, except for extremities, shall be determined by the formula, kPa:

.1 for ordinary framing and bottom plating of all compartments, provided that there is no counter-pressure from cargo or ballast, and under the following conditions:

in loaded condition \( p = 9.81 \left(T_{\text{load}} + r\right); \)  
(2.2.23.1-1)

in lightship condition \( p = 9.81 \left(T_{\text{light}} + r\right); \)  
(2.2.23.1-2)

with ballast \( p = 9.81 \left(h_b - T_{\text{load}} + r\right); \)  
(2.2.23.1-3)

.2 for web framing of cargo holds of dry cargo ships in full-loaded condition:

\( p = 9.81 \left(T_{\text{load}} - r\right); \)  
(2.2.23.2-1)

for web framing of spaces not subject to counter-pressure of cargo (flush deck ships, compartments of engine room, accommodation spaces of passenger ships and tugboats)

\( p = 9.81 \left(T_{\text{load}} + r\right); \)  
(2.2.23.2-2)

in lightship condition with ballast in the double bottom

\( p = 9.81 \left(T_{\text{load}} - r - h_{db}\right), \)  
(2.2.23.2-3)

where \( h_{db} \) — double bottom height, m;

in lightship condition with ballast outside the double bottom

\[ p = 9.81 (T_b + r); \]  
(2.2.23.2-4)

in lightship condition without ballast

\[ p = 9.81 (T_{\text{light}} + r); \]  
(2.2.23.2-5)
3 for the ordinary framing and the bottom of the shell plating of cargo tanks of tanker in loaded condition:

if there is no double bottom and the compartment is fully loaded

\[ p = \gamma_c \left( H_h + h_r \right) - 9.81 \left( T_{\text{load}} - h_s - r \right) ; \]
(2.2.23.3-1)

with not fully loaded compartment

\[ p = p_{\text{au}} - 9.81 ( T_{\text{load}} - r - h_s ) ; \]
(2.2.23.3-2)

if there is a double bottom, \( p \) is determined according to formula (2.2.23.2-2);

in lightship condition with ballast in the double bottom, the design load is determined according to formulae (2.2.22-1) and (2.2.22-2); in lightship condition without ballast, the design load is determined according to formula (2.2.23.2-5).

4 for ordinary framing and double bottom plating of dry cargo ships:

in fully loaded condition

\[ p = p_{\text{au}} ; \]
(2.2.23.4-1)

in lightship condition with ballast in the double bottom

\[ p = 9.81 ( h_b - h_{\text{db}} ) , \]
(2.2.23.4-2)

where \( h_{\text{db}} \) is taken as per 2.2.23.2.

5 for ordinary framing and double bottom plating of tanker in fully loaded condition:

with fully loaded compartment

\[ p = \gamma_c \left( H_{\text{heap}} - h_{\text{db}} + h_r \right) + 9.81 h_s ; \]
(2.2.23.5-1)

with not fully loaded compartment

\[ p = p_{\text{au}} + 9.81 h_s ; \]
(2.2.23.5-2)

6 for web framing of cargo compartments of tanker in fully loaded condition, the loading is determined by formula (2.2.23.3-1).

2.2.24 When calculating the web and ordinary framing, as well as the side shell plating, the load on the sides is considered to be distributed over the side’s height according to triangle or trapeze law.

Pressure on the sides and outer sides of double-sided ships at the bottom level (except for extremities) shall be taken equal to:

for all ships, except the ballast compartments area and the area of cargo compartments of tankers, according to formula (2.2.23.2-2);

in the area of cargo compartments of tankers, according to formula (2.2.23.3-1) or (2.2.23.3-2);

in the area of ballast compartments, according to formulae (2.2.22-1) and (2.2.22-2).

Pressure on the inner sides of double-sided ships at the level of double bottom shall be taken equal to, kPa:

for tankers, according to formula (2.2.23.5-1) or (2.2.23.5-2),

for dry cargo ships

\[ p = 9.81 ( H_{\text{sec}} - h_{\text{db}} ) , \]
(2.2.24-1)

for ships taking ballast into between-hull space,

\[ p = 9.81 ( H_b - h_{\text{db}} ) , \]
(2.2.24-2)

but not less than the value calculated by formula (2.2.24-1).

2.2.25 Design load on strong watertight bulkheads is considered to be distributed according to the triangle or trapeze law and at the bottom level it is considered equal to, kPa:

1 for the forepeak bulkhead of ships of all types and classes, for all bulkheads of passenger ships of М–СП, М–ПР, О–ПР, М and О classes, for the afterpeak bulkhead of pushed vessels of all classes

\[ p = 9.81 H_{\text{sec}} ; \]
(2.2.25.1)

2 for bulkheads enclosing compartments or tanks of ships of all types and classes (excepting bulkheads of cargo compartments of tankers)

\[ p = p_{\text{au}} , \]
(2.2.25.2)

where \( p_{\text{au}} \) is taken as per 2.2.19;

3 for the rest bulkheads of ships of all types and classes

\[ p = 5.9 H_{\text{sec}} . \]
(2.2.25.3)
Design load on the deck grillage is considered equal to, kPa:

1. for the cargo deck of dry cargo ships
   \[ p = p_{\text{nu}} \], (2.2.26.1)

2. for decks of tankers in the area of cargo compartments
   \[ p = 9.81 \left( h_{\text{tr}} + h_{\text{v}} \right) \], (2.2.26.2)

3. for open parts of the decks not intended for cargo stowage of the hulls of ships of all classes other than tankers:
   \[ p = 5; \] (2.2.26.3)

4. for enclosed parts of hull decks, superstructures and wheelhouses intended for passengers and crew accommodation
   \[ p = 3.5; \] (2.2.26.4)

5. for upper decks of superstructures and wheelhouses not accessible for passengers and not intended for cargoes
   \[ p = 1. \] (2.2.26.5)

2.2.27 When carrying out water-tightness and gas-tightness tests of ship hull, the load shall be taken with due regard to the agreed test schedule in accordance with instructions given in Appendix 10 RTSC.

Local loads during loading and unloading shall be determined according to 2.2.19 – 2.2.24 using the draught values in the given section at the particular cargo handling stage instead of \( T_{\text{fload}}, T_{\text{light}} \) and \( T_{\text{b}} \) and the level of the liquid inside the ballast tank or cargo tank for a current stage of the loading instead of \( H_{\text{icw}}, h_{\text{b}} \) and \( H_{\text{tr}} \) respectively.

Design wave half-height is taken as 0.2 m, if loading and unloading are not required for the ship. If the ship is required to carry out cargo handling operations in non-sheltered waters, the wave half-height shall be taken from Table 2.1.2 for ship operating in basin category comprising this water area.

2.2.28 Design local load on walls and decks of superstructures and wheelhouses of ship of M-CII class shall be set in the form of the design pressure determined:
   - on side walls, from Table 2.2.28-1;
   - on open decks not intended for cargo stowage, from Table 2.2.28-2;
   - on end walls, from Table 2.2.28-3.

For the ships of M-CII 4.5 class, the design pressures specified in Tables 2.2.28-1, 2.2.28-2 and 2.2.28-3 shall be increased proportionally to coefficient \( k_{p} \) determined by the formula:

\[ k_{p} = 0.57r, \] (2.2.28)

where \( r \) – see 2.2.18.

Values \( x/L \) — 0.5 and \( x/L = -0.5 \) in Tables 2.2.28-1 to 2.2.28-3 correspond to the cross-sections in the fore and aft perpendiculars at the design waterline draught, and \( x/L = 0 \) corresponds to the midship section.

For enclosed decks intended for accommodation of passengers, crew and equipment, the design pressure shall be not less than 5.0 kPa.

Proceeding from the ship’s design features, other combinations of local loads bringing to maximum local stresses shall be also taken into consideration. This requirement applies to the ships of all classes.

</table>

1 If the ship length differs from the values specified in the table, the design pressure shall be determined by linear interpolation of the tabulated data.

2 Numerator represents design pressures for the next lower tier of superstructure (wheelhouse), denominator for the next upper tier.

2.2.29 When cars and other motor vehicles with pneumatic tires are carried or when forklifts are used, the wheel pressure is considered as uniformly distributed over its footprint and equal to pressure in tires. The footprint of a vehicle wheel is considered to be rectangular-shaped with sides l₁ and l₂ (l₁ refers to the wheel width). The sides of the footprint shall be obtained from the equations, cm, as follows:

for a bias tire

\[
l_1 = \sqrt{(10K_dQ/p_t) b_t/ d_t},
\]

(2.2.29-1)

\[
l_2 = \sqrt{(10K_dQ/p_t) d_t/ b_t},
\]

(2.2.29-2)

for a radial tire (marked with symbols R or "Radial")

\[
l_1 = 0.7 b_t,
\]

(2.2.29-3)

\[
l_2 = 10K_dQ/(p_t l_1),
\]

(2.2.29-4)

where \(p_t\) — pressure in the tire, MPa;

\(Q\) — load applied to the tire, kN;

\(b_t\) — width of the tire, cm;

\(d_t\) — diameter of the tire, cm;

\(K_d\) — dynamic coefficient equal to \(K_d = 1\) for forklift and \(K_d = 1.1\) for the cars.

Where it is unknown at the design stage what tires will be used in the wheel vehicle, \(l_1\) and \(l_2\) shall be taken for a wheel with the minimal square of the footprint.

As regards the forklift, it is assumed that the whole load (weight of the forklift plus cargo) is transferred via its front axis only.

Global strength calculations

2.2.30 Global bending stress shall be determined for two cases: sagging, i.e. when the
deck is compressed, and hogging, i.e. when the bottom is compressed.

Calculation shall be made for those hull cross-sections where maximal summary stresses may be expected, for instance, at the weakest section of the middle part of ship, where main longitudinal members terminate, at cross-sections where different framing systems are joined or where hull material changes to another one.

2.2.31 The hull girder comprises all the longitudinal members in the cross-section under consideration, which are continuously extended to the length exceeding the doubled depth, provided that these members are so connected with the hull that they participate in the global bending (see also 2.4.43).

2.2.32 Where the cutout breadth $b_0$ (see Fig. 2.2.32) in the deck does not exceed 0.05 of the breadth $B_0$ of the continuous part of the deck in the given place, this cutout is not taken into consideration when calculating modulus of the cross-section. If the cutout breadth $b_0$ is equal to or more than 0.05 of the breadth of the continuous part of the deck in the given place, only the members outside the cutout (across the deck) shall be included in the hull girder. Here, a part of the members outside the cutout (along the deck) shall not be included in the hull girder.

2.2.33 Intercostal members in the areas where they terminate shall be included in the hull girder in accordance with Figs. 2.2.32 and 2.2.33 (the shaded areas shall not be included in the hull girder).

2.2.34 Single-tier superstructures (wheelhouses) or superstructures of the first tier supported by at least three transverse bulkheads shall be included in the hull girder in accordance with Fig. 2.2.33.

At end parts of longitudinal walls of superstructures (wheelhouses) there shall be no densely arranged windows or other cutouts whose breadth exceeds the distance between the cutouts.

2.2.35 Railings of cargo decks of flush deck ships and fenders of all ships are not included in the hull girder.

Special measures aimed at exclusion of the fenders and railings of flush deck ships from participation in global bending shall not cause excessive stress concentration.

2.2.36 Elements of the hull girder and normal stresses therein shall be calculated following the approximation method with respective reduction of flexible members like shell, inner bottom, platforms, decks, sides and longitudinal bulkheads.

Approximation step, at which the difference of normal stresses from global bending of the ship between the final and previous approximation steps does not exceed 5% for each extreme edge of the hull girder, shall be taken as the final approximation step.

2.2.37 The following is not subject to reduction:
.1 plate sections adjacent to longitudinal members at breadth equal to 0.25 of the short side of bearing contour from each side of the member (Figs. 2.2.37-1 and 2.2.37-2) but not more than 25-fold plate thickness;

.2 bilge plate throughout the length of the bilge curve;

.3 plates of the extended zone of the hull girder in case of the longitudinal framing system.

2.2.38 In case of the longitudinal framing system, the reduction coefficients for compressed plates shall be obtained from the formula

$$\varphi = \frac{\sigma_c}{\sigma_t},$$

(4.3.20)

where $|\sigma_c|$ — absolute value of the compressive stress in the rigid members at the level of plate's centre of gravity as obtained from calculation of the hull girder at the corresponding approximation step, MPa;

$\sigma_c$ — critical stress in the compressed plate calculated as per 2.2.72, MPa.

The reduction coefficient shall not exceed 1.

2.2.39 In case of the transverse framing system, the reduction coefficients of plates shall be specified in accordance with Table 2.2.39. When determining these coefficients, the local transverse load on the plate is to be specified according to instructions of 2.2.19 to 2.2.28, and the design value of sagging $h_0$ shall be taken not less than calculated by the formula, m:

$$h_0 = a \left(0.0015/t + 0.4\right)/55,$$

(2.2.39-1)

where $a$ — length of the shorter side of the plate, m;

$t$ — plate thickness, m.

Table 2.2.39

Reduction coefficients for transverse plates

For cargo deck plating and double bottom of the ships loaded with clamshells, the value of sagging $h_0$ calculated by formula (2.2.39-1) shall be doubled; initial sagging shall be considered cosine-shaped, and the strip girder to be considered rigidly fixed regardless of the fact whether the plating is under transverse load or not.

The reduction coefficient at compression $\varphi_c$ shall not exceed the value obtained from the equation:

$$\varphi = \left(19/|\sigma_t|\right)\left(100/t\right)^2 \left(1 + a^2/b^2\right)^2,$$

(2.2.39-2)

where $|\sigma_t|$ see 2.2.38;

$a$ — see 2.2.39-1;

$b$ — length of the larger side of the plate, m.

2.2.40 At global bending of the hull, the following stresses in the hull members shall be determined:

normal stresses, MPa,

$$\sigma_i = M_{\rho} C_i \cdot 10^{-3} / I;$$

(2.2.40-1)
tangent stresses, MPa, at the level of characteristic horizontal cross-sections along the hull girder height:

\[ \tau = \frac{M}{I \sum t}, \]  

(2.2.40-2)

where

\( M \) — the greatest design bending moment in the cross-section, kN\(m \);

\( I \) — area moment of inertia of the hull girder, m\(^4\);

\( z_i \) — distance between \( i \)th member and the neutral axis of the hull girder (with symbol plus when above the neutral axis and symbol minus when below the neutral axis), m;

\( N_r \) — the greatest design shear force in the cross-section, kN;

\( S \) — static moment, relative to the axis, of the part of hull girder cross-section situated either above or below the given horizontal cross-section, in which tangent stresses are calculated, m\(^3\);

\( \sum t \) — the sum of thicknesses of the sides, longitudinal coaming plates and longitudinal bulkheads in the given horizontal section, in which tangent stresses are calculated, mm.

### Local strength calculations

**2.2.41** The local strength calculations shall be performed for ships of all classes regardless of ship length.

When calculating the local strength, the following shall be assumed:

1. Web framing members — floors, web side frames and beams — shall be considered as rigid bearing for longitudinal bottom, side and deck girders (stiffeners); keelsons, side stringers and carlings, similarly, for ordinary bottom and side frames and beams; web stays and bulkhead shelves, similarly, for ordinary horizontal and vertical stiffeners;

2. Variability of rigidity characteristics of the web member sections resulting from knees shall not be taken into account when expanding static indeterminacy of the system;

3. Spans of members constituting a frame ring shall be taken as overall dimensions (hull depth, hull breadth, distance between longitudinal bulkheads);

4. When calculating stresses in bearing cross-sections of the frame girders, knees shall be taken into account when calculating the modulus of cross-section of the girder (by inclusion of the knee cross-section) and when calculating bending moment acting at knees’ edge;

5. Where the height of girders (floors, side web frames, bulkhead web stays, etc.) varies, it is allowed to use scantling of the mid girder span for calculation purposes;

6. Tangent stresses near cutouts in webs of web members shall be obtained by dividing the shear force by the area of the web cross-section minus the area of the cutout cross-section.

**2.2.24** When calculating the web frames, the following provisions shall be considered:

1. Sagging of beams and bilge curve radius shall not be accounted; members constituting the frame shall be considered rectilinear, and their length shall be taken in accordance with directions of 2.2.41.3;

2. Pillars supporting web frames shall be considered as only equalizing sags of bottom and deck branches and as loaded with point forces. When expanding static indeterminacy in calculations, the change of pillar length or influence of knee rigidity shall not be considered.

The pillars, whose rigidity is close to the rigidity of ring frame branches, shall be calculated as the frame ring elements loaded with end moments, in addition to axial force;

3. Where the web frames are relieved by longitudinal girders (that may be seen from preliminary calculation of the grillage), their relieving action shall be accounted as concentrated reaction forces. If there is no deck loading, frame rings with no pillars may be calculated as open frame rings, whose side branches rest freely on hard bearings in the deck junction;

4. Multi-tiered frame rings may be calculated as one-tiered ones, provided that the deck is not loaded;

5. Bracket floors in each span between keelsons may be calculated as girders loaded by water pressure from below and by cargo pressure from above. The top and bottom girders of bracket floors interconnected by a
vertical stay amidst the span may be calculated assuming that sags of the girders are equal at the points where the girders are connected with the stay.

2.2.43 When calculating the strength of the grillages, the restraint coefficient of the main direction girder ends shall be obtained from the calculation of the frame ring. If the frame ring is not calculated, restraint coefficients of floors at the bilge and of beams at the sides shall be determined by the formula

\[ k = \frac{1}{[1 + \zeta(H/B_i)]}, \]  

(2.2.43)

where \( \zeta \) — coefficient to be obtained from Table 2.2.43 depending on the number of longitudinal bulkheads, the loading conditions and ratio \( H/(B_i) \);

\( l \) — span of the side frame, m;

\( B_i \) — span of the beam or floor, m;

\( I \) — area moment of inertia of the beam or floor, m^4;

\( i \) — area moment of inertia of the side frame, m^4.

### Table 2.2.43

<td>0.50</td>
</tr>
</tbody>
</table>

2.2.44 Restraint coefficients \( k \) of the floors and beams shall be determined in the following way depending on availability of longitudinal bulkheads or trusses:

- where distances between adjacent longitudinal bulkheads/trusses or between a longitudinal bulkhead/truss and the side differ from each other by less than 20%, then \( k = 1 \);
- ditto, by more than 20%:
  - for smaller spans of girders \( k = 1 \);
  - for greater spans of girders \( k = 0.75 \).

2.2.45 Restraint coefficients \( k \) of intersecting members in the grillages shall be obtained as follows:

- where lengths of adjacent compartments differ from each other by less than 20%, \( k = 1 \);
- where lengths of adjacent compartments differ from each other by more than 20%, \( k \) is calculated by the formula:

\[ k = \left[ 1 + 0.5q\left(\frac{L'_{gr}}{L_{gr}}\right)^2 / q \right] / \left(1 + 0.5\frac{L'_{l}}{L_{l}}\right). \]

(2.2.45)

where \( q' \) — average arithmetical value of loads of the adjacent compartments, kPa;

\( q \) — load on the grillage under consideration, kPa;

\( L'_{l} \) — average arithmetical value of lengths of adjacent grillages, m;

\( L_{l} \) — length of the grillage under consideration, m.

2.2.46 Keelsons and carlings, floors and beams connected by pillars at each web frame may be calculated as a grillage by considering them to be a girder of summed rigidity and separating reaction forces in junctions proportionally to rigidities of keelsons and carlings.

For bottom grillages, it is necessary to verify tangent stresses in webs of girder bearing sections.

2.2.47 Trusses shall be considered as rigid bearings for web framing.

2.2.48 Ordinary frames and beams shall be calculated as multi-spanned girders assuming that longitudinal web members (keelsons, carlings and side stringers) are rigid non-shifting bearings for the ordinary frames and beams, and particular parts of the latter are in bending.

For the connection of the side ordinary frame and floor with a knee, the bottom end of the frame is be considered as rigidly attached.

For the connection of the side ordinary frame and floor with a knee, the bottom end of the frame is be considered rigidly attached.

Terms of service and privacy policy © copyright 2023

For the connection of the side ordinary frame and floor with a knee, the bottom end of the frame is be considered as rigidly attached.

For the connection of the side ordinary frame and floor with a knee, the bottom end of the frame is be considered rigidly attached.

Ends of ordinary frames and beams in the deck-to-side junction, as well as ends of half-beams adjoining to the coaming, shall be considered as freely resting.
2.2.49 Longitudinal girders (stiffeners) in the longitudinal framing system shall be calculated based on the requirements of:

.1 local strength as:
- girders rigidly attached to the web transverse members (floors, frames or beams) under symmetrical load;
- multi-spanned continuous girders under non-symmetrical load;
.2 buckling strength as girders freely resting on the transverse web members.

2.2.50 Side stringers shall be calculated within the structure of the side grillage.
If cross-connected, stringers of outer and inner sides shall be calculated as a system of girders with cross-members.

2.2.51 Bulkhead framing consisting of web stays and shelves, provided that shelves support these stays, shall be calculated as a grillage.
Where there is no shelves, ordinary vertical stays shall be calculated as single-spanned girders, and where there are shelves, as continuous multi-spanned girders.
Where there are no web stays, ordinary horizontal stiffeners shall be calculated as single-spanned girders, and where there are web stays, as girders rigidly attached on web stays, if distances between the latter are equal. Otherwise, the restraint coefficients of ordinary horizontal stiffeners shall comply with the requirements of 2.2.44.

2.2.52 Calculation of strength of the shell plates and plating shall be made under the assumption that all the plates carrying local load are plates of finite rigidity firmly fixed on long edges of the bearing contour.
Where bearing contour side ratio exceeds two, the plates shall be considered as bending over a cylindrical surface and be calculated as strip girders.

2.2.53 When calculating frame scantlings, width of the effective flange shall be specified as follows:

.1 when calculating longitudinal girders of deck, bottom and double bottom (with the longitudinal framing system), or ordinary beams and frames (with the transverse framing system), as well as ordinary girders, width of the effective flange shall be determined by the formula:

\[ c_i = 0.5a, \]  

where \( a \) — distance between the same-name ordinary girders (i.e. spacing), m.
Effective flange shall not be taken wider than its 50-fold thickness;

.2 when calculating the web members perpendicular to ordinary girders (beams, frames, floors in case of the longitudinal framing system, and carlings, keelsons and side stringers in case of the transverse framing system), the width of the effective flange for these members shall be obtained from the equation, m:

\[ c_2 = c_1 + (b - c_1)\phi, \]

where \( c_1 \) — width of the effective flange as per 2.2.53.1, m;
\( b \) — distance between the same-name web members arranged perpendicular to ordinary girders, m;
\( \phi \) — reduction coefficient obtained from Table 2.2.39.
If reduction coefficient is calculated (see 2.1.6) instead of obtaining from Table 2.2.39, the stress in rigid members being a part of the cubic equation shall be taken equal to normal stress in the web member under consideration with a respective sign;

.3 when calculating the web members co-directional to ordinary framing (carlings and floors in case of the transverse framing system, web frames in case of the longitudinal framing system, etc.), the cross-sections within the flange of ordinary framing stiffeners shall be added to design values of the effective flange area, and the width of the effective flange is calculated as follows, m:

\[ c_3 = 0.5d \left[ 1 + 0.45(100r/a)^2 \right], \]

where \( d \) — distance between same-name web members parallel to ordinary girders, m;
\( a \) — distance between the same-name ordinary girders (i.e. spacing), m.
In all cases, the following condition shall be met: \( c_2 \leq d; \)

.4 in all cases, the width of the effective flange of the framing girders shall not exceed...
1/6 of length of the design span of the girder under consideration;

5 for the web members located across corrugations and connected directly with a corrugated plate throughout its length, the width of the effective flange shall be taken equal to 12-fold thickness of the corrugated plate;

6 for the web members located across corrugations and having no direct connections with a corrugated plate throughout its length, the width of the effective flange shall be taken equal to zero;

7 for members running on the longitudinal girders (attached framing system), the width of the effective flange shall be taken equal to zero.

2.2.54 Design load on deck junction of truss or deck end of a separate pillar shall be determined by the formula, kN:

\[ P = f f + P_u, \]  

(2.2.54-1)

where \( f \) — area of the deck or a platform supported by the pillar, including cargo hatches in the area under consideration, m²;

\( p \) — design load on the area \( f \) to be obtained as per 2.2.26, kPa;

\( P_u \) — design load on the pillar from the upper pillar, kN.

Design load on bottom junction of truss or bottom end of a separate pillar shall be determined by the formula, kN:

\[ P_b = 9.81 f_b (T + r) \geq 0, \]  

(2.2.54-2)

where \( f_b \) — bottom area supported by the bottom junction of truss or a separate pillar, m²;

\( T \) — draught in considered ship loading case in vicinity of the truss or separate pillars, m;

\( r \) — design wave half-height, m.

The value of \( P_b \) shall not be less than zero. Forces in pillars and braces shall be determined based on calculation of truss loaded by forces \( P \) and \( P_b \). Truss span shall be considered equal to:

for transversal trusses, the distance between side and longitudinal bulkhead or between longitudinal bulkheads.

The loading on transversal trusses shall also include reaction forces resulting from interaction with longitudinal trusses.

Forces in separate pillars shall be determined from joint calculation of bottom and deck grillages. The force compressing a separate pillar may be taken as the greater of the forces \( P \) and \( P_b \).

When determining forces in braces and pillars, two cases shall be considered:

when the maximum permissible load acts on the deck in considered ship area. In this case, the minus is used in formula (2.2.54-2);

when there is no load on deck in the considered ship area. In this case, the plus is used in formula (2.2.54-2).

2.2.55 The cross-section area of the pillar or brace \( F \), m² shall be not less than

\[ F = 2 \cdot 10^{-3} |P|/\sigma_c, \]  

(2.2.55-1)

where \(|P|\) — absolute value of design force in pillar/brace determined taking into account the load on deck and bottom junctions (see 2.2.54) and truss structure, kN;

\( \sigma_c \) — critical stresses calculated according to 2.2.71 from the Euler stresses, MPa;

\[ \sigma_E = 2 \cdot 10^5 I / (l^2 F), \]  

(2.2.55-2)

where \( I \) — the minimum area moment of inertia of the pillar/brace, m⁴;

\( l \) — design length of the pillar/brace, m, taken equal to:

for pillar, the actual length of the pillar;

for brace, reduced length \( l_{\text{red}} \) determined by the formula:

\[ l_{\text{red}} = kl_{\text{p}}/\cos \alpha, \]  

(2.2.55-3)

where \( k \) is a coefficient taken equal to:

1, for trusses shown on Fig. 2.2.55 a) and 2.2.55 b);

0.66, for trusses shown on Fig. 2.2.55 c);

\( l_{\text{p}} \) — overall length of the brace, m;

\( \alpha \) — angle between longitudinal axis of the pillar and longitudinal axis of the brace.
Transverse strength of double-sided cargo ships with large deck openings is estimated by calculation of cargo bunker bottom grillage together with frame rings of the double sides, under assumption that all the junctions of these frame rings are fixed and both outer and inner sides act as a rigid bearing for floors, provided that the following inequality is met:

\[
(I_f I_e I_i) + (f_0 f_i f_e) \geq 2.7
\]

(2.2.56-1)

where \(l_h\) — length of the longest hold, m;
\(B_i\) — floor length (distance between the inner sides at the double bottom level), m;
\(d_i\) — distance between the floors, m;
\(k_{av}\) — average restraint coefficient of the floors:

\[
k_{av} = (k_{f_i} n_i + k_{hb} n_b)/(n_i + n_b)
\]

(2.2.56-2)

\(n_i\) — number of floors in the hold positioned in the frame ring planes;
\(n_b\) — number of floors in the hold positioned in the planes of half-bulkheads;
\(k_{av}\) — restraint coefficient of floor ends in frame rings:

\[
k_{av} = 1/\left(1 + I_f/B_i \left[ I_s/H + I_d/(b_h \alpha_s) \right]\right)
\]

(2.2.56-3)

\(H\) — side depth, m;
\(\alpha_s\) — shift coefficient:

\[
\alpha_s = 1 + 7.8I_d/(b_h^2 f_d);
\]

(2.2.56-4)

\(f_i, f_e, f_i\) — area moments of inertia of the floor in the cargo bunker area, the double bottom floor, and the inner side frame with effective flange, m^4;
\(f_0\) — cross-sectional area of inner side frame’s web, m^2;
\(b_h\) — double bottom width at the level of bottom deck, m;
\(k_{hb}\) — restraint coefficient of floors in half-bulkheads:

\[
k_{hb} = 1/[1 + 6I_f/(t_{hb}^2 B_f)]
\]

(2.2.56-5)

but not less than \(k_{fr}\);
\(t_{hb}\) — thickness of the half-bulkhead plate in its lower part, m;
\(h_d\) — double bottom height, m;
\(i_i\) — relative moment of inertia of the double side in case of constrained torsion:

\[
i_i = b_d^2 (t_d H + t_b h_d)/(12I_f)
\]

(2.2.56-6)

\(b_d\) — double bottom width at the level of deck, m;
\(i_b\) — relative moment of inertia of the double side in case of free torsion:

\[
i_b = Ht_d b_d^2 [1 + b_d t_d/(H h_d)]/I_n
\]

(2.2.56-7)

\(t_d, t_s\) — average deck plating thickness and side plating thickness (inner and outer sides), respectively, m;
\(b_d\) — double bottom width at the level of side half-depth.

If inequality (2.2.56-1) is not complied with, calculation of joint deformation of double sides and bottom grillage in still water under local loads as stipulated by this Part of the Rules shall be submitted.

For ships with large deck opening area, where inequality (2.2.56-1) is not complied with, additional (i.e. caused by waving) shear forces and bending moments in the centre plane cross-section of floor and inner side cross-section of floor shall be calculated and summed up with the same forces and moments in still water.

For ships of M-СП, M-ΠР, M and O classes, the maximum values of forces and
moments may be obtained from the following equations:

shear force in the inner side cross-section, kN,
\[
V_{def} = \pm 6.52hB; d_i e^{-kT} \left(1 - e^{-0.5kB}\right) / (kB);
\] (2.2.58-1)
bending moment in the inner side cross-section, kN·m,
\[
M_{def} = \pm h d_i \left[4.88\beta T \left(1 - e^{-kT}\right) + 0.710B_i^2 \times \left(k - k_i, \beta\right)e^{-kT} \left(1 - e^{-0.5kB}\right) / B\right] / k;
\] (2.2.58-2)
bending moment in the centre plane cross-section, kN·m,
\[
M_{ul} = \pm h d_i \left[3.96\beta T \left(1 - e^{-kT}\right) + 0.641B_i^2 \times \left(1.5 - k + k_i, \beta\right)e^{-kT} \left(1 - e^{-0.5kB}\right) / B\right] / k;
\] (2.2.58-3)

where \( h \) — wave height obtained from Table 2.1.2, m;
\( k \) — provisional wave number; for ships of O-ΠP and O classes it shall be taken equal to 0.140 m\(^{-1}\), for ships of M-ΙΠ, M-ΠP and M classes 0.0838 m\(^{-1}\);
\( T \) — draught in the middle of the hold, m;
\( B \) — ship breadth, m;
\[
\beta = k / \left( B; d_i \left[97.4(H/l_0)^2 i_1 + 3.80l_1\right] / l_0^2 + k_i; \right);
\] (2.2.58-4)
\( l_0 \) is be taken equal to the hold length, m for \( l_0 \leq 65 \) m, and equal to 65 m for \( l_0 > 65 \) m;
For \( B; d_1, i_1, l_2, k_i; \) see 2.2.56.

When calculating bending moments acting in sections of the floor placed in the frame ring plane, it shall be assumed that \( k = k_0; \) when calculating bending moments acting in sections of the floor located in the half-bulkhead plane, that \( k = k_{rb}; \)

2.2.59 When carrying vehicles and using forklifts, strength of the plating shall be determined through the value of the residual sag \( W_{res} \) caused by load from a wheel or a group of wheels. The sag shall comply with the following inequality:
\[
W_{res} / b \leq 0.01 ,
\] (2.2.59-1)
where \( b \) — minimum size of the plate in plan view (i.e. the distance between stiffeners, see Fig. 2.2.59), m.

Fig. 2.2.59 Arrangement of load spot on deck

Parameter \( W_{res} / b \) is calculated by the formula:
\[
W_{res} / b = 10^{-2} k_1 k_2 k_3 k_4 k_5 \sqrt{(\rho_i / \rho_y - 1)^3} ,
\] (2.2.59-2)
where \( k_1 \) is a coefficient equal to 1.40 for steel with \( R_{st} = 235 \) MPa and equal to 1.00 for higher strength steels;
\[
k_2 = 6.0 / (b / t_{min}) - 15 ;
\] (2.2.59-3)
\[
k_3 = 0.45 b_0 / b + 0.75 ;
\] (2.2.59-4)
\[
k_4 = 0.20 a_0 / b + 0.80 ;
\] (2.2.59-5)
\[
k_5 = 1.9 \left(\sigma_c \cdot 10^3 / E \right)^2 + 0.74 ;
\] (2.2.59-6)
\( \rho_i \) — pressure in the load spot (see Fig. 2.2.59) equal to the tire inner pressure, MPa;
\( \rho_y \) — pressure resulting in fiber yield:
\[
p_y = t_{min}^2 (R_{st} - \sigma_0) / (k_\sigma a_0 b_0) ;
\] (2.2.59-7)
\( t_{min} \) — thickness of the plating at the end of ship’s service life without renewal repair as calculated by formula (2.2.59-11), m;
\( \sigma_c \) — absolute value of maximal compressive stresses in the rigid members at the plating level: in case of the transverse framing system, in the effective flange of a carling or keelson at global hull bending; in case of the longitudinal framing system, in the effective flange of a beam or floor at the grillage bend-
ing; when calculating effect of vehicle wheels during the voyage, it shall be found with due regard to waves; when calculating effect of forklift wheels, with due regard to loads acting during cargo handling operations, MPa;

\[ \sigma_0 = \text{stresses equal to } \sigma_c \text{ or } \sigma_E, \text{ whichever is less}; \]

\[ \sigma_E = 19 \left(100 \frac{\sigma_{\min}}{b}\right)^2; \quad (2.2.59-8) \]

\( a_0 \) — size of the load spot along the longer side of the plate, m;

\( b_0 \) — ditto, along the shorter side, m;

\( R_{eh} \) — yield point of the plating material, MPa;

\( E \) — Young’s modulus, MPa;

\( k_\sigma \) — stress coefficient in the plate, as obtained from Table 2.2.59.

| Table 2.2.59 Coefficient \( k_\sigma \) depending on ratios \( b_0/b \) and \( a_0/b \) |
|----------------------------------|----------|--------|--------|--------|
| \( b_0/b \)                        | 0.3      | 0.6    | 1.2    | 1.8    | 2.4    |
|----------------------------------|----------|--------|--------|--------|
| 0.2                               | 1.056    | 0.904  | 0.652  | 0.492  | 0.387  |
| 0.4                               | 0.896    | 0.766  | 0.550  | 0.409  | 0.316  |
| 0.6                               | 0.734    | 0.630  | 0.456  | 0.342  | 0.266  |
| 0.8                               | 0.602    | 0.518  | 0.376  | 0.284  | 0.222  |
| 1.0                               | 0.494    | 0.424  | 0.309  | 0.233  | 0.183  |

Sizes of the load spot \( a_0 \) and \( b_0 \) are considered to be equal to \( l_1 \) and \( l_2 \) with due regard to the wheel orientation. Values of \( l_1 \) and \( l_2 \) are determined as per 2.2.29.

For twin wheels \( l_1 \) is replaced with \( l_1^* \)

\[ l_1^* = l_1 + b_t + \Delta , \quad (2.2.59-9) \]

where \( b_t \) is referred to in 2.2.29, and pressure in the tire \( p \) is replace by the reduced pressure \( p^* \)

\[ p^* = 2p l_1/l_1^* , \quad (2.2.59-10) \]

where \( \Delta \) — distance between tires of a twin wheel.

If \( b_0 > b \), \( b_0 = b \). If \( p < p_t \), residual sag \( W_{ns} = 0 \).

Formula (2.2.59-2) is applicable when:

\[ 30 \leq b/t_{\min} \leq 170 ; \]

\[ 0.15 \leq a_0/b \leq 2.10 ; \]

\[ 0.20 \leq b_0/b \leq 1.00 ; \]

\[ 0.11 \leq 100 R_{eh}/E \leq 0.17 ; \]

\[ 0 \leq \sigma_c \cdot 10^4 /E \leq 8,0 . \]

Plating thickness at the end of ship’s service life without renewal repair is determined as:

\[ t_{\min} = t - \Delta t , \quad (2.2.59-11) \]

where \( t \) — design thickness of the plating, which shall be not less than specified in 2.4.1, m;

\( \Delta t \) — wear over the service life, m:

\[ \Delta t = 8 \cdot 10^{-5} \tau , \quad (2.2.59-12) \]

\( \tau \) — ship service life without renewal repair, years.

2.2.60 The following stresses shall be determined in the area of cutouts in webs of web members where the greatest shear force occurs, MPa:

normal stresses

\[ \sigma = \left[ \frac{Mz/I + V_{sh} (0.5 l_{cut} - x)}{z_{br}/I_{br}} \right] \cdot 10^{-3} ; \quad (2.2.60-1) \]

tangent stresses

\[ \tau = 10^{-3} V/F_w , \quad (2.2.60-2) \]

where \( M \) — bending moment on the girder in the cross-section in the middle of the cutout, kN-m;

\( I \) — central area moment of inertia of the girder in the cutout area, m\(^4\);

\( z \) — distance between the point where the stress is determined and the girder’s neutral axis, m;

\( \Delta t \) — distance between the point where the stress is determined and the girder’s neutral axis, m;

\( l_{cut} \) — cutout length, m;

\( x \) — distance between the design cross-section and the left edge of the cutout, m;

\( I_{br} \) — area moment of inertia of the girder cutout bridges above or below the cutout, relative to their own neutral axes, m\(^4\);

\( z_{br} \) — distance between the point under consideration and the neutral axis of the web bridge, m;

\( V, F_w \) — shear force, kN and the weakest cross-section area of the girder web, m\(^2\), correspondingly.
**Summation of stresses**

2.2.61 Design stresses in hull members caused by global bending and local loads shall be determined depending on the values, positions and directions of acting external loads.

The greatest normal and tangent stresses, which shall not exceed those permitted by the Rules, shall be considered design stresses in the hull member under consideration.

2.2.62 Strength of longitudinal hull members participating in global bending shall be verified by stresses resulting from algebraic summation of stresses caused by longitudinal global bending stresses and stresses caused by local load.

2.2.63 For ships not carrying cargo on deck, summary stresses shall be determined only in bottom members. Global bending stresses are considered to be design stresses in deck members for those ships. However, if in those ships some load is transmitted by pillars from the bottom to the deck and causes bending in deck members, total stresses in deck members shall be calculated as regards that load (for instance, total stresses in deck members of flush deck ships in lightship condition).

2.2.64 For all ships carrying cargo on deck, summary stresses in deck members shall be calculated as regards the local load on the deck.

2.2.65 Stresses are determined and summed up for design both sagging and hogging moments.

Local load stresses to be summed up with global bending stresses, which are determined for each of the aforementioned moments, shall be calculated at the respective local load.

2.2.66 Total stresses caused by global bending and grillage bending shall be determined for outer and inner edges of its members on the bearing and in the span.

**Permissible stresses**

2.2.67 When calculating stresses caused by global bending and local load, as well as when calculating total stresses, the following stresses to be taken as unsafe normal and tangent stresses:

\[
\sigma_0 = k_n R_{sh} \quad \text{and} \quad \tau_0 = 0.57 \sigma_0 ,
\]

(2.2.67-1)

where \( R_{sh} \) — yield point of the material;

\[
k_n = 1 - 0.089 \left( \frac{R_{sh}}{235} - 1 \right) - 0.129 \left( \frac{R_{sh}}{235} - 1 \right)^2.
\]

(2.2.67-2)

2.2.68 Values of permissible stresses are given in Table 2.2.68.

**Table 2.2.68**

### Buckling strength calculations

**2.2.69** Verification calculations of buckling shall be made for the following hull members:

1. deck grillages, bottom grillages of ships without double bottom, longitudinal deck stiffeners, bottom, double bottom, sides, longitudinal bulkheads – for maximum compressive stresses due to global bending;

2. pillars (single pillars and pillars within trusses) and braces – for maximum compressive stresses;

3. side shell and plates of longitudinal bulkheads – for maximum tangent stresses due to global bending.

**2.2.70** Buckling shall be checked with due regard to deviations from Hooke’s law of critical stresses (revised Euler stresses) $\sigma_{cr}$.

**Notes.** 1. In calculations of the hull strength for ship lifting and launching, for carrying out watertightness and gas-tightness tests, as well as in case of a flooded compartment, the regulated permissible stresses (due to global bending and local load) shall be taken equal to 0.95 of the yield point of the member material.

2. For separately working members (pillars and braces) to be checked for buckling, the regulated permissible stresses at compression shall be taken equal to 0.50 and for intersecting braces equal to 0.75 of the critical stress, but not more than 0.50 of the yield point of the member material.
Critical stresses shall be determined depending on Euler stresses \( \sigma_E \) calculated under assumption that the hull material is subject to Hooke’s law at the moment when loss of buckling occurs.

**2.2.71** For compressed steel members, critical stress \( \sigma_{cr} \), MPa shall be obtained by the formulae:

\[
\begin{align*}
\sigma_{cr} &= \sigma_E \quad \text{when } \sigma_E \leq 0.6 R_{eH}, \\
\sigma_{cr} &= (1.12 - 0.312 R_{eH}/\sigma_E) R_{eH} \quad \text{when } 0.6 R_{eH} < \sigma_E < 2.6 R_{eH}, \\
\sigma_{cr} &= R_{eH} \quad \text{when } \sigma_E \geq 2.6 R_{eH},
\end{align*}
\]

(2.2.71)

where \( R_{eH} \) — yield point of the material.

**2.2.72** Critical stresses of plates, MPa compressed along the longer edge shall be calculated by the formulae:

\[
\begin{align*}
\sigma_{cr} &= \sigma_E \quad \text{when } \sigma_E \leq 0.6 R_{eH}, \\
\sigma_{cr} &= (1.63 - 0.8 \sqrt{R_{eH}/\sigma_E}) R_{eH} \quad \text{when } 0.6 R_{eH} < \sigma_E < 1.6 R_{eH}, \\
\sigma_{cr} &= R_{eH} \quad \text{when } \sigma_E \geq 1.6 R_{eH},
\end{align*}
\]

(2.2.72-1)

where \( \sigma_E \) — Euler stresses, MPa:

\[
\sigma_E = 78.5 \left(100 t/a\right)^2, 
\]

(2.2.72-2)

\( t \) — plate thickness, cm;
\( a \) — length of the shorter edge, cm;
\( R_{eH} \) — yield point of the material, MPa.

**2.2.73** Critical stresses at compression of the bottom and deck grillages, as well as the longitudinal stiffeners shall not be less than the yield stress of the material.

In case of the transverse framing system, rigidity of bottom ordinary frames and ordinary beams shall not be less than the critical one. Critical stresses of bottom and deck grillages, as well as longitudinal stiffeners may be decreased down to values, at which the following condition is met:

\[ \sigma_{cr} \geq K_s \sigma_c, \]

(2.2.73-1)

\( \sigma_c \) — maximum compression stress in the grillage or longitudinal stiffener at global bending due to design loads, MPa;
\( K_s \) — stability coefficient determined by the formula:

\[
K_s = K_{cl} \left(0.75 + 0.25 R_{eH}/235\right),
\]

(2.2.73-2)

where \( R_{eH} \) — see 2.2.71, MPa;
\( K_{cl} \) — stability coefficient for ship classes: 
M-CH, M-CHP and M - 1.43
Others - 1.33

**2.2.74** At buckling calculations, ordinary longitudinal stiffeners are considered freely resting on the respective transverse members (floors, web frames and beams). Euler stresses at compression in longitudinal stiffeners, MPa are as follows:

\[
\sigma_{cr} = \pi^2 E I \left[b^2 \left(f + a t\right)\right],
\]

(2.2.74)

where \( E \) — Young’s modulus, MPa;
\( I \) — area moment of inertia of the stiffener with effective flange, whose dimensions are determined as per 2.2.53.1, m^4;
\( b \) — stiffener span, m;
\( f \) — cross-sectional area of the stiffener without the effective flange, m^2;
\( a \) — distance between stiffeners (length of the shorter side of the plate), m;
\( t \) — plate thickness, m.

**2.2.75** Tangent stresses of plates of sides and bulkheads at global bending as determined by formula (2.2.40-2) shall not exceed 0.95 of critical tangent stresses determined by the formula, MPa:

\[
\begin{align*}
\tau_{cr} &= \tau_s \quad \text{when } \tau_E \leq 0.5 R_{eH}/\sqrt{3}, \\
\tau_{cr} &= R_{eH} \left[1 - R_{eH}/(4 \tau_E \sqrt{3})\right]/\sqrt{3} \quad \text{when } \tau_E > 0.5 R_{eH}/\sqrt{3},
\end{align*}
\]

(2.2.75-1)

where \( R_{eH} \) — see 2.2.71,
\( \tau_E \) — Euler’s tangent stresses determined by the formula:

\[
\tau_E = 19k \left(100 t/a\right)^2, 
\]

(2.2.75-2)

where \( k \) — coefficient obtained from Table 2.2.75 depending on plate side ratio \( b/a \) (\( b \) — length of the longer side of the plate, m);
\( t, a \) — see 2.2.74.

**Calculation of ultimate global strength**

**2.2.76** In all cases the hull’s global strength shall be verified by ultimate moments.
The ultimate moment is a bending moment inducing normal global bending stresses equal, in absolute values, to the unsafe stresses in at least one longitudinal members included into the hull girder; in this case stresses in all the other members shall not exceed the unsafe stresses. For members not subject to local load the unsafe stresses are taken as
\[
\sigma = \frac{\varphi}{R} k_n n, \quad (2.2.76-1)
\]
and for the members subject to local load
\[
\sigma = 0.9 k_n R, \quad (2.2.76-2)
\]
where \( R \) is yield point of material of the member under consideration;
\( k_n \) is calculated by formula (2.2.67-3).

If for ships of Ì-ÑÏ class the requirement of 2.5.2 is met, the calculations of global strength of ships with a length less than 50 m (except passenger ships) may be omitted.

2.2.77 The two ultimate moments \( M_\alpha \) shall be determined: one moment at sagging and the other at hogging of the hull, kN·m:
\[
M_\alpha = W_\alpha \sigma_o \cdot 10^3, \quad (2.2.77)
\]
where \( W_\alpha \) — section modulus of the hull girder relative to the member where the stresses are equal to the unsafe ones, m³;
\( \sigma_o \) — unsafe stress in the member under consideration, MPa.

2.2.78 When calculating the section modulus \( W_\alpha \), the reduction coefficients in case of the longitudinal framing system shall be set in accordance with requirements of 2.2.38, and in case of the transverse framing system as per Table 2.2.78.

2.2.79 The compressed "rigid" hull members (longitudinal girders of decks, platforms, sheerstrake, bottom, double bottom plating) having critical stresses \( \sigma_{cr} \) calculated as per 2.2.71 and 2.2.74 less than stresses in rigid members \( \sigma_i \) caused by ultimate moment, are also subject to reduction. The reduction coefficient of these members is obtained from the equation
\[
\phi = \frac{\sigma_{cr}}{\|\sigma_i\|} \leq 1. \quad (2.2.79)
\]

2.2.80 In order to ensure hull strength by ultimate moment, the following condition shall be met:
\[
[M_\alpha] \geq k [M_\alpha], \quad (2.2.80)
\]
where \( k \) — safety coefficient with regard to ultimate moment;
\( M_\alpha \) — design bending moment at sagging and hogging, kN·m.

2.2.81 Values of the coefficient \( k \) regardless of the steel grade is taken as 1.35 for ships of all classes.

2.2.82 For cargo ships, the hull strength by ultimate moment shall be additionally verified using the expression:
\[
M_\alpha \geq k \alpha D L, \quad (2.2.82)
\]
where \( k_\alpha \) — coefficient of the ultimate moment to be defined as per Table 2.2.82;
\( D \) — displacement of the ship in fully loaded condition, kN.

Calculation of hull global strength at the end of the ship’s service life

Estimation of service life for particular hull members

2.2.83 For ships with a length of 50 m and more, the hull global strength for a planned period of service without the hull renewal repair shall be verified. This period is specified by shipowner (design customer) or designer.

For all ships, the service life of particular hull members shall be estimated as regards the residual thickness values permissible for operation.

The calculations shall be made for the operating conditions stated in the design specification (operation basin category, tonnage, types of cargo to be carried, conditions of cargo handling operations), which influence the hull strength, and designed scantlings.

The calculations shall be made as per 2.2.84 to 2.2.97.

2.2.84 Global strength at the end of the service life is verified by the ultimate moments.

The two ultimate moments shall be determined: one moment at sagging and the other at hogging of the hull, kN-m:

\[ M_{ul,w} = \sigma_u W_{ul,w} \cdot 10^3, \] (2.2.84)

where \( W_{ul,w} \) — section modulus of the hull girder cross-section calculated taking into account wear and local residual deformations of the hull members relative to the member where the stresses are equal to the unsafe ones, m³;

\( \sigma_u \) — unsafe stress in the member under consideration, MPa; it is specified as per 2.2.76.

2.2.85 When determining the section modulus \( W_{ul,w} \), hull flexible members shall be reduced on the assumption that in one of these members the normal global bending stresses are equal, in absolute values, to the unsafe stresses, and with due regard to simultaneous wear of the hull members as per 2.2.86 to 2.2.88 and their local deformations as per 2.2.89 to 2.2.92. Wear and deformations shall be determined at the ship’s age equal to the planned service life minus 5 years.

2.2.86 Service life of particular hull members \( T \) is to be calculated by the formula:

\[ T = \left( t_d - [t] \right) / c_p + 5, \] (2.2.86-1)

where \( t_d \) — thickness of the member under consideration specified in the design, mm;

\( [t] \) — permissible residual thickness, which shall be taken for shell and deck plating from Table 2.2.86 and calculated for the girders by the formula:

\[ [t] = \alpha t_d, \] (2.2.86-2)

where \( \alpha \) — coefficient equal to 0.6 for longitudinal deck and bottom girders, and 0.5 for other girders.

When using the data in Table 2.2.86, the following shall be considered:

1. If spacing is taken more than 550 mm, the hull member thicknesses stated in the table (except for 5.1) shall be increased by correction value \( \Delta t = \left( a/a_0 - 1 \right) \cdot [t] \), where: \( a \) — actual spacing, mm; \( a_0 \) — normal spacing taken equal to 550 mm; \( [t] \) — tabular permissible residual thickness of an individual hull member;

2. If spacing is taken less than \( a_0 \) and/or hull members are made of higher strength steel, than the member thicknesses specified in the table (except for 5.1) are to be decreased by correction value

\[ \Delta t = \left( 1 - 15.3 a / a_0 \sqrt{R_{yH}} \right) \cdot [t], \] where \( a \), \( a_0 \), \( [t] \) — see above (if \( a > a_0 \), \( a = a_0 \)); \( R_{yH} \) — yield point of the member material, MPa.

Permissible residual thicknesses obtained after application of correction \( \Delta t \) to the tabular values \([t] \) shall not be taken less than thicknesses regulated by 3.5.5.2 of RSSS;

3. For ships of М-СП, М-ПР, М, О-ПР and О classes with a length over 50 m, in case of the transverse framing system in the middle part of ship, residual thickness specified by the table is to be increased: by the value of \( 1.2 \left( L - 50 \right) / 90 \) for bottom plating (see 1.1); by the value of \( 0.7 \left( L - 50 \right) / 90 \) for double bottom plating (see 3.1) and lower plates of inner sides of tankers within the cargo tank area (see 4.6);

Notes. 1. Member plate thicknesses are specified in the table assuming the spacing is equal to 550 mm. 2. The residual thickness of individual shell and deck plating of ships less than 25 m long shall be taken according to the requirements to average residual thicknesses of appropriate member group set forth in Table 3.6.2 of RSSS for ship group II. 3. For ships with a sledge-shaped fore extremity, the provision of 1.6 applies to the hull part extending above the flush part of the bottom in the bow raising area by 4% of the ship’s breadth. 4. Instructions of 1.6 of the table on residual thickness of bottom plating at the fore extremity for ships of M-CPI class are applied to hull section located within 0.2L from the
fore perpendicular. For ships of M-CII class that may operate at sea with wave height limited to 3.5 m, for hull section located within 0.15\(L\) to 0.20\(L\) from the fore perpendicular, the residual thickness is to be reduced down to the values required for the middle part of ship; 

.5 the residual thickness of individual plates of the ice strake for ships with ice reinforcement notation shall be not less than 0.8 of the thickness required by the Rules for respective hull area for ice reinforcement category specified for the ship;

.6 residual thickness of individual plates of the ice strake of ice breakers shall be not less than 0.8 of the design thickness;

.7 regardless of values in the table, residual thicknesses of outer shell and deck plating of tugboats, pushboats, icebreakers (beyond the ice strake), floating cranes, plating of transverse bulkheads of tugboats, pushboats, icebreakers (for sheets adjoining to the side), plating of longitudinal and transverse bulkheads of floating cranes, shall not be less than required average residual thicknesses of respective member group as specified in Table 2.2.86 of RSSS for ship group II;

.8 Bottom plating thickness required by 1.6 for ships of M-CII, M-IIIP and M classes is to be reduced by 0.5 mm in the hull sections where the bottom framing consists of ordinary longitudinal girders and transverse web girders at each spacing;

.9 For ships of M-CII 4.5 class, the hull member thicknesses stated in 1.1, 1.6, 2.1 and 2.3 of Table 2.2.86 shall be increased by value \(\Delta t_{\text{max}}\) determined by the formula:

\[
\Delta t_{\text{min}} = (\sqrt{k_p} - 1) t,
\]

where \(t\) — member permissible residual thickness specified in Table 2.2.86 for ship of M-CII class;

\(k_p\) — coefficient determined according to 2.2.28.

Calculated values of the service life of particular members shall not be less than the planned service life of the ship as specified in the design.

2.2.87 Designed wear rate is calculated by the formula:

\[
e_p = (1 + k_q v)c, \tag{2.2.87-1}
\]

where \(v\) — coefficient of variation of the wear rate:

\[
v = 0.51 - 1.06c; \tag{2.2.87-2}
\]

\(k_q\) — coefficient taken equal to:

0 when verifying the hull global strength using the ultimate moment at the end of the service life;

1.65 when estimating the service life of a particular member;

\(c\) — recommended mean wear rate assigned from Table 2.2.87, mm/year.

When using the data from Table 2.2.87, the following shall be considered:

.1 For inland navigation ships intended for operation in basins of northern and eastern rivers, mean wear rates of the hull members, which are not in contact with carried cargoes, may be halved. In this case, the navigation areas, for which the design mean wear rates of members were reduced because of specific navigation conditions, shall be mentioned in the specification as the areas allowed for navigation;

.2 For river-sea ships of all classes intended for operation in Arctic Ocean seas, mean wear rates of the hull members can be taken as for ships of M, O, P and J classes;

.3 For ships of M-CII class intended for operation in the Baltic and White seas, mean wear rates can be taken as for ships of M-IIIP class;

.4 For ships intended for operation in the Black, Marmara, Ionian, Aegean, Mediterranean, Caspian and Arabian seas (regardless of the main class notation), the recommended mean wear rates of the inner and outer side members shall be taken according to the requirements to ships of M-CII class. For other members, recommended mean wear rates shall be taken not less than those required for ships of M-IIIP class;

.5 If while verifying the strength at the end of service life of ship, mean wear rates were reduced under requirements of 2.2.87.2 and 2.2.87.3, navigation area of the ships subjected to such a reduction shall be mentioned in specification as allowed for navigation.

### 9 Bottom and inner bottom framing

9.1 Vertical keel, bottom stringers, floors and longitudinal bottom girders of single-bottom ships:

- 9.1.1 in vicinity of cargo holds: 0.10 0.07 0.06 0.05
- 9.1.2 in ballast compartments: 0.12 0.08 0.07 0.06
- 9.1.3 in compartments not intended for flooding, including flush deck ships: 0.10 0.07 0.06 0.05
- 9.2 Vertical keel, bottom stringers, floors, bottom and inner bottom longitudinal girders in the double bottom compartments:
  - 9.2.1 not intended for filling: 0.1 0.07 0.06 0.05
  - 9.2.2 in fuel tanks: 0.16 0.13 0.13 0.12
  - 9.2.3 in ballast compartments: 0.12 0.08 0.07 0.06

**Notes:**

1. If no fender guards are provided, the mean wear rate of the outer shell plating shall be doubled.
2. The mean wear rate of the bottom plating of ships intended for operation mostly on shallow waters shall be taken as 0.10 mm/year.

**2.2.88** Local residual deformations (dents) of longitudinal girders together with shell or plating shall be taken into account for the deck of flush deck ships, inner bottom plating and inclined walls of the cargo bunker or inner sides of dry cargo ships.

**2.2.89** Summary width of dents is taken to be equal to the breadth of the structure within the limits of the cargo zone. Camber of an individual dent in a cross-section shall be taken as harmonically distributed between longitudinal web members.

**2.2.90** Maximum camber $h$ at the midpoint between longitudinal web members is calculated by the formula, mm:

$$h = 501 k_s k_p k_k b (\tau - 5)^{0.73} \sqrt{R_{ch} W_b}$$

(2.2.90-1)

where $k_s$ — coefficient taken equal to:

- in case of cross-members between ordinary 0.5 longitudinal stiffeners of the inner bottom plating and the bottom plating fitted in mid of span
- in other cases 1.0

$k_p$ — coefficient taken equal to:
where cargo handling operations by load cranes of lifting capacity 200 kN or more is stipulated

\[ k_k = \text{coefficient taken equal to:} \]

- for cargo decks of flush deck ships \( 1.0 \)
- for inner deck plating of dry cargo ships \( 0.7 \)
- for walls of the cargo bunker and inner sides \( 0.7 \cos \alpha \)

Here, \( \alpha \) — angle of slope of the bunker wall and inner sides with respect to the base plane;

\( b \) — girder length, cm, equal to the distance between transverse web members, on which the girder rests;

\( \tau \) — planned service life of the ship, years;

\( R_{eh} \) — yield point of the girder material, MPa;

\( W_0 \) — stiffener cross-section modulus, cm³:

\[ W_0 = f_\delta (y_0 + 0.05 t_d), \quad (2.2.90-2) \]

where \( f_\delta \) — design cross-sectional area of the girder without effective flange, cm²;

\( y_0 \) — distance between the centre of gravity of the girder cross-section without effective flange and the plating, cm;

\( t_d \) — design width of the effective flange, mm.

2.2.91 Distorted longitudinal girders with effective flanges, whose width is equal to half of the distance between the girders, shall be included into the hull girder with reduction coefficients \( \varphi \), obtained depending on the following parameters:

\( h \) — sag of the deformed girder as per 2.2.90, cm;

\( a \) — distance between girders, cm;

\( \Gamma, k \) — cross-sectional area, cm² and moment of inertia of this area relative to the neutral axis, cm⁴, respectively, of the deformed and worn-off girder with effective flange having width equal to \( a \);

\( z_{max} \) — distance between the extreme flange fiber and the neutral axis of the aforementioned cross-section, cm;

\( \rho \) — radius of inertia, cm:

\[ \rho = \sqrt{F_p / F_p}; \quad (2.2.91-1) \]

\[ E, R_{eh} \] — Young’s modulus and the yield point, respectively, of the girder material, MPa;

\( b \) — girder length, cm, equal to the distance between transverse web members, on which the girder rests;

\( \sigma_k \) — Euler stress in the girder material, MPa:

\[ \sigma_k = \pi^2 E \frac{I_p}{b^4}; \quad (2.2.91-2) \]

\( \sigma_r \) — stress in rigid members at the level of the gravity centre of the cross-sectional area of the girder with effective flange, MPa:

- at tension \( \sigma_r > 0 \)
- at compression \( \sigma_r < 0 \)

\( n \) — relative stress:

\[ n = \sigma_r / R_{eh}; \quad (2.2.91-3) \]

\( p \) — cargo pressure on the plating supported by the girder as per 2.2.19 to 2.2.23.

For girders supporting a shell or plating not under pressure of cargo it shall be taken \( p = 0 \);

\( H_p \) — girder height, cm.

Reduction coefficient \( \varphi_p \) is to be calculated by the formulae:

\[ \varphi_p = \varphi_0 Y k_p \]

\[ \varphi_p = \varphi_0 k_p \]

\[ \varphi_p = \varphi_0 \]

\[ \varphi_p = \varphi_0 X_1 \]

where \( \varphi_0 \) — coefficient obtained from Table 2.2.91;

\[ Y = \frac{a}{b}, \quad X_1 = \frac{a}{b}, \quad k_p = \text{coefficient taken equal to:} \]

- for deck girders of flush deck ships and inner bottom girders \( 1.0 \)
- in other cases \( 0.85 \)

\( n_1, n_2 \) — number obtained by the formula:

\[ \frac{h_i / \rho}{h_i / \rho} \text{ for } \frac{\sigma_k}{\sigma_k} \text{ equal to } \frac{h_i / \rho}{h_i / \rho} \text{ for } \frac{\sigma_k}{\sigma_k} \text{ equal to } \]

</table>

\[ k_p \] — coefficient taken equal to:

- for deck girders of flush deck ships and inner bottom girders \( 1.0 \)
- in other cases \( 0.85 \)

\( n_1, n_2 \) — number obtained by the formula.
\[ n_{1,2} = \pm \left( 1.056 + 0.021 h_0^2 / \rho^2 - 0.145 h_0 / \rho - 0.131 z_{\text{max}} / \rho \right). \quad (2.2.91-5) \]

where number \( n_1 \) is negative, \( n_2 \) is positive; \( X, X_1, Y \) — values calculated by the formulæ:

\[ X = 1 + n \left[ -0.402 + 1.60 h_0 / b - 0.015 \sigma_E / R_{\text{H}} - 0.982 n - 45.2 h_0^2 / b^2 + 0.614 h_0 \sigma_E / (b R_{\text{H}}) - 0.00142 \sigma_E^2 / R_{\text{H}}^2 - 0.362 n^2 \right]; \quad (2.2.91-6) \]

\[ X_1 = 1 + n \left[ 0.400 - 2.90 h_0 / b + 0.0137 \sigma_E / R_{\text{H}} - 0.896 n + 50.1 h_0^2 / b^2 - 0.522 h_0 \sigma_E / (b R_{\text{H}}) + 0.00123 \sigma_E^2 / R_{\text{H}}^2 + 0.329 n^2 \right]; \quad (2.2.91-7) \]

\[ Y = 1 - 1 \cdot 10^{-3} p a b^2 H_p \times \left( 0.0271 + 0.169 h_0 / b - 0.00292 \sigma_E / R_{\text{H}} / (I_p R_{\text{H}}) \right) / (I_p R_{\text{H}}). \quad (2.2.91-8) \]

When any coefficient is calculated by formulæ (2.2.91-6) to (2.2.91-8) as negative, it shall be taken equal to zero, and when as positive, it shall be taken equal to one.

2.2.92 Reduction coefficients of plates in vicinity of dents, in case of the longitudinal framing system, shall not be taken higher than reduction coefficient of deformed longitudinal girders included into the bearing contour of those plates, as determined as per 2.2.91.

Reduction coefficients of plates in vicinity of dents, in case of the transverse framing system, except for cargo decks of flush deck ships and inner bottom plating of dry cargo ships, shall be taken from Table 2.2.98. Reduced parts of plates of cargo decks of flush deck ships and inner bottom plating of dry cargo ships, in case of the transverse framing system, are not included into the hull girder.

2.2.93 To ensure the global strength by ultimate moment \( M_{\text{ul,w}} \) with due regard to wear and local residual deformations of the hull members, the following condition shall be met:

\[ |M_{\text{ul,w}}| > K_w |M_d|, \quad (2.2.93) \]

where \( K_w \) — safety coefficient by ultimate moment taking into account wears and local residual deformations of the hull members; \( M_d \) — design bending moment at sagging and hogging, kN·m.

2.2.94 Coefficient \( K_w \) in the strength condition (2.2.93) is taken equal to coefficient \( K_s \) as stipulated in 3.3 Appendix 1 to RSSS.

2.2.95 For cargo ships, it is necessary to verify additionally the global strength by ultimate moment \( M_{\text{ul,w}} \) taking into account wear and local residual deformations of the hull members, using the following equation:

\[ |M_{\text{ul,w}}| > k_{\text{ul,w}} DL, \quad (2.2.95) \]

where \( k_{\text{ul,w}} \) — ultimate moment coefficient taking into account wear and local residual deformations of the hull members.

2.2.96 Values of the coefficient \( k_{\text{ul,w}} \) at the end of ship’s service life shall be taken from Table 2.2.96.

2.2.97 Requirements of 2.2.93 to 2.2.95 shall be met during the entire planned service life of the ship.

2.3 DESIGNING OF THE HULL

General requirements

2.3.1 When designing the hull, a principle of alignment of members in the same plane shall be complied with in order to compose closed structures like: carling — transverse bulkhead web stay — keelson; deck/platform longitudinal girder — transverse bulkhead ordinary stay — double bottom/platform longitudinal girder; floor — frame — beam; side
stringer – transverse bulkhead shelf – longitudinal bulkhead shelf, etc.

2.3.2 Thickness, height, cross-section and shape of hull members shall have smooth transitions.

A difference of thickness of adjacent plates shall not exceed 30% of the thickest of the joined plates or 5 mm, whichever is less. The said does not concern plates forming seams, as well as thickened plates placed at ends of superstructures, under anchor hawsepipes or under the ship machinery. The thicker edge shall be beveled down to thickness of the thinner plate according to applicable national standards^1^.

2.3.3 Transition of heights of webs of girders and stiffeners from higher to lower or vice versa shall be arranged over a part whose length shall be at least five-fold difference in web heights for keelson and carling webs in the middle part of ship, and at least two-fold difference in web height for other members.

Girder flanges shall have similarly smooth transition between each other.

2.3.4 It is necessary to ensure the continuity of most possible number of main longitudinal members.

2.3.5 Transition from one framing system to another shall be smooth. Not more than 1/3 of ordinary longitudinal girders and not more than two longitudinal web members placed on the bottom or under the deck may be interrupted in the same cross-section of the hull. Sections where longitudinal members are interrupted shall be at least two spacings apart from each other.

2.3.6 Longitudinal members shall not be terminated in areas weakened by cutouts or in stress concentration areas, e.g. in way of rounded corners or rectangular cutouts, ends of superstructures, or longitudinal coamings.

2.3.7 At the ends of decks, platforms, double bottom plating or longitudinal bulkheads, knees or other structures shall be fitted to relief stress concentration (Fig. 2.3.7).

---

^1^ GOST 8713, GOST 52640, GOST 14771

Fig. 2.3.7 Design of ends of decks, platforms, inner bottom plating, longitudinal bulkheads

2.3.8 Ends of stiffeners shall extend to a transverse member and reinforced by knees.

The ends of the following members may be mitered:

- .1 counter-vibration stiffeners;
- .2 stiffeners supporting webs of members;
- .3 ordinary stays of transverse bulkheads in ships with the transverse framing system, except for peak bulkheads and engine room bulkheads;
- .4 ordinary stays of longitudinal bulkheads in ships with the longitudinal framing system.

Stiffeners shall not be mitered at the ends near a cutout with non-reinforced edge, including cutouts for ordinary girders.

^Note^: End mitering means machining the ends of ordinary members (stays), stiffeners, and flanges of web members, knees and brackets as shown in Fig. 2.3.8.
2.3.9 Longitudinal web girders shall be terminated at transverse bulkheads or transverse web members.

At the opposite side, a knee shall be fitted with a length of at least 1.5 height of the terminated girder; this knee shall extend to a transverse web girder and be welded to it. The knee height shall be equal to the height of the terminated girder with the decrease at the end down to 1/4 of that height. Web thickness and flange dimensions of the knee shall be the same as for the terminated girder. The flange shall be mitered (Fig. 2.3.9, a and b). When the terminated web girder is transiting to an ordinary longitudinal girder, the knee may not be extended to a transverse girder (Fig. 2.3.9, c).

2.3.10 In case of the longitudinal framing system of deck, bottom or platform, ends of ordinary frames shall be reinforced with knees to be extended to nearest longitudinal girders.

In case of the combined framing system of sides (see 2.4.33), where ordinary frames attach to side stringers or platforms, knees shall be fitted in the frame planes.

In case of the combined or longitudinal framing systems of sides, knees shall be provided between web frames at the bilge and at the side-to-deck connection; those knees shall be placed in the plane of each actual frame and be extended to the nearest longitudinal girders.

2.3.11 Structural measures shall be taken in order to increase strength and rigidity of hull structures, which in operation are subject to local concentrated or impact loads not taken into consideration in the strength calculations, for instance, deck (in vicinity of bearing drum), sides and bottom of floating cranes; extremities of pushboats and pushed ships; decks of flush deck ships; inner bottom and inner sides of dry cargo ships, etc.

Designing of framing girders

2.3.12 Girders whose webs are in the same plane (beam and frame, frame and floor, etc.), shall be connected by knees fitted in the plane of their webs, and the web girders themselves shall be welded to each other. Ordinary transverse girders may be connected by overlapping knees.

When connecting web girders, knees shall overlap the members for at least the height of the smaller girder, and for ordinary girders – for at least twice height of the smaller girder (for overlapping knees, the overlap is measured from the girder flange). Thickness of the knees connecting web and ordinary girders shall be not less than thickness of the web of the smaller connected girder. Thickness of
knees connecting ordinary girders may be reduced: for non-flanged knees – by 1 mm for girder web thickness of 7 to 9 mm inclusive and by 2 mm for girder web thickness of 10 mm and more; for flanged knees and knees with welded strip — by 1 mm for girder web thickness of 6 to 8 mm and by 2 mm for girder web thickness of 9 mm and more.

2.3.13 Knees fitted in web girder connections shall have a mitered flange/strip at their free edge. For the rest cases, the free edge shall be reinforced if the length of a welded side of the knee/bracket exceeds 35-fold thickness of the knee/bracket. The thickness of strip welded to knee shall be not less than the knee web thickness, and its width shall be not less than 8-fold thickness of the strip but not less than 40 mm at one side from the welding line. The flange thickness shall be not less than 8-fold thickness of the knee but not less than 40 mm. Maximal width of the flange measured from the knee web shall not exceed 10-fold its thickness. The cross-sectional area of the knee flange in the web girder junction shall be not less than 0.8 of cross-sectional area of flange of the smaller connected girder.

2.3.14 In the places of intersection of web girders with bulkheads, the former shall be supported from both sides by knees overlapping them at a length at least equal to their height. Webs and flanges of girders shall be welded to the bulkhead plating. For bulkheads of the engine room and the extremities, as well as bulkheads taking alternating loads, girder flanges shall be mitered.

2.3.15 Ordinary members shall go through cutouts in non-tight web members or non-tight bulkheads. Web of an ordinary girder shall be welded to web of a non-tight web member or non-tight bulkhead, or the members shall be connected by means of knees, plates (Fig. 2.3.15-1), stiffeners or by combination of the said methods.

The knee thickness shall be taken according to 2.3.12, the thickness of plate and/or stiffener shall be not less than the thickness of web of the web girder or bulkhead.
knee shall have a bent flange regardless of the thickness and dimensions of the knee sides (Fig. 2.3.16).

![Fig. 2.3.16. Intersection between ordinary girder and watertight web member](image)

Legs of the knee shall be at least 1.5 of the height of ordinary girder, and stiffener height shall be at least 0.6 of height of this girder. Requirements for stiffeners stated in 2.3.20 shall also be met. Misalignment of knee or stiffener from the plane of unsymmetrical profile web shall not exceed the weld leg plus 1 mm.

In case of attached framing structure, the ordinary girders made of angle bars may be connected with web girders by means of welding the flanges by two welds. When using bulb profiles as ordinary members, the connection shall be made with knees.

For attached (two-tier) framing, finished rolled or welded I-beams or channel beams, as well as bent channels with same-width flanges may be used as web girders.

2.3.17 In order to form drain openings near the transverse members, the bottom and deck longitudinal girders may be not extended to the webs of respective members. The distance between the web end and member's web shall not exceed 10-fold thickness of the bottom plating but not exceed 100 mm, whichever is less. Longitudinal ordinary girders shall be connected according to 2.3.16.

2.3.18 Ends of ordinary members, which interrupt at bulkheads or web members, shall not be welded to non-reinforced plates via knees. There shall be a stiffener in the plane of knee (Fig. 2.3.18-1) or a stiffener made of a flat or a rolled profile shall be placed at the end of one of the knees; this stiffener shall extend to the nearest girders (Fig. 2.3.18-2). The stiffener ends may be mitered.

The knee supporting the end of ordinary girder at the transverse web girder shall be extended to the flange of the latter. A process gap of 10 to 20 mm may be provided (Fig. 2.3.18-3).

![Fig. 2.3.18-1. Eliminating dead point at the ends of knees using vertical stiffener](image)

![Fig. 2.3.18-2. Eliminating dead point at the ends of knees using horizontal stiffener](image)
The side of the knee or bracket to be welded to the flange of web girder shall not be extended to the free edge of the flange by 10 to 20 mm.

Where reaching the outer plating, the flanges of web members shall be mitered, and a gap of 10 to 20 mm shall be provided between the end of the flange and the plating.

2.3.19 Where three mutually perpendicular structures (e.g. a platform, longitudinal bulkhead and transverse bulkheads) intersect, knees or stiffeners shall be fitted in order to spread loads arising in the intersection point (Fig. 2.3.19).

2.3.20 Webs of web members, where ratio of height $h$, cm, to thickness $t$, cm, exceeds $80\sqrt{235/R_{eh}}$ (where $R_{eh}$ — yield point of the girder material), shall be reinforced by stiffeners fitted perpendicular or parallel to flanges of the web members so that the following conditions are met:

1. distance between the supporting stiffeners $S$, cm, fitted perpendicular to web member flanges shall not exceed:

$$S = (0.24 \frac{h}{t} - 9.5) \frac{h\sqrt{R_{eh}/235}}{(h/t - 75\sqrt{235/R_{eh}})};$$

(2.3.20.1)

2. area moment of inertia of the stiffeners fitted perpendicularly to the web member flanges, including effective flange, cm$^4$, shall be not less than:

$$i = 0.1St^3 \frac{KS}{h},$$

(2.3.20.2)

where $K$ — coefficient taken from Table 2.3.20.2;

<table>
<thead>

3. area moment of inertia of the stiffeners fitted in parallel to the web member flanges, including effective flange, cm$^4$, shall be not less than:

$$i = 5.1 \cdot 10^{-7} R_{eh} \left( f + at \right)^2,$$

(2.3.20.3)

where $R_{eh}$ — yield point of the stiffener material, MPa;

$f$ — cross-section area of the stiffener (excluding effective flange), cm$^2$;

$a$ — distance between supporting stiffeners, cm;

$l$ — length of supported part of the web, cm.

The stiffeners may be made of flat if their height to thickness ratio does not exceed 10; here, web height shall be not less than 50 mm and the thickness not less than 0.8 of the thickness of the web to be supported.

The $h/t$ ratio for webs of web members subject to high local loads (side framing of all ships; deck framing of flush deck ships to be
2.3.21 Web member web thickness shall be not less than stated in Table 2.3.21-1 depending on the adjacent plating thickness.

<table>

When the plating thickness is 12 mm and more, the web thickness may be made 4 mm less than the plating thickness.

The web thickness of web members adjacent to the deck stringer or coaming of open ships may be reduced by more than stated above but not less than one-half of the thickness of said adjacent plates.

Thickness of webs of web members of cargo ships with a length of 50 m and more shall be taken not less than stated in Table 2.3.21-2.

<table>
<thead>

2.3.22 Thickness of girder’s welded flange shall not exceed the doubled web thickness. Width of symmetrical flange shall not exceed 24-fold its thickness, and width of single-sided flange shall not exceed 12-fold thickness. Thickness of bent flange shall be taken within 8- to 12-fold its thickness.

For L-shaped profiles, the flange width to flange thickness ratio shall not exceed 30. Width of additional small flange shall be not less than 30 mm.

2.3.23 When calculating the section modulus and the area moment of inertia of unsymmetrical girder with bent flange, flange area \(f_f\) shall be multiplied by coefficient \(\varphi\) determined by the formula:

\[
\varphi = \left(1 + \frac{3}{1 + 12\left[\frac{h}{\left(10\eta\beta\right)}\right]^4 \left(\frac{f_w}{f_f}\right)^2 \left(t/f\right)}\right)^{-1},
\]

where \(l\) — span of the beam, cm; 
\(\eta\) — coefficient depending on end attachment method and taken equal to:
- for both ends constrained 1.5
- with one end is constrained and the other one is freely resting 1.25
- for both ends freely resting 1
\(h\) — web height, cm; 
\(f_w\) — cross-sectional area of the web, cm\(^2\); 
\(f_f\) — cross-sectional area of the flange, cm\(^2\); 
\(t\) — flange thickness, cm; 
\(b\) — flange width, cm.

Cutouts in hull structures

2.3.24 Rectangular cutouts in longitudinal members shall be rounded in their corners with a radius of not less than 0.1 of the cutout width. Radii of rounding of cargo hatch cutouts in main decks enclosed by continuous longitudinal coamings may be reduced down to 0.5 m.

2.3.25 Cutouts in longitudinal members shall be arranged with the longer side lengthways the ship.

2.3.26 Members in way of cutouts shall be ended at a specially fitted member and welded to the it (Fig. 2.3.26). Where there are several cutouts, they shall be arranged on the same line along the ship so far as practicable and not in the same cross section.
2.3.27 Cutouts in girder webs are not allowed in vicinity of supports and knees. The cutouts shall be at least 50% clear of the girder depth from the knee end.

2.3.28 Summary height of cutouts in webs of web girders for passing ordinary girders shall not exceed 0.5 of the web member depth. Where webs of girder are connected by welding and cutout is reinforced by a plate, the height of such a cutout may be increased up to 0.6 of depth of the web member. In way of double sides, height of cutout may be taken equal to 0.6 of depth of the web half-beam. The total height of cutouts for passing ordinary members through webs of continuous floors and keelsons of the double bottom and continuous web frames of “diaphragms” and double side platforms shall not exceed 0.4 of the depth (width) of the said members.

The height of lightening cutouts and access cutouts shall not exceed 50% and width shall be not exceed 75% of the web member depth in the given place.

The distance from edges of all cutouts in web members to edges of cutouts for passing ordinary girders shall not be less than the depth of those girders.

2.3.29 The height of drainage openings in members shall not exceed 20% of the girder depth, and the length shall not exceed 15-fold thickness of the shell or plating.

2.3.30 Web member web weakened by a cutouts shall be reinforced by stiffeners fitted in parallel to girder flanges with area moment of inertia, including effective flange, not less than that defined by formula (2.3.20.3).

2.3.31 Stiffeners provided in 2.3.30 for girders with cutouts may be omitted, if the cutouts are of a circle shape, their diameter does not exceed 20% of web girder depth, and they are located at a distance at least than double girder depth from each other or from other cutouts.

2.3.32 Web member web section adjacent to the inner side, transverse or longitudinal bulkheads shall be reinforced by sloping stiffeners (Fig. 2.3.32); the cutout shall be made in the middle of the web to be supported. The sloping stiffeners shall have a cross-sectional area $f$ (without effective flange) not less than, $cm^2$:

$$f = \left(12.7V - F_w \tau_0 \right)/\left(2R_{el} \sin \alpha\right)$$

and area moment of inertia $i$ of stiffeners, including effective flange, not less than, $cm^4$:

$$i = 5.1 \cdot 10^{-7} R_{el} \left[ f + h t / (6 \sin \alpha) \right] h^2 / \sin^2 \alpha,$$

where $V$, $F_w$ — shear force, kN, and the weakest cross-section of the girder web, $cm^2$, correspondingly;

$\tau_0$ — dangerous tangent stress of web material according to (2.2.67-2), MPa;

$R_{el}$ — yield point of the stiffener material, MPa;

$h$, $t$ — depth and thickness of the web, correspondingly, cm;

$\alpha$ — angle of slopping of the stiffeners regarding to neutral axis of the web, deg.

2.3.33 Corrugated structures may be used for watertight and permeable bulkheads of the hull and subordinate structures not participat-
ing in global bending, i.e. enclosures, walls and roofs of wheelhouses.

2.3.34 A strength of corrugated structures shall not be less than the strength of relevant flat structures.

2.3.35 Corrugates of hull watertight bulkheads shall be continuous of trapeze (Fig. 2.3.35, a) or wavy (Fig. 2.3.35, b) cross section.

Corrugates of transverse bulkheads shall be located vertically and corrugates of longitudinal bulkheads shall be located either horizontally or vertically. Where corrugates of a longitudinal bulkhead are vertically, the bulkhead is not included in the hull girder.

2.3.36 At the ends of knees of girders adjacent to corrugated platings, transverse stiffeners shall be provided (extended to the nearest edges of the corrugates), shelves or other structures to distribute concentrated load from the knee corners (Fig. 2.3.36).

Welding joints

2.3.37 Butts of the outer shell and deck plating shall not be located directly in places of increased stress concentration, i.e. in corners of large cutouts, e.g. in the vicinity of the ends of foundations.

2.3.38 Welds shall not be congested, i.e. intersect at acute angles, or failure to comply with requirements of 2.3.39.

2.3.39 The distance between parallel intersection butt and fillet welds shall be at least $10t$ for plate thickness $t = 3$ to $10$ mm and $100$ mm for $t > 10$ mm.

The distance between parallel butt and fillet welds inside a section shall be at least $30$ mm.

Fig. 2.3.35. Types of corrugate cross-sections of watertight bulkheads:

a) trapeze; b) wavy

Fig. 2.3.36. Example of distribution of the concentrated load at the knee ends
2.3.40 The angle between two butt welds shall be over 60°.

2.3.41 Assembling joints of deck plating and outer shell of sections and blocks shall be in the same plane.

2.3.42 Where hull elements are butt welded, the welds shall be fused through entire thickness of the connected parts.

2.3.43 For T-joint welds loaded by tensile load and subject to vibration, variable or impact loads, continuous double-sided welds shall be applied with full fusion of the abutting web.

2.3.44 Types of T-welds in hull structures are stated in Table 2.3.44-1.

Table 2.3.44-1

2.3.45 Welds shown in Table 2.3.44-2 may be replaced by welds of equal strength of other type with different dimensions of design features in accordance with national standards¹.

2.3.46 Numbers of T-welds for hulls of ships intended for operation in various water basin categories are to be specified according to Table 2.3.46.

2.3.47 On tug-and-push boats and pushed ships, the framing shall be welded by continuous welds to the outer shell and the deck in area of coupling arrangements.

2.3.48 For T-joints loaded by tensile load, weld No. 1 shall be used to ensure strength (both shear and tensile) equal to the abutting web.

1 GOST 2.312, GOST 14771, GOST 5264

2.3.49 Free ends of webs of ordinary girders and free ends of stiffeners, in case of one side welding, shall be continuously welded around, and the weld shall pass over to the other side for at least double depth of the girder/stiffener.

In case of one side welding, ordinary girder webs in way of cutouts and cutouts in bulkheads shall be continuously welded around, and weld shall pass over to the other side for at least double height of profile.

<td>2 3</td>
</tr>
</tbody>
</table>

2.3.50 Cutouts shall be provided in webs of web members in places of their intersection with plating welds, if these platings are to be welded after installation of the members.

2.3.51 Dotted welds as per Table 2.3.44-2 are not allowed in the underwater part of the hull, as well as in way of local vibration and impact loads (in vicinity of engine room, propellers, ice strengthening, fore extremity).

2.3.52 Weld No. 2 shall be used to connect ordinary members to webs of web members, permeable bulkheads, enclosures and platforms, where the ordinary members pass through cutouts and no knees (plates, stiffeners) are provided.

2.3.53 Ends of web girders (i.e. webs and free flanges) not supported by knees shall be connected by weld No. 2 over a length equal to the girder profile depth.

For intercostal web girders (floors, beams, keelsons, carlings, stringers), the ends are understood as sections adjacent to intersecting members (sides, bulkheads, trusses) being the rigid supports for the girders.

Ends of ordinary girders not supported by knees shall be connected by weld No. 2 over a length equal to double girder profile depth.

2.3.54 At the girder areas supported by knees (within distances a and a’ from support to the outer edge of the knee, Fig. 2.3.54), girder webs shall be connected to flanges and
plates by welds whose numbers are specified equal to the numbers of welds of the knees.

2.3.55 T-welds of coupling arrangements and stops shall be double-side continuous.

2.3.56 Welded joints shall be made in accordance with the requirements of 7 Part X of the Rules.

2.3.57 Flanges of the deck and bulkhead penetrations shall be welded to watertight bulkheads and decks at both sides by continuous welds.

### 2.4 ARRANGEMENT, SCANTLING AND CONSTRUCTION OF INDIVIDUAL HULL MEMBERS

#### Thickness of plates and spacing

2.4.1 Thickness of members shall be not less than that specified in Tables 2.4.1-1 to 2.4.1-4.

For ships of M-ΠΠ, O-ΠΠ, M and O classes with a length over 50 m, in case of the transverse framing system in the middle part of ship, minimal thickness specified by the Table 2.4.1-1 shall be increased: by 1.2 (L – 50)/90 for bottom plating (see 1.1, Table 2.4.1-1); by 0.7 (L – 50)/90 for double bottom plating (see 3.1, Table 2.4.1-1) and lower plates of inner sides of tankers within the cargo tanks area (see 4.10, Table 2.4.1-1).

Bottom plating thicknesses required by 1.5 in Tables 2.4.1-1 and 2.4.1-2 for ships of M-СΠП, M-ΠΠ and М classes may be reduced by 0.5 mm in the hull areas where the bottom framing consists of longitudinal girders and transverse girders at each spacing.

Requirements to minimum thickness of outer shell in the fore extremity for ships of M-СΠΠ class (1.5 and 1.6, Table 2.4.1-2) apply to the ships that may operate at sea with minimum draught $T_f < 0.035L$. In case of larger minimum draught, the outer shell thickness in the fore extremity shall be taken according to the requirements of Table 2.4.1-1 for ships of M-ΠΠ and М classes.

</table>

**Notes.**

1. For ships with a sledge-shaped fore extremity, the provision of 1.5 applies to the hull part extending above the flush part of the bottom in the bow raising area by 4% of the ship’s breadth.
2. The minimum values of Member plate thickness comply with spacing of 550 mm and are to be adjusted taking into account the actual spacing in accordance with the requirements of 2.4.3 and 2.4.4.
3. The rounding rule is stated in Note 2 to Table 2.4.1-1.

</tr>
</tbody>
</table>

**Notes.** 1. The plate thicknesses are given for structures made of steel.
2. The rounding rule is stated in Note 2 to Table 2.4.1-1.
3. In case of ship length does not coincide with values specified in the table, the minimum plate thicknesses are determined by linear interpolation of the tabulated data.

### Table 2.4.1-4

<table>
<thead>
<tr>
<th>Name of members</th>
<th>Minimum thicknesses of member plates, mm, at ship length, m</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>25</td>
</tr>
<tr>
<td>1. Outer shell plating in the middle part of ship and aft extremity</td>
<td>5.0</td>
</tr>
<tr>
<td>2. Sheer strake and deck stringer in the middle part of ship</td>
<td>6.0</td>
</tr>
<tr>
<td>3. Outer shell plating of forepeak</td>

</tr>
<tr>
<td>6. Upper deck plating in fore and aft extremities within 0.15L from the fore and aft perpendiculars</td>
<td>5.5</td>
</tr>
<tr>
<td>7. Platform plating</td>
<td>4.5</td>
</tr>
<tr>
<td>8. Watertight bulkhead plating</td>
<td>5.0</td>
</tr>
</tbody>
</table>

**Notes.** 1. Values of minimum thicknesses of member plates correspond to spacing of 550 mm and shall be corrected for the actual spacing according to the requirements of 2.4.3 and 2.4.4.
2. The rounding rule is stated in Note 2 to Table 2.4.1-1.
3. In case of ship length does not coincide with values specified in table, the minimum thicknesses of the member plates are determined by linear interpolation of the tabulated data.

Thickness of deck and shell plating of superstructures stated in Table 2.4.1-3 in area of their interconnection shall be increased by 1 mm over a width not less than 300 mm.

Thickness of upper deck plating stated in Table 2.4.1-4 except for areas in extremities (6, Table 2.4.1-4) at spacing equal to 550 mm shall be taken not less than 5.5 mm for any ship length.

For ships of M-CII 4.5 class, the hull member thicknesses stated in 1.1, 1.5, 2.1 and
2.3 of Table 2.4.1-2 shall be increased on the value $\Delta t_{\text{min}}$ determined by the formula:

$$\Delta t_{\text{min}} = \left( \sqrt{R_p} - 1 \right) t,$$  \hspace{1cm} (2.4.1-1)

where $t$ — permissible residual thickness of member as specified in Table 2.2.86 for ship of M-CP class;

$k$ — coefficient determined according to 2.2.28.

For tankers of M-CP class with longitudinal cylindrical built-in cargo tanks, minimum thicknesses of outer plating in the middle part of ship, sheer strake and deck stringer in the middle part of ship shall be taken according to Table 2.4.1-2 as for ships with conventional length $L_1 = LH/H_1$, where $H_1$ — height of hull girder. Vertical distance between the upper edge of the cylindrical tank and the deck in the centreline plane shall not exceed $1.2R$.

Plate thicknesses of walls and decks of superstructures and wheelhouses of the M-CP class ships regardless of calculation results and steel grade shall not be less than those specified in Table 2.4.1-3. Here:

1. if spacing is taken more than 550 mm, the minimum thicknesses of grillage plates stated in Table 2.4.1-3 shall be increased proportionally to the increase of spacing compared with 550 mm;

2. if spacing is taken less than 550 mm, the minimum thicknesses of grillage plates stated in Table 2.4.1-3 may be decreased proportionally to the decrease of spacing compared with 550 mm. Thicknesses may not be decreased by more than 10%;

3. if the structure is made of light alloys, the minimum thicknesses of its plates shall be taken not less than it is required for correspondent structure made of steel.

Plate thicknesses of hull members of tugboats and ice breakers of the M-CP class regardless of calculation results and steel grade shall be not less than those specified in Table 2.4.1-4.

The requirements of 2.5.15 to 2.5.22 apply to the tugboats of the M-CP class. The plate thickness of hull members in any cases shall not be less than specified in Table 2.4.1-4, and additional increase by 1 mm of thickness of watertight bulkheads as regulated by 2.5.20 is not required.

For tugboats of the M-CP 4.5 class, member thicknesses specified in 1, 4 and 6 of Table 2.4.1-4 shall be increased by $\Delta t_{\text{min}}$ as determined by formula (2.4.1-1).

2.4.2 Spacing means a distance between longitudinal or transverse girders; it shall not exceed 650 mm. Recommended spacing is 550 mm.

2.4.3 Where spacing is taken more than $a_0$, than the thicknesses of the hull members specified in Table 2.4.1-2 (other than stated in 4.9, 4.12, 5.1 to 5.3) shall be increased by $\Delta t$ as determined by the formula, mm:

$$\Delta t = \left( a/a_0 - 1 \right) [t],$$  \hspace{1cm} (2.4.3)

where $a$ — actual spacing, mm;

$a_0$ — standard spacing taken equal to 550 mm;

$[t]$ — permissible residual thickness of a particular hull member as specified in Table 2.2.86 (without corrections set forth by Notes 2 and 3 of the said table), mm.

2.4.4 Where spacing is taken less than $a_0$ and/or the members are made of higher strength steel, than the thickness of the hull members specified in Table 2.4.1-2 (other than stated in 4.9, 4.12, 5.1 to 5.3) may be reduced by $\Delta t$ as determined by the formula, mm:

$$\Delta t = \left[ 1 - 15.3a/a_0 \sqrt{R_{\text{st}}} \right] [t],$$  \hspace{1cm} (2.4.4)

where $a, a_0, [t]$ — see above (if $a > a_0$, $a = a_0$);

$R_{\text{st}}$ — yield point of the member material, MPa.

2.4.5 Width of the thickened strakes of bulkheads (see 4.5, 4.7, 4.9, 4.12 of Table 2.4.1-1) shall not be less than 0.6 m.

2.4.6 Thicknesses specified in 1.4 and 2.2 of Table 2.4.1-1 are related to ships with side depth $H \geq 2.5$ m. Width of the sheer strake shall not be less than $0.2H$, and width of the deck stringer not less than 0.6 m.

When $H < 2.5$ m, the width of the sheer strake may be taken equal to the thickness of the outer shell.
2.4.7 Thicknesses of plate structures subject to specific wear and damages (i.e. increased mechanical wear, increased wear of deck plat- ing and framing in way of tanks of tankers carrying sulfide oil products, high corrosion wear due to carriage of corrosive cargoes) shall be increased as compared with Tables 2.4.1-1 and 2.4.1-2 depending on the actual wear rates.

2.4.8 Thicknesses of the bottom shell plat- ing and the bilge strake of ships intended for operation in shallow waters shall be increased by 1 mm in respect to those specified in 1.1 to 1.3 and 1.5 of Table 2.4.1-1.

2.4.9 Plate thickness change in the transition areas shall be smooth (see 2.3.2).

Bottom framing in single-bottom ships and single-bottom compartments

2.4.10 The distance between the floors, m, shall be aliquot to the spacing and shall not exceed:

for flush deck ships 1.8
for passenger ships and tankers 2.4
for ships of other types 2

2.4.11 Section modulus of floor including effective flange W, cm³, shall not be less than:

\[ W = 7k_1k_2dB_1^2(T + r), \] (2.4.11-1)

and for ships of Ι class, in addition, not less than

\[ W = 7k_1k_2dB_1^2(0.6T + 0.72), \] (2.4.11-2)

where \( k_1, k_2 \) — coefficients taken from Tables 2.4.11-1 and 2.4.11-2;

\( d \) — distance between the floors, m;

\( B_1 \) — value to be taken equal to the greatest distance between longitudinal bulkheads (trusses) or between them and ship side, m.

For three or four longitudinal bulkheads (trusses), value \( B_1 \) shall be taken not less than B/3, for five or more longitudinal bulkheads (trusses) not less than B/4. Where longitudinal bulkheads (trusses) are not available, \( B_1 \) is taken equal to B;

2.4.12 In case of the transverse framing system of the bottom with floors not at each spacing, bottom ordinary frames shall be installed between them.

The section modulus of the bottom ordinary frame, cm³, including effective flange, shall not be less than:

---

1 Water area where the depth to ship draught ratio does not exceed 3.
and the moment of inertia, cm\(^4\), not less than:
\[
I = 3\left[2 - a/(d - a)\right](t/a)^3 \times c^4, \tag{2.4.12-2}
\]
where:
- \(a\) — spacing, m;
- \(c\) — maximum distance between keelsons or between keelson and longitudinal bulkhead (or side), m;
- \(t\) — bottom plating thickness according to 2.4.1, cm;
- \(T, r, d\) — taken according to 2.4.11.

2.4.13 A continuous central keelson shall be fitted in all ships. Instead of the central keelson, two keelsons may be fitted, one from each side of the centre line. Here, coefficient \(k_1\) in formulae (2.4.11-1) and (2.4.11-2) shall be taken same as when the central keelson is fitted. A distance between keelsons and between keelsons and the side or longitudinal bulkhead shall not exceed 2.5 m. The keelsons shall be extended as far as possible forwards and abaft. Section modulus of the central and side keelsons shall be not less than section modulus required for floors.

2.4.14 In case of the longitudinal framing system, bottom stiffener section modulus, cm\(^3\), including effective flange, shall be not less than:
\[
W = 10a_1d^2 \times (T + r), \tag{2.4.14-1}
\]
and the moment of inertia, cm\(^4\), shall be not less than
\[
I = 2.8d^2 \times (f + 100a_1t), \tag{2.4.14-2}
\]
where:
- \(a_1\) — distance between the stiffeners, m;
- \(f\) — cross-section area of the stiffener without effective flange, cm\(^2\);
- \(d, T, r\) — see 2.4.11, \(t\) — see 2.4.12.

2.4.15 In ships with deadrise, a depth of floors amidships within \(0.125B\) from side shall be not less than a half of its depth in the centre line.

2.4.16 In ships with deadrise, floors in way of bilge shall rise smoothly towards the side starting at least \(0.05B\) from the side, in order to get a connection with a ordinary side frame. The depth of such a rising measured over the side (from the floor upper edge line extended to side) shall be not less than three-fold depth of the ordinary side frame. If this rising of floors is arranged using knees, their thickness shall be equal to the floor thickness; in addition, free edge of the knee shall be fitted with the same strip as the floor, or a flange shall be bent out.

### Bottom framing in double bottom compartments

2.4.17 The distance, m, between floors shall be aliquot to the spacing and shall not exceed:
- for dry cargo ships within cargo holds 1.8
- for passenger ships and tankers 2.4
- for dry cargo ships outside the cargo holds area and for the rest types of ships 2.4

2.4.18 The height of the double bottom space, m, shall be not less than the following for ships with a length:
- \(120\) m and less 0.8
- over \(120\) m 0.9

2.4.19 In double bottom compartments of all ships, continuous centre keelsons, and — if it is provided by the Rules — side keelsons shall be fitted.

A distance between keelsons and between keelsons and the side or longitudinal bulkhead shall not exceed 3 m. The keelsons shall be extended as far as possible forwards and abaft.

2.4.20 Minimum thickness of the floor plates shall correspond to 5.1 and 5.2 of Tables 2.4.1-1 and 2.4.1-2.

2.4.21 In case of the transverse framing system with floors not at each spacing, bracket floors shall be fitted between them.

2.4.22 The bracket floors shall consist of upper and lower continuous girders interconnected by brackets in way of keelsons (longitudinal bulkheads) and at the bilge.

2.4.23 Edges of brackets shall have welded or bent flanges. Thickness of the brackets shall be not less than the floor thickness.

2.4.24 Ends of the upper and lower girders of the bracket floors shall overlap the brackets...
over at least double depth of the corresponding girder (Fig. 2.4.24).

**2.4.25** Width of the brackets at both sides of the vertical keel and at the bilge shall be at least 0.5 height of the double bottom space. Width of the brackets near keels shall be at least 0.3 height of the double bottom space. The use of intercostal girders at the bracket floors is allowed, which are cut in way of kee. In this case, brackets shall be fitted at each side of the keels, width of the brackets shall be not less than 0.3 height of the double bottom space.

**2.4.26** Cross-members may be installed between the brackets to connect the upper and lower girders of the bracket floor and divide the span of bracket floor girder in two halves. Cross-sectional area of the cross-member shall be not less than the cross-sectional area of the smaller bracket floor girder.

**2.4.27** Section modulus of the lower girder of bracket floor, cm$^3$, including effective flange, shall be at least

\[ W = 5.5K_0a_1s_1^2(T + r), \]  

(2.4.27-1)

Section modulus of the upper girder of bracket floor, cm$^3$, including effective flange, shall be at least

\[ W = 4K_0a_1^2H_c, \]  

(2.4.27-2)

and for cargo ships at least

\[ W = 0.4K_0a_1^2p \]  

(2.4.27-3)

In the above formulae:
- \( s_1 \) — the greatest distance between inner edges of the brackets, m;
- \( H_c \) — depth of the ship’s side in the section under consideration, m;
- \( p \) — cargo pressure on the double bottom plating to be taken according to 2.2.23.4, kPa;
- \( a \) — see 2.4.12,
- \( T, r \) — see 2.4.11.

**2.4.28** In case of the longitudinal framing system of the bottom, section modulus of bottom longitudinal girders, including effective flange, cm$^3$, shall be not less than

\[ W = 10K_0a_1d^2(T + r), \]  

(2.4.28-1)

and the moment of inertia, cm$^4$, shall be not less than

\[ I = 2.8d^2(f + 100a_1t), \]  

(2.4.28-2)

Section modulus of double bottom longitudinal girders, including effective flange, cm$^3$, shall be not less than:

\[ W = 7K_0a_1d^2H_c, \]  

(2.4.28-3)

and for cargo ships, in addition, not less than

\[ W = 0.7K_0d^2p \]  

(2.4.28-4)

In the above formulae:
- \( K_0, H_c, p \) — taken as per 2.4.27;
- \( a_1, f \) — see 2.4.14;
- \( d, T, r \) — see 2.4.11;
- \( t \) — see 2.4.12.

**2.4.29** Cross-sectional area of a cross-member fitted between the bottom and the double bottom longitudinal girders shall be not less than a cross-sectional area of the smaller of the girders being so connected.

---

![Fig. 2.4.24. Design of bracket floor](image-url)
2.4.30 In ships intended for carriage of bulk cargoes and loaded/unloaded with clamsheells, the section modulus of the upper girder of bracket floors \( W_1 \) and double bottom longitudinal girders \( W_2 \) including effective flange, cm³, within the cargo hatches shall be not less than

\[
W_1 = 91ka_s, \quad (2.4.30-1)
\]

where \( a, s \) are taken according to 2.4.27;

\[
W_2 = 91ka_d, \quad (2.4.30-2)
\]

where \( a_1, d \) are taken according to 2.4.28;

\( k \) — coefficient taken, for cranes with the following lifting capacity, kN, equal to:

<table>
<thead>
<tr>
<th>Lifting Capacity</th>
<th>Coefficient</th>
</tr>
</thead>
<tbody>
<tr>
<td>50</td>
<td>0.5</td>
</tr>
<tr>
<td>100 and 160</td>
<td>1.0</td>
</tr>
<tr>
<td>200</td>
<td>1.5</td>
</tr>
</tbody>
</table>

In case of cross-members as per 2.4.26, the values of \( W_1 \) and \( W_2 \) may be reduced by 30%.

2.4.31 Where the double bottom terminates at the inner side, the floor depth in double bottom space near the inner side shall be equal to the double bottom height. A smooth transition shall be provided from the inner bottom plating to free flange of that floor by means of scalloped or attached knees fitted in the plane of the floor flange. Width of the scalloped knee or the total width of the flange and attached knees (where they are connected to the inner side) shall be at least 0.25 of the distance between the floors. The knee thickness shall be taken equal to the double bottom plating thickness. The knee thickness may be reduced by 2 mm if the double bottom plating is thickened for loading/unloading with clamsheells.

2.4.32 In case of the longitudinal framing system of the bottom and the double bottom extended to the outer side, at the section between floors in the plane of each actual frame, bilge brackets shall be provided and extended to the nearest longitudinal girders of the bottom and the double bottom. The thickness of the brackets shall be taken equal to the thickness of the floors.

### Side framing

2.4.33 The side framing shall be made according to the following framing systems: transverse framing system where web frames alternate with ordinary frames; uniform transverse framing system with web frames; combined framing system, i.e. longitudinal framing system in the upper and the lower areas of the side and transverse system in the middle area of the side).

2.4.34 Web frames shall be installed in the floor planes.

The distance between the web frames shall not exceed values specified for floors.

2.4.35 Web frame web depth in single-bottom compartments shall be not less than 0.65 of the floor depth. Cross-sectional area of web frame's free flange in single-bottom compartments shall be not less than 0.65 of cross-sectional area of the floor's free flange.

2.4.36 Section modulus of a web frame including effective flange, cm³, shall be not less than

\[
W = 10kH_{sec}d, \quad (2.4.36-1)
\]

where \( k \) — coefficient determined by the formulae:

\[
k = \sqrt{2+0.085L}, \quad (2.4.36-2)
\]

for all types of ships other than tankers

\[
k = \sqrt{2+0.050L}, \quad (2.4.36-3)
\]

for tankers

where \( H_{sec} \) — depth of the ship’s side in the section under consideration, m;

\( d \) — distance between web frames, m.

2.4.37 Section modulus of ordinary frame including effective flange, cm³, shall be not less than

\[
W = 12kla, \quad (2.4.37)
\]

where \( k \) — coefficient taken according to 2.4.36;

\( l \) — the greatest distance measured over a side between the bottom (double bottom plat- ing) and a side stringer, between side stringers, or between a side stringer and the deck, m;

\( a \) — spacing, m.
2.4.38 In case of uniform transverse side framing system, the section modulus of a frame including effective flange, \( \text{cm}^3 \), shall be at least
\[
W = 14kH_e a, \tag{2.4.38}
\]
where \( k \) — coefficient taken according to 2.4.36.

2.4.39 At the ends of frames, beam and bilge knees shall be installed.

A beam knee of an ordinary frame or a frame, in case of the uniform transverse side framing system, shall overlap the bilge rounding. The height of a bilge knee shall be such as a frame overlaps the knee over a length of its double depth.

If the section modulus of bottom ordinary frames is not less than that required for side ordinary frames, then the bottom frames may be extended upwards along the bilge and side and no bilge knees may be installed.

2.4.40 In ships with double bottom and single sides, web and uniform frames shall be terminated at the inner bottom by means of knees with dimensions corresponding to requirements of 2.3.12. Knees fitted in the girder web plane may be replaced by attached or scalloped knees located in the girder flange plane. The total width of attached knees plus flange or width of scalloped knee shall be at least three-fold flange width. In the plane of these knees below the inner bottom plating, either stiffeners or brackets shall be installed.

2.4.41 Section modulus of the side longitudinal stiffeners including effective flange, \( \text{cm}^3 \), shall be at least
\[
W = 6kd^2, \tag{2.4.41}
\]
where \( k \) and \( d \) are taken according to 2.4.36.

2.4.42 Where the side depth \( H_s \) exceeds 2 m, one side stringer shall be fitted; where the side depth is 4 m and more, at least two side stringers shall be fitted. Where side depth exceeds 2 m and there are two fender guards fitted, a side stringer shall be fitted at the level of the lower fender guard. When a ship is fitted with fender strips, a side stringer is mandatory. Scantlings of side stringers shall be not less than those required for web frames or side frames, in case of the uniform transverse framing system.

2.4.43 In order to enlarge the designed area of the hull girder's upper flange, in case of the transverse side framing system, it is allowed to fit mitered intercostal longitudinal stiffeners (made of the profile used for ordinary frames) along the sheer strake and the upper part of the inner side. Stiffeners may be made of a flat with a thickness equal to the plating thickness and having a height equal to maximum 10 times the thickness. The distance between ends of the stiffeners and the frames shall not exceed 30 mm.

Intercostal longitudinal stiffeners are not included into the hull girder, while their effective flanges are.

2.4.44 The inner side plating shall either be extended to the bottom plating, or, when it terminates on the double bottom plating, be prolonged in the double-bottom space as an additional keelson.

Both transverse and longitudinal systems of the inner side framing are permitted. Scantlings of the web and ordinary members shall be not less than those required for the outer side without taking into account ice strengthening.

2.4.45 In double-sided ships, platforms may be fitted instead of inner and outer side stringers situated at the same level, and diaphragms may be fitted instead of web girders. Thickness of the platforms and diaphragms shall be in compliance with 2.3.21, and when the double-bottom space is used as a ballast tank, to be in compliance with 2.4.1. Cutouts for manholes sized according to 2.3.28 shall be made to provide access to all double bottom areas. Platforms and diaphragms shall be reinforced by stiffeners according to 2.3.20 and 2.3.30. The height of cutouts in the diaphragms may be increased provided that additional reinforcements are available, which will provide section moduli for the framing members as required by the Rules.

2.4.46 Required section moduli of web girders of inner and outer sides may be reduced by 30% if one platform is provided or
by 50% if two platforms are provided. The section moduli may be reduced in a similar way if one or two cross-members are fitted. The minimal cross-member cross section area \( F, \text{ cm}^2 \), shall be at least

\[
F = 0.22dH^2, \quad (2.4.46-1)
\]

and minimal area moment of inertia of cross-member \( I, \text{ cm}^4 \) shall be at least

\[
I = 0.25H^2dl^2, \quad (2.4.46-2)
\]

where \( H \) — side depth, m;

\( d \) — web spacing, m;

\( l \) — length of the cross-member span, m.

**Deck framing**

2.4.47 Web beams shall be fitted in the plane of each web frame, as well as in the planes of transverse coamings of cargo hatches, trunks of engine rooms and in way of reinforcements under the deck machinery and arrangements.

2.4.48 Section modulus of the beams with effective flange, \( \text{cm}^3 \), shall be not less than:

1. for parts of decks intended for cargo stowage,

\[
W = 0.1k_0k_1k_2dB_1^2p, \quad (2.4.48.1-1)
\]

where \( k_0 \) — coefficient equal to:

- for ordinary beams, where loading and unloading by clamshells are not provided
- for ordinary half-beams
- for web beams
- for web half-beams of single-sided ships

\( k_1 \) — coefficient, which for ordinary beams and half-beams shall be taken as \( k_1 = 1 \) and for web beams from Table 2.4.11-1 where instead of the word “keelson” the word “carling” shall be read;

\( k_2 \) — coefficient, which for ordinary beams and half-beams shall be taken as \( k_2 = 1 \) and for web beams from Table 2.4.11-2 where instead of the word “floor” the word “beam” shall be read;

\( d \) — spacing for ordinary beams and half-beams; distance between adjacent web beams or half-beams for web beams and half-beams, m;

\( B_1 \) — the greatest distance, m;

between sides or between a side and a longitudinal bulkhead (truss) or between the bulkheads (trusses) – for web beams;

between carlings or between a carling and a longitudinal bulkhead (side) – for ordinary beams. The value \( B_1 \) for web beams shall be taken not less than \( B_1/3 \) in case of three or four longitudinal bulkheads (trusses), and not less than \( B_1/4 \) in case of five or more longitudinal bulkheads (trusses);

\( p \) — design cargo pressure, kPa, determined by the formula

\[
p = 9.81M/f, \quad (2.4.48.1-2)
\]

where \( M \) — maximum weight of cargo, t, that may be placed onto the given loaded deck part;

\( f \) — area of the given loaded part of the deck, \( \text{m}^2 \).

If there is a number of pillars installed in the hull between the side and the longitudinal bulkhead (truss), the value of \( W \) may be reduced by 20%. The distance between the pillars shall not exceed the double distance between the floors.

The pressure \( p \) shall be not less than the cargo pressure obtained in accordance with 2.2.19. If loading and unloading by clamshells are provided, the value of \( W \) for web beams shall be not less than that obtained according to 2.4.48.5;

2. for deck parts of tankers in the cargo tanks area

\[
W = k_0k_1k_2dB_1^2, \quad (2.4.48.2)
\]

where \( k_0, k_1, k_2 \) — coefficients (see 2.4.48.1);

3. for open parts of decks not intended for cargo stowage for all types of ships other than tankers:

\[
W = k_0k_1k_2dB_1^2, \quad (2.4.48.3)
\]

where \( k_0 \) — coefficient equal to:

- for ordinary beams of ships of M-СП, М-ПП, М, О-ПП and О classes
- for ordinary beams of ships of P and JI classes
- for ordinary beams of ships of M-СП, М-ПП, М, О-ПП and О classes
- for ordinary half-beams of ships of P and JI classes

between sides or between a side and a longitudinal bulkhead (truss) or between the bulkheads (trusses) – for web beams;

between carlings or between a carling and a longitudinal bulkhead (side) – for ordinary beams. The value \( B_1 \) for web beams shall be taken not less than \( B_1/3 \) in case of three or four longitudinal bulkheads (trusses), and not less than \( B_1/4 \) in case of five or more longitudinal bulkheads (trusses);

\( p \) — design cargo pressure, kPa, determined by the formula

\[
p = 9.81M/f, \quad (2.4.48.1-2)
\]

where \( M \) — maximum weight of cargo, t, that may be placed onto the given loaded deck part;

\( f \) — area of the given loaded part of the deck, \( \text{m}^2 \).

If there is a number of pillars installed in the hull between the side and the longitudinal bulkhead (truss), the value of \( W \) may be reduced by 20%. The distance between the pillars shall not exceed the double distance between the floors.

The pressure \( p \) shall be not less than the cargo pressure obtained in accordance with 2.2.19. If loading and unloading by clamshells are provided, the value of \( W \) for web beams shall be not less than that obtained according to 2.4.48.5;

2. for deck parts of tankers in the cargo tanks area

\[
W = k_0k_1k_2dB_1^2, \quad (2.4.48.2)
\]

where \( k_0, k_1, k_2 \) — coefficients (see 2.4.48.1);

3. for open parts of decks not intended for cargo stowage for all types of ships other than tankers:

\[
W = k_0k_1k_2dB_1^2, \quad (2.4.48.3)
\]

where \( k_0 \) — coefficient equal to:

- for ordinary beams of ships of M-СП, М-ПП, М, О-ПП and О classes
- for ordinary beams of ships of P and JI classes
- for ordinary beams of ships of M-СП, М-ПП, М, О-ПП and О classes
- for ordinary half-beams of ships of P and JI classes
for web beams of ships of M-СП, M-
P, M, O-ПП and О classes
for web beams of ships of P and І clases
for web beams of single-sided ships of
M-СП, M-ПП, M, O-ПП and О classes
for web half-beams of ships of P and І clases

2.4.49 Depth of web of a web beam or web
half-beam shall be taken not less than 2/3 of
that of a web frame near the deck. Cross-
sectional area of free flange of a web beam or
web half-beam shall be not less than 0.75 of
cross-sectional area of free flange of the web
frame near the deck.

2.4.50 Area moment of inertia of a web
beam with effective flange, cm4, shall be not
less than

\[ I = 3B_W \]  

Moment of inertia, cm4, of an ordinary
beam or a half-beam shall be not less than
that defined by formula (2.4.12-2), where:
\[ c \] — the greatest distance between carlings
or between a carling and a longitudinal bulk-
head (side), m;
\[ t \] — deck plating thickness, cm.

2.4.51 Section modulus of longitudinal un-
der-deck stiffeners with effective flange, cm3,
shall be not less than:

\[ W = k_1a_d \]  

1. for deck parts intended of cargo stow-
age in ships where loading and unloading by
clamshells are not provided
\[ W = 115ka_s, \]  

2. for decks of flush deck ships where
loading and unloading by clamshells are pro-
vided:
\[ W = 115ka_d, \]  

3. for deck parts of tankers in the cargo
tanks area
\[ W = 115ka_d, \]  

4. for open parts of decks not intended
for cargo stowage for ships of all types of
M-СП, M-ПП, O-ПП, M and О classes
other than tankers:
in the middle part of ship
\[ W = 15a_d^2, \]  

\[ W = k_1a_d^2 \]  

where \( a_1 \) — distance between the stiffeners, m;
\[ d \] — distance between web beams, m;
\( p \) is taken according to 2.4.48.1;

\[ W = 15a_d^2, \]  

k is determined according to 2.4.30.

\[ W = 15a_d^2, \]  

where \( L_b/B_1 < 0.7 \), dimensions of web
beams shall be taken equal to that of carlings
deﬁned according to 2.4.53.

Here, \( L_b \) — distance between transverse
bulkheads or trusses.
in fore and aft extremities

\[ W = 7.5a_{1}d^{2}, \quad (2.4.51.4-2) \]

for ships of P and J classes in the middle part of ship

\[ W = 10a_{1}d^{2}, \quad (2.4.51.4-3) \]

in fore and aft extremities

\[ W = 5a_{1}d^{2}, \quad (2.4.51.4-4) \]

.5 for enclosed parts of the hull decks intended for passengers and crew accommodation, for ships of all classes, in the middle part of ship

\[ W = 2.5a_{1}d^{2}; \quad (2.4.51.5-1) \]

in fore and aft extremities

\[ W = 2.5a_{1}d^{2}; \quad (2.4.51.5-2) \]

.6 for parts of superstructure decks not participating in global bending and intended for passengers and crew accommodation

\[ W = 2.5a_{1}d^{2}. \quad (2.4.51.6) \]

For top decks of superstructures and wheelhouses not intended for cargo stowing and non-accessible for passengers, the value of \( W \) may be reduced by 30% in comparison with that calculated by the formula (2.4.51.6).

2.4.52 Area moment of inertia of under-deck stiffeners with effective flange, \( \text{cm}^4 \), shall be not less than:

\[ i = 0.0127R_{e1} \left( f + 100a_{1}t \right) d^{2}, \quad (2.4.52) \]

where \( R_{e1} \) — yield point of the material, MPa;

\( f \) — cross-section area of the under-deck stiffener without effective flange, \( \text{cm}^2 \);

\( t \) — deck plating thickness, cm;

\( a_{1}, d \) are taken according to 2.4.51.

2.4.53 Scantling of carlings where \( L_{b}/B_{1} \geq 0.7 \) shall be not less than the scantlings required for web beams.

Section modulus of carling \( W, \text{cm}^3 \), where \( L_{b}/B_{1} < 0.7 \) shall be not less than:

.1 for parts of decks intended for cargo stowage

\[ W = 0.72k_{1}k_{2}b_{1}l_{c}^{2}p, \quad (2.4.53.1) \]

where \( k_{1} \) — coefficient equal to 1 for one web beam supporting the carling and is determined from Table 2.4.53-1 for three or more beams;

\( k_{2} \) — coefficient determined from Table 2.4.53-2;

2.4.54 Carlings shall be installed in the same planes with keelsons.
2.4.55 The width of a cutout in the deck shall not exceed 0.70 ship's breadth $B$ in the given place. The cutout may be increased up to 0.85$B$, when special measures are taken (increase in transverse framing strength, installation of double sides with half-bulkheads, reduction of cutouts' length).

2.4.56 Where the width of hatch cutout exceeds 0.70$B$, longitudinal coamings of hatches shall be continuous along the whole length of all holds and shall be terminated with knees having a length at least two heights of the coaming. Longitudinal coamings fitted along the length of each hatch shall be terminated with knees of a length equal to at least two heights of the coaming if the longitudinal coaming it is not smoothly conjugated with transverse coamings or if the longitudinal coaming is conjugated with transverse coaming by a horizontal knee with free flange fitted in the deck plane.

2.4.57 Coaming webs shall be in the same plane with the carling web.

2.4.58 No butt welds or cutouts may be located near corners of the hatches arranged in the middle part of ship within the area with dimensions shown on Figs. 2.4.58, where $r$ — rounding radius of hatch corner according to 2.3.24, $b_0$ — width of hatch.

2.4.59 Vertical brackets shall be fitted to coaming webs in the planes of web beams. The width of brackets at the deck level shall be not less than web beam height or half-height of the coaming, whichever is less, but not less than the width of the coaming flange. The upper edge of the bracket shall be welded to the coaming flange. Strips or flanges supporting the free edge of the bracket shall be mitered and not reach the coaming web, and near the deck they shall be mitered or widened and welded to the plating; here, stiffeners or brackets eliminating “dead points” shall be fitted on the reverse side of the plating.

2.4.60 Upper edges of coamings shall be reinforced by a strip or a profile to ensure adequate buckling strength of coaming plates. Where the coaming height to thickness ratio exceeds 40, the coaming web shall be reinforced also by horizontal stiffeners in accordance with 2.3.20.3.

2.4.61 Cargo hatch coaming plates shall be extended to the level of the lower edge of web beams, and the lower edge of coaming shall have a bent flange with the width in the range of 8 to 12 times the thickness of the coaming.

2.4.62 Single cutouts in designed deck located between the side and the line of cargo hatches in the middle part of ship, shall be located well away from the corners of openings of cargo hatches and machinery space trunks, as well as from end bulkheads of superstructures. When the width (diameter) of the cutout exceeds 20--fold thickness of the deck plating or 0.05 of the width of continuous part of deck as per Fig. 2.2.32 (whichever is less), the opening shall be reinforced in such a way that deck strength properties with cutout are not worse than without cutout.

**Fig. 2.4.58. Deck areas where butt welds may not be located**
Watertight bulkheads

2.4.63 The number and location of strong watertight transverse bulkheads shall be determined depending on ship operation area, type and purpose.

In ships, for which, according to 4 Part II of the Rules, floodability shall be provided, the number and location of watertight transverse bulkheads and half-bulkheads shall be substantiated by respective floodability calculations.

2.4.64 In all ships, forepeak and afterpeak transverse watertight bulkheads shall be provided.

The forepeak bulkhead shall be fitted abaft the fore perpendicular at a distance not less than the half-breadth of the hull. For ships with more than 14 m in breadth, the forepeak length may be reduced based on technical reasons.

2.4.65 For pushed ships suitable for being coupled to pushboat by either extremity, both peak transverse bulkheads shall comply with the requirements of the Rules specified for the forepeak bulkhead.

2.4.66 Self-propelled ships shall have watertight transverse bulkheads bounding the engine room.

2.4.67 All the transverse watertight bulkheads shall be extended from the bottom to the freeboard deck.

2.4.68 No doors or manholes in the forepeak and afterpeak bulkheads are allowed. If doors or manholes are made in other watertight transverse bulkheads, they shall be watertight and capable of being closed from both sides, and, moreover, they shall be capable of being closed from the main deck in ships, for which special floodability requirements are laid down.

2.4.69 All pipes, cables, moving parts of steering ropes going through watertight bulkheads shall be laid in bulkhead cups using sealing glands or other structures that ensure watertightness of the bulkheads.

2.4.70 For dry cargo ships, the minimal number of watertight transverse bulkheads, including forepeak and afterpeak bulkheads, shall be as follows depending on ship length, m:

<table>
<thead>
<tr>
<th>Number of bulkheads</th>
<th>20 to 60</th>
<th>61 to 80</th>
<th>81 to 100</th>
<th>≥101</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td></td>
</tr>
</tbody>
</table>

2.4.71 In double-bottomed and doublesided ships, double side watertight half-bulkheads (diaphragms) shall be fitted for at least in each 15 spacings. The thickness of half-bulkheads shall be assigned as per 2.4.45, and their framing shall meet the requirements of 2.4.74, 2.4.75, 2.4.77, 2.4.78.

2.4.72 The flush deck ships shall be fitted with longitudinal bulkhead in the centre plane and trusses or pillar rows maximum 2.5 m apart. The distance between pillars shall not exceed the double distance between the floors.

For ships less than 50 m in length, a truss may be installed in the centre plane instead of longitudinal bulkhead.

In addition to transverse bulkheads as per 2.4.70, transverse trusses shall be fitted in these ships. The distance between transverse trusses or between transverse trusses and bulkhead shall not exceed 12-fold spacing for ships with a side depth of 2.5 m or less, and 18-fold spacing for ships with a side depth over 2.5 m.

2.4.73 Watertight bulkheads may be either flat or corrugated. Minimal thickness of watertight bulkhead plating shall be not less than specified in Tables 2.4.1-1, 2.4.1-2 and 2.4.1-4.

2.4.74 Flat bulkheads shall be reinforced by framing.

Transverse bulkhead stays fitted in the planes of keelsons and carlings shall be web stays.

If carlings and keelsons are in different vertical planes, partial web stays may be fitted, which are extended to the nearest shelf and have a transition to ordinary stays as per Fig. 2.3.9(c), and in case of horizontal stiffeners, they shall be terminated by a knee, which has
2 Structure and Strength of Steel Hull

2.4.75 Where side stringers are fitted, shelves shall be installed in the same planes on bulkheads.

Section modulus of a shelf with effective flange shall be not less than the required section modulus of a side stringer.

2.4.76 Ordinary stays of the forepeak bulkhead shall be fitted not more than 0.6 m apart from each other. On other bulkheads, ordinary stays shall be fitted not more than 0.75 m apart from each other.

In case of the longitudinal framing system of the deck and bottom, ordinary stays of transverse bulkheads shall be fitted in the planes of deck and bottom ordinary longitudinal girders and be attached to them by knees.

2.4.77 For watertight bulkheads, the section modulus of ordinary vertical stays with effective flange shall be not less than the required section modulus of an ordinary frame with effective flange required by 2.4.37.

2.4.78 Section modulus of horizontal stiffeners of watertight bulkheads with effective flange shall be not less than that required by formula (2.4.41); the value of \( d \), m, shall be taken equal to the distance between vertical web stays.

2.4.79 For longitudinal bulkheads, the area moment of inertia of the uppermost horizontal stiffener with effective flange shall be not less than required for decks as per 2.4.52.

2.4.80 Corrugated bulkheads shall be so designed as to meet the following instructions:

1. corrugated transverse bulkheads in hull shall be installed onto continuous tight floors or directly onto bottom plating or double bottom plating.

Centre lines of vertical corrugates of a transverse bulkhead shall coincide with planes of webs of the keelsons adjoining to the bulkhead.

Carlings, keelsons and ordinary longitudinal stiffeners of the deck and the bottom shall be attached to corrugations by means of knees (see 2.3.36);

2. bulkheads with vertical corrugations shall be reinforced by shelves fitted in the plane of side stringers.

Bulkheads with horizontal corrugations shall be reinforced by web stays fitted in the planes of web frames;

3. bulkhead corrugations shall have the section modulus not less than required by 2.4.77 and 2.4.78;

4. section moduli of corrugations (Fig. 2.3.35), cm³, are calculated by the following formulae:
   for trapeze corrugations
   \[
   W = th(a + b/3);
   \] (2.4.80.4-1)
   for wavy corrugations
   \[
   W = \gamma R^2,
   \] (2.4.80.4-2)
   where
   \[
   \gamma = \left( \beta_0 + 2\beta_0 \cos^2 \beta_0 - 1.5 \sin 2\beta_0 \right) / (1 - \cos \beta_0),
   \] (2.4.80.4-3)
   where \( \beta_0 \) — corrugation angle (see Fig. 2.3.35);

5. corrugations shall be sized in such a way (see Fig. 2.3.35) that the following ratios are fulfilled:
   for trapeze corrugations
   \[
   a/t < 55 \quad \text{when} \quad a \geq b,
   \]
   \[
   b/t < 55 \quad \text{when} \quad a < b;
   \] (2.4.80.5-1)
   for wavy corrugations
   \[
   R/t < 65.
   \] (2.4.80.5-2)

Pillars and trusses

2.4.81 Cross-sectional area of a pillar or a brace, m², shall be not less than an area calculated by the formula
\[ F = 98.1 \cdot 10^{-4} \frac{fm}{(nR_{eH})}, \quad (2.4.81-1) \]

where \( f \) — area of the deck or a platform supported by the pillar, including cargo hatches in the area under consideration, m\(^2\);

\( n \) — coefficient determined from Table 2.4.81 depending on the value \( N \) calculated by the formula

\[ N = \beta \sqrt{fm/(\eta_l l)}; \quad (2.4.81-2) \]

\( \beta \) — coefficient taken equal to:

- for a tubular section 1.00
- for a square box section or cross-shaped section made of two equal-sided angle bars 0.61
- for a single equal-sided angle bar 0.44

\( \eta_l \) — coefficient equal to:

\[ \eta_l = \frac{R_{eH}}{235}; \quad (2.4.81-3) \]

\( l \) — pillar length, m;

\( R_{eH} \) — yield point of steel, MPa.

\( m \) — coefficient, for decks of cargo compartments of tankers \( m = 1.0 \), for dry-cargo ships decks intended for cargo stowage is determined by the formula

\[ m = M/f, \quad (2.4.81-4) \]

for parts of decks not intended for cargo stowing

\[ m = 0.5j; \quad (2.4.81-5) \]

where \( M \) — maximum weight of cargo, t, distributed over the deck area \( f \);

\( j \) — number of decks supported by the pillar.

2.4.82 The minimal area moment of inertia of a pillar or a brace, cm\(^4\), shall be not less than that determined by the formula

\[ I = \beta^2 F^2, \quad (2.4.82) \]

where \( \beta \) — coefficient determined according to 2.4.81;

\( F \) — cross-sectional area of a pillar or a brace calculated according to 2.4.81.

2.4.83 Pillars made of several shaped profiles shall be installed on connecting spacers placed every 1 meter or closer. Ends of pillars supporting cargo decks and decks of tankers shall be fastened to the bottom and deck framing by four knees; ends of pillars supporting other decks may be fastened only by two knees. The height of these knees shall be not less than the double height of pillars’ cross section.

2.4.84 Pillars shall be installed where floors intersect with keelsons and carlings with beams. If this is impracticable, where a pillar is installed outside a keelson to floor intersection, members of the same scantling as main web members in the given place extended to the nearest web members from both sides shall be installed under the pillar on the bottom. The like structure shall be where a pillar is connected with deck web members. No cutouts are allowed in webs of keelsons or floors just below pillars.

2.4.85 For flanged members, the pillar’s axis shall coincide with vertical webs of the members. The tubular pillars installed onto the flanged members shall be supported by horizontal knees.

2.4.86 Pillar axes shall be arranged in the same vertical plane in superstructure spaces and below the main deck.

2.4.87 Structure of transverse and longitudinal trusses (see Fig. 2.2.55) shall be formed by floors and beams or by keelsons and carlings, correspondingly, connected by pillars and braces.

2.4.88 Longitudinal and transverse members (keelsons plus carlings and floors plus beams, correspondingly) forming chords of
longitudinal or transverse trusses shall be made of T-profiles.

2.4.89 Knees or brackets shall be installed at ends of braces and where braces intersect with each other. Knees or brackets shall be sized in such a way as to end of the brace could be fastened to them over a length equal to the double height of the profile. The thickness of knees (brackets) shall be not less than thickness of the respective chord of the truss.

2.4.90 Braces made of several same profiles shall have at least three connecting spacers for trusses according to Fig. 2.2.55(a) and 2.2.55(b) and at least two connecting spacers for trusses according to Fig. 2.2.55(c).

2.4.91 Pillars of trusses shall be fabricated according to the instructions of 2.4.82 to 2.4.86.

**Hull framing in engine room**

2.4.92 Continuous floors shall be installed at each frame. A distance between web frames and beams shall not exceed 3-fold spacing. The spacing shall not exceed the spacing in the middle part of ship.

Bottom, side and deck members shall meet the requirements of 2.4.10 to 2.4.62, and their scantlings shall be not less than those required for respective members in the middle part of ship regardless of allowance for loading and unloading by clamshells.

Members in the engine room shall have an appropriate structural bond with members in the compartments adjacent to the engine room.

In engine room of ships of M-CTI class, each second frame shall be web frame, and section modulus \( W \) of carling with effective flange, \( m^3 \), for engine room shall not be less than:

\[
W = 5.8 \times 10^{-6} a_1 d_1^2, \tag{2.4.92}
\]

where \( a_1 \) — average breadth of the deck area supported by the carling, m;

\( d_1 \) — maximum carling span measured between transversal bulkheads or pillar centres and transversal bulkhead, m.

Profile of cross-section of beams of ships of M-CTI class shall be taken same as for carlings.

2.4.93 No floors or keelsons with bent flanges shall be used.

2.4.94 The engine room floor web thickness shall exceed the required thickness of the floor web in the middle part of ship by at least 1 mm. For dry cargo ships, the floor web thickness in the middle part of ship is determined in this case regardless of allowance for loading and unloading by clamshells.

2.4.95 The number and location of keelsons shall correspond to location of machinery foundations and keelsons in adjacent compartments.

One of the longitudinal girders of main engine foundations shall coincide with one of the keelsons. Where it is impracticable to have keelsons coinciding with longitudinal girders of main engine foundations, additional keelsons shall be fitted throughout the whole length of the engine room in the plane of longitudinal foundation girders (from bulkhead to bulkhead), and these keelsons shall be connected with vertical web stays of transverse bulkheads.

Scantlings of engine room keelsons shall be not less than those of floors.

**Framing of extremities**

2.4.96 Framing system in fore and aft extremities shall be transverse. In ships with sledge-shaped contours, longitudinal framing may be used in the forepeak and the afterpeak areas with floors two spacings apart.

The scantling shall be not less than that required for framing in the middle part of ship; here, requirements of 2.4.97 to 2.4.99 shall be met.

The distance between girders shall not exceed the respective values for the middle part of ship.

2.4.97 Framing of the fore extremity shall be made with due regard to the following instructions:
floors in the fore extremity shall be fitted at each transverse spacing which shall not exceed 550 mm. The floor web thickness shall exceed that required in the middle part of ship by 1 mm.

Floors installed in ordinary frame planes abaft from forepeak bulkhead within 0.2L from the fore perpendicular of ships of M-CP class shall have web thickness equal to thickness of webs of floors fitted in web frame planes, and height not less than 1/3 of height of double bottom in this area and not less than 2.5 of height of ordinary longitudinal girders. Free edges of these floors shall be reinforced by welded bent flanges.

For ships to be moored by bow to a non-equipped shore, the forepeak floor web thickness shall exceed that required by the Rules in the middle part of the ship by 2 mm.

For ships with a sledge-shaped or spoon-shaped fore extremity, section modulus of a floor including effective flange as calculated by formula (2.4.11-1) or (2.4.11-2) shall be increased by 1.5 times; here, $B_1$ is determined at the level of the floor flange nearest to the forepeak bulkhead. In ships with wedge-shaped fore extremity, the floor height shall be not less than 80% of the floor height in the middle part of ship;

the centre keelson shall be connected with the stem and stern and, where there is a transom, it shall be connected with the transom web stay.

Keelson profile sizes shall be not less than floor sizes;

distance between web frames shall not exceed two spacings.

Section modulus of web frames and ordinary frames shall be increased by 25% as compared with that determined by formulae (2.4.36-1) and (2.4.37);

forepeak of ships of M-CP class shall be provided with not less than three carlings. The web height of carlings and web beams shall be not less than 2.5 heights of ordinary beams;

Section modulus $W$ of ordinary beam with effective flange, for ships of M-CP class, within 0.2L from the fore perpendicular, $m^3$, shall be not less than:

$$W = 5.5 \cdot 10^{-6} dB_1^{1.5},$$  \hspace{1cm} (2.4.97.5)

where $d$ — distance between beams, m;

$B_1$ — maximum beam span measured between carlings or between carlings and a longitudinal bulkhead or side, m;

side stringers shall be installed in accordance with c 2.4.42.

Where a side stringer terminates at the stem, they shall be connected by a breasthook of thickness equal to the stringer thickness.

The length of the breasthook shall not be less than one spacing. Sizes of breasthook's free flange shall correspond to sizes of the side stringer's free flange.

If fore draught of a ship of M-CP class is less than 3.5% of ship length, the bottom structure reinforcement as per requirements of .1 to .6 shall be provided for 0.2L abaft the fore perpendicular.

2.4.98 The spacing in the afterpeak shall not exceed 550 mm.

In ships of M-CP, M-PI, O-PI, M, O and P classes, floors in afterpeak shall be installed at each frame. Floors shall be extended above propeller shaft or stern tube at a height of not less than half diameter of the opening in the floor web. They may be also extended to propeller shaft or stern tube, above which transverse connecting flats with flanges shall be welded to frames; the strip thickness shall be equal to the floor thickness (Fig. 2.4.98).

Keelons shall be extended as far abaft as possible as the continuation of keelons and foundation girders of the engine room. The distance between web frames shall not exceed two spacings.

Ships with full aft contours shall be fitted with cant frames located perpendicular to the shell plating. The distance between radial frames shall not exceed the spacing taken for the middle part of ship.

Section modulus of web frames and ordinary frames including effective flange shall be increased by 15% as compared with that determined by formulae (2.4.36-1) and (2.4.37).
2.4.98 Design of floor located below the propeller shaft

For ships of M-СП class, the above mentioned reinforcements shall be provided from the aft bulkhead of the engine room to fore extremity including afterpeak.

2.4.99 Ends of pushed ships shall be reinforced in such a way that loads from supports are distributed uniformly to sides and longitudinal hull members.

In the plane of supports, longitudinal bulkheads or trusses shall be installed, which shall be strongly connected with the hull and extended to the forepeak (afterpeak) bulkhead. Closed frame rings shall be arranged in the area of supports.

Stems, sterns, keels, propeller shaft brackets

2.4.100 Scantlings of a stem made of steel flats below the load waterline shall be not less than, mm:

\[
\begin{align*}
t &= 12 + 0.4L; \\
a &= 64 + 1.5L \quad \text{when } L \leq 50m; \\
a &= 90 + 1.0L \quad \text{when } L > 50m;
\end{align*}
\]

for ships of M-СП, M-ПП, О-ПП, М, О classes and tugboats/pushboats of all classes

\[
\begin{align*}
t &= 10 + 0.2L; \\
a &= 55 + 0.5L \quad \text{when } L \leq 50m; \\
a &= 30 + 1.0L \quad \text{when } L > 50m;
\end{align*}
\]

where \( t \) — flat thickness, mm; 
\( a \) — flat width, mm.

2.4.101 Diameter of the stem made of steel bars below the load waterline shall be not less than, mm:

for ships of M-СП, M-ПП, О-ПП, М, О classes and tugboats/pushboats of all classes

\[
d = 46 + 0.96L;
\]

(2.4.101-1)

for ships of P and J класс except for tugboats/pushboats

\[
d = 32 + 0.63L.
\]

(2.4.101-2)

2.4.102 The cross-sectional area of stems made of steel equal-sided angle bars below the load waterline shall be not less than, cm²:

for ships of M-СП, M-ПП, О-ПП, М, О classes and tugboats/pushboats of all classes

\[
F = 11 + 0.22L;
\]

(2.4.102-1)

for ships of P and J класс except for tugboats/pushboats

\[
F = 7 + 0.22L.
\]

(2.4.102-2)

2.4.103 Stem cross-sectional area above the load waterline may be reduced gradually down to 70% of that determined by the formulae (2.4.102-1), (2.4.102-2) at the upper end.

Where a stem consists of several parts, their butt connection shall not be located in the load waterline area.

The upper end of the stem shall be extended to the nearest deck or platform located above the load waterline.

The lower end of the stem shall be extended to a section located not more than 2 to 3 spacings forward from the forepeak bulkhead.

2.4.104 For bent stems (Fig. 2.4.104), steel plates of thickness exceeding by 25% the shell plating thickness in the fore extremity area may be used.

2.4.105 Stems together with adjacent shell plating shall be supported by breasthooks located corresponding with side stringers and
other framing members in the fore extremity. The thickness of breasthooks shall be not less than the thickness of adjacent shell plating.

2.4.106 For plate bent stems, the breasthook shall overlap the butt joint of the outer shell plating with the stem for at least 5-fold stem thickness (see Fig. 2.4.104).

2.4.107 Scantlings of stern frame’s sternpost above the propeller shaft stern boss, mm, made of steel bars shall be not less than:

For ships of M-СП, M-ПР and M classes

\[
t = 16 + 0.25L + 0.8H^2; \\
a = 55 + 2L \text{ when } L < 20 \text{ m}; \\
a = 65 + 1.5L \text{ when } 20 \leq L \leq 50 \text{ m}; \\
a = 90 + L \text{ when } L > 50 \text{ m};
\]

(2.4.107-1)

For ships of О-ПР and О classes

\[
t = 12 + 0.25L + 0.8H^2; \\
a = 30 + 2L \text{ when } L < 20 \text{ m}; \\
a = 50 + L \text{ when } 20 \leq L \leq 50 \text{ m}; \\
a = 40 + 1.2L \text{ when } L > 50 \text{ m};
\]

(2.4.107-2)

For ships of P and Й classes

\[
t = 10 + 0.18L + 0.8H^2; \\
a = 30 + 2L \text{ when } L < 20 \text{ m}; \\
a = 50 + L \text{ when } 20 \leq L \leq 50 \text{ m}; \\
a = 40 + 1.2L \text{ when } L > 50 \text{ m};
\]

(2.4.107-3)

where \(a, t\) — width and thickness of the sternpost, respectively, mm.

2.4.108 Thickness of the sternpost and the rudder post below the stern boss shall be increased by two times as compared with that obtained by formulae (2.4.107-1) to (2.4.107-3). Width of the sternpost and the rudder post in upper part may be reduced by 15% from the values determined by those formulae.

2.4.109 Sternpost boss web thickness (in reamed condition) shall be not less than 60% of the thickness calculated by formulae (2.4.107-1) to (2.4.107-3).

2.4.110 A sole between the sternpost and the rudder post shall be as short as practicable and have a cross-sectional area increased by 25% of the cross-sectional area with dimensions \(a\) and \(t\) as calculated by formulae (2.4.107-1) to (2.4.107-3).

In order to ensure a reliable connection with the shell plating, the stern frame’s sole shall extend forwards of the sternpost for at least 10-fold width of the cross-sectional area below the stern boss. The lower part of a stern frame sole shall slightly rise towards of the rudder post with a 1/10 slope.

At the upper part of stern frame, 1 or 2 stiffeners (bosses) shall be fitted for fastening the transverse framing members.

2.4.111 Where a bar keel is fitted, its cross-section shall be not less than determined by the formulae:

\[
h = 100 + L; \quad b = 12 + 0.4L,
\]

(2.4.111-1) (2.4.111-2)

where \(h, b\) — height and width of a bar keel, respectively, mm.

2.4.112 Brackets of propeller shafts may be either single or double-branched; branches shall be positioned at an angle of 80 to 100°, branch axes shall intersect at a propeller shaft axis.

Dimensions of double-branched brackets shall be not less than those determined by the formulae:
\[
\begin{align*}
t_b &= 0.45d; \\
F_b &= 0.47d^2; \\
\ell_h &= 3d; \\
\ell_h &= 0.33d, \\
\end{align*}
\]  
(2.4.112)

where \(t_b\), \(\ell_h\) — thickness of the branch and the hub correspondingly, mm;

\(d\) — diameter of the propeller shaft, mm;

\(F_b\) — cross-sectional area of the branch, \(\text{mm}^2\);

\(\ell_h\) — length of the hub, mm.

A hub web thickness for double-branched brackets may be reduced down to 0.25 \(d\) in ships up to 25 m in length.

Branches of brackets shall be attached to the hull framing members and to the outer shell by means of welding. Thickness of the outer shell plating in the area of bracket branch connection shall be increased by 25% in comparison with shell plating thickness in the aft extremity as determined from Tables 2.4.1-1, 2.4.1-2 and 2.4.1-4.

Hull strengthening for navigation in broken ice

2.4.113 Ships of all classes navigating occasionally in broken ice shall be provided with strengthening meeting the requirements of 2.4.115 to 2.4.129. These requirements are specified for fine broken ice thickness specified in Table 2.4.113.

<table>

</tbody>
</table>

2.4.114 Ships intended for navigation in more severe ice conditions than specified in Table 2.4.113 shall be provided with hull strengthening designed with due regard to the type, purpose and conditions of navigation of the ship.

2.4.115 An ice strake of the outer shell shall be fitted throughout the whole length of a ship, with an upper edge located 0.5 m above the load waterline and lower edge 0.5 m below the lightship waterline, with due regard to possible trim of the ship.

When at the fore extremity a vertical distance between the lightship waterline and plates of the bottom outer shell plating is less than 0.5 m, thickness of the whole outer shell plating bellow the load waterline in the bow extremity to the parallel body but at least over a distance equal to a ship breadth shall be the same as the ice strake thickness.

2.4.116 Thickness of ice strake plates \(t_i\) shall be not less than specified by Table 2.4.116.

Note. Fore section means a section with the after border corresponding to third actual frame of the hull’s parallel body, and for ships with a length of the parallel body being less than 0.3L — to a frame where the angle between tangent line to the waterline at fully loaded condition and the centre plane is \(7^\circ\), but over a length equal to at least the ship’s breadth.

When using the data in Table 2.4.116, the following shall be considered:

If spacing is taken greater than \(a_w\), than ice strake plating thickness specified in the Table 2.4.116, mm, shall be increased by the value:

\[
\Delta t = 0.8(\xi a/a_w - 1)t_i, \quad (2.4.116-1)
\]
where $a$ — actual spacing, mm;
\[ a_0 = \text{standard spacing taken equal to, mm:} \]
for the bow section (see Note to Table 2.4.116) 400
for other hull sections 550
\[ \xi = \left(10\chi h + 0.5a_0\right)/\left(10\chi h + 0.5a\right); \]
(2.4.116-2)
\[ h = \text{fine broken ice thickness taken depending on ice strengthening notation as per Table 2.4.113, cm;} \]
\[ \chi = \text{coefficient connecting the ice load application height and ice thickness and calculated by the formula:} \]
\[ \chi = \mu \left(0.001D\right)^{1/3} \leq 1.0; \] (2.4.116-3)
\[ \mu = \text{coefficient equal to:} \]
for fore section 0.55
for afterpeak section 0.39
for other sections of the ship 0.49

If spacing is taken less than $a_0$ and/or hull members are made of higher strength steel, than the ice strake plating thickness specified in Table 2.4.116, mm, may be reduced by the value:
\[ \Delta t = 0.8\left[1 - 15.3\xi a/\left(a_0\sqrt{R_{\text{ext}}}\right)\right]l, \] (2.4.116-4)
where $a$, $a_0$, $\xi$ — see 2.4.3 (if $a > a_0$, $a = a_0$);
\[ R_{\text{ext}} = \text{yield point of the member material, MPa.} \]

2.4.119 Section modulus of side web frames including effective flange $W$, cm$^3$, shall be not less than the values determined by the formulae:
\[ W = 18.5H_d\sqrt{2} + 0.085L; \] (2.4.119-1)
\[ W = 14.5H_d\sqrt{2} + 0.085L; \] (2.4.119-2)
\[ W = 12.5H_d\sqrt{2} + 0.085L, \] (2.4.119-3)
where $d$ — distance between side web frames, m;
\[ H_d = \text{side depth, m, in the relevant area of ship.} \]

2.4.120 Section modulus of main ordinary side frames including effective flange $W$, cm$^3$, shall be not less than determined by the formulae:
\[ W = 21.5la\sqrt{2} + 0.085L; \] (2.4.120-1)
\[ W = 17.5la\sqrt{2} + 0.085L; \] (2.4.120-2)
\[ W = 15la\sqrt{2} + 0.085L, \] (2.4.120-3)
where $a$ — spacing (a distance between main ordinary side frames), m;
\[ l = \text{the greatest distance measured over a side between the bottom (double bottom plat-} \]
ing and a side stringer, between side stringers, or between a side stringer and the deck, m, in the relevant area of ship.

2.4.121 Section modulus of intermittent side frames including effective flange shall be not less than 75% of the required section modulus of main ordinary frames including effective flange.

2.4.122 Throughout the length of a ship in the ice strake area, side stringers shall be provided with one of them being located below the load waterline. Where variations of operational draughts are not significant, one stringer may be sufficient.
2.4.123 Lower sections of intermediate side frames shall overlap the bilge. They shall be attached to the nearest bottom framing member or to the double bottom plating.

Upper ends of the intermittent frames shall be extended to a deck, a platform or a side stringer but shall not be below the upper edge of the ice strake.

2.4.124 In ships with full contours, frames in the forepeak and the afterpeak areas shall be installed perpendicularly to the shell plating.

2.4.125 Horizontal stiffeners shall be installed on the forepeak and afterpeak bulkheads and bulkheads enclosing the engine room, which shall be extended over 25% of the bulkhead’s width, at both sides, with a section modulus not less than that of the vertical ordinary stay. A bulkhead stay, up to which the stiffeners are extended, shall be reinforced.

2.4.126 Cross-sectional area of the stem shall be increased by 50% as compared with that required by 2.4.100 to 2.4.104. Plate edges of the outer shell plating adjacent to the stem shall be protected against ice.

2.4.127 Cross-sectional area of the stern frame shall be increased by 15% as compared with that required by 2.4.107 to 2.4.110.

2.4.128 Propellers and rudders shall be protected against ice by a cruiser-shaped aft, anti-ice bosses or any other structures.

2.4.129 Framing members in the area of the hull strengthening for the navigation in broken ice shall be welded by means of continuous welds.

Superstructures and steps on main deck

2.4.130 Superstructure transverse framing members shall be fitted in the same planes with the hull transverse framing members.

The section modulus of the superstructure side stringers including effective flange in ships of М-СП, М-ПР, О-ПР, М, О classes shall be at least 9 cm³.

2.4.131 Longitudinal walls of the superstructures shall be extended beyond the end bulkheads of the superstructures over a length equal to the superstructure height and smoothly connected to the deck.

The sheer strake throughout at least three spacings abaft each end bulkhead of the superstructure, as well as protruding part of the lowermost strake of the superstructure plating and its section extended into the superstructure for a length equal to one-half height of the superstructure, shall be thickened by 40% for ships of М-СП, М-ПР and М classes, by 25% for ships of О-ПР and О classes and by 10% for P and J classes.

Deck stringer of the upper deck shall be thickened along the same length as for the sheer strake by 20% for ships of М-СП, М-ПР, О-ПР, М, О classes and by 10% for ships of P and J classes.

Where a length of the forecastle and the poop is less than 0.25L, the thickening may be dispensed with.

2.4.132 In the area of the main deck step, special reinforcements shall be provided. Deck carlings shall be smoothly interconnected. The sheer strake in the stepped area shall be thickened by 35% at both sides of the step over at least three spacings.

In case of inclined step, it shall be extended for at least the double height.

A length of an area where the main deck and raised deck overlap, shall be determined with due regard to the global strength of the hull, and for ships of up to 50 m in length with due regard to conditions of 2.5.2, with the cross-sectional areas of the deck plating and the side plating of this area being included in calculations according to instructions of 2.2.32 to 2.2.34. Where a cross-sectional area of the deck plating of the above said decks is increased by means of installing longitudinal vertical brackets between them, length of the brackets shall be equal to at least double depth of the bracket, and thickness not less than required by the Rules for the bulkheads in that area. Bracket ends shall be attached in accordance with 2.3.7. The brackets shall be reinforced by stiffeners.
Where planes of longitudinal walls of a superstructure (wheelhouse) do not coincide with the side planes, they shall bear on the carlings fitted in planes of those walls.

**Bulwark**

2.4.133 Areas fitted with the bulwark, its extension and height shall be assigned in accordance with the requirements of 10.1 and 10.2.

2.4.134 Thickness of the bulwark plates may be taken by 2 mm less than that required for the side plating in the middle part of ship, but not less than 2 mm.

2.4.135 The bulwark shall be so designed as not to be participating in global bending of the hull.

2.4.136 The bulwark shall be reinforced by stanchions installed at least three spacings apart.

2.4.137 Supporting stanchions shall be installed in the areas of side hawsepipes and stair accesses; here, the thickness of the bulwark plates shall be increased by 1 mm as compared with the rest plates.

**Tanks**

2.4.138 Fuel, oil, oily water and sewage tanks may be independent or built-in.

2.4.139 Fuel tanks shall not have common bulkheads with drinking water tank or be placed in front of forepeak bulkhead.

2.4.140 Main fuel tanks shall be part of the ship's structure and shall be located outside machinery spaces where engines and boilers are installed. Where these tanks, other than double bottom tanks, are necessarily located adjacent to or within machinery spaces stated above, at least one of their vertical walls shall be contiguous to the machinery space bulkhead and shall have a common boundary with the double bottom tanks, and the area of the tank boundary common with the machinery space shall be kept to a minimum. Where such tanks are situated within the boundaries of machinery spaces where engines and boilers are installed, they shall not contain a fuel having a flashpoint less than 60°C.

2.4.141 In ships where independent main fuel tanks are used, they shall not be mounted in machinery spaces where engines and boilers are installed. Independent daily tanks and other fuel tanks shall be installed on a fuel-tight spill tray having a drain pipe leading to a spill oil tank.

2.4.142 Tanks shall be so designed as their content do not touch the bottom and side plating.

The distance between the bottom of built-in tanks in the its lowest part and the bottom plating shall be at least 800 mm, and the distance between the side walls of the tank and the side plating shall be such as to ensure the access for inspection and repair. Access to the independent tanks including cargo tanks shall be provided from all sides. The distance from independent tank bottom in the its lowest part to the bottom plating shall be at least 800 mm, and the distance between tank walls and side plating or transverse bulkheads shall be at least 760 mm.

2.4.143 The wall thicknesses of built-in tanks and plate structures shall comply with the requirements of 4.1 and 5.2 of Tables 2.4.1-1 and 2.4.1-2.

Section moduli of web and ordinary members shall be taken similar to the relevant bulkhead members.

**2.5 ADDITIONAL REQUIREMENTS FOR PARTICULAR TYPES OF SHIPS**

**Ships less than 50 m in length**

2.5.1 For ships of all classes less than 50 m in length, where the requirements of 2.5.2 are not complied with, calculations of global strength shall be made as per 2.2. In this case, the bending moment \( M_{\text{sw}} \) may be determined using data of the prototype ship having the same hull architecture and design as the ship under consideration, similar dimensions, displacement and similar longitudinal location of the engine room, or using the itemized calculation of the bending moment at the midship...
as the algebraic sum of moments from different weights and support forces. In all cases, absolute value of the bending moment shall be taken not less than, kN·m,

\[ M_{sw_{\min}} = a_0 D, \]

where \( a_0 = 1.1 \) for self-propelled ships and \( a_0 = 0.74 \) for non-self-propelled ships.

\( D \) — ship displacement in fully loaded condition, kN.

Distribution of the calculated value of \( M_{sw} \) over the ship’s length shall be assumed as constant within \( \pm 0.25L \) from the midship and linearly decreasing to the extremities.

When complying with the requirements of 2.3 and 2.4, calculations of local strength required by 2.2 may be omitted (see 2.1.6).

2.5.2 For ships less than 50 m in length, the total cross-sectional area of the deck and bottom strake longitudinal members taken separately shall be not less than, cm²:

\[ F = D' L \eta \alpha \left[ \left( 0.1L/T - 1 \right)/k_1 + k_2 \right]/H, \]

(2.5.2)

where \( D' \) — ship displacement in fully loaded condition, t;

\( k_1 \) — coefficient determined from Table 2.5.2;

\( \eta \) — coefficient equal for members:
- deck strake not bearing any local load 0.65
- bottom and deck strakes bearing local load 0.75

\( \alpha \) — coefficient depending on relative distance \( x/L \) of the design cross-section under consideration from the midship and taken as:

\[
\begin{align*}
\alpha &= 1.0 & \text{when } |x/L| \leq 0.25; \\
\alpha &= 2.0 - |x/L|/0.25 & \text{when } |x/L| > 0.25;
\end{align*}
\]

\( x \) — distance of the design cross-section under consideration from the midship, m.

The value of expression in brackets of formula (2.5.2) shall not exceed 0.125. For dry cargo ships, if such cargo handling operations are allowed in non-sheltered waters as cargo stowing in one layer by one crane or two cranes in the same direction, the total cross-sectional area of the deck strake and bottom strake longitudinal members, taken separately, shall be not less than the value calculated by formula (2.5.2) with \( k_2 \) increased by 20%. Values of coefficient \( k_1 \) in this case shall be assigned taking into account the operation area comprising such a water area. Value of parenthetical expression in formula (2.5.2) in this case shall not be taken above 0.15.

Where cargo is stowed in one layer by two cranes in different directions, the hull strength shall be verified by direct strength calculations using values of bending moments and shear forces on still water, determined as per requirements of 2.2.1 and 2.2.2.5.

The following shall be included in the total cross-sectional area of the deck strake:

- 65% of the cross-sectional area of the deck plating in case of the longitudinal framing system;
- full cross-sectional area of the plating sections with a breadth equal to 0.25 of the spacing at each side of a longitudinal member in case of the transverse framing system;
- 10% of the rest area of the plating in case of the transverse framing system;
- continuous longitudinal ordinary girders;
- continuous longitudinal coamings and continuous longitudinal girders supporting the aforementioned coamings;
- carlings;
- the upper part of the sheer strake raised over the deck, as well as a part of the sheer strake below the deck with a height equal to 0.5 of the spacing in case of the transverse side framing system and equal to 0.25 of the spacing in case of the longitudinal side framing system;

The following table shows the values of coefficient \( k_1 \) at ship length, m:

<table>

\(^{1}\) Maximum value of the expression in square brackets of the formula (2.5.2) is not limited.
the upper under-deck sections of longitudinal bulkheads and inner sides with a height of 0.5 of the spacing in case of the transverse framing system and 0.25 of the distance between longitudinal girders in case of the longitudinal framing system.

The following shall be included in the total cross-sectional area of the bottom strake:
- 65% of cross-sectional area of the bottom plating and the double bottom plating in case of the longitudinal framing system;
- full cross-sectional area of the bottom plating and the double bottom plating sections with a breadth equal to 0.25 of the spacing at each side of each longitudinal member in case of the transverse framing system;
- 10% of the rest area in case of the transverse framing system;
- continuous longitudinal ordinary bottom girders and keelsons with supporting continuous longitudinal girders;
- continuous longitudinal stiffeners of a double bottom plating ordinary girder;
- the bilge plate in the rounded part;
- lower part of longitudinal bulkheads, outer and inner sides up to the level located 0.25 of the spacing above the double bottom plating or floors.

Longitudinal members included into the total cross-sectional area of the deck and the bottom strakes shall comply with 2.2.31 with due regard to their position relatively to the cross-section in question, extension and connection with the hull.

Cross-sections, for which strength shall be verified according to the requirements of present paragraph, shall be selected as per 2.2.30.

Requirements of 2.5.1 and present paragraph do not apply to passenger displacement ships of M-CPI class.

**Dry cargo ships**

2.5.3 Ships of M-CPI class shall have double bottom and double sides in the cargo hold area.

2.5.4 In ships intended for carriage of cargo containers (see GOST R 53350), sockets for corner fittings of containers shall be provided and respective reinforcements shall be made.

**Tankers**

2.5.5 Oil transporting tankers shall have double bottom and double sides in the cargo tanks area, or cargo tanks shall be independent (see 2.5.111 to 2.5.126, 2.5.157 to 2.5.161) or built-in (see 2.5.142 to 2.5.156).

Provisions of 2.5.6 to 2.5.8 do not apply to ships with independent or built-in tanks.

2.5.6 Tankers up to 80 m in length shall be fitted with one longitudinal bulkhead in the centre plane in the cargo tanks area, and ships with a length of 80 m and more with at least two longitudinal bulkheads. In double-sided ships, one longitudinal bulkhead in the centre plane shall be sufficient.

Where no expansion trunks are provided above the cargo tanks, this shall be substantiated by calculations with due regard to the temperature conditions and the availability of free under-deck volumes.

2.5.7 In ships with $B/H > 3.5$, longitudinal trusses or pillars shall be fitted in addition to the longitudinal bulkheads. The distance between the longitudinal bulkhead and longitudinal truss or between longitudinal trusses and the side shall not exceed 2.5 m.

2.5.8 Tankers shall be fitted with transverse bulkheads located at the distance from each other of not more than, for ships with the side depth $H$, m:

- $\leq 2.5$ 24 frames
- $> 2.5$ 36 frames

Non-self-propelled tankers shall be fitted with transverse trusses or pillars or non-tight transverse bulkheads between transverse bulkheads. The distance between the transverse bulkheads or the bulkheads and the trusses shall not exceed 12-fold spacing for ships with the side depth $H \leq 2.5$ m and 18-fold spacing for ships with the side depth $H > 2.5$ m.

**Displacement passenger ships**

2.5.9 Hulls of displacement passenger ships may be of the following types:
one-decked ships with light superstructures not participating in the hull global bending;

2 multi-decked ships with strong main deck and strong superstructure deck of the first tier included in the hull girder;

3 open ships fitted with or without the double bottom and with a superstructure either participating in global bending or not.

2.5.10 If a superstructure (wheelhouse) is participating in hull global bending, the strength of its upper strong deck members and strength of superstructure connections with the hull in way of the greatest tangent stresses at ends of its continuous longitudinal walls shall be provided.

In case the aforementioned requirements are not met, structural measures shall be taken to reduce superstructure (wheelhouse) participation in the hull global bending and to prevent excessive stress concentration in the superstructure and in the deck on which the superstructure rests.

2.5.11 Longitudinal walls of the superstructure (wheelhouse) with a length exceeding 6-fold height of the superstructure not coinciding with the hull sides, shall be connected with transverse end walls smoothly according to a radius of at least 1/3 of the superstructure height. For superstructures (wheelhouses) of a smaller length the aforementioned rounding radius may be reduced pro rata. Superstructures (wheelhouses), whose longitudinal walls do not coincide with longitudinal walls of the superstructures situated below, shall also meet this requirement.

2.5.12 Thickness of a stringer of the uppermost strong deck and of the deck next below of passenger ships shall be not less than required in 2.1 of Tables 2.4.1-1 and 2.4.1-2.

2.5.13 Thickness of the deck plating of passenger ships in the middle part shall be not less than required in 2.1 of Tables 2.4.1-1 and 2.4.1-2.

2.5.14 Thickness of the superstructure (wheelhouse) walls shall be not less than required in 5.6 of Tables 2.4.1-1 and 2.4.1-2, and of superstructure (wheelhouse) participating in global bending of the hull not less than required in 5.7 of Tables 2.4.1-1 and 2.4.1-3.

Tugboats and pushboats

2.5.15 Thickness \( t \) of the outer shell plating of tugboats and pushboats in the middle part and in the aft extremity shall be not less than, mm:

\[
 t = \left( L + 100 \right) / 30 + t_{\text{add}},
\]

(2.5.15)

where \( t_{\text{add}} = 0 \) for ships with power of 330 kW or less;

\[
t_{\text{add}} = 0.06 \sqrt{1.36P_e - 450} \quad \text{— for ships with power exceeding 330 kW, where } P_e \text{ — power of the tugboat/pushboat, kW.}
\]

For lock and harbour tugboats and pushboats of all classes, as well as for raft transporting ships of M and O classes, the outer shell plating thickness shall be increased by 2 mm as compared with the thickness determined by formula (2.5.15).

In all cases, the outer shell plating thickness in the middle part of ship shall be not less than specified in Tables 2.4.1-1 and 2.4.1-4.

2.5.16 Sheer strake and bilge strake thickness shall be taken equal to the outer shell plating thickness in the given hull section, but not less than specified in 1.3 and 1.4 of Tables 2.4.1-1 and 2.4.1-4.

2.5.17 Outer shell plating thickness of the fore part of tugboats and pushboats shall be not less than thickness in the middle part of ship determined as per 2.5.15 and 2.5.16, but not less than the shell plating thickness in the fore extremity specified in Tables 2.4.1-1 and 2.4.1-4.

2.5.18 The deck stringer thickness in the middle part of ship shall be not less than the side shell thickness. The deck stringer width shall be not less than 500 mm.

2.5.19 The deck plating thickness of tugboats and pushboats in the middle part of ship and in the fore and aft extremities, mm, shall be not less than:

for open areas
\[ t = \left( \frac{220 + L}{60} \right) + t_{\text{add}} \tag{2.5.19-1} \]

for areas enclosed by superstructures
\[ t = \left( \frac{180 + L}{60} \right) + t_{\text{add}} \tag{2.5.19-2} \]

where \( t_{\text{add}} \) is taken as per 2.5.15.

For lock and harbour tugboats and pushboats, the deck plating thickness shall be not less than the outer shell plating thickness in the middle part of ship required by the Rules.

2.5.20 Bulkhead plate thickness shall be not less than determined as per Tables 2.4.1-1 and 2.4.1-2 plus 1 mm.

2.5.21 Thickness of the transom bulkhead plate in pushboats and thickness of stop plates shall be not less than the deck plating in the fore extremity.

2.5.22 Fore extremities of pushboat hulls shall be reinforced in such a way that to provide the uniform distribution of forces from stops to sides and longitudinal hull members.

In the plane of supports, longitudinal bulkheads or trusses shall be installed, which shall be strongly connected with the hull and extended to the forepeak bulkhead.

In the area of stops, closed frame rings (floors, side web frames and beams) shall be arranged.

Icebreakers

2.5.23 The requirements of 2.5.24 to 2.5.68 apply to ice-breakers which meet the condition \( D^{1/3}P^{1/3} < 230 \) and have the following main dimension ratios and hull lines:
- \( L/B = 3.3 \pm 5.0 \);
- \( B/T = 4.0 \pm 6.5 \);
- \( \alpha = 15 \pm 35 \);
- \( \varphi = 11 \pm 25 \);
- \( \beta = 30 \pm 50 \);
- \( \beta_M = 10 \pm 25 \),

where \( D \) — ship displacement at the draught at design waterline, kN;
- \( P \) — total propeller shaft power, kW;
- \( L \) — design waterline length, m;
- \( B \) — design waterline breadth amidships, m;
- \( T \) — moulded draught / draught to design waterline, m;
- \( \varphi \) — angle between a tangent to the stem line and base plane at the level of the design waterline, deg;
- \( \alpha \) — angle between a tangent to the design waterline and the centre line at 0.15\( L \) from the fore perpendicular, deg;
- \( \beta \) — angle between a vertical line and a tangent to the theoretical frame at 0.15\( L \) from the fore perpendicular at the design waterline level, deg;
- \( \beta_M \) — angle between a vertical line and a tangent to the midship at the design waterline level, deg.

2.5.24 The following definitions of the ship sections are adopted in 2.5.25 to 2.5.68:
- **fore part** is a hull section within 0.3\( L \) from the fore perpendicular;
- **middle part** is a hull section 0.5\( L \) long between the fore and aft sections;
- **aft part** is a hull section within 0.2\( L \) from the aft perpendicular.

2.5.25 Hulls of ice-breakers (excepting the outer shell plating) shall be made of hull structural steel of not less than D and E grades, and the outer shell plating shall be made of steel of at least E grade.

2.5.26 Strength and buckling calculations, permissible stresses, structural design and scantlings of ice-breaker hull members shall comply with the requirements of 2.1 to 2.4, 2.6, unless otherwise specified in 2.5.27 to 2.5.68.

2.5.27 When calculating local strength of the hull structures for ice loads, permissible stresses shall be taken equal to 0.95 of the yield point of the material \( R_{th} \).

2.5.28 For the bottom and the side longitudinal members subject to ice load, general and local bending stresses are not to be summed up.

2.5.29 Design ice pressure applied to the ice strake shell plating in the fore part \( p_f \) is determined by the formula, MPa,
\[ p_f = 1.4 + 0.004D^{1/4}P^{1/3} \tag{2.5.29} \]

where \( D \) and \( P \) — see 2.5.23.

2.5.30 Design ice pressure applied to the ice strake shell plating is determined by the formula, MPa:
in the middle part
$$p_m = 0.60 p_f ;$$  
(2.5.30-1)
in the aft part
$$p_a = 0.75 p_f ,$$  
(2.5.30-2)
where \( p_f \) — see 2.5.29.

2.5.31 Design ice pressure applied to the bottom plating outside the ice strake \( p_{bot} \) is determined by the formula, MPa:
$$p_{bot} = p_f D^{1/4} P^{1/3} / 400 ,$$  
(2.5.31)
where \( p_f \) — see 2.5.29,
\( D, P \) — see 2.5.23.
Pressure \( p_{bot} \) shall not exceed \( p_m \).

2.5.32 Design intensity \( q_f \) of ice load applied to the side framing in the fore part of the ice strake in case the ship would strike against ice cover is determined by the formula, kN/m
$$q_f = 12.6 k \sqrt{D v^2 p_f^2} ,$$  
(2.5.32)
where \( k \) — dimensionless coefficient taken from curve in Fig. 2.5.32 depending on angles \( \alpha \) and \( \beta \);

![Fig. 2.5.32 Curves for determining coefficient k](image)

\( v \) — design speed of the ice-breaker at the moment when the ship strikes against ice, m/s, taken equal to 60% of maximum speed of the ice-breaker in clear water;
\( D \) — see 2.5.23; \( p_f \) — see 2.5.29.

2.5.33 Design intensity of ice load applied to the side framing shall be taken as follows, kN/m:
in the middle part, not less than the greatest value of
$$q_m = 0.6 q_f ;$$  
(2.5.33-1)
$$q_m = 0.028 L^2 / \sin \beta_m ;$$  
(2.5.33-2)
in the aft part
$$q_a = 0.75 q_f ,$$  
(2.5.33-3)
where \( q_f \) — see 2.5.32.
In any case the intensity \( q_f \) shall be not less than the taken value of \( q_m \).

2.5.34 Design intensity \( q_{bot} \) of ice load applied to longitudinal girders and ordinary frames of the bottom outside the ice strake, kN/m:
$$q_{bot} = 10 p_{bot} L .$$  
(2.5.34)
The intensity \( q_{bot} \) shall not exceed the value of \( q_m \) determined by the formula (2.5.33-1).

2.5.35 The spacing in the fore part shall be taken not over 300 mm. It may be increased up to 600 mm provided that intermediate side frames are fitted.

2.5.36 The spacing in the middle part and aft part of the ice-breaker shall not exceed 500 mm. It may be increased up to 650 mm provided that intermediate side frames are fitted.

2.5.37 The ice strake of the outer shell plating shall be fitted over the whole length of ice-breaker’s hull.

2.5.38 The upper edge of the ice strake shall be located at least 0.6 m above the waterline corresponding to the greatest draught, and the lower edge of the ice strake shall be 0.02 \( L \) but not less than 0.8 m below the waterline corresponding to 10% stores and fuel without ballast.

2.5.39 In the fore part over a length of at least 0.2 \( L \) from the fore perpendicular and in the aft part over a length of at least 0.15 \( L \) from the aft perpendicular, the lower edge of the ice strake shall be extended to the centre line.
2.5.40 The thickness of the ice strake plating shall be taken not less than calculated by the formula, mm:

\[ t = 720s\sqrt{p/R_{th}}, \]  

(2.5.40)

where \( s \) — distance between framing girders, m;

\( p \) — design ice pressure determined by formulae (2.5.29) to (2.5.31) depending on longitudinal position of the plates, MPa;

\( R_{th} \) — yield point of the outer shell plating material, MPa.

2.5.41 The outer shell plating thickness outside the ice strake shall be determined by the formula (2.5.15), where \( P_a \) is taken equal to the total propeller shaft power \( P \), kW.

2.5.42 Thickness of outer shell plating shall be decreased smoothly along the height so that adjacent plates differ not more than by 30% of the thickness of the thinner connected plate.

2.5.43 Thickness of the deck plating shall be determined by formulae (2.5.19-1) and (2.5.19-2) with due regard to 2.5.15.

2.5.44 A distance between the web frames in the fore part of the ship shall not exceed 1.2 m, while over the rest length of the ship this distance shall not exceed 2.0 m.

Minimum thickness of webs of the web frames within the ice strake is 10 mm and for the rest length of the ship is 8 mm.

2.5.45 A side stringer or a platform shall be fitted throughout the length of an ice-breaker at design waterline level (or maximum 0.25 m lower).

2.5.46 Within the ice strake, a distance between the side stringers (a stringer and the deck or a platform, a stringer and the bottom) shall be taken not more than 1.2 m; thickness of the mentioned stringer webs and platform plates adjacent to the outer plating in the ice strake area shall be not less than the web thickness of web frames fitted in this area.

2.5.47 In places where ordinary frames and side stringers intersect, knees shall be fitted.

2.5.48 Ordinary side frames are calculated as multi-spanned girders resting on stringers (platforms), deck plating, keelson or bilge bottom plate. Concentrated load \( Q \), kN, to which side ordinary frames are calculated, shall be obtained by the formula

\[ Q = qs, \]  

(2.5.48)

where \( q \) — design intensity of ice load, kN/m, for relevant section of the ice strake (see 2.5.24) as per 2.5.32 and 2.5.33;

\( s \) — distance between ordinary frames or between the ordinary frame and the web frame, m.

A point of force \( Q \) application shall be taken in the middle of the longest frame span within the ice strake.

Where intermediate frames are fitted, \( s \) in formula (2.5.48) shall be taken equal to the distance between the intermediate and ordinary frames. Intermediate frames are calculated as ordinary ones.

In case of the homogeneous transverse side framing system, the side frames are calculated as ordinary frames in case of the side framing system with deep frames. It shall be kept in mind that in case of the homogeneous framing system, the side stringers distribute the load and, therefore, they shall not be considered as supports for frames.

2.5.49 Strength of side stringers and web frames shall be calculated considering them being included in the side grillage; for this purpose, in the middle part of ship, the ice load application length is taken throughout the whole length of the side grillage. A length of ice load application, m, in the fore and aft parts is calculated by the formula

\[ l = 0.01q/p, \]  

(2.5.49)

where values of the design pressure \( p \) and the design ice load intensity \( q \) are obtained according to 2.5.29 to 2.5.34.

2.5.50 Webs of ordinary and web frames at the level of the ice strake throughout the ship’s length shall be connected to the outer shell plating by a continuous double-sided weld.
2.5.51 Frames installed in extremities shall meet the requirements of 2.4.124.

2.5.52 Continuous floors shall be fitted at each frame throughout the fore and the aft parts of ship.

A distance between continuous floors amidships shall not exceed 2.0 m.

2.5.53 Strength of continuous floors and keelsons shall be calculated considering them a part of bottom grillages loaded by uniformly distributed ice pressure equal to 0.3\( p_{\text{bot}} \), where \( p_{\text{bot}} \) is determined by formula (2.5.31).

2.5.54 Bottom ordinary frames shall be considered as a single-span girders constrained at the ends and having a length equal to the greatest distance between keelsons or between a keelson and the side or a longitudinal bulkhead. A concentrated load \( Q \), kN, to which the bottom ordinary frames are calculated, shall be considered as applied in the middle of the span and determined by the formula:

\[
Q = q_{\text{bot}} s,
\]

where \( q_{\text{bot}} \) — design ice load intensity, kN/m, determined by formula (2.5.34);

\( s \) — distance between the bottom ordinary frames or between a bottom ordinary frame and a floor, m.

Longitudinal ordinary girders are calculated on the assumption that span’s length is equal to the distance between continuous floors, and the \( s \) value is equal to the distance between the girders.

2.5.55 Transverse bulkheads shall be flat and their structure shall meet the requirements of 2.5.20, 2.5.21, 2.5.56 to 2.5.59.

2.5.56 Thickness of the bulkhead plate adjacent to the side and bottom platings shall be not less than the thickness of webs of web frame and floor, correspondingly.

2.5.57 Horizontal stiffeners connected to the side framing members shall be fitted on transverse bulkheads. Length of these stiffeners from each side to the centre line shall be not less than 10% of the bulkhead’s width. The nearest bulkhead stay, to which these stiffeners are extended, shall be a web stay.

Section modulus of stiffeners shall comply with the requirements of 2.4.78, and the stiffeners’ ends shall be mitered. In addition, the following conditions shall be met:

1. the distance \( a \) between the stiffeners shall be not less than obtained by the formula, m:

\[
a = 0.88 t \sqrt[3]{R_{EH}},
\]

where \( t \) — thickness of the bulkhead plate in the section adjacent to the side, mm;

\( R_{EH} \) — yield point of the bulkhead material, MPa;

2 moment of inertia \( i \), cm\(^4\), of a stiffener with effective flange of the bulkhead plating with a width of 1/6 of a length of stiffener’s span shall be not less than determined by the formula:

\[
I = 191 p s l^2,
\]

where \( p \) — design ice pressure applied to the ice strake plating for the relevant part of a ship, MPa;

\( s \) — distance between the ordinary frames and between the ordinary and web frames, m;

\( l \) — stiffener span, m;

3 moment of inertia \( I \), cm\(^4\), of a bulkhead web stay with effective flange, to which horizontal stiffeners are extended, shall be not less than determined by the formula:

\[
I = 0.32 \left( \frac{l}{l_1} \right)^3 l,
\]

where \( l_1 \) — stay span, m;

\( l \) — stiffener span, m;

\( i \) — moment of inertia of the stiffener with effective flange, cm\(^4\).

2.5.58 Horizontal stiffeners and shelves fitted on transverse bulkheads at the level of the ice strake shall be welded to bulkhead plates by continuous double-sided weld.

2.5.59 Strength of transverse bulkheads shall be calculated for buckling and bending under ice loading and under hydrostatic pressure of water filling the compartment up to the deck, respectively.
2.5.60 If a longitudinal bulkhead is fitted in the centre line above the stem, its length shall be not less than stem length, and the bulkhead plate thickness shall be not less than forepeak bulkhead plate thickness.

2.5.61 The stem and stern frame of an ice-breaker shall be made of forged or cast steel. The stem may be made of steel plates with a thickness being at least two times more than thickness of the ice strake plates adjacent to the stem.

2.5.62 The stem shall have a rabbet or other similar structure protecting edges of adjacent outer shell plates from striking against ice.

2.5.63 The stem is fitted in the centre line throughout the entire bow raising of the bottom from the upper deck till the nearest transverse bulkhead.

2.5.64 The stem shall be connected with the adjacent outer shell plating and a longitudinal bulkhead fitted as per 2.5.60 by a continuous weld.

2.5.65 In the ice strake area, the stem shall be supported by breasthooks maximum 0.5 m from each other in the vertical plane. Here, the breasthook web and flange sizes shall be taken equal to those of web frames fitted in the forepeak. Breasthooks shall be extended to the frames.

2.5.66 Cross-sectional area of the stem, \( F \), at the ice strake level shall be not less than that determined by the formula:

\[ F = 2L. \]  
(2.5.66)

Upwards from the ice strake, the cross-sectional area of the stem may be smoothly reduced down to 70% of the value \( F \) calculated by formula (2.5.66).

2.5.67 Cross-sectional area of the stern frame shall be increased by 1.5 to 2 times compared with the values determined by formula (2.4.107-1). The requirements of 2.4.110 shall be met as well.

2.5.68 In the aft extremity of an icebreaker, provision shall be made to protect propellers and rudders against broken ice when moving astern.

**Industrial ships**

2.5.69 Industrial ship scantlings shall be taken as per 2.1.6, and the requirements of 2.5.70 to 2.5.73 shall be met.

2.5.70 Calculations of global and local strength, rigidity and vibration of the hull shall be performed with due regard to operational conditions of industrial ships and specific operation of special mechanisms, devices and equipment.

2.5.71 In the dredging tower and the frame lifting tower areas, the framing of the main hull shall be reinforced. Supports of the frame lifting tower may be ended at the deck. Pillars, web stays and other equivalent structures shall be provided under them. Supports of the dredging tower shall be extended to the bottom and be attached to the longitudinal and transverse members, or transverse bulkheads shall be fitted under them.

The deck plating in places where dredging tower supports pass through and below the supports of the frame lifting tower shall be thickened by 25%.

2.5.72 The side framing system in the area of suction tube connections shall be of transverse type with web frames being provided; thickness of the outer shell plating shall be increased by 25%.

2.5.73 In the soil pump room, watertight sections of floors and keelsons forming a drainage well shall be provided.

**Ships less than 25 m in length**

2.5.74 The requirements of 2.5.75 to 2.5.110 apply to ships less than 25 m in length, types of which are specified in 2.1.4.

These ships shall comply with the requirements of 2.1, 2.3, 2.4, 2.5.75 to 2.5.110.

2.5.75 Thickness of the hull members shall be taken not less than 2.5 mm in all cases.

2.5.76 Thickness of the bottom plating and the bilge strake plating \( t \), mm, in the middle
part and the aft extremity of ship shall be not less than obtained by the formula:

\[ t = 1060a \sqrt{p + r + m R_{\text{sh}}} \]  \hspace{0.5cm} (2.5.76)

where \( a \) — spacing, m;
\( T, r \) — see 2.4.11;
\( m \) — a value, m, taken equal to, for ship classes:
\[ \begin{array}{c|c|c}
\text{M-СП, М-ПР, О-ПР, М, О} & 0.6 \\
P and І & 0.9
\end{array} \]
\( R_{\text{sh}} \) — yield point, MPa.

2.5.77 Thickness of the bottom and the bilge strake plating of tugboats and ships, which may operate in shallow waters and for timber rafting, shall be increased by 1 mm in comparison with that required by formula (2.5.76).

2.5.78 Thickness of the outer shell plating in the fore part of all ships (except those mentioned in 2.5.79) shall be increased by 1 mm in comparison with that required by 2.5.76.

2.5.79 Thickness of the outer shell plating of ships operating in shallow water and timber rafting shall be increased by 2 mm in comparison with that required by formula (2.5.76).

2.5.80 Thickness of the side shell plating may be taken by 1 mm less than it is required for the bottom plating of ships of all purposes, except for tugboats and ships intended for timber rafting.

2.5.81 Deck plating thickness, mm, shall be not less than determined by the formula

\[ t = 35a \sqrt{p R_{\text{sh}}} \]  \hspace{0.5cm} (2.5.81)

where \( a \) — spacing, m;
\( p \) — design load taken according to 2.2.26, kPa.

2.5.82 Bulkhead plate thickness, mm, shall be not less than

\[ t = 62a \sqrt{H_s R_{\text{sh}}} \]  \hspace{0.5cm} (2.5.82)

where \( a \) — distance between stays, m;
\( H_s \) — side depth in the given section, m.

2.5.83 Floor web thickness in extremities may be taken equal to floor web thickness in the middle part of ship.

2.5.84 Web framing thickness may be taken by 1 mm less than shell or flooring thickness, but not less than 2.5 mm.

2.5.85 Angle bars may be installed in way of the bilge with sharp lines, and the side and the bottom plating shall be overlap welded to bilge angle bar. Thickness of angle flanges shall be equal to the bottom plating thickness, but not less than 4 mm.

2.5.86 In case of the longitudinal framing system, section modulus of the bottom and deck longitudinal girders with effective flange shall be not less than, cm³,

\[ W = 130pal^2 R_{\text{sh}} \]  \hspace{0.5cm} (2.5.86)

where \( p \) — design load on grillage, kPa, determined as per 2.2.16 to 2.2.29;
\( a \) — distance between girders, m;
\( l \) — girder span, m.

2.5.87 Bulkheads shall be reinforced by stays. Section modulus of stays with effective flange, cm³, shall be not less than

\[ W = 75pal^2 R_{\text{sh}} \]  \hspace{0.5cm} (2.5.87)

where \( p \) — design pressure at the level of the lower end of the stays determined according to 2.2.25, kPa;
\( a \) — distance between stays, m;
\( l \) — span of the stay, m.

Ends of the stays shall be fastened by knees or mitered.

2.5.88 A distance between continuous floors shall be aliquot to the spacing and shall not exceed 1.5 m, and for tugboats 1.0 m.

2.5.89 The height and the cross-sectional area of a keelson may be reduced by 15% as compared with the height and the area of continuous floors over the whole compartment or a part thereof.

2.5.90 Longitudinal ordinary girders and longitudinal web members fitted along the bottom or the deck may be intercostal at the peak bulkheads in the same section.
2.5.91 Length of the knee as per 2.3.9 may be taken equal to the spacing.

2.5.92 Side web frames, beams and bulkhead stays as well as continuous floors, shelves and side stringers may be dispensed with, when the hull strength is provided by non-web members. Here, the required section moduli of longitudinal and transverse members shall be determined from strength calculation carried out in accordance with 2.2.

2.5.93 At least two transverse bulkheads shall be installed.

2.5.94 The engine room shall be separated by bulkheads from other spaces. The engine room bulkhead may be considered as the afterpeak bulkhead provided that requirements of the Rules for floodability and damaged stability are met.

2.5.95 The requirements of 2.3.7 do not apply to the ships up to 12 m in length.

2.5.96 Corrugated structures may be used for bulkhead plates, side plating, deck plating, superstructure walls, as well as for enclosures, walls, roofs of wheelhouses and other secondary walls and flooring plates.

2.5.97 For side plating, trapeze or semicircle corrugates shall be used. Corrugates of watertight hull bulkheads shall be continuous of trapeze, wavy semi-circle or rounded-tip triangle cross-section. For deck plating, only semicircle cross-section corrugates shall be used.

2.5.98 The total height of cutouts in webs of web members for ordinary girders shall not exceed 50% of web member height.

2.5.99 The height of cutouts for drain opening in members shall not exceed 30% of the member height.

2.5.100 Breadth of deck area between the side and the cutout shall be not less than 0.2 m.

2.5.101 Cutouts in the deck plating more than 6 spacings in length and more than 0.2B in width situated in the middle part of ship and forward of the aft engine room shall be rounded with a radius of not less than 10% of the cutout width; similar cutouts situated in the rest part of the deck shall be rounded with a radius of at least 5% of the cutout width. Other cutouts shall be rounded with a radius of at least 5-fold thickness of the deck plating.

2.5.102 Thickness of the bulwark plates may be taken by 2 mm less than that required for the side plating in the middle part of ship, but not less than 1.5 mm.

2.5.103 Cross-section area of the stem made of flat or rod steel determined according to 2.4.100, 2.4.101 may be reduced by 25%.

2.5.104 Cross-section area of the stem made of steel equal-sided angle bars determined according to 2.4.102 may be reduced by 50%. Other symmetrical rolled profiles may be used also.

2.5.105 Cross-section area of the bar keel determined as per 2.4.111-1 and 2.4.111-2 may be reduced by 50%.

2.5.106 Global strength calculations required by 2.2 may be dispensed with, provided that the requirements of 2.5.2 are met. Here, coefficient $k_1$ shall be taken from Table 2.5.2 for ships with the length of 25 m.

2.5.107 Hull global vibration calculation may be omitted.

2.5.108 Watertight bulkheads with a thickness of 3 mm and less (except for the forepeak bulkhead, the afterpeak bulkhead and tank bulkheads) shall be connected to the outer shell plating by continuous single-side weld with a leg equal to the bulkhead plate thickness; the same applies to the butt welds of these bulkheads.

2.5.109 Free ends of girders shall be connected to the shell plating or floor plating by intermittent or dotted welds with reduced pitch and shall be welded around as per 2.3.49.

2.5.110 Framing girders may be connected to each other by overlapping knees. For overlapping joint, the connection places shall be welded around the whole contour.
Tankers with vertical independent tanks

2.5.111 The requirements of 2.5.112 to 2.5.126 apply to tankers fitted with vertical cylindrical independent tanks (cargo tanks), which have draft in fully loaded condition not exceeding 2.25 m and gross tonnage not exceeding 1000 t. The requirements of 2.1, 2.2, 2.3 and 2.4 shall be met as well, if they do not contradict with the requirements of 2.5.112 to 2.5.126.

2.5.112 The main dimension ratios $L/H$ and $B/H$ shall be not more than indicated in Tables 2.1.3-1 and 2.1.3-2 for self-propelled and non-self-propelled dry cargo ships with holds.

2.5.113 Minimum number of watertight transverse bulkheads shall comply with the requirements of 2.4.70.

2.5.114 Design mean wear rate of deck plating shall be taken according to 1.1, 1.5, that of underdeck framing according to 7.1.1, 7.1.5, that of coamings according to 2 of Table 2.2.88, and that of uppermost, middle and lowermost plates of inner sides and bulkheads within cargo holds area according to 5.1.1, 5.1.4 and 6.1.1 of Table 2.2.87. Design mean wear rates of other members are designated according to Table 2.2.87.

2.5.115 Minimum thicknesses of hull members are assigned from Tables 2.4.1-1 and 2.4.1-2 as for dry cargo ships. Here, thickness of all the strakes of watertight bulkheads and inner sides bounding the cargo compartments shall be designated according to 4.1, thickness of the deck plating between the side and a cargo tank of flush deck ships according to 2.1, and thickness of the plating of trunk decks and decks of flush deck ships throughout the breadth of cargo tanks according to 2.3 of Tables 2.4.1-1 and 2.4.1-2.

2.5.116 Vertical independent tanks shall be fitted on and be connected with the web framing of the bottom. One cargo hold bounded at ends by transverse watertight bulkheads may accommodate maximum two cargo tanks. Additionally, transverse trusses shall be installed between the tanks inside the cargo holds. For double-sided tankers, trusses shall be installed in the same plane as the double-side half-bulkheads required by 2.4.71.

In tankers with single sides, in the plane of longitudinal coamings of the cargo holds or carlings situated between the side and the cargo tank, longitudinal trusses or pillars shall be installed in places where respective keelsons intersect with each floor.

In tanker’s deck, in the way of vertical independent tanks, circular cutouts fitted with coaming shall be provided. Diameter of the clear cutout shall exceed the tank diameter by 80 to 100 mm and shall not be more than 0.75 of the ship’s breadth.

Vertical independent tank shall be connected with the ship’s deck by a horizontal circumference member laid around the shell and connected both to the shell and to the coaming of the relevant deck cutout by continuous weld.

2.5.117 Bottom in the cargo holds may be of single type. The distance between floors shall be aliquot to the spacing and shall not exceed 2.0 m.

2.5.118 When determining loads taken for strength calculations of bottom grillage of the cargo compartment, the gravity force of light tank and the gravity force of loaded tank may be assumed distributed uniformly over the whole surface of the grillage. Here, loads $p_{\text{light}}$ and $p_{\text{load}}$, kPa, from the weight of a light tank and loaded tank correspondingly are determined by the formulae:

$$p_{\text{light}} = 9.81Q_{\text{light}}/(L_b B_l); \quad (2.5.118-1)$$

$$p_{\text{load}} = 9.81Q_{\text{load}}/(L_b B_l), \quad (2.5.118-2)$$

where $Q_{\text{light}}$, $Q_{\text{load}}$ — weight of a light tank and loaded tank correspondingly, t;

$L_b$ — see Table 2.4.11-1;

$B_l$ — design floor span taken equal to: for single-sided tankers not fitted with longitudinal trusses in the cargo hold – the ship’s breadth B; for single-sided tankers fitted with longitudinal trusses between the cargo tank and the side – the distance between the longitudinal trusses; for double-sided tankers — the distance between inner sides.
2.5.119 When choosing design spans of floors and beams and when determining design loads on pillars for trunk deck tankers, if there is a continuous longitudinal coaming with the rigidity exceeding the rigidity of the keelson situated under the coaming in question by at least 8 times, and if there are pillars fitted between the coaming and the keelson in places where the keelson intersects with each floor, the system “coaming + keelson” is considered equal to a longitudinal truss.

2.5.120 Section modulus, cm², of a floor of the cargo hold with effective flange, if no double bottom is provided, shall be not less than

\[ W = \frac{0.428k_1k_2dB^2}{p} \]  

(2.5.120-1)

where \( p \) — design pressure on the bottom, kPa, taken equal to the greatest of the values obtained from the formulae:

\[ p = 9.81(T + r + m) - p_{\text{light}} \]  

(2.5.120-2)

\[ p = p_{\text{load}} - 9.81(T - r - m) \]  

(2.5.120-3)

where \( k_1, k_2, d, T, r \) — see 2.4.11;

\( p_{\text{light}}, p_{\text{load}} \) — see 2.5.118;

\( m \) — value, m, taken equal to, for ship classes:

- M-СП, M-ПП, O-ПП, М, О 0.6
- P and ІІ 0.9

Value of \( p \) calculated by formula (2.5.120-3) shall not exceed \( p_{\text{load}} \).

2.5.121 The cargo hold bottom area supported by one pillar of a traverse truss, m², is calculated by the formula:

\[ f = 0.5L_bB_1/(n_k + 2n_t) \]  

(2.5.121-1)

where \( L_b \) — taken from Table 2.4.11-1;

\( B_1 \) — taken as per 2.5.118;

\( n_k \) — number of keelsons between longitudinal trusses or inner sides and, where the latter are not provided, between the outer sides;

\( n_t \) — number of floors between transverse bulkheads or between a transverse bulkhead and a truss.

The cargo hold bottom area supported by a pillar of a longitudinal truss, m², is calculated by the formula:

\[ f = 0.5L_bB_1/(n_k + n_t) + 0.5L_bB/(n_t + 1) \]  

(2.5.121-2)

where \( b \) — distance between the side and the longitudinal truss.

Design load taken by a pillar of the truss, kN, is determined by the formula:

\[ P = fp \]  

(2.5.121-3)

where \( p \) — see 2.5.120.

If there are no longitudinal trusses in the hold, the force taken by one pillar of the longitudinal row of pillars is determined as per 2.2.54 and 2.2.26.3.

2.5.122 Design load on the sides in the independent tanks area is determined in accordance with 2.2.24 as for dry cargo ships. If there is no double bottom, in formulae (2.2.24-1) and (2.2.24-2) it shall be taken as \( h_{db} = 0 \).

2.5.123 Design load applied to transverse cargo hold bulkheads in the area of vertical independent tanks is determined according to 2.2.25.3.

2.5.124 Design load for tanker deck in the vertical independent tanks area is determined according to 2.2.26.3.

2.5.125 Section modulus of beams and half-beams with effective flange in the vertical independent tanks area is determined according to 2.4.48.3.

2.5.126 Section modulus of under-deck longitudinal girders with effective flange in the vertical independent tanks area is determined according to 2.4.51.4.

Floating cranes

2.5.127 The requirements of 2.5.128 to 2.5.141 apply to non-propelled boom grab-hooked floating cranes of O-ПП (неа) and O (nea) classes with full-swing upper lifting structure non-movable along the hull (pontoon) with a lifting capacity up to 25 t, a length up to 50 m and main dimensions ratio \( L/H \leq 15, B/H \leq 7 \).

In addition, the requirements of 2.1 to 2.3 shall be met if they are not contradict with the requirements of 2.5.128 to 2.5.141.
Note: the О-ПП and О classes for floating cranes are assigned according to the navigation conditions for towing with boom fastened in the cruising position. Limiting wind and wave operation conditions are designated by a designer.

If main dimension ratios differ from those given in this paragraph, structure and scantlings shall be verified by additional strength calculations.

2.5.128 Structure of crane foundation shall consist of a bearing ring, a drum and a cross made of longitudinal and transverse bulkheads (Fig. 2.5.128).

Fig. 2.5.128 Crane foundation design
1 — bearing ring, 2 — drum, 3 — longitudinal bulkheads of the cross, 4 — transverse bulkheads of the cross, 5 — forepeak bulkhead, 6 — afterpeak bulkhead

2.5.129 Peak bulkheads shall be located at the distance of at least one spacing towards the middle frame from the beginning of the parallel body. In all cases, the forepeak length shall be not less than 7-fold spacing and the afterpeak length not less than 5-fold spacing.

2.5.130 Pontoon sides, the forepeak and the afterpeak shall have the transverse framing system. The spacing in the forepeak and the afterpeak shall be not more than 400 mm and floors shall be installed at each frame.

Where the spacing is over 400 mm, in the fore and aft extremities intermediate frames shall be fitted at the sides with the section modulus with effective flange meeting the requirements of 2.4.121.

2.5.131 Transverse bulkheads of the cross shall be flat over the entire pontoon’s breadth and longitudinal bulkheads of the cross shall be flat over at least three spacings forwards of and abaft the place of connection with the drum. Other bulkheads of floating cranes may be corrugated.

Longitudinal bulkheads of the cross shall be installed either over the entire pontoon’s length or between the forepeak and the afterpeak bulkheads.

Ordinary framing of the flat bulkheads as well as corrugations shall be arranged vertically.

2.5.132 Thicknesses of the below mentioned pontoon hull members with regard to ice strengthening shall be taken not less than, mm:
- outer shell plating and deck plating over the entire pontoon’s length 8.0
- plates of flat transverse bulkheads of the cross over the entire pontoon’s breadth and of longitudinal bulkheads of the cross over at least three spacings forward of and abaft the place of connection with the drum 8.0
- rest plates of bulkheads 6.0
- bilge strake over the entire pontoon’s length 10.0

2.5.133 Drum wall thickness \( \delta \), mm, shall be not less than one obtained by the formula

\[
\delta = \left( P_c + Q_c \right) \left( 1 + 2C/R \right) / (16R),
\]

(2.5.133)

where \( P_c \) — crane lifting capacity, t;
\( Q_c \) — crane weight (upper structure), t;
\( R \) — drum radius, m;
\( C \) — distance from the drum axis to the crane’s C.G. with the greatest load at the maximum boom reach, m.

Regardless of the calculation results, the drum wall thickness shall not be taken less than 8 mm.

2.5.134 A distance between the side and the longitudinal bulkhead of the cross shall be taken as a design span \( B_i \) of floors and web beams, when determining their section modulus; here, \( B_i \) shall be not less than 0.38 \( B \).

2.5.135 Section modulus of a side web frame with effective flange over the entire pontoon’s length, cm\(^3\), shall be not less than

\[
W = 0.14LBHd_i,
\]

(2.5.135)

where \( d_i \) — distance between the web frames in the middle part of ship, m.
2.5.136 Section modulus of a side ordinary frame with effective flange over the entire pontoon’s length, \( cm^3 \), shall be not less than

\[
W = 0.10LBla,
\]

(2.5.136)

where \( l \) — the greatest distance measured along the side between the bottom and a side stringer or between a side stringer and the deck, m;

\( a \) — spacing in the middle part of ship, m.

2.5.137 Transom stays shall be maximum 400 mm apart.

Web stays shall be installed in the keelson planes. Free flange of the web stay shall have a cross-sectional area of at least 0.65 of the cross-sectional area of a keelson free flange.

Section modulus of an ordinary stay or intermediate stay with effective flange shall be not less than a section modulus of an ordinary frame with effective flange determined in accordance with 2.5.136.

Where a distance between stays is more than 400 mm, intermediate stays shall be fitted and their section modulus with effective flange shall be not less than 75% of the section modulus of main ordinary stays with effective flange.

2.5.138 Thickness of a bearing ring web shall be not less than 10 mm, thickness of a free flange not less than 20 mm. Thickness of webs of vertical knees supporting the web and the flange shall be not less than 10 mm. A distance between the knees measured over a chord of the bearing ring shall not exceed 0.70 m.

Constructional difference in wall thickness of the bearing ring and the drum shall be compensated by fitting, between the bearing ring and the drum, a horizontal circular piece at least 12 mm thick which may be made of separate rectangular plates.

Fastening of the bearing ring to the deck shall be such as to prevent formation of stress concentration centres. Knees shall not be welded to non-reinforced deck plates; in the plane of knees under the deck a stiffener or another structural element shall be fitted which shall be adequately connected with the framing.

2.5.139 Section modulus of vertical web stays with effective flange of the drum and flat bulkheads of the cross (mentioned in 2.5.131) shall be not less than that determined for the side web frame according to 2.5.135.

2.5.140 Distance between vertical members of the drum measured over a chord shall not exceed 0.70 m.

Section modulus of ordinary stays with effective flange of the drum and flat bulkheads of the cross (mentioned in 2.5.131) shall be not less than that determined for the side ordinary frame according to 2.5.136.

2.5.141 Local strength of the forepeak and the afterpeak bulkheads shall be ensured with due regard to the design load as specified in 2.2.25.1.

**Tankers fitted with longitudinal round cylindrical built-in tanks**

2.5.142 The requirements of 2.5.143 to 2.5.156 apply to tankers fitted with one or two longitudinal cylindrical built-in tanks rigidly connected to the hull and participating in global bending.

2.5.143 In all cases not stipulated in 2.5.144 to 2.5.162, the requirements of 2.1 to 2.4 are applied.

2.5.144 Vertical distance between the upper edge of the cylindrical tank and the deck in the centreline plane shall not exceed, for ship classes:

- О-ПР, О, P, J — 0.7\( d_t \)
- М-СП, М-ПР, М — 0.6\( d_t \)

where \( d_t \) — diameter of the cylindrical tank, m.

2.5.145 Vertical distance between the lower edge of the cylindrical tank and the deck in the centreline plane shall not exceed, for ship classes:

- М-СП — 200
- М-ПР, М — 235
- О-ПР, О, P — 285
In any case, thickness $t$ shall be at least, mm, for ship class:

- M-СІІ: 14
- М-ПР, М: 12
- О-ПР, О, П: 10

Plating thickness $t_1$ of below-deck section of the cylindrical tank may be taken by 30% less than that of above-deck section. For ships of M-СІІ class the thickness $t_1$ of below-deck section of the cylindrical tank shall be at least 10 mm.

2.5.147 Constructional difference in wall thickness in butts and seams of the adjoining plates of the cylindrical tank shall not exceed 15% of the thickest plate thickness or 3 mm, whichever is less. Constructional angular offset of the cylindrical tank in the field joint area (angular offset of the cylinder generatrix may occur during ship construction due to constructional difference in shapes of cross-sections of the adjoining shells) shall not exceed the thickest plate thickness. Diameter tolerance of the cylindrical tank measured in any direction in the frame plane shall not exceed 0.3% of the design diameter value.

2.5.148 Provision shall be made for smooth ends of longitudinal cylindrical tanks in fore and aft extremities of the ship using flat inclined sections at the tank ends. The inclination angle of such a flat section to the deck shall not exceed 30°.

2.5.149 The transverse bulkheads and trusses shall be installed in the hull according to the 2.5.8. End transverse bulkheads and one midship transverse bulkhead in the tanks shall be arranged in the same vertical plane with the transverse hull bulkheads. Other transverse bulkheads may be fitted in the planes of hull’s web frames.

2.5.150 Below-deck cylindrical shells shall be reinforced by circular web frames fitted maximum 4 m apart and running along the external surface of the shell in the planes of hull’s web frames.

2.5.151 A keelson running over the whole length of the tank shall be fitted between each cylindrical tank and the hull bottom. The tanks shall be connected to the bottom by means of brackets fitted between the tank’s circular web frames and the hull’s floors. At each side of the keelson, brackets shall be fitted over the floor length equal to the shell radius.

2.5.152 Scantlings of the ships under consideration are determined according to 2.4 as for single-bottom dry cargo ships; here, the value of $B_1$ (see 2.4.11) is not less than $B/2$ for tankers with one tank and not less than $B/3$ for tankers with two tanks.

2.5.153 Minimal thickness of the shell plating, sheerstrake and deck stringer in the middle part of ship shall be determined from Tables 2.4.1-1 and 2.4.1-2 as for ships with reduced length

$$L_{red} = LH/H_1,$$

where $H_1$ — hull girder height, m.

2.5.154 Maximum normal stresses in the upper edge of longitudinal cylindrical shell under compression in the limit state (during ship sagging), MPa, shall not exceed the critical stresses determined by the formula:

$$\sigma_{cr} = kE t/R,$$  \hspace{1cm} (2.5.154)

where $k$ — coefficient equal to 0.36 for $75 < R/t < 300$;

$E$ — Young’s modulus of the shell material, MPa;

$R/t$ — cylindrical shell radius to thickness ratio in the above-deck section.

2.5.155 Critical pressure $p_{cr}$ caused by depression due to cargo unloading and uniformly distributed along the cylindrical shell surface, kPa, shall comply with the following condition

$$p_{cr} \geq 1.5p_E,$$  \hspace{1cm} (2.5.155-1)

where $p_E$ — vacuum during cargo unloading, corresponding to the breathing valve setting, kPa, equal to 7 kPa.

The critical stress value, kPa, is taken as the following

$$p_{cr} = 920E(R/L_1)(t/R)^{2.5},$$  \hspace{1cm} (2.5.155-2)

where $E$ — Young’s modulus of the shell material, MPa;
$R$ — cylindrical shell radius, mm;  
$L_t$ — maximal length of the cargo hold (distance between transverse bulkheads in the cylindrical tank), mm;  
$t$ — cylindrical shell thickness in the above-deck section, mm.

2.5.156 Circular normal stresses in the lowermost point of the cylindrical shell (in the longitudinal plane), MPa, shall comply with the following condition

$$
\sigma_y = \left( p_e + 19.62 \cdot 10^{-3} R \right) \left( R/t_1 \right) \cdot 10^{-3} \leq 0.8 R_{th},
$$

(2.5.156)

where $p_e$ — excessive pressure in the cargo hold corresponding to the breathing valve setting, kPa;  
$R$ — cylindrical shell radius, mm;  
t_1 — cylindrical shell thickness in the below-deck section, mm;  
$R_{th}$ — yield point of the cylindrical shell material, MPa.

Tankers fitted with longitudinal cylindrical independent tanks

2.5.157 The requirements of 2.5.158 to 2.5.161 apply to tankers fitted with one or two longitudinal cylindrical independent tanks not participating in global bending. The tanks shall be fastened in such a manner as to prevent transfer of loads or displacements with respect to the hull structures. Weight of independent tanks and loads induced by them shall be uniformly distributed between the hull structures.

2.5.158 The pressurized tanks shall be designed for strength according to 8 Part IV of the Rules, and testing methods shall comply with the requirements of Appendix 10 RTSC.

2.5.159 Cargo tank material shall be resistant to aggressive cargoes or the internal surfaces of the cargo tanks shall have a suitable protective coating.

2.5.160 Covers of the cargo tank hatches and manholes shall be tight.

2.5.161 The distance between the independent tanks and the side or bottom shall be not less than that for ships with built-in tanks.

2.6 VIBRATION STRENGTH

General requirements

2.6.1 The present requirements are set up to provide strength of the hull structures and reliable operation of onboard equipment.

2.6.2 When calculating vibration, it is necessary to verify the absence of resonance by comparing natural oscillation frequencies with frequencies of exciting forces due to operation of main and auxiliary engines, propellers and other sources of vibration.

2.6.3 In addition to meeting the requirements of 2.6.2, the following shall be verified:

1. global vertical oscillations of the hull for the first two tones in design loading conditions: fully loaded condition and lightship condition with ballast;
2. local first-tone oscillations of ordinary members, stiffeners and outer shell plating, decks, platforms, bulkheads and webs of web members.

2.6.4 Local oscillations shall be checked in the following areas:

1. the bottom between the transom and a section located 3 propeller diameters forward of the centre of propeller disc for single-propeller ships and 4 propeller diameter forward of the centre of propeller disc for two- or three-propeller ships;
2. ship compartments where engines (main and auxiliary) and other similar machinery are installed;
3. tanks adjacent to the engine room.

2.6.5 Calculations of global and local vibration, as well as experimental determination of vibration parameters shall be carried out for:

1. first ship in a series;
2. ships of single construction;
3. ships after a major overhaul repair;
4. ship on which main and auxiliary engines or other similar machinery were replaced or propellers of different dimensions were installed.

Global vibration calculation

2.6.6 In order to prevent resonance, natural oscillation frequencies of the first tone
shall differ by 15%, and those of the second tone by 20%, from the frequency of exciting forces equal to:

.1 propeller revolution frequency;
.2 propeller revolution frequency multiplied by the number of blades;
.3 engine crankshaft revolution frequency;
.4 doubled engine crankshaft revolution frequency;
.5 engine crankshaft revolution frequency multiplied by a number of operation cycles \( n_c \) in the engine cylinders per revolution as obtained by the formula:

\[
n_c = ki, \quad (2.6.6.5)
\]

where \( k \) — coefficient equal to:

- for two-stroked engine 1
- for four-stroked engine 0.5

\( i \) — number of engine cylinders;
.6 running frequency of the scoop chain when running from the upper drum;
.7 bottom scoop drum revolution frequency;
.8 mechanical loosener revolution frequency;
.9 mechanical loosener revolution frequency multiplied by the number of cutters.

2.6.7 Frequency \( N_1 \) of the first-tone natural vertical oscillations relating to the hull, Hz, shall be determined by the formulae:

.1 for cargo ships (including tankers)

\[
N_1 = 6.25 \cdot 10^6 \sqrt{I/[1.2 + B/(3T)]D' L^2}; \quad (2.6.7.1)
\]

.2 for passenger ships and cargo-and-passenger ships

\[
N_1 = 5.92 \cdot 10^6 \sqrt{I/[1.2 + B/(3T)]D' L^2}; \quad (2.6.7.2)
\]

.3 for tugboats and pushboats

\[
N_1 = 5.27 \cdot 10^6 \sqrt{I/[1.2 + B/(3T)]D' L^2}; \quad (2.6.7.3)
\]

where \( I \) — area moment of inertia of the hull girder midship section, \( m^4 \) (see 2.2.9);

\( B \) — ship breadth, m;

\( T \) — ship draught amidships, m;

\( D' \) — ship displacement, t;

\( L \) — ship length at the actual waterline, m.

Values of these parameters are taken for design loading conditions.

The moment of inertia shall be determined with due regard to the superstructure participation in the hull global bending as per 2.2.34.

2.6.8 Frequency \( N_2 \) of natural vertical oscillations of the second tone relating to the hull, Hz, shall be determined by the formulae:

.1 for cargo ships

\[
N_2 = 2.6N_1; \quad (2.6.8.1)
\]

.2 for passenger ships and tugboats (pushboats)

\[
N_2 = 2.3N_1. \quad (2.6.8.2)
\]

Local vibration calculation

2.6.9 In order to prevent resonance, natural oscillation frequencies of the first tone shall exceed – by at least 50% for plates and by 30% for ordinary members and stiffeners – the frequencies of exciting forces equal to:

.1 shaft revolution frequency multiplied by the number of propeller blades;
.2 engine crankshaft revolution frequency multiplied by the number of operating cycles in the engine cylinders per revolution of the crankshaft;
.3 revolution frequency of lower or upper scoop drum, whichever is greater;
.4 mechanical loosener revolution frequency multiplied by the number of cutters (see footnote in 2.6.9.1).

The required frequency excess shall be ensured for all basic operational modes of the ship.

Note. For basic operational modes of prime movers, generators and cargo pumps, the exciting

1 In the area of intensive affection of exciting forces due to operation of propellers (see 2.6.4.1).

2 In the area of compartments where the engines and other machinery are installed.

3 In the area of effectors.
force frequency may exceed (by at least 30%) the natural oscillation frequency.

If the required frequency excess is not ensured, design measures shall be provided to increase the natural oscillation frequency. Efficiency of these measures shall be verified by repeated calculation.

The above frequencies may be exceeded by 25% for plates and by 15% for ordinary framing and stiffeners, provided that a designer submits a well-grounded calculation of forced vibration to prove that oscillation amplitude of the mentioned components does not exceed the permissible value (see 2.6.25).

2.6.10 Natural oscillation frequency $N$ of the first tone of an outer shell plate resting on web members and not reinforced by ordinary members or stiffeners, Hz, is determined by the formula:

$$N = \pi \left(1 + a^2 / b^2\right) \sqrt{E / \left[12 \rho (1 - \mu^2)\right]} / \left(2a^2\right),$$

(2.6.10)

where $a$ — shorter side of the plate, m;
$b$ — longer side of the plate, m;
$E$ — Young’s modulus of the plate material, Pa;
$\rho$ — plate material density, kg/m$^3$;
$\mu$ — Poisson’s ratio of the plate material.

2.6.11 Natural oscillation frequency $N^*$ of the plate with due regard to added masses of liquid, Hz, shall be calculated by the formula:

$$N^* = N / \sqrt{k_p},$$

(2.6.11-1)

where $N$ — see 2.6.10;
$k_p$ — added mass coefficient to natural oscillation frequencies of plates determined by the formulæ:

- when the plate is washed by liquid from one side,
  $$k_p = 1 + \alpha \rho_{liq} a / (\rho t)$$
  (2.6.11-2)
- when the plate is washed from both sides by liquids of different densities,
  $$k_p = 1 + \alpha \rho_{liq} / (\rho_{liq} + \rho_{liq}^* ) / (\rho t)$$
  (2.6.11-3)

$\rho_{liq}$, $\rho_{liq}^*$ — densities of liquids, kg/m$^3$;
$\rho$ — plate material density, kg/m$^3$;
$\alpha$ — coefficient determined depending on the plate sides ratio from Table 2.6.11;
$t$ — plate thickness, m.

2.6.12 Natural oscillation frequency $N_p$ of the first tone of outer shell plate cells resting on web members and reinforced by ordinary members or stiffeners (Fig. 2.6.12), Hz, is determined by the formula:

$$N_p = 0.5 \pi \left(1 + c^2 / l^2\right) \sqrt{E t^2 / [12 \rho (1 - \mu^2)]} / (2c^2),$$

(2.6.12)

where $c$ — shorter side of the plate cell formed by web and ordinary members, m;
$l$ — longer side of the plate cell, m;
$E$, $t$, $\rho$, $\mu$ — see 2.6.10 and 2.6.11.

2.6.13 Natural oscillation frequency $N_{p*}$, Hz, of the plate cell with due regard to added masses of liquid shall be calculated by the formula (2.6.11-1). Here, liquid added mass coefficient is determined by the formulæ:
when the plate is washed by liquid from one side,
\[ k_p = 1 + \alpha a p_{\text{liq}} / (p t), \] (2.6.13-1)
when the plate is washed from both sides by liquids of different densities,
\[ k_p = 1 + \alpha a (p_{\text{liq}}' + p_{\text{liq}}^*) / (p t), \] (2.6.13-2)
where \( \alpha \) — coefficient determined from Table 2.6.11 depending on the ratio of the cell sides.

\( c \) — shorter side of the plate cell, m;
\( \rho_{\text{liq}}, \rho_{\text{liq}}', \rho, t \) — see 2.6.11.

2.6.14 Natural oscillation frequency of the first tone of the ordinary members or stiffeners, Hz, is determined by the formula:
\[ N_p = K \sqrt{E i / (m_p t^4)}, \] (2.6.14-1)
where \( K \) — coefficient equal to:
- when both ends of profiles are freely resting \( 1.57 \)
- when one end of profile is freely resting and the other one is constrained \( 2.46 \)
- when both ends of profile are constrained \( 3.56 \)
\( E \) — Young’s modulus, Pa;
\( i \) — area moment of inertia, \( m^4 \), of a stiffener or ordinary member with effective flange of the plating, whose scantlings are determined according to 2.2.53.1;
\( m_p = p (f + ct), \) (2.6.14-2)
\( l \) — length of the stiffener, m;
\( f \) — cross-sectional area of the isolated stiffener, \( m^2 \);
\( t \) — see 2.6.10;
\( c \) — see 2.6.12.

2.6.15 Natural oscillation frequency \( N_{fr}^* \), Hz, of the ordinary members or stiffeners with due regard to the added masses of liquid shall be calculated by the formulae:
\[ N_{fr}^* = N_{fr} / \sqrt{k_{fr}}, \] (2.6.15-1)
where \( k_{fr} \) — coefficient of the added masses effect which shall be determined regardless of orientation of stiffeners by the formula:
\[ k_{fr} = 1 + \alpha p_{\text{liq}} a / (\rho t_{\text{red}}), \] (2.6.15-2)
where \( p_{\text{liq}} \) — see 2.6.11.

Values of coefficient \( \alpha \) shall be taken from Table 2.6.11 depending on the \( a/b \) ratio, i.e. dimensions of plates before ordinary members or stiffeners are fitted.

Reduced thickness \( t_{\text{red}} \) of plate with stiffener, m:
\[ t_{\text{red}} = t + f / c, \] (2.6.15-3)
where \( t, f, c \) — see 2.6.14.

When the plate reinforced by ordinary members is washed by liquid from both sides, \( k_{fr} \) is determined by the formula
\[ k_{fr} = 1 + \alpha (p_{\text{liq}}' + p_{\text{liq}}^*) a / (\rho t_{\text{red}}), \] (2.6.15-4)
where \( p_{\text{liq}}' \) and \( p_{\text{liq}}^* \) — see 2.6.11.

2.6.16 A ratio of natural oscillation frequencies of the ordinary members (or stiffeners) and an outer shell plate shall meet the condition \( N_p^*/N_{fr}^* > 2 \).

2.6.17 Natural oscillation frequency \( \sigma \), Hz, of the first tone of the inner structure plates resting on web members and not reinforced by ordinary members or stiffeners shall be determined by the formula:
\[ N = 1.13 \pi \sqrt{1 + 0.605 a^2 / b^2 + a^4 / b^4} \times \sqrt{E i / \left[ 12 \rho (1 - \mu^2) \right]} \right] / a^2, \] (2.6.16)
where \( a, b, E, t, \mu \) — see 2.6.10.

2.6.18 Natural oscillation frequency of plates mentioned in 2.6.17 with due regard to added masses of liquid shall be calculated by formulae (2.6.11-1) to (2.6.113). Coefficient \( \alpha \) shall be taken according to Fig. 2.6.18 depending on the \( a/b \) side ratio from the \( n = 1 \) curve.

2.6.19 Natural oscillation frequency, Hz, of the inner structure plate cells resting on web members and reinforced by ordinary members or stiffeners (see Fig. 2.6.12) shall be determined by the formula:
\[ N_p = 1.13 \pi \sqrt{1 + 0.605 c^2 / l^2 + c^4 / l^4} \times \sqrt{E i / \left[ 12 \rho (1 - \mu^2) \right]} \right] / c^2. \] (2.6.19)
2.6.20 Natural oscillation frequency $N_{sp}^*$, Hz, of the plate cell with due regard to added masses of liquid shall be calculated by formula (2.6.11-1). Added-mass coefficient shall be determined by formulae (2.6.13-1) and (2.6.13-2). Coefficient $\alpha$ in these formulae shall be selected using Fig. 2.6.18 depending on the ratio of cell sides $c/l$ from the curve corresponding to $n$ equal to number of cells.

2.6.21 Natural oscillation frequency of the first tone of the ordinary members or stiffeners for inner structures, when they oscillate in the air, shall be determined by formulae (2.6.14-1) and (2.6.14-2). The liquid added masses is regarded by formulae (2.6.15-1) to (2.6.15-4).

2.6.22 Calculation of natural oscillation frequency of plates and ordinary members or stiffeners for inner structures shall be considered completed, when $N_{sp}^*/N_{sp}^* > 2$ (or $N_{sp}/N_{p} > 2$ for structures in the air). Otherwise, interaction between the plates and stiffeners, when they oscillate, shall be considered (see 2.6.23).

2.6.23 Natural oscillation frequency $N_c$, Hz, of the first tone of the plates by the inner structure stiffeners, which support these plates, with due regard to its interaction shall be calculated by the formula:

$$
N_c^2 = \frac{A_1 + A_2 \pm \sqrt{(A_1 + A_2)^2 - 4A_1A_2(1-\beta_1\beta_2)}}{2(1-\beta_1\beta_2)},
$$

(2.6.23-1)

where $A_1$ and $A_2$ — squares of natural frequencies of a plate and a stiffener (or an ordinary member) correspondingly, determined as per 2.6.19 to 2.6.21;

$\beta_1, \beta_2$ — coefficients calculated by the formulae:

$$
\beta_1 = 4\left[1 + \sqrt{1.5(k_p^2 - 1)(k_p^2 - 1)t_{red}/l}\right]/(3k_p);
$$

(2.6.23-2)

$$
\beta_2 = 0.5r\left[1 + \sqrt{1.5(k_p^2 - 1)(k_p^2 - 1)t_{red}/l}\right]/(t_{red}k_p);
$$

(2.6.23-3)

$t_{red}$ — reduced thickness of the plate with a stiffener determined by the formula (2.6.15-3).

Frequency $N_c$ shall comply with the requirements of 2.6.9 as for plates.

**Vibration norms**

2.6.24 Regardless of the calculation results of global and local vibration in ships listed in 2.6.5, vibration amplitudes and frequencies of the following structures shall be measured:

1. the aft extremity of hull;
2. plates of the outer shell plating and the inner structures of the hull and the superstructure;
3. ordinary members and stiffeners;
4. bearing surfaces of foundations;
5. web members in the grillage;
6. engines and similar equipments.

In these ships, it is recommended to obtain experimentally frequencies of vertical hull oscillations of the first two tones and to compare them with frequencies obtained by calculation.

In these ships, it is recommended to obtain experimentally frequencies of vertical hull oscillations of the first two tones and to compare them with frequencies obtained by calculation.

These measurements shall be made on deep water\(^1\), as well as at limited depth under

\(^1\) Deep water means that depth $H$ of a water body does not affect propulsion performance
of the bottom (shallow water conditions) at design draught in loaded conditions and lightship conditions for all basic operational modes of the main and auxiliary engines and onboard equipment in accordance with the program of vibration testing elaborated by a designer meeting the requirements of the Rules and approved by the River Register.

2.6.25 Oscillation amplitudes measured during the experiment shall not exceed the vibration norms defined by the following formulae:

1. Permissible amplitudes $A_1$, mm, of vertical oscillations of the aft extremity of ship are defined by the formula:

$$ A_1 = 2 \left( 1 + 0.04N^2 \right) \frac{N}{1 + 0.04N^2}, $$

where $N$ — actual oscillation frequency measured during the experiment, Hz.

2. Permissible oscillation amplitudes $A_2$, mm, of bearing surfaces of the engine foundations for frequencies $N = 10$ Hz are 0.5; for frequencies over 10 Hz the amplitudes $A_2$ are determined by the formula:

$$ A_2 = 1 \left( 0.02N^2 \right), $$

3. Permissible oscillation amplitudes $A_3$, mm, of plates in their centre are determined by the formula:

$$ A_3 = 0.125 \left( \frac{a}{100t} \right)^2 t, $$

where $a$ — shorter side of the plate, mm;
$t$ — plate thickness, mm.

4. Permissible oscillation amplitudes $A_4$, mm, of ordinary members and stiffeners in the middle of the span are determined by the formula:

$$ A_4 = 4000W^2 \left( E_i \right), $$

where $W$ — section modulus of the profile with effective flange, $m^3$;
$l$ — span of an ordinary member or a stiffener, m;
$E$ — Young’s modulus of the material, MPa;
$i$ — area moment of inertia of the profile with effective flange, $m^4$;

5. Permissible oscillation amplitudes $A_5$, mm, of web members in the grillage are defined as the least of the two values determined by formulae (2.6.25.1) and given below:

$$ A_5 = 1250W^2 \left( E_i \right). $$

Vibration reducing measures

2.6.26 When vibration exceeds the normative value, measures aimed at its reducing down to the values required by respective norms shall be developed.

Efficiency of the introduced measures shall be proved by repeated measurements of vibration for all basic operational modes of main and auxiliary engines of the ship.

2.6.27 Measures aimed at reducing the global vibration at the frequency equal to the propeller shaft revolution frequency include:

1. Checking propeller’s geometry (pitch of blades, pitch of sections and positional relationship of the axis of blades on the propeller circle). Where deviations exceeding the design limits are found, this propeller shall be replaced;

2. Filling or discharge of ballast tanks;

3. Changing propeller shaft revolution frequency.

2.6.28 Measures aimed at reducing the global vibration with frequency aliquot to the number of propeller blades include:

1. Changing location of the propeller with respect to the hull or a propeller duct;

2. Changing the number of propeller blades;

3. Changing the contours of protruding parts in order to have them streamlined;

4. Fitting special arrangements to make the field of velocities in the propeller disc more even;

5. Fitting shock absorbers in the hull above the propellers.

2.6.29 In order to reduce local vibration of frequency aliquot to the number of propeller
blades, in addition to the measures listed in 2.6.28 proceed as follows:

1. thicken the oscillating plates or reinforce them by intermediate stiffeners;
2. check correctness of design of connections in the places of intersection of longitudinal and transverse members; arrange closed framing rings; check quality of welded joints.

2.6.30 In order to reduce local vibration of frequency aliquot to the frequency of the engine crankshaft revolution, in addition to the measures listed in 2.6.29 proceed as follows:

1. place engines on shock absorbers or suspended joist foundations;
2. connect the engines installed on shock absorbers with other onboard machinery by elastic couplings.

2.6.31 The list of measures stated in 2.6.29 and 2.6.30 is not exhaustive. Other measures to reduce vibration down to the required values shall be taken in each particular case on the basis of analysis of vibration measurements.
3 DESIGN OF DISPLACEMENT SHIP ALUMINUM ALLOY HULLS

3.1 GENERAL REQUIREMENTS

3.1.1 In regard to provisions not specified in the present Section, refer to the requirements of 2.1 to 2.5.

3.2 MATERIALS AND MINIMUM THICKNESSES OF HULL MEMBERS

3.2.1 The materials used for fabrication of hull structural components of aluminum alloys shall comply with the requirements of 4 Part X of the Rules.

3.2.2 The minimum permissible plate thickness of the hull members shall not be less than that stated by the requirements of the Rules to steel ship hulls.

3.3 DETERMINATION OF HULL STRENGTH MEMBERS’ SCANTLING

3.3.1 Influence of the hull flexibility on the bending moment and shear force shall be regarded, if

$$L^4 B/(EI) > 6.01 \cdot 10^3,$$  \hspace{1cm} (3.3.1)

where $L, B$ — design DWL length and breadth of a ship, m;
$E$ — Young’s modulus of the hull material, MPa;
$I$ — area moment of inertia of the hull girder, m$^4$;

3.3.2 When calculating the framing girders, width of effective flange, cm, shall be determined by the following formulae:

1. for the bottom and double bottom longitudinal stiffeners, ordinary frames and beams (Fig. 3.3.2.1, a, d)

$$c_1 = 0.5a;$$  \hspace{1cm} (3.3.2.1)

2. for floors, beams and frames in case of the longitudinal framing system, keels and carlings in case of the transverse framing system (Fig. 3.3.2.1 b, d)

$$c_2 = c_1 + (b - c_1)\varphi_1,$$  \hspace{1cm} (3.3.2.2)

where $c_1$ — width of effective flange as per 3.3.2.1, cm;
$\varphi_1$ — coefficient equal to zero for compressed effective flange and defined from Table 3.3.2.2 for tensioned effective flange of plating;

3. for floors, beams and frames in case of the transverse framing system, keels and carlings in case of the longitudinal framing system (Fig. 3.3.2.1, b, d)

$$c_3 = 0.5na(1 + \varphi_2),$$  \hspace{1cm} (3.3.2.3)

where $n$ — number of rigid and reduced sections;
$\varphi_2$ — coefficient equal to 1 for tensioned effective flange and defined from diagram on Fig. 3.3.2.3 for compressed effective flange.

**Note.** $\sigma_{\text{perm}}$ — permissible stress; $t$ — plate thickness, cm.

#### 3.3.5 For constrained plates, maximum stresses $\sigma$ in a section at the bearing contour, when subjected to transverse load, shall be determined by Fig. 3.3.5.

#### 3.3.6 For plates, for which stresses in the bearing sections are not regulated, $\sigma$ due to transverse load shall be found by Fig. 3.3.6.

#### 3.3.7 Euler’s stresses in plates, MPa, shall be calculated by the formulae:

- in case of compression along the long side of the bearing contour
  \[ \sigma_E = 26 \left( \frac{100t}{a} \right)^2; \]  
  (3.3.7-1)
- in case of compression along the short side of the bearing contour
  \[ \sigma_E = 120 \left( \frac{100t}{a} \right)^2; \]

### Notes
- The effective flange width in all cases shall not exceed $\frac{1}{6}$ length of design span of the girder concerned.
- **3.3.3** Webs of profiles, in case of web height to thickness ratio exceeds 60, shall be reinforced by stiffeners.
- **3.3.4** A free flange width $b_f$ to thickness $t_f$ ratio shall not exceed the value determined by the formula:
  \[ b_f/t_f = 100 \sqrt{2.65/R_{\text{Hy}}} \]  
  (3.3.4)
  where $R_{\text{Hy}}$ — yield point of the material, MPa.
  The $b_f/t_f$ ratio shall not exceed 14.
\[ \sigma_E = 6.37 \left( 100 t / a \right)^2 \left( 1 + a^2 / b^2 \right)^2; \]  
(3.3.7-2)

in case of shear forces (the side plates)

\[ \tau_E = 6.37k \left( 100 t / a \right)^2, \]  
(3.3.7-3)

where \( t \) — plate thickness, cm;
\( a \) — length of the short side, cm;
\( b \) — length of the long side, cm;
\( k \) — coefficient determined from Table 2.2.75.

3.3.8 The spacing of a transversely framed hull shall be taken not more than 500 mm.

In case of the longitudinal framing system of the bottom and decks, the spacing shall not exceed 600 mm.

The spacing in way of forepeak shall be decreased down to 400 mm.

3.3.9 Continuous floors shall be installed at least every three spacings. Bracket floors are not allowed.

3.3.10 Section modulus of the continuous floors, \( cm^3 \), shall be at least

\[ W = 62.5Q B_t / \sigma_p, \]  
(3.3.10)

where \( Q \) — total load on the floor, kN;
\( B_t \) — hold width at a level of the upper floor edge, m;
\( \sigma_p \) — permissible stresses, MPa.

3.3.11 Keelsons shall be installed in such a way that a distance between them, for ships of all classes, does not exceed 2 m. Area moment of inertia of centre keelson shall not be less than 1.5 of the area moment of inertia of continuous floor and 0.75 of that of the side keelsons.

3.3.12 The minimum thickness of the outer shell plating shall be specified based on the calculation results.

3.3.13 Area moment of inertia of side branch of a web frame, \( cm^4 \), shall not be less than

\[ I_1 = 2IH / B_t, \]  
(3.3.13)

where \( I \) — area moment of inertia of the floor, \( cm^4 \);
\( H \) — height of the side frame branch, m;
\( B_t \) — hold width at the level of the upper floor edge, m.

3.3.14 Where the side depth is 2 to 3 m, one side stringer is required; when it exceeds 3 m, two side stringers are required.

3.3.15 Thickness of the side outer shell plating shall be taken the same as that of the bottom.

3.3.16 A ratio of critical normal stress and the yield point is a buckling criterion of the grillage's girders \( \sigma_{cr} / R_{el} \); this ratio is determined by the diagram (Fig. 3.3.16) and shall be not less than the following:

for longitudinal web members of the deck and bottom grillages (carlings, keelsons) of all ship types

for longitudinal girders of the deck grillages:

where keelsons are participating in global bending of the grillages;

where keelsons are not participating in global bending at \( l / B_c > 1.5 \) (\( l_c \) and \( B_c \) are the length and width of the grillage, respectively);

for longitudinal girders of the deck grillages:

for open ships

for closed ships

for longitudinal girders of the deck and bottom grillages for flush deck ships

![Diagram for determination of critical normal stresses](image-url)
3.4 PERMISSIBLE STRESSES

3.4.1 For stresses caused by global bending and local load and for summary stresses, the unsafe normal stresses $\sigma_0$ of a constant nature shall be taken as follows, MPa:

1. under tension

$$\sigma_0 = kR_{p_{0.2}}, \quad (3.4.1.1)$$

where $R_{p_{0.2}}$ — yield point of the material corresponding to residual deformation of 0.2%, MPa.

Values of $k$ are taken equal to:

- for riveted structures 0.9
- for welded structures:
  - at $3 \leq t < 4$ 0.7
  - at $t \geq 4$ 0.8

Here, $t$ — thickness of structure elements to be connected, mm;

2. under compression

$$\sigma_0 = \sigma_{cr}, \quad (3.4.1.2)$$

3. unsafe tangent stresses are taken as

$$\tau_0 = 0.57\sigma_0. \quad (3.4.1.3)$$

3.4.2 The regulated permissible normal and tangent stresses are stated in Table 3.4.2.

3.5 WELDING JOINTS

3.5.1 Tee-joints with double-sided welds shall be applied for welding of:
.1 joints of the main hull structure members (floors to keelsons, frames to stringers, beams to carlings and coamings, etc.);
.2 watertight bulkheads, floors, keelsons, etc. to the outer shell plating and flooring;
.3 hull structures in areas of engine room and propulsion units and areas of local vibration, alternate or impact loads;
.4 foundations of engines (main and auxiliary) and of other machinery.

3.5.2 Intermittent fillet welding is not allowed for tee-joints of strength hull structures.

3.5.3 Free ends of girder webs, stiffeners, knees and flanges, as well as sections of girder webs and bulkheads in way of cutouts, in case of single-side welding, shall be continuously welded around with the weld passed over to the other side for at least 30 mm.
4 DESIGN OF CATAMARAN HULLS

4.1 GENERAL REQUIREMENTS

4.1.1 The requirements of the present section apply to the following types of catamaran of M, O, P and J classes:
1. self-propelled aft-engined one-decked dry cargo ships;
2. passenger ships;
3. tugboats and pushboats.

4.1.2 Catamaran general dimensions:
- $L$ — design waterline length, m;
- $B$ — design waterline breadth amidships, m;
- $B_h$ — one hull design waterline breadth amidships, m;
- $H$ — outer side depth amidships, m;
- $H_{fb}$ — freeboard amidships, m;
- $c$ — horizontal clearance (the least distance between inner sides of the hulls at design waterline), m;
- $h_{vi}$ — vertical clearance at $i$th theoretical frame (a distance from the design waterline to plating of the bridge or bottom point of a framing measured at the centre line), m.

4.1.3 The requirements of present chapter are applied to ships whose general dimension ratios correspond to the following conditions:
- $L / H < 25$;  \hspace{1cm} (4.1.3-1)
- $L / B = 4 \div 6$;  \hspace{1cm} (4.1.3-2)
- $h_{vi} / H_{fb} > 0.65$,  \hspace{1cm} (4.1.3-3)

where $h_{vi}$ — vertical clearance amidships in fully loaded condition.

4.1.4 The catamaran hulls shall be made of steel or aluminum alloys complying with the requirements of Part X of the Rules.

4.1.5 In the present chapter, a connection of the catamaran hulls is provided by one of the following ways:
1. by means of a strong superstructure or wheelhouse, whose length is not less than a half of the hull’s length and which are fitted with at least three transverse bulkheads (in the fore, middle and aft parts of a superstructure or a wheelhouse);
2. by means of a bridge, which is a system of transverse girders with a single-sided or double-sided lining. When calculating a strength, short superstructures of a length not exceeding $0.15L$ in the fore and aft extremities shall be considered as a part of the bridge.

4.1.6 Cutouts with width exceeding a half of one hull breadth and with length exceeding a half of the hold length are not allowed in catamaran hull decks if they are connected by means of the bridge. This requirement does not apply to cutouts, above which superstructures or wheelhouses with strong walls (bulkheads) are installed, if requirements of 4.4.3 and 2.4.55 to 2.4.57 are met.

4.1.7 The requirements for checking catamaran hulls’ strength specified in this chapter apply to ships with length-based Froude number not exceeding 0.4.

4.1.8 In regard to issues not specified in this section, refer to the requirements of 2 for steel catamaran hulls and 3 for light alloy catamaran hulls.

4.1.9 A sufficient strength of the hull shall be verified by strength tests of the lead ship in a series conducted according to a program approved by the River Register. The test program shall provide instrumental measurements of both wind and wave conditions and associated loads and stresses, as well as a possibility of subdividing the latter into statical variables and impact components.

The strength assessment of the hull members, the sensors shall be placed in sections where maximum stresses and deformations are expected from the calculations. The
number of sensors shall be sufficient to plot the stress diagram in the section.

During the tests, a stress condition shall be evaluated in components of connecting structures participating in the transverse strength, including transverse bulkheads of superstructures or wheelhouses with adjacent parts of plating. Sensors shall be placed near the inner sides and in the centre plane in order to evaluate symmetrical and unsymmetrical deformations of the transverse members.

A synchronous record of sensor readings shall be ensured.

4.1.10 Design and scantlings of catamaran hull members shall meet the requirements of 4.4.

The scantling of hull members of ships with a length over 50 m shall be also verified by calculation in accordance with the requirements of 4.2 and 4.3.

4.2 CALCULATION OF GLOBAL LONGITUDINAL STRENGTH

4.2.1 Bending moments $M_{sw}$ and shear forces $F_{sw}$ on still water shall be calculated by integrating a load curve over at least 21 equidistant ordinates.

4.2.2 Additional wave bending moment in the middle part of ship, kN·m,

$$M_{aw} = \pm 2 \cdot 9.81 k_0 k_1 k_2 k_3 B_0 L^2 h,$$

(4.2.2-1)

where $k_0$ — coefficient calculated by the following formulae:

for ships of M and O classes

$$k_0 = 1.24 - 1.7 B_0 / L,$$

(4.2.2-2)

for ships of P and Î classes

$$k_0 = 1.24 - 2 B_0 / L,$$

(4.2.2-3)

values of $k_0$ shall not exceed 1;

$B_0$ — design breadth to be taken equal to:

breath of one hull $B$, where the ship’s length $L \leq 30$ m for ships of M class and $L \leq 20$ m for ships of all the rest classes;

breath of ship B, where the ship’s length $L \geq 60$ m for ships of M class and $L \geq 40$ m for ships of all the rest classes;

intermediate values of $B_0$ between $B_0$ and $B$ shall be determined by linear interpolation;

$k_1$ — coefficient determined from Table 4.2.2;

$k_2$ — coefficient taken equal to the greatest of the three values:

$$k_2 = 1;$$

(4.2.2-4)

$$k_2 = 2 - 20 T_f / L;$$

(4.2.2-5)

$$k_2 = 1 + 4.5 k_{av} [1 - (k_{av} / h)^2] \sqrt{1 - (k_{av} / h)^2} / B_0,$$

(4.2.2-6)

$T_f$ — forward draught for design loading condition of the ship, m;

c — horizontal clearance amidships, m;
$h_{av}$ — average value of a vertical clearance over a section from the bridge’s fore extremity to the fifth theoretical frame, if the bridge is extended to the plane of a zero theoretical frame, m,

$$h_{av} = 0.2 \left[ 0.5 (h_{s1} + h_{s5}) + h_{s2} + h_{s4} + h_{av} \right],$$

(4.2.2-7)

when the fore extremity lays at the distance $x_0$, m, to the aft from the theoretical frame,

$$h_{av} = \left[ 0.5 (h_{s1} + h_{s4}) + h_{s2} + h_{s3} + h_{s5} + 0.5 (h_{s4} + h_{s5}) (1 - 2 x_0 / L) / \sqrt{5 - 20 x_0 / L},$$

(4.2.2-8)

$h_{av}$ — vertical clearance at the fore extremity of the bridge;

$k$ — coefficient equal to:

$$k = 2 \beta_c \beta_h / (1 + 3 \psi_c \psi_h);$$

(4.2.2-9)

$\beta_c$, $\beta_h$ — coefficients considering influence of horizontal and vertical clearances in the fore extremity on constraint of flow between the hulls.

### Table 4.2.2

</table>
\[ \beta_c = (0.15 + 3.5 \frac{h}{L}) c_2 / B_h \quad (4.2.2-10) \]
\[ \beta_h = 1 \quad \text{when } h_2 / h \leq 1.25 \]
\[ \beta_h = -0.56 + 1.25 h_2 / h \quad \text{when } h_2 / h > 1.25 \]  
\[ (4.2.2-11) \]
\[ c_2 \] — horizontal clearance at the second theoretical frame, m;
\[ \psi_c, \psi_h \] — coefficients considering influence of the clearances amidships on pitching of catamarans:
\[ \psi_c = 0.43 c / B_h \quad (4.2.2-12) \]
\[ \psi_h = 0.2 + 0.07 \left( 2h_{v10} / h \right) \quad (4.2.2-13) \]
\[ k_3 \] — coefficient dependent on the length-based Froude number:
\[ k_3 = \begin{cases} 1 & \text{when } Fr \leq 0.2 \\ 0.6 + 2Fr & \text{when } 0.2 < Fr \leq 0.4 \end{cases} \quad (4.2.2-14) \]
\[ k_4 \] — coefficient considering the influence of decrease of the bridge length in the fore extremity on reduction of the impact moment; it is taken equal to 1 if the bridge is extended to the zero theoretical frame; where the fore extremity of the bridge is located at the distance \( x_b \) to the aft from the theoretical frame, it is calculated by the following formulae:
\[ k_4 = \begin{cases} 1 & \text{when } 0 \leq x_b / L \leq 0.05 \\ 0.5 & \text{when } x_b / L > 0.05 \end{cases} \quad (4.2.2-15) \]
\[ \delta \] — block coefficient for the design loading conditions, for which the value of \( M_{sw} \) is obtained;
\[ h \] — design wave height, m, taken from Table 2.1.2;

4.2.3 Normal and tangent stresses due to global longitudinal bending shall be calculated according to 2.2.40; here, bridge members are included into the hull girder.

4.2.4 Stresses in longitudinal members due to global longitudinal bending and local bending are summed in accordance with the requirements of 2.2.61 to 2.2.66.

4.2.5 Maximum normal and tangent stresses due to global longitudinal bending and summary stresses shall not exceed permissible stresses specified in:

1. Table 2.2.68 for steel ships;
2. Table 3.4.2 for ships of light alloys.

4.2.6 The global strength of the hull shall be verified checked with regard to ultimate moments in accordance with 2.2.76 to 2.2.94.

4.3 STRENGTH CALCULATIONS OF A BRIDGE STRUCTURE

4.3.1 Calculations proving a sufficient strength of members connecting the hulls in case of unfavorable combination of loads shall be made.

4.3.2 Strength calculations of members connecting the hulls shall be made in accordance with strength calculation method of catamaran hull body bridges (Appendix 1) or other method approved by the River Register.

4.4 DESIGNING OF THE HULL

4.4.1 The minimum permissible thicknesses of hull member plates shall correspond to Table 2.4.1-1. For ships with a length less than 25 m, the minimum thickness is determined according to 2.5.74 to 2.5.84, 2.5.101.

For hulls with deadrise, keel strake thickness shall be not less than that indicated in Table 2.4.1-1 for the bilge strake. For ships with a length of less than 25 m, the bilge strake thickness shall be not less than that specified in 2.5.75.

The minimum thickness of strong lining participating in global and local strength of the bridge shall be taken according to thicknesses specified in Table 2.4.1-1 for the outer shell plating in the middle part of ship. For ships with a length of less than 25 m, the strong lining thickness shall be not less than specified in 2.5.75.

The minimum thickness of strong lining participating in global and local strength of the bridge shall be taken according to thicknesses specified in Table 2.4.1-1 for the outer shell plating in the middle part of ship. For ships with a length of less than 25 m, the strong lining thickness shall be not less than specified in 2.5.75.

4.4.2 If the transverse system is used for bridge framing, the transverse web and ordinary members of the bridge shall be placed in the same plane with appropriate hull members.

4.4.3 Where cutouts in hull deck exceed 0.7 of the hull breadth, the deck shall be rein-
forced in the area of such a cutout plus over a distance of 0.5 cutout width forwards and abaft the cutout.

4.4.4 In case of curvilinear shape of cross-sections of the hulls in the area of the parallel body, and in case of the transverse framing system of the side and the longitudinal framing system of the bottom, ordinary side frames shall be finished at the side keelsons or strengthened longitudinal girders.

4.4.5 Where a transverse strength of a catamaran is ensured by superstructure transverse bulkheads or trusses installed above the deck, transverse bulkheads shall be installed in the hulls in the planes of these bulkheads or trusses. If, due to arrangement of spaces, this requirement is impracticable, strengthened side web frames with a web depth at least 1.5 floor depth may be provided instead of the bulkheads. In joints of the strengthened side web frames and web beams, knees shall be fitted.

4.4.6 Thickness and scantlings of superstructure bulkhead members participating in global transverse strength of the catamaran shall be specified according to the requirements of 2.4.63 to 2.4.80. Here, horizontal stiffeners shall be fitted between the centre lines of the hulls, and web stays shall be fitted in vertical planes passing through the upper edge of inner side plating (unless longitudinal bulkheads are provided in these planes).

In the superstructure bulkheads participating in the global transverse strength, cutouts with a width exceeding 0.5 of the bulkhead height are not permitted and existing openings shall be reinforced by coamings. Door cutouts shall be clear of web stays located in planes of inner sides and of bulkhead ends at least for a half of the height of the opening.

4.4.7 Bridge structure shall be so designed as to be accessible for inspection and repair.

The height of a closed (doubled) bridge confined by a watertight strength lining from the bottom and by a watertight deck from the top shall not be not less than 800 mm.

4.4.8 Minimum web thickness of web beams and carlings of the closed bridge shall be taken according to 5.1 to 5.3 of Table 2.4.1-1.

4.4.9 Depth of hull's web beam in way of inner side shall be equal to the depth of closed bridge's web beam. The beam depth shall decrease gradually at least over a distance from the inner side to the nearest carling of the hull. An area of the strip in this section shall be increased by 1.5. In the hulls at the level of bridge lining, stringers according to Fig. 4.4.9-1 or strengthened knees according to Fig. 4.4.9-2 shall be provided.

![Fig. 4.4.9-1 Fitting a stringer at the level of bridge lining](image)

4.4.10 When specifying scantlings of web beams of the bridge open from the top or from the bottom (including bridges with a light bottom lining not participating in strength of bridge members and global strength of the ship and bridges with detachable upper deck) requirements of 2.4.48 shall be met.

Scantling of bridge's web beams shall be not less than scantling of hull's web beams.

4.4.11 In the place where web beam of the bridge open from the bottom is attached to the inner side, vertical knees corresponding to directions of 2.3.12 and 2.3.13 or horizontal knees according to Fig. 4.4.11 shall be fitted.

4.4.12 Flange of a web beam of a bridge open from the top shall be connected to the deck by means of horizontal knees according to Fig. 4.4.12.
4.4.12 In case of the transverse framing system in the closed bridge and the bridge opened from the top and fitted with detachable deck, between the web beams, bracket beams shall be fitted consisting of upper and lower ordinary girders connected by brackets in way of carlings and inner sides.

4.4.13 Width of the brackets shall be not less than 0.3 of height of the closed bridge or the distance between the lining and detachable deck; thickness of the brackets shall be not less than the web beam's web thickness; if bracket width to thickness ratio exceeds 35, free edges of the bracket shall have welded to bent flanges.

4.4.15 In a span between the brackets, the upper and lower girders may be connected by means of cross-members. For the bridge opened from the top, where a distance between carlings or between a carling and the inner side exceeds 1.5 m, the installation of the cross-members is mandatory. Cross-sectional area of the cross-member shall be
not less than the cross-sectional area of the least of girders being connected.

4.4.16 Scantling of ordinary beams of bridge deck and upper girders of the bracket beams shall be specified in accordance with requirements of 2.4.48. Here, in case of detachable deck, section modulus of the upper girder shall be taken without effective flange.

4.4.17 Scantling of ordinary beams of the bridge lining shall be not less than those taken for ordinary frames or for inner side stiffeners.

4.4.18 Where cross-members are fitted, section moduli of the upper and lower girders of a bracket beam may be reduced by 40%.

4.4.19 In case of the longitudinal framing system of the inner side and the hull deck, a knee extended to the uppermost side stiffener shall be fitted between the deck longitudinal stiffener and the side plating in the plane of bracket beam’s bracket.

4.4.20 Ordinary beam of the deck of the bridge open from the bottom shall be connected to the inner side by means of a knee.

4.4.21 Where a transverse strength of catamaran is provided by particular strengthened girders (i.e. where the bridge structure is not homogeneous), these girders shall coincide with hull’s transverse bulkheads. If the above is impracticable, strengthened ring structures may be used instead of the bulkheads.

Web of the strengthened girders shall be fitted in the same plane with web frames of the hulls.

4.4.22 Connection of the strengthened girder with the hull shall be effected by means of extending the girder inside the hull over at least 0.25 the hull’s breadth or by means of festoons fitted in the hull at a level of the bottom flange of the girder. Knees shall be fitted where the girder flange is connected with the inner side.
5 DESIGN OF HYDROFOIL CRAFT HULLS

5.1 GENERAL REQUIREMENTS

5.1.1 The requirements of present chapter applies to hydrofoil craft of O-ΠП, O, P and Л classes with two lightly submerged foils and the following characteristics:

\[ I / D' L^3 > 3 \cdot 10^{-8}, \]  

(5.1.1-1)

for rigidity

\[ \sqrt[3]{D'} < 18, \]  

(5.1.1-2)

for speed

where \( I \) — area moment of inertia of the weakest cross-section of the hull girder in the middle part of ship, \( m^4 \);  

\( D' \) — ship displacement in fully loaded condition, t;  

\( L \) — the greatest length of hull (Fig. 5.1.1), m;  

\( v \) — design speed in foilborne mode on still water, m/s.

5.1.2 The requirements of present chapter are focused on the longitudinal framing system of the hull and superstructure.

In the present Section, superstructure means a part of the ship above the lower edge of window cutouts and, where the latter are not provided, a part of the ship above the upper deck.

5.1.3 For fabrication of hull and superstructure structures, aluminum alloys shall be used which comply with the requirements of 4 Part X of the Rules.

5.1.4 Materials to be submitted to the River Register shall comprise the calculations of:

1. global strength of ship;
2. local strength of ship;
3. strength of foil arrangements;
4. vibrations.

5.1.5 The lead ship in a series of every design shall be tested to verify strength and vibration level under a program approved by the River Register.

The test results shall be submitted to the River Register.

5.1.6 Ships with strength meeting the requirements of 5.2, are allowed to operate in displacement mode at wave height, \( m \), in basin of category:

\[ \begin{array}{c|c}
O-ΠП, O & 2.0 \\
P & 1.2 \\
Л & 0.6 \\
\end{array} \]

5.2 GLOBAL STRENGTH AND BUCKLING CALCULATIONS

5.2.1 The global strength of a ship shall be checked with regard to normal and tangent stresses caused by design bending moments and shear forces in foilborne mode at design wave height.
The buckling of structures in the whole and their elements shall be checked also.

5.2.2 For a hydrofoil craft underway in foilborne mode, the values of design wave height $h$ shall be taken at least equal to that specified below, $m$, for basin of category:

<table>
<thead>
<tr>
<th>O-IP, O</th>
<th>P</th>
<th>I</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.3</td>
<td>0.8</td>
<td>0.4</td>
</tr>
</tbody>
</table>

5.2.3 Design bending moment $M_d$, kN·m, and shear force $N_d$, kN, shall be calculated by the formulae (see Fig. 5.1.1):

- \[ M_d = M_s \left(1 + k_M n\right) \], \quad (5.2.3-1)
- \[ N_d = N_s \left(1 + k_N n\right), \quad (5.2.3-2) \]

where $M_s$, $N_s$ — bending moment, kN·m, and shear force, kN, in a cross-section under consideration in foilborne mode on still water;

$k_M$, $k_N$ — coefficients depending on the longitudinal position of the cross-section under consideration and defined by the formulae:

- \[ k_M = 1 - 0.040j \]; \quad (5.2.3-3)
- \[ k_N = 0.7 - 0.015j \], \quad (5.2.3-4)

where $j$ — number of the design frame: for extreme fore frame $j = 0$ and for extreme aft frame $j = 20$;

$n$ — additional design overload (ratio between additional acceleration in a cross-section above the bow foil arrangement in foilborne mode at design waves and the acceleration of gravity).

The value of $n$ shall be obtained using a prototype or from model tests. Where those data are not available, it may be calculated by the formula

\[ n = kmw^2 \sqrt{h/D_{\text{red}}}, \quad (5.2.3-5) \]

where $D_{\text{red}}$ — reduced displacement of ship, t:

\[ D_{\text{red}} = D/\left[1 + 15 \left(l_L/L\right)^2\right], \quad (5.2.3-6) \]

$l_L$ — distance between the centre of gravity and the centre of supporting force at the fore foil (point 0 in the Fig. 5.2.3-1);

$k$ — coefficient equal to, at $h$, $m$:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1.5</td>
<td>0.035</td>
<td></td>

<td></td>
</tr>
<tr>
<td>0.8</td>
<td>0.020</td>
<td></td>
</tr>
<tr>
<td>0.4</td>
<td>0.010</td>
<td></td>
</tr>
</tbody>
</table>

Fig. 5.2.3-1 Determination of point of supporting force at the fore foil

$m$ — coefficient determined from Fig. 5.2.3-2 and depending on design deadrise angle of the bottom $\beta$, deg, in section A–A (Fig. 5.2.3-3);

- \[ m = \text{Fig. 5.2.3-2 Coefficient } m \text{ vs. design bottom deadrise angle } \beta \]

\[ \text{Fig. 5.2.3-3 Cross-section where bottom deadrise angle } \beta \text{ is determined} \]

$v_w$ — ship’s speed in foilborne mode in design wave conditions, km/h, determined by the formula

\[ v_w = 0.85v, \quad (5.2.3-7) \]

where $v$ — ship’s speed in foilborne mode on still water, km/h.
For intermediate values of wave height, coefficient $k$ is to be determined by linear interpolation.

Values of $v_w$ and $k$ shall be adjusted based on model testing or prototype ship trials.

Values of $n$ in formulae (5.2.3-1) and (5.2.3-2) shall be not less than, at $h$, m:

<table>
<thead>
<tr>
<th>$n$</th>
<th>1.5</th>
<th>1.0</th>
<th>0.9</th>
<th>0.8</th>
<th>0.6</th>
<th>0.4</th>
<th>0.3</th>
</tr>
</thead>
</table>

Design wave height in foilborne mode (within the wave height range for the relevant operation area) shall be specified on the basis of the technical design assignment. This value of the wave height is limiting for a ship in foilborne mode and shall be indicated in the Operation Manual.

5.2.4 When calculating bending moments $M_t$ and shear forces $N_t$, the following directions shall be complied:

.1 a load curve shall be plotted by a common way using at least 21 equidistant ordinates;

.2 design values of foil supporting force, kN, shall be determined by the formulae:

for the fore foil

$$F_{sb} = 9.81D' - F_{ss},$$  (5.2.4.2-1)

for the aft foil

$$F_{ss} = 9.81D'l / l_0;$$  (5.2.4.2-2)

where $l_0$ — distance between supporting force point at the fore and aft foils, m;

.3 points of foil supporting forces $F_{sb}$ and $F_{ss}$ are determined according to Fig. 5.2.3-1;

.4 foil supporting forces $F_{sb}$ and $F_{ss}$ are distributed over the design spacings depending on extension of the fore (aft) foil struts along the hull.

5.2.5 Checking the ship’s global strength due to normal design stresses shall be carried out in cross-sections (see Fig. 5.1.1) where the greatest normal stresses are assumed:

in section I — I in way of the fore foil arrangement, where a continuous part of superstructure wall is not available forwards of the foil arrangement.

If the design bending moment in section I — I differs from a moment in section II — II or III — III by less than 10%, the calculation of the global strength in section I — I may be omitted.

5.2.6 When determining the hull girder section moduli, in sections I — I, II — II and III — III the hull and superstructure members shall be considered and in section IV — IV only hull members shall be considered.

For riveted superstructure and welded hull, superstructure members shall be included in the hull girder with a coefficient of 0.9.

5.2.7 If the breadth of window cutouts is greater than the distance between them, two extreme continuous parts of superstructure walls shall be provided with a length $c$ (see Fig. 5.1.1) exceeding the window height by at least 20% or other construction measures shall be taken to prevent the superstructure from participation in global bending of the ship.

5.2.8 Compressed plates are included to the hull girder with a reduction coefficient

$$\phi = \sigma_{cr} / \sigma_p \leq 1,$$  (5.2.8-1)

where $\sigma_{cr}$ — critical normal stress of the compressed plate which is determined by Fig. 3.3.16 depending on the ratio $\sigma_E / R_{sh}$

$\sigma_E$ — normal Euler’s stress of a plate, MPa, which shall be calculated by formula (3.3.7-1) in case of the longitudinal framing system;

$\sigma_p$ — permissible normal stress due to global bending of the ship.

Parts of the plate adjacent to longitudinal girders of width equal to the following values at each side are not subject to reduction:

$$0.25a \quad \text{when} \quad a/t \leq 80;$$  (5.2.8-2)

$$20t \quad \text{when} \quad a/t > 80,$$  (5.2.8-3)

where $a$ — distance between the longitudinal girders;

$t$ — plate thickness.
5.2.9 Design normal stresses in extreme members of the hull girder shall be determined by the formulae:

\[ \sigma_u = 10 \alpha_u M_d / W_u ; \]  
\[ \sigma_l = 10 \alpha_l M_d / W_l ; \]

where \( \sigma_u, \sigma_l \) — design stresses in the uppermost and lowermost members of the hull girder (superstructure), MPa;

\( \alpha_u, \alpha_l \) — coefficients equal to:
- for sections passing through continuous parts of superstructure walls (beyond the window cutouts) as well as for section IV — IV (see Fig. 5.1.1) 1.0
- for sections in way of window cutouts 0.85 and 1.40

\( M_d \) — design bending moment in the cross-section under consideration (see 5.2.3);

\( W_u, W_l \) — section moduli for the uppermost and lowermost members of the hull girder (see 5.2.6).

For riveted superstructure and welded hull, coefficient \( \alpha_u \) shall be reduced by 10 %.

5.2.10 Global strength due to tangent stresses shall be checked in sections where the greatest tangent stresses are expected:
- in sections V — V and VI — VI (see Fig. 5.1.1) where the greatest shear force occurs;
- in weakened sections;
- in sections in extreme continuous parts of the superstructure walls.

5.2.11 Design tangent stresses, MPa, shall be determined by the formula:

\[ \tau = N_d S / (I \sum t) , \]  

where \( N_d \) — design shear force in a cross-section, kN;

\( I \) — area moment of inertia of the hull girder, m\(^4\);

\( S \) — static moment, relative to the axis, of the part of hull girder cross-section situated either above or below the given horizontal cross-section, in which tangent stresses are calculated, m\(^3\);

\( \sum t \) — the sum of thicknesses of the sides, longitudinal coaming plates and longitudinal bulkheads in the given horizontal section, in which tangent stresses are calculated, mm.

5.2.12 In sections weakened by the window or door cutouts, the design tangent stresses \( \tau \) shall be determined by formula (5.2.11) regardless of a part of the superstructure above the cutout.

5.2.13 In sections in extreme continuous parts of superstructure walls, the design tangent stresses \( \tau' \), MPa, shall be taken equal to the greatest of those calculated in accordance with directions of 5.2.11 and by the formula

\[ \tau' = \sigma_d f / (k t c) , \]

where \( \sigma_d \) — design stresses in the superstructure deck in section II — II (see Fig. 5.1.1), MPa;

\( f \) — cross-sectional area of the superstructure longitudinal members above the window cutouts in section II — II having regard the reduction, cm\(^2\);

\( k \) — coefficient equal to:
- for extreme continuous part of the superstructure deck in section II — II having regard the reduction, 3.0
- for extreme continuous part of the superstructure wall in the middle part of ship, 1.5

\( t, c \) — thickness and length of the given extreme continuous part of the superstructure wall, correspondingly, cm.

5.2.14 Critical normal stresses shall meet the following conditions:
- for the superstructure deck longitudinal stiffeners

\[ \sigma_{cr} / \sigma \geq 1.5 ; \]

(5.2.14-1)

for the bottom longitudinal stiffeners

\[ \sigma_{cr} / R_{p0.2} \geq 0.7 , \]

(5.2.14-2)

where \( \sigma \) — design stresses in the superstructure deck, MPa;

\( R_{p0.2} \) — yield stress of the material, MPa, corresponding to residual deformation of 0.2%.

Critical normal stresses of a stiffener \( \sigma_{cr} \) are determined according to Fig. 3.3.16 depending on the ratio \( \sigma_d / R_{p0.2} \), where \( \sigma_d \) is Euler’s normal stress of a stiffener material when the stiffener ends are assumed resting freely.
5.2.15 Euler’s normal stresses of plates of the side plating and the superstructure walls shall meet the condition

\[ \tau_h / \tau \geq 1.5, \]  

(5.2.15)

where \( \tau \) — design tangent stresses of plates in the section.

When determining \( \tau_h \), plates shall be considered freely resting around the contour.

5.3 LOCAL STRENGTH CALCULATIONS

5.3.1 Values of local loads specified by a design pressure \( p \), kPa, over ship length for checking strength of plates of bottom plating and longitudinal bottom stiffeners shall be taken equal to (Fig. 5.3.1-1):

\[ p = \alpha p_0 \]  

(5.3.1)

\( p_0 \) — load applied along a section from the zero design frame to section A — A (see Fig. 5.3.1-1);

\[ p_0 = kmv \sqrt{D_{\text{red}}} \]  

(5.3.1)

\( \alpha p_0 \) at the 10th design frame;

\( 0.7 \alpha p_0 \) at the 20th design frame;

where \( \alpha \) — coefficient determined from Fig. 5.3.1-2 depending on the ratio \( \beta_{10}/\beta_{A} \) (here, \( \beta_{10} \) and \( \beta_{A} \) are the angles measured as shown in Fig. 5.2.3-3, at the 10th design frame and in section A — A).

5.3.2 Strength of the floors and bottom grillages shall be checked with regard to uniformly distributed load specified by pressure equal to 0.5\( p \), where \( p \) is a pressure for the floor under consideration or a floor located in the middle of the span (when calculating the grillage) according to 5.3.1.

5.3.3 A design load on a side shell plating and side framing shall be uniformly distributed over the side depth according to a trapezoidal law and specified by a pressure varying from 3 kPa at the level of the lower edge of window cutouts up to 0.5\( p \) at the bilge level, where \( p \) is a pressure determined according to 5.3.1 for shell plating and longitudinal stiffeners and according to 5.3.2 for frames and side grillages.

5.3.4 Design load, kPa, shall be set by pressure equal to:

- for decks and platforms intended for transportation of passengers and crew as well as for parts of superstructure decks where passengers may be present while boarding
- for decks in way of passenger seats
- for superstructure decks

Those loads shall be taken for deck parts bordered by a line, for which an angle between a tangent to the shell plating and the base line is not less than 30°.
5.3.5 Strength of beams and half-beams of the superstructure deck shall be checked with regard to bending moment, kN·m, calculated by the formula:

\[ M_k = 9.81 \cdot 10^7 k_b B^2, \]  

(5.3.5-1)

where \( k_b \) — coefficient obtained from Fig. 5.3.5;

\[ B \] — ship’s breadth at the deck level, m.

When determining bending moment for beams, \( d \) shall be taken equal to, m:

\[ d = 0.500 (d_1 + d_2), \]  

(5.3.5-2)

where beams and half-beams are fitted

\[ d = 0.375 (d_1 + d_2), \]  

(5.3.5-3)

where \( d_1, d_2 \) — distances from the beam under consideration to the nearest beams or transverse bulkheads, m.

When calculating bending moment of half-beams, \( d \) shall be taken equal to

\[ d = 0.500 (d'_1 + d'_2), \]  

(5.3.5-4)

where \( d'_1, d'_2 \) — distances from the half-beam under consideration to the nearest beams or transverse bulkheads, m.

Scantling of beams and half-beams may be obtained taking load as uniformly distributed and equal to 1.47\( d \), kN/m.

Area moment of inertia, cm\(^4\), of beams and half-beams including effective flange shall be not less than

\[ I = 0.55dB^3. \]  

(5.3.5-5)

5.3.6 The design load, kPa, on front walls and windows of the superstructure shall be taken as follows for basin of category:

<table>
<thead>
<tr>
<th>Category</th>
<th>( P )</th>
<th>( J )</th>
</tr>
</thead>
<tbody>
<tr>
<td>O-IIP, O</td>
<td>20</td>
<td>5</td>
</tr>
<tr>
<td>P</td>
<td>10</td>
<td></td>
</tr>
</tbody>
</table>

Design pressure on the side walls and windows of the superstructure shall be taken equal to 3 kPa.

5.3.7 Design load on transverse watertight bulkheads shall be taken uniformly distributed according to triangle law and specified by maximum pressure at the level of the ship’s bottom which is equal to a distance between the bottom to the bulkhead deck and, where the latter is not provided, double average draught in displacement mode.

5.3.8 Design load on structures enclosing the tanks is taken distributed over a height according to trapeze law and specified by maximum pressure at the tank bottom level which is equal to a distance between the tank bottom and the upper end of an air outlet.

5.3.9 During strength calculations for the loads specified in the present chapter, the plates shall be considered absolutely rigid and constrained at a bearing contour not subject to deformation.

During local strength calculations, longitudinal girders shall be considered constrained.

5.3.10 Elements of cross-sectional area of the framing girders shall be determined with due regard to effective flanges or flooring. For members directly connected to the shell plating, the effective flange width \( c \) shall be taken equal to:

\[ c = 0.5a \quad \text{at} \quad a/t \leq 80; \]  

(5.3.10-1)

\[ c = 40t \quad \text{at} \quad a/t > 80, \]  

(5.3.10-2)

where \( a \) — average distance between the same-name members;

\( t \) — thickness of shell plating or flooring.
The effective flange width in all cases shall not exceed 1/6 of the design span of the girder.

For members laid onto the longitudinal girders (attached framing system), the effective flange width shall be taken equal to zero.

5.3.11 During buckling calculations of girders, when determining their cross-sectional area, the effective flange width shall be taken equal to the average distance between the same-name girders, and when determining the area moment of inertia of girders, the effective flange width shall be taken according to 5.3.10.

5.3.12 Local strength calculations for dry docking and lifting by a crane shall be carried out for light ship condition. Here, buckling strength of the structures shall be provided with a safety factor of 1.5 relatively to design stresses.

5.3.13 Local strength and buckling calculations of the hull structures in the places where the foil arrangements are attached shall be carried out for loads specified in 5.4.1.

5.3.14 Dimensions of bridges between windows shall meet one of the following ratios:

\[ \frac{h_0}{b_0} > 5 ; \]  
\[ \frac{h_0}{b_0} < 2.5 , \]

where \( h_0 \) — height of a bridge/window, m; \( b_0 \) — width of a bridge (i.e. distance between windows), m.

Rounding radius for window cutout corners, m, shall be not less than

\[ r = 0.15h_0 . \]

5.4 CALCULATION OF FOIL ARRANGEMENT STRENGTH

5.4.1 A foil arrangement shall be calculated as a frame consisting of rods with cross-sections varied over rod length and with struts rigidly attached to the hull.

Foil arrangement strength shall be checked for the effect of loads specified by vertical forces equal to:

for the fore foil

\[ P_b = kF_{sb} ; \]  
\[ P_5 = 0.75kF_{ss} , \]

where \( k \) — coefficient equal to the following for ships designed for the design wave height \( h \), m (in foilborne mode):

\[
\begin{array}{c|c|c}
\text{wave height} & k \\
\hline
1.5 & 2.2 \\
1.3 & 2.0 \\
0.8 and less & 1.8 \\
\end{array}
\]

\( F_{sb}, F_{ss} \) — supporting forces at the fore foil and the aft foil determined by formulae (5.2.4.2-1) and (5.2.4.2-2).

For intermediate wave heights, value of \( k \) is to be determined by linear interpolation.

Strength of foil arrangements, kN, shall be checked also for simultaneous action of the forces \( F_{sb}, F_{ss} \) and horizontal loads generated by horizontal point forces applied at places where the struts connect with respective foils, and the resultant force shall be calculated by the formula

\[ P_r = 20.59 \cdot 10^{-3} D Y^2 / l_0 , \]

where \( l_0 \) — distance between points of supporting force at the fore and aft foils, m;

Resultant force \( P_r \) shall be distributed between the struts pro rata projections of their submersed surfaces onto the centre plane.

Forces \( F_{sb}, F_{ss}, P_f \) and \( P_{af} \) shall be taken uniformly distributed over the foil spread and directed perpendicularly to the foil bottom plane (Fig. 5.4.1).

5.4.2 Euler’s stresses in plates of hollow foils plating shall be not less than stresses obtained at calculation of the foil arrangement for loads \( P_f \) and \( P_{af} \).
5.4.3 Strength of additional bow foils and flaps, kN, shall be checked for the effect of load due to vertical force \( Q \)

\[
Q = 0.49 k c_L v_1^2 S_1,
\]

(5.4.3-1)

where \( v_1 \) — minimal speed corresponding to additional foil borne mode on still water, m/c;

\( c_L \) — lift coefficient at an angle of attack \( \alpha_1 \) corresponding to additional bow foil;

\[
\alpha_1 = \alpha_{set} + \psi - \alpha_0;
\]

(5.4.3-2)

where \( \alpha_{set} \) — setting angle of additional foil or flap;

\( \psi \) — angle of trim corresponding to additional foil borne mode on still water;

\( \alpha_0 \) — zero lift angle of the profile of additional foil or flap;

\( k \) — coefficient determined according to 5.4.1;

\( S_1 \) — area of the additional bow foil or flap, m².

Where experimental data are not available, it is allowed to take:

\[
k c_L = 1; \quad (5.4.3-3)
\]

and

\[
v_1 = 0.7 v. \quad (5.4.3-4)
\]

5.5 NORMS OF PERMISSIBLE STRESSES AND MINIMUM THICKNESSES

5.5.1 Permissible normal stresses \( \sigma_p \) for global and local strength calculations shall be taken equal to the least of the values specified in Table 5.5.1 (in fractions of the yield strength \( R_{p0.2} \) or tensile strength \( R_m \) of the material).

5.5.2 Permissible tangent stresses \( \tau_p \) shall be taken equal to 0.57 of corresponding permissible normal stresses:

\[
\tau_p = 0.57 \sigma_p. \quad (5.5.2)
\]

5.5.3 Value of critical normal stress in a structure element shall be not less than double normal stress due to design loads.

5.5.4 Thicknesses of the outer shell plating, the deck plating and the bulkhead plating regardless of the material grade shall be not less than those specified in Table 5.5.4.

5.6 VIBRATION CALCULATIONS AND NORMS

5.6.1 Local vibration shall be checked for ship hull structures in the aft extremity area and the engine room area, as well as for the aft foil arrangement and propeller shaft brackets.

Table 5.5.1

Regulated permissible normal stresses depending on structure element and design stress characteristics.
5.6.2 In order to avoid a resonance, natural oscillation frequencies of particular structures, as calculated according to 2.6.9 to 2.6.23, shall exceed frequencies of exciting forces in basic operational modes (foilborne and displacement modes):

1. propeller revolution frequency by at least 30%, for the aft foil arrangement and propeller shaft brackets;
2. propeller shaft revolution frequency multiplied by the number of blades by at least 50%, for plates of hollow foils;
3. propeller revolution frequency and that multiplied by the number of blades by at least 50% and 30% correspondingly, for the bottom plates and stiffeners in the aft extremity;
4. crankshaft revolution frequency and doubled crankshaft revolution frequency of the main and auxiliary machinery by at least 50 and 30% correspondingly, for plates and hull framing members in the engine room area.

5.6.3 Reduction of difference in frequencies as compared with that regulated by 5.6.2 may be allowed on condition that justified data are submitted proving that the amplitudes of and stresses due to vibration do not exceed the permissible levels (see 5.6.4 and 5.6.5).

5.6.4 Permissible amplitudes of vibration in the centres of plates of the hull and superstructure, mm, shall not exceed the values determined by the formula:

\[ A_p = k \left( \frac{a}{100t} \right)^2, \]  

(5.6.4)

where \( k \) — coefficient equal to:

for plates welded around the contour by means of continuous double-sided weld or riveted to the framing: 2.90
for plates welded around the contour by continuous single-sided or intermittent double-sided weld: 1.45
\( a \) — short side of the plate, cm;
\( t \) — plate thickness, cm.

5.6.5 Vibration of the framing is considered to be permissible, if the greatest stresses measured or calculated from measured amplitudes do not exceed 20 MPa.

5.6.6 In places where engine foundations are installed, where foil arrangements are attached to the hull, and where pulsating pressure caused by propellers acts, plates shall be welded around the bearing contour by continuous double-sided weld.
6 DESIGN OF HOVERCRAFT HULL

6.1 GENERAL REQUIREMENTS

Scope of application

6.1.1 The requirements of the present chapter apply to passenger, crew and cargo hovercraft of skeg and amphibian types of O-IIP, O, P and J classes capable of moving in the hovering and displacement modes and complying with the following conditions:

\[ \frac{EI}{(D'L)} > 13 \]  \hspace{1cm} (6.1.1-1)

\[ \frac{L}{\sqrt{g} L} < 2 \]  \hspace{1cm} (6.1.1-2)

where \( E \) — Young’s modulus, kPa;

\( I \) — area moment of inertia calculated on the assumption that a strength superstructure is fully participating in global bending, m\(^4\) (for hovercraft without strength superstructure it is area moment of inertia of the hull only);

\( g \) — acceleration of gravity, m/s\(^2\).

Other designations are given in 6.1.10.

For skeg-type hovercraft, the requirements of the present chapter apply to craft with main dimension ratios meeting the following conditions:

\[ \frac{L}{H} < 20 \]  \hspace{1cm} (6.1.1-3)

\[ \frac{L}{B} = 3 + 6 \]  \hspace{1cm} (6.1.1-4)

\[ \frac{H}{h_{kh}} = 2 + 3 \]  \hspace{1cm} (6.1.1-5)

6.1.2 Requirements of present chapter apply to hovercraft made of aluminum alloys meeting the requirements of 4 Part X of the Rules.

6.1.3 The present chapter considers the most unfavorable loading conditions of ship hull of skeg and amphibian types which are assumed. Particular scope of calculations (for instance, the necessity of global transverse strength calculation) is defined by a designer depending on design features of a ship.

Grounds for sufficiency of the scope of calculations for estimation of global and local strength of the hull shall be included in the materials which are submitted to the River Register.

6.1.4 Design wave height for basins of O-IIP, O, P and J categories is taken according to Table 2.1.2.

Design speed values for hovering and displacement modes are stated in the design specification of a ship.

6.1.5 The first ship in a series shall undergo trials under conditions provided by the design specification according to a test program approved by the River Register.

The test results shall be submitted to the River Register.

6.1.6 Permissible wave characteristics with regard to strength and the corresponding speeds of hovercraft in hovering and displacement modes are adjusted on the basis of tests of the first ship in a series.

Definitions and explanations

6.1.7 In the present chapter superstructure means a part of the ship above the bottom edge of window cutouts and, where the latter are not available, a part of the ship above the uppermost deck.

6.1.8 Overload means a ratio of summed vertical acceleration in the given point of the hovercraft hull and the acceleration of gravity.

6.1.9 The following designations have been adopted in the present section:

\( L \) — design waterline length in displacement position, m;

\( B \) — design waterline breadth amidships, m;
$H$ — ship’s depth amidships measured from the bottom edge of skeg (or from the bottom, when skegs are not available) to a superstructure line defined in accordance with 6.1.7, and for ship without superstructure — to the uppermost deck, m;

$T$ — ship’s draught in displacement position measured from the bottom edge of skeg (or from the bottom, when skegs are not available) to the design waterline, m;

$D'$ — ship displacement in fully loaded condition, t;

$D'_a$ — total displacement of skegs corresponding to the design displacement of a ship $D'$, t;

$h_a$ — height of a skeg, m;

$l_0$ — distance of ship’s centre of gravity from the after perpendicular, m;

$v$ — design speed of a ship in hovering mode on still water, m/s;

$L_{ac}$ — air cushion length, m;

$F_{ac}$ — air cushion area, m$^2$;

$p_{ac}$ — pressure in the air cushion at normal operation conditions, MPa.

6.2 STRENGTH AND BUCKLING CALCULATIONS

Design loads at global bending and torsion

6.2.1 Design loads bringing to global bending and torsion of a hovercraft hull are determined for the following conditions:

.1 moving in hovering mode at design rolling;

.2 moving in displacement mode at design rolling;

.3 entering the shore (erection on supports);

.4 lifting by crane.

6.2.2 For conditions indicated in 6.2.1 the most unfavourable load cases shall be considered depending on design and performance features of a hovercraft.

6.2.3 Design loads which bring to global bending and torsion of a hovercraft hull, are defined by the greatest loads measured in the centre of gravity $G$ of a ship (Fig. 6.2.5). Values of overloads at hovercraft moving in rolling conditions shall be defined by results of model scale tests of a ship in design or by a prototype (separately for each mode and each kind of global deformation of the hull).

Values of overloads in other points are determined by the formula

$$ n = \left[ 1 + \mu_1 \left( \frac{(x_1 - x_g)(x - x_g)}{\rho_1^2} + y_1y/\rho_2^2 \right) + 
\mu_2 \left( \frac{(x_2 - x_g)(x - x_g)}{\rho_1^2} + y_2y/\rho_2^2 \right) \right] n_g, $$

(6.2.3-1)

where $\mu_1$, $\mu_2$ — coefficients determined by Table 6.2.5;

$x_1$, $x_2$, $y_1$, $y_2$ — co-ordinates of external forces in accordance with Fig. 6.2.5;

$x_g$ — abscissa of the centre of gravity of a ship;

$x$, $y$ — co-ordinates of a point where the overload is calculated;

$\rho_1$ — radius of inertia of the ship mass related to transverse axis crossing the centre of gravity, m;

$\rho_2$ — radius of inertia of the ship mass related to longitudinal axis crossing the centre of gravity, m;

$n_g$ — overload in the centre of gravity of the ship.

Where the data are not available, at initial stages of designing an overload in the centre of gravity of a hovercraft for moving in hovering mode, which is required for longitudinal strength calculation, is recommended to be determined by the formula

$$ n_g = 1 + \left( 0.085\sqrt{h} + 0.04 \right) v^2 \sqrt{D'}. $$

(6.2.3-2)

6.2.4 Overload values are adjusted at trials of the first ship in a series in accordance with 6.1.5 with the following correction of strength calculations on the basis of actual overload values.

6.2.5 Scheme of application and design ratios of external forces for hovering and displacement modes in rolling conditions are taken in accordance with Fig. 6.2.5 and Table 6.2.5.

Note. For amphibian-type hovercraft: e₁ = 0.2B; e₂ = 0.4B; for skeg-type hovercraft: e₁ = bₛ; e₂ = 0.5(B+bₛ).

Values of external forces are taken equal to, kN:

\[ P₁ = 9.81 \mu₁ \sigma_ x ; \quad (6.2.5-1) \]
\[ P₂ = 9.81 \mu₂ \sigma_ y \] ; \quad (6.2.5-2)

### 6.2.6 Design loads for the erection on supports and lifting by crane

Supports and hoisting rings shall be so located that bending moments in hovercraft cross-sections do not exceed values corre-
sponding to operational loading cases as far as practicable.

6.2.7 Summed bending moments $M$ and shear forces $N$ at longitudinal bending shall be calculated by means of integration of design load curve, which is a difference of gravity forces $g(x)$ multiplied by overload factor $n_g$ in the centre of transverse spacing under consideration and buoyancy forces calculated according to 6.2.3 to 6.2.6.

6.2.8 Summed bending moment, kNm, amidships at longitudinal bending at initial design stages shall be determined by the formulae:

1. when moving in hovering mode for amphibian and skeg types

$$M_0 = 9.81\left[k_{sw} \pm 0.5(0.15 \pm k_{sw})(n_g - 1)\right]D'L;$$

(6.2.8.1)

2. when moving in displacement mode for amphibian-type ships

$$M_0 = 4.9\left(0.15 \pm k_{sw}\right)D'L n_g;$$

(6.2.8.2)

3. when moving in displacement mode for skeg-type ships

$$M_0 = 9.81\left[k_{sw} \pm 0.5(0.15 \pm k_{sw})\left(n_g + D'_k / D'\right)\right]\times$$

$$\times D'L \pm 50b_h \left(0.1L\right)^2 h,$$

(6.2.8.3)

where $k_{sw} = M_{sw} / (9.81D'L)$ — coefficient of longitudinal bending moment on still water (with due regard to the sign);

$M_{sw}$— longitudinal bending moment at still water calculated with regard to requirements of 2.2.1.

$n_g$— is determined by the formula (6.2.3-2). The sign (+) in formulae (6.2.8.1), (6.2.8.2) and (6.2.8.3) corresponds to hogging. Coefficient $n_g$ in formulae (6.2.8.2) and (6.2.8.3) is determined by a prototype or by results of model scale testing.

Maximum shear force

$$N_0 = 4M_0 / L.$$

(6.2.8.4)

Calculated values of summed bending moments and shear forces in hovercraft cross-sections in this case are taken according to Fig. 6.2.8.

6.2.9 Bending moments $M'$ and shear forces $N'$ at transverse bending are calculated by means of integration of the design load curve, which is a difference of gravity forces $g(y)$ multiplied by the overload factor in the centre of the transverse spacing under consideration and buoyancy forces calculated in accordance with 6.2.3 to 6.2.6.

6.2.10 Summed bending moment, kNm, in the hovercraft centre line at transverse bending at initial design stages shall be determined by the formulae:

1. when moving in hovering mode for amphibian and skeg types

$$M'_0 = 9.81\left[k'_{sw} - 0.5(0.15 - k'_{sw})\left(n'_g - 1\right)\right]D'B;$$

(6.2.10.1)

2. when moving in displacement mode for amphibian-type ships

$$M'_0 = 4.9\left(0.15 - k'_{sw}\right)D'B n'_g;$$

(6.2.10.2)

3. when moving in displacement mode for amphibian-type ships

$$M'_0 = 9.81\left[k'_{sw} - 0.5\left(0.25 - b_h / k'_{sw}\right)\right]D'B n'_g,$$

(6.2.10.3)

where $k'_{sw} = M_{sw} / (9.81D'L)$ — coefficient of transverse bending moment on still water (with due regard to the sign).

$M_{sw}$— transverse bending moment calculated with regard to the requirement of 2.2.1 where instead of the word “longitudinal” the word “transverse” shall be read. Coefficient $n'_g$ in formulae (6.2.10.1), (6.2.10.2) and (6.2.10.3) is determined by a prototype or by results of model scale testing.

Maximum shear force, kN, is calculated by the formula
6.2.11 External torsion moments \( M_{\text{ext}} \), kN·m, are calculated by means of integration of the design torsion moment intensity curve. The latter is algebraic sum of moment intensity \( m_1 \) due to buoyancy force \( P_1 \), moment intensity \( m_2 \) due to buoyancy force \( P_2 \) and linear moment \( m_3 \) due to inertia forces on the ship masses relating to a longitudinal axis of revolution. Here:

\[
\begin{align*}
  m_1 &= 9.81 \mu_1 D' n_g y_1 / l_1 ; \\
  m_2 &= 9.81 \mu_2 D' n_g y_2 / l_2 ; \\
  m_3 &= -g(x)(\mu_1 y_1 + \mu_2 y_2) .
\end{align*}
\] (6.2.11-1, 6.2.11-2, 6.2.11-3)

Values of the moment intensity \( m_1 \) and \( m_2 \) over ship length are taken in accordance with Fig. 6.2.5 and Table 6.2.5. Value of moment intensity \( m_3 \) is throughout the whole length of a ship.

6.2.12 At the strength trials of a first ship in a series at waves according to 6.1.6 a summed bending moment amidships at longitudinal bending shall be adjusted.

When a found value is over than that calculated according to 6.2.8, strength calculations, design and scantlings of the hull members of serial ships shall be adjusted in accordance with longitudinal bending moment of hovercraft amidships obtained at the strength trials.

Design local loads

6.2.13 Local load applied to the bottom and skegs is determined for the following cases:

1. pressure in the air cushion (when there is no contact between the structure and water);
2. impact of structures by the water;
3. hydrostatic pressure (for displacement mode);
4. erection on supports.

6.2.14 Distribution of air cushion pressure on the bottom over hovercraft length, when there is no contact with water is taken as uniform.

![Distribution of air cushion pressure on the bottom over hovercraft length](image)

Ordinates of the pressure diagram are equal to:

\[
\begin{align*}
  p_1 &= 9.81 \times 2 D' n_g / F_{ac} ; \\
  p_2 &= 9.81 D' n_g / F_{ac} .
\end{align*}
\] (6.2.14-1, 6.2.14-2)

Design pressure value shall be not less than pressure induced by ventilator installation at zero air output increased by 30%.

6.2.15 Pressure distribution throughout the length at flat impact of the bottom by a wave is taken in accordance with Fig. 6.2.15. The pressure is taken as uniformly distributed over the ship’s breadth.

![Pressure distribution throughout the length at flat impact of the bottom by a wave](image)

Pressure values applied to the structure during the impact are taken equal to, kPa:

\[
\begin{align*}
  p_0 &= 9.81kD'n_g / (0.3LB) ; \\
  p_{10} &= 9.81kD'n_g / (0.4LB) ; \\
  p_{20} &= 9.81kD'n_g / (0.4LB) .
\end{align*}
\] (6.2.15-1, 6.2.15-2, 6.2.15-3)

where \( k \) — non-uniformity coefficient equal to:

1. for calculation of grillages
2. for calculation of longitudinal girders and plates in way of 0 — 10 frames;
3. for calculation of longitudinal girders and plates in way of 20th frame.

\( N'_0 = 4M'_0 / B . \) (6.2.10.4)
6.2.16 Hydrostatic pressure, kPa, is taken equal to:

- on the bottom
  \[
  p = 9.81 \left( T + 0.5h - h_{sh} \right);
  \]  
  \[
  (6.2.16-1)
  \]

- on skegs and sides
  \[
  p = 9.81 \left( T + 0.5h - z \right),
  \]  
  \[
  (6.2.16-2)
  \]

where \( h \) — design wave height, m;

\( z \) — distance over a height from the base plane to the skeg or side point under consideration, m.

6.2.17 Local loads on the bottom and skegs at erection on supports are defined in accordance with 6.2.6.

6.2.18 Air cushion pressure on inner surfaces of skegs is taken uniformly distributed over the depth. Air cushion pressure is taken distributed over the length of hovercraft in accordance with Fig. 6.2.14.

6.2.19 Design load, kPa, for decks is taken equal to:

- 1.0 for parts of decks where accumulation of passengers or crew members may be crowded;
- 2.0 for decks in way of passenger seats;
- 3.0 for plates and longitudinal girders of superstructure decks;
- 4.0 for beams of superstructure decks.

6.2.20 Uniformly distributed design load, kPa, on front walls and windows of the first tier superstructure is taken equal to, for basin category:

- O-ПР, O: 20
- P: 10
- Ю: 5

For side walls and windows of the first tier superstructure the uniformly distributed design load is taken equal to 3.0 kPa.

6.2.21 Design loads applied to the structures bounding tanks and watertight compartments are taken in accordance with the requirements of 2.2.

6.2.22 Design load applied to watertight bulkheads is taken as distributed by a triangle over a bulkhead height having a maximum force at the base plane level equal to a distance from the base plane of a ship to bulkhead deck; where the bulkhead deck is not available — to double hovercraft draught in displacement condition.

6.2.23 As design load applied to cargo decks shall be taken the cargo pressure with due regard to possible non-uniformity multiplied by the overload factor in the point under consideration. When carrying wheel or caterpillar vehicles, the loads applied to the deck are determined on the basis of load distribution on axes, the number and the area of wheel prints, dimensions of bearing surface of tracks having regard to actual disposition of the vehicles in the cargo compartment and ship overload when moving in rolling conditions.

Global strength calculations

6.2.24 The global strength of the hull shall be checked with regard to normal and tangent stresses. At longitudinal bending the checking with regard to summed stresses and ultimate bending moments shall be carried out also.

6.2.25 The checking of the global longitudinal strength shall be performed for the most unfavourable cases of the design load corresponding to maximum hogging and sagging of the hull. Here, the most distinctive hull sections with regard to strength shall be considered: in way of action of maximum bending moments and shear forces as well as torsion moments; in way of large cutouts. The number of sections to be checked is taken depending on the design features of a designed ship and shall be grounded in strength calculations submitted to the River Register.

6.2.26 When calculating the longitudinal strength, the members shall be included in the hull girder as per 2.2.33. Cross-sectional area of superstructure horizontal grillages with the ratio of the superstructure length and the grillage breadth less than five shall be included in the hull girder with a reduction coefficient \( \phi_r \), considering non-uniformity of distribution of normal stresses along the breadth which is determined from Table 6.2.26, where:
6 Design of Hovercraft Hull

$B_l$ — grillage breadth, m;

$l_s$ — design length (a distance between the end bulkheads) of the superstructure, m.

**Table 6.2.26**

<table>
<thead>

<td>0.6</td>
<td>0.58</td>
</tr>
<tr>
<td>0.4</td>
<td>0.74</td>
<td>0.7</td>
<td>0.52</td>
</tr>
</tbody>
</table>

6.2.27 Buckling strength of entire grillages and its particular elements (framing girders and plates) shall be checked in accordance with 6.2.5. Rigid parts of plates adjacent to longitudinal girders at either side are taken equal to:

0.25 of the spacing if $h/t \leq 80$

20t at $h/t > 80$.

6.2.28 Stresses in cross-sections of a hovercraft with a strength superstructure are calculated with due regard to participation of the superstructure in global bending. Where a superstructure is riveted and the hull is welded, cross-sectional area of the superstructure members shall be included in the hull girder with a coefficient of 0.9.

6.2.29 Normal stresses due to constrained torsion in the hull cross-sections are not regarded.

6.2.30 Summed design values of normal and tangent stresses between windows of a strength superstructure are determined by the formulae:

$$\sigma_0 = \sigma_{0, \text{tor}} + \sigma_{0, \text{ben}},$$

$$\tau_0 = \tau_{0, \text{tor}} + \tau_{0, \text{ben}},$$

where $\sigma_{0, \text{tor}}$, $\sigma_{0, \text{ben}}$, $\tau_{0, \text{tor}}$, $\tau_{0, \text{ben}}$ — normal and tangent stresses between windows due to the ship torsion, MPa;

$\sigma_{0, \text{ben}}$, $\tau_{0, \text{ben}}$ — normal and tangent stresses between windows due to global longitudinal bending of the ship, MPa.

6.2.31 Summed design tangent stresses in cross-sections of the hull are taken equal to:

$$\tau = \tau_{\text{tor}} + \tau_{\text{ben}},$$

where $\tau_{\text{tor}}$ — tangent stresses in the hull due to torsion, MPa;

$\tau_{\text{ben}}$ — tangent stresses in the hull due to the global longitudinal bending, MPa.

6.2.32 To ensure the global ultimate strength of a ship the following condition shall be met

$$M_{\text{lim}} \geq kM_b,$$

(6.2.32)

where $M_b$ — bending moment at longitudinal bending or hogging, kN·m;

$M_{\text{lim}}$ — limiting bending moment, kN·m;

$k$ — safety factor of limiting moment taken equal to 1.5.

6.2.33 When moving in displacement mode the ultimate global strength shall be checked with regard to summed stresses of global and local bending in the bottom and skeg members. Local load is taken having regard to directions of 6.2.16.

For ships carrying cargoes the checking shall be made also for the cargo deck (platform) when moving in both hovering and displacement modes. Local load in the latter case is determined by 6.2.23.

6.2.34 Scope and method of global transverse strength calculations are taken depending on the design features of a designed ship.

**Local strength calculations**

6.2.35 At local strength calculations a sag of beams not exceeding 10% of grillage breadth need not be considered.

6.2.36 For girders directly connected to the shell plating an effective flange width $d$, cm, is taken equal to:

1 at calculation of ordinary members and web members located perpendicularly to the ordinary members,

$$d = 0.5b \text{ at } b/t \leq 80;$$

(6.2.36.1-1)

$$d = 40t \text{ at } b/t > 80;$$

(6.2.36.1-2)

2 at calculation of web members of the same direction with ordinary members

$$d = 0.5A/b \text{ at } b/t \leq 80;$$

(6.2.36.2-1)

$$d = 40tA/b \text{ at } b/t > 80;$$

(6.2.36.2-2)
where \( b \) — distance between same-name ordinary girders, cm;
\( A \) — distance between the same-name web members, cm.

Stiffeners of the same direction with web members located at the effective flange level shall be included into the effective flange.

For web members laid above ordinary stiffeners (attached framing structure), the effective flange is taken equal to zero.

In all cases the effective flange shall not exceed 1/6 length of design span of a girder.

**Buckling strength calculations**

6.2.37 At buckling strength calculations of framing girders in order to determine its cross-sectional area the effective flange width is taken equal to an average distance between same-name girders, while at determination of the area moment of inertia of girders, the effective flange is taken in accordance with 6.2.36.

6.2.38 Corrected (critical) Euler’s normal stresses of stiffeners shall meet the following condition
\[
\sigma_{cr} \geq 1.5 \sigma .
\] (6.2.38)

6.2.39 Euler’s tangent stresses in a plate of side, superstructure and bulkhead plating participating in global bending shall meet the following condition
\[
\tau_E \geq 1.5 \tau .
\] (6.2.39)

6.2.40 Buckling strength of web members of compressed grillages is determined by the required rigidity of transverse web members, at which the grillage withstands the given compressing stress.

6.2.41 Buckling strength of separately working members (pillars, braces, etc.) shall be ensured with a safety factor of 2 as compared with design stresses.

**Permissible stresses**

6.2.42 Permissible stresses \( \sigma_p \) and \( \tau_p \) at global and local strength calculation of the hovercraft hull are taken according to Table 6.2.42 as fractions of unsafe stresses.

6.2.43 Unsafe normal stresses are taken equal to:
- at tension \( \sigma_0 = kR_{p0.2} \);
- at compression \( \sigma_0 = \sigma_{cr} \).

Unsafe tangent stresses \(\tau_0\) are taken equal to 0.57 of unsafe normal stresses \(\sigma_0\) in the given section.

6.3 DESIGNING OF THE HULL

6.3.1 Thickness of hull members shall be not less than indicated in Table 6.3.1.

6.3.2 Plates of the outer shell plating in way of engine foundations, propeller shaft and water-jet brackets and plates subject to intensive mechanical wearing are thickened by at least 40%.

6.3.3 The distance between ordinary girders (the spacing) shall not exceed 300 mm at plating thickness of less than 3 mm and 400 mm in the rest cases.

\(^*\) Hovercraft do not belong to small vessels.
6.3.4 The distance between web frames shall not exceed 1200 mm in case of the spacing up to 300 mm and 1500 mm in the rest cases.

6.3.5 The distance between keelsons as well as between a keelson and a side or a longitudinal bulkhead shall not exceed 1500 mm in ships without double bottom and 2000 mm in ships with double bottom.

6.3.6 In the bottom edge area the skeg shall be strengthened by means of thickening a plating or fitting a special reinforcement. Strengthening thickness shall be not less than double thickness of the skeg plating. In ships intended for operating in fresh water only, steel reinforcement brackets may be applied.

6.3.7 Measures shall be taken for increase of deck rigidity in areas where passengers may be crowded during boarding. The deck thickness in that area shall be at least 3 mm.

6.3.8 Where window cutout are located close to each other in the superstructure, two continuous end parts (fore and after) shall be provided in the superstructure walls. The length of each of the above parts shall exceed the window cutout height by at least 20%.

6.4 VIBRATION STRENGTH AND VIBRATION NORMS OF THE HULL

General requirements

6.4.1 Vibration calculations means checking of the absence of resonance by means of determination of natural oscillation frequencies and comparing them with frequencies of exciting forces due to the operation of the ship machinery and the propulsion unit.

The following shall be checked:

.1 general vertical oscillations of the hull for the design loading conditions of ship, i.e. full loaded condition and lightship condition;
.2 local oscillations of members, stiffeners and outer shell plating, deck and bulkhead plating.

6.4.2 Local oscillations shall be checked for the following areas:

.1 the bottom in the propulsion unit area;
.2 the bottom in the area of engines and ventilators.

Global and local vibration calculations

6.4.3 At global vibration calculations natural oscillation frequencies of the hull of the first, second, and higher tones shall be determined for the ship in displacement and hovering modes based on methods developed in accordance with requirements of the Rules and agreed with the River Register. Those frequencies shall be different from exciting force frequencies at basic operational modes which are numerically equal to:

.1 propeller rotor revolution frequency;
.2 propeller rotor revolution frequency multiplied by the number of blades;
.3 engine crankshaft revolution frequency;
.4 revolution frequency of engine crankshaft multiplied by the number of ignitions per one revolution;
.5 ventilator revolution frequency multiplied by the number of blades.

6.4.4 Frequency difference assigned by a designer shall be grounded by a calculation which shall prove that global vibration amplitudes do not exceed the permissible values (see 6.4.13).

6.4.5 Natural oscillation frequency of the hull of the first, second and higher tones shall be adjusted by experience on the first ship in a series.

6.4.6 In order to avoid resonance, natural oscillation frequencies of the first tones of particular hull structures shall exceed frequencies of exciting forces at basic operational modes (in hovering and displacement modes) as the following:

.1 for plates and stiffeners of the hull bottom in the aft extremity — the propeller rotor revolution frequency by at least 50 and 30% correspondingly;
.2 for plates and stiffeners in way of main engines — crankshaft revolution frequency and double crankshaft revolution frequency of the main engines by at least 50 and 30% correspondingly.
6.4.7 Natural oscillation frequencies of the plates and stiffeners shall differ from frequencies of exciting forces numerically equal to:

.1 in the aft extremity — the propeller rotor revolution frequency multiplied by the number of the blades;
.2 in way of main engines — the engine crankshaft revolution frequency multiplied by the number of ignitions per revolution of the crankshaft;
.3 in way of ventilators — the ventilator revolution frequency multiplied by the number of the blades.

6.4.8 Difference between the natural oscillation frequency and the frequency of exciting forces assigned by a designer (see 6.4.7) shall be substantiated by forced vibration calculation to verify that amplitudes at vibration shall not exceed the permissible values (see 6.4.14).

6.4.9 Natural oscillation frequency of plates, Hz, resting on web members and not reinforced by intermediate ordinary members or stiffeners may be calculated by the formulae (2.6.10), (2.6.11-1), (2.6.11-2).

6.4.10 Natural oscillation frequency of plates, Hz, resting on web members and reinforced by intermediate ordinary members or stiffeners is calculated by the formulae (2.6.12) to (2.6.13-2).

6.4.11 Natural oscillation frequency of intermediate ordinary members or stiffeners, Hz, determined regardless of its interaction with the plate is calculated by the formula (2.6.14).

6.4.12 At trials of the first ship in a series according to 6.1.5 periodical exciting forces due to propellers, engines, ventilators, dynamic interaction forces with waves etc. and its ranges shall be obtained in experimental way according to methods developed in accordance with the Rules and agreed with the River Register. The test results shall be submitted to the River Register.

Vibration norms

6.4.13 Permissible amplitudes of vibration of the aft extremity shall not exceed the values calculated by formula (2.6.25.1).

6.4.14 Permissible amplitudes of vibration in the centre of plates of the hull and superstructure, mm, shall not exceed the values determined by the formula

\[ A_p = k \left( \frac{a}{100t} \right)^2 t, \]  

(6.4.14)

where \( k \) — coefficient equal to:

- for plates welded around the contour by means of continuous double-sided weld or riveted to the framing: \( k = 2.90 \);
- for plates welded around the contour by continuous single-sided or intermittent double-sided weld: \( k = 1.45 \);

\( a \) — shorter side of the plate, cm;
\( t \) — plate thickness, cm.

6.4.15 Vibration of the framing is considered to be permissible, if the greatest stresses measured or calculated from measured amplitudes do not exceed 20 MPa.

6.5 DESIGN REQUIREMENTS AND STRENGTH NORMS OF AIR CUSHION FLEXIBLE SKIRT

6.5.1 The requirements stated in this chapter apply to flexible skirts of air cushion (FS) of skeg and amphibian type inland navigation hovercraft made of rubber-textile materials complied with the Rules using glue-pierced, bolted and riveted joints.

6.5.2 Dimensions, design, type of connections and joints of FS shall be chosen at the initial stages of hovercraft designing according to the design specification with due regard to design and operation experience of similar craft and data on physical and mechanical properties of FS materials submitted by the manufacturer and obtained by laboratory tests.

6.5.3 In case if FS structure has novelty in design, materials or it is intended for specific operation conditions, manufacture and tests of an experimental model of FS shall be provided. FS experimental model shall undergo test cycle on a type hovercraft in operation conditions during the service period planned for this FS according to the methods developed according to the requirements of the Rules and agreed with the River Register.
6.5.4 FS shall be designed so as to meet the following requirements:
1. it shall ensure hovercraft reliable operation in operation conditions;
2. metal parts of FS fastenings shall be made of corrosion-resistant alloys or have corrosion-resistant coating;
3. it shall be processable, easily accessible for maintenance, repair, mounting, dismantling and ensure the possibility of replacement or repair of defect components and parts outside the workshop conditions;
4. FS shape and structure in hovering mode above the even screen shall ensure the adequate air cushion height and prevent unforeseen bending deformations and air leakages at sheet butts and in fastening joints of the bag member.

Flexible skirt strength calculations and norms

General directions

6.5.5 Global strength of the FS main structural components shall be checked according to tension calculation methods in soft shells subject to excessive internal pressure. The calculation method shall be agreed with the River Register.

6.5.6 FS strength condition is determined by the formula:
\[ T \leq T_{\text{perm}}, \]  
(6.5.6)

where \( T \) — design tension,
\( T_{\text{perm}} \) — permissible tension in FS components.

6.5.7 Permissible tension in FS material at the hovercraft design stage is determined as:
\[ T_{\text{perm}} = mR_{\text{H}}, \]  
where \( R_{\text{H}} \) — tensile stress of FS material, kN/cm,
\( m \) — strength reducing coefficient due to processing tolerances for FS assembling, wear and natural ageing of the material, which is assigned according to Table 6.5.7.

6.5.8 At the hovercraft design stage the dynamic stress increasing coefficient relating to basic calculation case \( n \) shall be assigned according to Table 6.5.7.

6.5.9 Basic calculation cases are as follows:
1. still hovering above the horizontal screen on calm water (basic case)
2. interaction with the water surface at waves and in hovering cruise mode with amplitude equal to the air cushion height:
\[ 2z = h_{\text{c}}, \]
3. contacting obstacles longitudinally and transversely oriented relatively to the FS plane view in hovering mode.

6.5.10 Correction of coefficients \( n \) and \( m \) is made with regard to operational trials of hovercraft’s FS.

* Including additional wear of the aforementioned FS components when contacting the ground.
6 Design of Hovercraft Hull

6.5.11 Bag member is the upper tier shell of double-tier full-contour FS secured to the hovercraft hull by upper and lower fastenings as well as inflatable skeg (bag) as FS component of respective hovercraft types.

6.5.12 Tensions in the outer branch of the bag member shell (bounding the ambient atmosphere) $T_B$ in the still hovering mode (basic calculation case) are determined using the formula:

$$T_B = 10^{-4} P_B r_{out},$$

where $P_B$ — pressure in the bag member, kPa;
$r_{out}$ — radius of curvature of the outer branch of the bag member shell, cm.

Note. According to equilibrium conditions of the FS bag member shell, tensions in the inner branch of the shell (bounding the air cushion) are equal to tensions in the outer shell.

6.5.13 Maximal tensions in the shell of the bag member cylindrical section $T_B^c$ in hovering cruise mode at waves (calculation cases 1 and 2), kN/cm, are determined by the formula:

$$T_B^c = n P_{ac} r_{out} \cdot 10^{-4},$$

where $n$ — pressure increasing coefficient determined for each calculation case according to the test results of similar prototype or, if such prototype is not available, according to Table 6.5.7.

6.5.14 Maximal tensions in toroidal sections of the bag member shell $T_B^{tor}$ (fore section and aft angular sections) are determined by the formula, kN/cm:

$$T_B^{tor} = 1.5 \cdot 10^{-4} n P_B r_{out}.$$

6.5.15 Half-bag member is the upper tier shell of double-tier half-contour FS secured to the hovercraft hull only by upper fastening.

6.5.16 Tensions in the shell of the half-bag member cylindrical sections $T_{HB}^c$, kN/cm, are determined by the formula:

$$T_{HB}^c = n P_{ac} r_{out} \cdot 10^{-4},$$

where $P_{ac}$ — pressure in the air cushion, kPa.

6.5.17 Maximal tensions in toroidal sections of the half-bag member shell (fore section and aft angular sections) $T_{HB}^{tor}$ are determined by the formula, kN/cm:

$$T_{HB}^{tor} = 1.5 \cdot 10^{-4} n P_{ac} r_{out}.$$

6.5.18 Tensions in the material of open-type finger $T_e$, kN/cm, are determined by the formula:

$$T_e = n P_{ac} r_e \cdot 10^{-4},$$

where $r_e$ — radius of curvature of the outer branch of the finger cross-section, cm.

6.5.19 Tensions in the material of closed-type finger are determined by the respective formulae for the bag member.
7 DESIGN OF REINFORCED-CONCRETE HULL

7.1 GENERAL REQUIREMENTS

7.1.1 The present Section sets up requirements for the materials, structure, strength and construction of reinforced-concrete hulls and superstructures.

7.1.2 All the materials used to construct ships shall comply with the requirements of Part X of the Rules.

7.2 DESIGNING OF HULL AND SUPERSTRUCTURE

General requirements

7.2.1 Hull of reinforced-concrete ships may be framed by the transverse, longitudinal or combined framing systems.

For floating objects of landing stage and fire-watch types up to 35 m in length a hull may be designed according to non-frame (non-rib) system with transverse bulkheads the number of which exceeds the one required by the Rules based on floodability conditions.

A combined construction of a hull made of rib and non-rib elements is allowed. The latter shall be used for inner parts of the hull (e.g. bulkheads and platforms).

7.2.2 Hulls of reinforced-concrete ships may be of assembled, assembled-monolithic and monolithic design.

7.2.3 Parts of weather decks in reinforced-concrete ships shall be inclined to ensure drainage of water overboard. Bottom of floating objects more than 30 m in length shall be risen above the load waterline at the extremities.

7.2.4 Watertight bulkheads shall be so located in the hull as to provide the ship’s floodability in accordance with the requirements of 4 Part II of the Rules.

7.2.5 Floating objects of P and J classes bulkheads may be permeable in way of their connection with the deck, provided that for the most unfavourable flooding conditions the freeboard depth is not less than 0.7 m. The above does not apply to forepeak and afterpeak bulkheads as well as to bulkheads of the engine room which in all cases shall be tightly connected with the deck.

7.2.6 Outer parts of the hull subject to impacts during operation shall be protected by fender bars, special baffles or platings.

Protective structures of the hull shall transfer forces of impacts to rigid members (bulkheads, framing girders or special reinforcements).

7.2.7 Surfaces subject to intensive local wear (plates of shell plating and decks in way of anchor hawsepipes, cargo hatch coamings) shall be lined with metal or other protective material.

7.2.8 Number and location of armature in elements of reinforced-concrete hull shall be designated on condition of ensuring strength and restriction of crack propagation with observance of respective structural requirements of the Rules.

7.2.9 Cross-sectional area of tensioned armature as a share of geometrical section area of the element shall be as follows, %, min, for armature made of steel of grade:

<table>
<thead>
<tr>
<th>Type</th>
<th>Grade</th>
<th>Cross-sectional Area</th>
</tr>
</thead>
<tbody>
<tr>
<td>A-I</td>
<td>A240</td>
<td>0.5</td>
</tr>
<tr>
<td>A-II</td>
<td>A300</td>
<td>0.4</td>
</tr>
<tr>
<td>A-III</td>
<td>A400</td>
<td>0.3</td>
</tr>
</tbody>
</table>

7.2.10 For all hull components, the required cross-sectional area of armature shall be ensured using the greatest possible number of rods of minor diameter thus maintaining the minimum permissible distance between the rods (see 7.2.11). Here, the rod diameter
shall be not less than 10 mm for longitudinal armature rods of girders and 6 mm for lathing of plates and loops and for armature designated from a construction point of view.

7.2.11 Location of armature rods in the hull elements shall meet the following requirements:

1. clear distance between the nearest parallel rods shall be not less than their diameter, but not less than 20 mm;
2. minimum clear distance between extended parts of overlaps and onlays of butts and the nearest parallel armature rods shall be 10 mm and more;
3. armature rods shall not enclose the openings through which concrete is supplied to the lower parts of construction, by more than 40% of their area.

7.2.12 Hull armature shall be welded and consist of flat welded lathings or volume welded carcasses.

Tied armature is allowed for the manufacture of monolithic parts of a hull, as well as for particular sections on condition that their armature is assembled on the place of manufacture and is not transported in assembled condition.

7.2.13 Butt connections of the rods shall be performed by means of contact or arc welding (by side fillet welds or bath method in channel onlays). In all cases the armature in the place of connection shall be equally strong to the rods to be connected and, when connecting rods of different diameters, equally strong to the least diameter rod.

7.2.14 Connections of intersecting rods shall be performed by spot welding, semi-automatic CO2–shielded welding, manual arc welding in hardly accessible places.

7.2.15 Connections of the rods with metal structures shall be fulfilled by arc welding (by continuous, spot gas-shielded or submerged arc welding).

7.2.16 Ends of armature rods shall be reliably fastened, for this the following is necessary:

1. to complete by end hooks all regarded in strength calculation tensioned rods of armature of 10 mm in diameter and more, as well as all the anchors subject to tension and of less than 20 diameters in length;
2. to fasten tensioned rods within compressed zone;
3. to overlap the rods at places, where they are required by the calculation, for the following length:
   - strained rods of armature steel (see 2.10 Part X of the Rules) of A-I (A240) and A-II (A300) grades — for 30 diameters, of A-III (A400) grade — for 40 diameters;
   - compressed rods of steel A-I (A240) grade without hooks — for 30 diameters, of other grades — for 10 diameters less than tensioned ones;
4. to weld all loaded longitudinal rods ending up in a point of intersecting or abutting of girders to special anchors and the nearest intersecting rods.

7.2.17 Armature bends are carried out by arc of a radius not less than 10 diameters.

Normal end hooks of armature shall be of a clear diameter not less than 2.5 rod diameter, straight hooks shall have a length of bent part of not less than 3 diameters.

7.2.18 Hogging of tensioned armature at angles less than 165° is not allowed. In this case the armature shall consist of individual intersecting rods located along side edges of connected elements.

At angles exceeding 165° the hogging of tensioned armature is allowed provided that loops are installed.

7.2.19 Thickness of protection concrete layer for all outer surfaces of the hull and inner surfaces subject to moistening shall be not less than 10 mm and for other surfaces — not less than 5 mm.

Parts of the hull contacting with sea water as well as deck parts subject to high wearing which are not covered with special coating shall have a thickness of protection layer increased by at least 5 mm in comparison with the aforementioned.
For armature of more than 10 mm in diameter thickness of protection layer shall be not less than a rod diameter.

7.2.20 When designing a hull, no new strength concentration spots shall be formed. For this the following shall be complied with:
   .1 ends of rods in the main hull members shall be distributed over a length and breadth of the element in such a way that in one section an area of a tensioned armature is changed by not more than 25% for plates and 30% for girders, and for compressed armature — by not more than 40%;
   .2 ending members shall be fastened to the nearest intersecting members or reinforced parts of plates;
   .3 to change the thickness of plates and dimension of girders smoothly, with a slope not more than 1:3;
   .4 to provide chamfers of at least 25 mm for right and acute corners of concrete parts.

Plates

7.2.21 Thickness of the hull plates shall be designated depending on the type and main dimensions of a ship, her construction and strength condition. In all cases a thickness of plates shall be not less than that indicated in Table 7.2.21.

<table>

</tr>
</tbody>
</table>

Notes. 1. The less values of thickness relate to ships up to 40 m in length.
2. In ships with non-framed structure thickness of shell plating shall be not less than 60 mm.

7.2.22 Thickness of plates in way of bilge, as well as in way of built-in parts locations or fastening of machinery and arrangements shall be increased by at least 25%.

7.2.23 Hull plates shall be reinforced by two single lathings apart at a distance not less than a thickness of the protection layer (see 7.2.19).

7.2.24 When reinforcing thin plates not subject to impact loads (plates of bulkheads, enclosures and decks protected by covering) instead of the two single lathings one sesquialteral lathing may be used consisting of middle distributing rods to both sides of which perpendicularly located working rods are fitted.

Plates of shell plating shall not be reinforced by the sesquialteral lathing.

7.2.25 Armature of plates in way of bilge, deck stringer as well as in places subject to significant impact or concentrated loads shall be reinforced by increase of dimensions or installation of additional rods and local lathings.

7.2.26 Cross-sectional area of distributing armature located throughout a longer edge of a plate in all cases shall be not less than 20% of cross-sectional area of working armature located throughout a shorter edge of the plate but not less than that required by 7.2.9.

7.2.27 Dimensions and location of armature rods shall meet the following requirements:
   .1 in one row of the lathing over the whole span length there shall be not less than 5 and not more than 25 rods per 1 m of length;
   .2 a distance between working rods shall not exceed 2.5 times the plate thickness and that between distributing rods — 4 times the plate thickness;
   .3 rods of basic lathings at plate thickness up to 80 mm shall be located in staggered order and not one above the other;
   .4 a rod diameter shall be not less than 6 mm and more than 0.25 the plate thickness;
   .5 at reinforcing plates with rods of different diameters the latter may differ from each other by not more than 2 mm.

7.2.28 In the bottom, deck and bulkhead plates up to 40% of the total number of working armature of outer lathing may be made as
individual rods located in area of the plate bearing provided that their length is not less than the bearing breadth plus 0.4 times the plate span.

7.2.29 Supporting sections of plates shall be strengthened by means of haunches.

If a haunch is included in strength calculation, it shall be reinforced with special rods or lathings in such a way that there are at least 5 rods perpendicular to the rib per 1 m of the haunch length.

During arrangement of the haunch no separate rods mentioned in 7.2.28 may be used.

7.2.30 Armature of plates forming a corner shall be connected by means of welding or overlapping from one plate into another not less than 60% of rods to the length of 15 times rod diameter but not less than 150 mm.

7.2.31 Armature of plates forming T-section is connected by means of welding or bending out of all the lathing rods of abutting plate between lathings of another plate. A length of the bending shall be not less than 10 times the rod diameter.

**Girders**

7.2.32 A rib height shall not exceed 10 times the plate thickness and breadth shall be less than 1.5 times the plate thickness.

7.2.33 Working armature of girders shall meet the following requirements:

1. Diameter of working rods shall be not less than 10 mm and that of the assembling rods — not less than 6 mm;
2. The design armature shall be located by not more than 3 rows over the height and not less than 2 rows over the breadth both in compressed and tensioned zones;
3. Where a girder height is 500 mm and more, additional longitudinal armature of rods with a diameter not less than 8 mm shall be installed. A distance between the rods along the girder depth shall be not less than 200 mm.

7.2.34 Sloped armature of girders shall be effected by bending of longitudinal armature passed from tensioned zone to compressed zone or by entering of special bent out rods ending by straight sections and welded by overlap to longitudinal armature. An angle between the bendings and the girder axis shall be not less than 30° and not over 60°.

No individual rods not connected with the basic armature may be used.

7.2.35 Transverse armature of girders performed as loops shall meet the following requirements:

1. The loop diameter shall be 0.25 times the diameter of longitudinal armature but at least 6 mm;
2. A distance between the loops shall not exceed the least of the following values: 0.75 times the girder depth, 15 times the diameter of compressed armature rods and 250 mm.

In pillars and girders subject to longitudinal compression a loop pitch, besides that, shall not exceed 1.5 times the rib breadth;

3. If cross-sectional area of compressed armature exceeds 3% of cross-sectional area of the element, a distance between the loops shall not exceed 10 times the rod diameter of the aforementioned armature;

4. Each loop shall not embrace more than 6 compressed rods within the rib. If this is impracticable, additional loops, buckles or rods shall be installed to bind the longitudinal armature or opposite branches of the loops.

7.2.36 When reinforcing the girders with welded frames the latter shall have transverse members, i.e. rods or bars.

A distance between transverse members in tensioned zone of the rib shall not exceed 20 times the rod diameter of longitudinal armature, and shall be not more than 500 mm.

In compressed zone of the rib a distance between transverse members shall not exceed 15 times the diameter of longitudinal armature but shall be not more than twice rib breadth. If cross-section area of armature exceeds 3% of the girder cross section, a distance between the transverse members shall not exceed 10 times the diameter of longitudinal armature.

7.2.37 A connection of a girder with a plate is performed by:
.1 passing two longitudinal rods of the girder between lathings of the plate (at closed loops);
.2 entering bent ends of loops (tenons) of a length not less than 10 times diameter (at opened loops) between the plate lathings, here, above the bent end of the loops one rod is located passing over the entire length of the girder.

7.2.38 In framing members of the hull fuel and ballast compartments, water drain and air passing openings shall be arranged.

The drain openings shall not penetrate the longitudinal armature of the girders. A distance from the drain opening edges to the longitudinal armature shall be 10 mm and more.

7.2.39 In way of intersecting of the girders continuity of their longitudinal armature shall be ensured by means of locating the rods at different levels over the height.

If heights of the mentioned girders differ by more than 20%, a low girder shall be strengthened in way of connection with a high girder by means of reinforced haunch.

Haunches need not be fitted for girders, the dimensions of which are designated by the design.

Cutouts

7.2.40 Cutouts in the deck plates reducing a cross-sectional area of the element included in the hull’s girder by more than 15% shall be supported by compensating armature and reinforced-concrete or metal coamings.

7.2.41 All cut rods shall be reliably connected to the compensating armature and the coaming.

7.2.42 Corners of rectangular cutouts are recommended to be rounded or abated.

By corners of large cutouts where dangerous concentration of stresses is possible, rods shall be installed perpendicularly to the corner bisector.

7.2.43 Hull sections shall be joined to each other and to monolithic manufactured elements on armature dowels.

For joining of inner hull elements built-in parts may be employed.

Butts of sections shall be located as far as possible in less stressed areas. Relieve strength of concrete shall be not less than 70% of the grade strength (see GOST 26633).

7.2.44 When designing butts, the following conditions shall be observed:

.1 for butt joints on armature dowels, a distance between edges of sections shall be: for plates — not less than two plate thickness, and for girders — not less than double breadth or half of girder height and in all cases not less than 100 mm;
.2 a distance between parallel rods of armature or connecting details within the butt shall be equal to half an armature diameter but not less than 10 mm;
.3 in way of butts no plate thickenings protruding outside are allowed.

7.2.45 For butt joints on armature dowels connection of rods is carried out by overlap or butt welding with onlays.

In fillet joints armature dowels not subject to tension may be ended in concrete of the butt with due regard to requirements 7.2.16 in respect to anchoring of armature rod ends.

7.2.46 Butts of built-in parts shall be fastened.

In watertight butts a distance between the built-in parts shall not exceed 250 mm.

Construction of the built-in parts and their anchors shall permit easily laying of concrete at butt grouting.

7.2.47 Strength, water-tightness and frost-resistance properties of concrete of the butts shall be not less than those of concrete of the main hull.

7.2.48 Butt grouting shall be made by means of common (manual) or mechanised method. Butt grouting of inner hull elements of ships up to 35 m in length (butts of bulkheads and enclosures with the bottom, deck and sides, butts of superstructure elements with the hull and each other) may be performed by means of caulking.
7.2.49 Concreting butts and monolithic elements at negative temperatures may be performed only using the special technology developed by the Manufacturer and preventing the concrete freezing. The specified technology shall be agreed with the River Register.

7.2.50 Stripping of butts and monolithic-made elements is allowed after achieving by the concrete the following strength, % from grade strength, for elements:

- vertical: 35
- horizontal: 50

7.2.51 Loading of butts and monolithic elements (water-tightness test, move of ship along a slipway, launching) is allowed after the concrete has reached the strength of not less than 70% of the grade strength.

Fastening of machinery and equipment to the hull

7.2.52 A ship’s hull in way of ship’s equipment shall be reinforced.

7.2.53 Machinery and equipment shall be fastened to the hull by means of built-in parts, exit or anchor bolts.

7.2.54 Fastening by means of exit bolts is allowed only to the deck and framing girders as well as to protruding parts of the hull.

7.2.55 Anchor bolts of 12 mm in diameter and more may be used for fastening to all parts of the hull except plates of shell plating and watertight bulkheads provided that reliable connection is ensured.

7.2.56 If built-in parts are fastened by means of welding, their thickness shall be not less than 5 mm; for fitting of the detail into concrete at least two anchors are required of a diameter not less than 8 mm.

In order to avoid an excessive overheating of adjacent concrete and significant welding deformations of built-in parts, they shall be welded by spot or intermittent welds with a welded length not more than 40 mm and leg not over 5 mm.

7.2.57 Pipes piercing watertight bulkheads or shell plating shall be fastened to the plate by means of special built-in parts (sockets with flanges, boxes, built-in plates) fitted with anchors or welded to the plate armature.

7.2.58 Insulation and inner finishing may be secured to the hull by means of fitted into concrete armature dowels of 8 mm and more in diameter.

7.2.59 Fastening of elements active load in which do not exceed 20% of assumed by the Rules may be performed by means of screws and plates fitted in framing girders or in deck plates of at least 60 mm thick.

7.2.60 Non-essential and slightly loaded details may be fastened to concrete by special glues.

Reinforced-concrete superstructures

7.2.61 The reinforced concrete superstructure shall be so designed as not to be participating in global bending of the hull.

7.2.62 Where necessary, reinforced-concrete superstructures may be solid, i.e. participating in general bending of the hull. In these cases a reliable connection of the superstructure and the hull shall be provided ensuring their mutual work.

Material and structure of the solid superstructure shall meet the requirements of the present Section for the main hull.

7.3 STRENGTH CALCULATIONS AND NORMS

General requirements

7.3.1 Values of external loads are determined in accordance with the requirements of 2.2.

7.3.2 External loads acting on hull and its separate parts are divided into constant, occasional and extraordinary loads.

The constant load is a load acting all the time or within considerable period including: load weight, structure dead load, load on hull when a ship is at calm water, when design ship is at dry-docking (for floating docks).
The occasional load is a load acting within limited number of times including: wave load, load on hull when docking or on the stock; ice load, loads when constructing and testing, docking of an off-design ship (for floating docks).

The extraordinary load is a one-time load resulting from violation of specified operation conditions including loads arising when compartment flooding, grounding or

7.3.3 External loads acting to the damaged hull shall be determined from the condition of single- or two-compartment flooding (see 4.2.3 and 4.2.4 Part II of the Rules) which is the most unfavourable with regard to general strength of a ship.

7.3.4 In case of assembled elements strength checking during their transportation and mounting, the weight of the construction multiplied by dynamic coefficient equal to 1.5 is taken as design load.

7.3.5 When calculating the strength of the hull structures, the internal forces from total and local loads (normal and shear forces, bending moments) as well as transfer and turn angles shall be determined with regard to inelastic concrete deformations, crack formation and nonlinear relationship between stresses and deformations according to methods developed in accordance with the requirements of the Rules and agreed with the River Register.

**Design forces, moments and stresses due to global bending**

7.3.6 Basic designations:
- \( M \) — bending moment, \( \text{kNm} \);
- \( N \) — longitudinal forces, \( \text{kN} \);
- \( Q \) — shear force, \( \text{kN} \);
- \( \tau \) — tangential stresses, \( \text{MPa} \);
- \( I \) — area moment of inertia of reduced cross-sectional area of the hull girder, \( \text{cm}^4 \);
- \( S \) — static moment of reduced cross-sectional area of the hull girder located at one side of the neutral axis taken relating to the neutral axis of the hull girder, \( \text{cm}^3 \);
- \( S_e \) — static moment of reduced cross-sectional area of the considered element relating to the neutral axis of the hull girder, \( \text{cm}^3 \);
- \( F_e \) — reduced cross-sectional area of the considered element, \( \text{cm}^2 \);
- \( F_t \) — reduced cross-sectional area of bottom and deck strakes of the hull girder, \( \text{cm}^2 \);
- \( H \) — ship depth measured between outer plates of the bottom and deck, \( \text{m} \);
- \( \sum t \) — sum of thicknesses of the sides and longitudinal bulkheads at level of the neutral axis of the hull girder, \( \text{cm} \);
- \( E_c \) — initial Young’s modulus of elasticity of concrete, \( \text{MPa} \);
- \( E_a \) — Young’s modulus of elasticity of armature, \( \text{MPa} \).

7.3.7 For determination of design forces, moments and stresses due to global bending the hull shall be considered as the hull girder.

7.3.8 Design forces, moments and stresses shall be found for two possible positions of a ship: the sagging — at compressed deck, and the hogging — at compressed bottom.

7.3.9 Design forces, moments and stresses shall be calculated for sections in which elements are most stressed (sections in the middle part of ship, in way of cutouts, in way of change of framing system, discontinuity of longitudinal members).

7.3.10 Longitudinal members of the hull and reinforced-concrete superstructure shall be included in the hull girder in conditions mentioned in 2.2 as similar members of steel ships. Weakening due to individual cutouts which greatest dimension does not exceed 5 times the plate thickness and which do not reduce the section area of effective flange of the hull girder by more than 3% may not be regarded.

7.3.11 Longitudinal forces due to bending moment in elements of the hull girder shall be determined regardless of the concrete behaviour in tensioned zone by the formula, \( \text{kN} \):

\[
N = 100MS_{HG}/I .
\]  
(7.3.11-1)

For one-decked ships with flat single bottom the longitudinal forces due to bending
Design of Reinforced-Concrete Hull 181

7.3.11 The moment may be calculated by the formula, kN:

\[ N = MF_{HG} / (HF_F) \]  
\[ (7.3.11-2) \]

7.3.12 The whole cross-sectional area of the armature and cross-sectional area of concrete compressed zone multiplied by ratio \( E_c/E_a \) shall be included in the reduced cross-sectional area.

7.3.13 The greatest tangential stresses in vertical elements of the hull girder (sides and longitudinal bulkheads), MPa:

\[ \tau = 10QS / (I \sum t) \]  
\[ (7.3.13-1) \]

For one-decked ships with flat single bottom the greatest tangential stresses, MPa, may be determined by the following approximate formula:

\[ \tau = 0.1Q / (H \sum t) \]  
\[ (7.3.13-2) \]

Design forces, moments and stresses due to local load

7.3.14 Basic designations:
- \( Q \) — design load intensity, kN/m;
- \( p \) — design pressure on the strip girder, kPa;
- \( h_{wh} \) — water head creating hydrostatic load to a side or bulkheads, m;
- \( M_{bs} \) — bending moment in bearing section of strip girder, kN\( \cdot \)m;
- \( M_s \) — bending moment in the middle of a span of the strip girder, kN\( \cdot \)m;
- \( l \) — span of the strip girder between the axes of the supports, m;
- \( l_1 \) — clear span of the strip girder, m;
- \( l_h \) — length of haunch, m;
- \( h \) — plate thickness, cm;
- \( h_d \) — design thickness of a plate in way of the haunch, cm;
- \( h_h \) — entire height of the haunch, cm;
- \( h_{hd} \) — design height of the haunch, cm.

7.3.15 The design forces in hull members due to local bending are determined in accordance with the requirements of 7.3.5.

7.3.16 If the design forces in hull members due to local bending are determined using design methods of elastic systems not provided by the Rules, in order to determine the ratio of their stiffness in the reduced cross-sectional area of the members when calculating the moments of inertia, the whole concrete and armature cross-section multiplied by ratio of moduli of elasticity of armature and concrete \( E_c/E_a \) are included.

7.3.17 Rectangular plates resting on three or four edges are calculated as girders of a span equal to the shortest side of the plate, if a side ratio is more than 2:1.

At the side ratio equal or less than 2:1, rectangular plates may be calculated according to formulae for a thin isotropic plate.

Plates resting on two edges are calculated as girders of a span equal to a distance between the born edges.

7.3.18 A distance between axes of the supports shall be taken as a design span of girders and plates.

Geometrical dimensions of frame rings are taken over the internal surface of the plating.

7.3.19 In girders and plates having haunches with a ratio \( h_h/l_h \leq 1/3 \) haunches shall be fully accounted in relevant sections.

Haunches with a ratio \( h_h/l_h > 1/3 \) are assumed to have a ratio \( h_h/l_h = 1/3 \) (Fig. 7.3.19).

7.3.20 When determining framing girder elements, effective flanges of the plates shall be taken into account.

Design width of effective flange shall be taken equal to half-sum of plate spans adjacent to the stiffener but not more than 20
times the plate thickness (or 25 plate thickness, when it is connected to the stiffener reinforced with haunches). Here, effective flange width shall not exceed 1/3 of design span of the girder.

7.3.21 For continuous girders and girder plates a moment at bearing stiffener edge section is taken as design support moment. Here, for the strip girder constrained at the bearings with reinforced haunches and loaded by uniformly distributed load, bending moments, kN·m, may be determined as for a non-prismatic girder:

on a bearing
\[ M_s = -ql^2 \xi / 12 \]  
(7.3.21-1)
in a span
\[ M_s = ql^2 (3 - 2\xi) / 24 \]  
(7.3.21-2)
where \( \xi \) — coefficient to be determined by Table 7.3.21.

7.3.22 When checking strength of side plates in case of the transverse framing system and bulkheads with vertical stiffeners design pressure on a strip girder is assumed equal to the greatest of the values calculated by the formulae, kPa:

\[ p = 9.81 (h_{wh} - 0.5l) \]  
(7.3.22-1)
\[ p = 9.81 \cdot 2h_{wh} / 3 \]  
(7.3.22-2)

### Strength checking of the elements of common reinforced concrete hull

7.3.23 Basic designations:
\( R_{ac} \) — tensile strength of concrete at axial compression, MPa;
\( R_{at} \) — tensile strength of concrete at axial tension, MPa;
\( R_{yH} \) — yield point of armature, MPa.
\( M \) — bending moment due to design load in normal section of the element, kN·m;
\( M_b \) — design breaking moment in normal section of the element, kN·m;
\( N \) — longitudinal force due to design load, kN;
\( N_d \) — design longitudinal breaking force, kN;
\( Q \) — shear force due to design load, kN;
\( Q_b \) — design breaking shear force, kN;
\( Q_c \) — projection of limiting force in a concrete of sloped section of the element on a perpendicular to the element axis, kN;
\( \sigma_{m.t} \) — main tension stresses, MPa;
\( \tau \) — greatest tangential stresses in the sides and longitudinal bulkheads due to global bending, MPa;
\( F_s \) — cross-sectional area of tensioned or the most tensioned armature, cm²;
\( F'_s \) — cross-sectional area of compressed or the least tensioned armature, cm²;
\( F_{sh} \) — cross-sectional area of vertical or horizontal armature per 1 m of a side or longitudinal bulkhead section length, cm²/m;
\( a \) — distance from the centre of gravity of armature \( F_s \) to the nearest edge of the section, cm;
\( h \) — entire height of rectangular or T-section; thickness of side and longitudinal bulkhead plates, cm;
\( b \) — breadth of rectangular cross-section; breadth of rib of T-section, cm;
\( h_0 \) — effective height of the section equal to \( h - a \), cm;
\( e_0 \) — eccentricity of the longitudinal force, equal to \( 10^7 \) M/N, cm;
\( k \), \( k_1 \) — safety factors taken according to Table 7.3.23.

7.3.24 Strength of the elements shall be checked:

.1 in normal sections for action of bending moments, longitudinal forces, as well as for mutual action of bending moments and longitudinal forces;

.2 in sloped sections for action of shear forces.

Note. When checking strength of assembled element due to action of forces occurring during transportation and mounting, the safety factors shall be not less than k = 1.5 and k_1 = 2.0.

Fig. 7.3.26 Sloped sections subjected to strength check

Sides and longitudinal bulkheads shall be also checked for action of shear force due to general bending.

7.3.25 Checking of strength in normal sections shall be performed in way of action of the greatest bending moment, abrupt change of the element cross-section and cut of the armature.

In this case the following conditions shall be complied with:

during action of bending moments

\[ M_p / M \geq k \]  

(7.3.25-1)

during action of longitudinal forces as well as mutual action of the bending moment and longitudinal forces

\[ N_p / N \geq k \]  

(7.3.25-2)

7.3.26 Checking of strength in sloped sections for action of shear force shall be performed (see Fig. 7.3.26) as applied to the following locations:

in way of action of the greatest shear force;

in way of abrupt change of cross section of the element;

sections passing through the support edge (section I – I);

sections passing through beginnings of bends located in tensioned zone (sections II – II, III – III, IV – IV);

sections passing through points of change of the transverse reinforcement intensity located in tensioned zone (section V – V).

Here, the following conditions shall be met:

\[ Q_p / Q \geq k_1 \]  

(7.3.26-1)

where k_1 — safety factor taken according to Table 7.3.23.

\[ Q \leq 0.1bh_0R_{sc} / 7 \]  

(7.3.26-2)
Where bent rods are available, value of design shear force is taken as follows:

for bends of the first plane — equal to value of the shear force in way of the support edge;

for bends of each of the following planes — equal to value of the shear force in way of lower point which is previous as regards support of the bending plane.

7.3.27 Check of strength in sloped sections for action of shear forces may be omitted, if the following condition is met
\[ 0.1b_{0}R_{p}Q / k_{1} \geq k_{1} \]  
(7.3.27)

7.3.28 Checking of strength of eccentrically compressed elements for action of shear forces shall be performed as for elements being bent regardless of axis compression.

7.3.29 Strength of eccentrically tensioned elements for action of shear forces shall be checked with due regard to the following directions:

1. at minor eccentricities (tension force is applied between the centres of gravity of cross-sectional areas $F_{a}$ and $F'_{a}$ of the armature) the entire shear force in sections located at an angle of 60° or less to longitudinal axis of the element at and less shall be assumed as transverse armature. Checking of strength in sections located at an angle over 60° to the longitudinal axis may be omitted;

2. at major eccentricities (tension force is applied outside the centres of gravity of cross-sectional areas $F_{a}$ and $F'_{a}$ of the armature) the checking of strength shall be performed as for bent elements.

If $e_{o} \leq 1.5h_{b}$, value of $Q$, calculated by the formula (7.3.49-2) shall be multiplied by a coefficient $k_{v}$ equal to
\[ k_{v} = e_{o} / h_{b} - 0.5 \]  
(7.3.29)

7.3.30 At major eccentricity checking of strength of eccentrically tensioned elements for action of shear forces may be performed if conditions (7.3.30-1) and (7.3.30-2) or at least one of the following conditions is met:
\[ \sigma_{mt} \leq R_{p} / k_{1} \]  
(7.3.30-1)
\[ Q \leq 0.1k_{v}R_{p}b_{0}h_{0} / k_{1} \]  
(7.3.30-2)
where $k$ — coefficient calculated by the formula (7.3.29).

At minor eccentricities checking of strength is not omitted if the condition (7.3.30-1) is met.

7.3.31 When checking strength of sides and longitudinal bulkheads for action of shear force due to general bending the following conditions shall be met:
\[ \tau \leq R_{ac} / 7 \]  
(7.3.31-1)
for vertical armature
\[ F_{ab}R_{cht} / (100th) \geq k \]  
(7.3.31-2)
for horizontal armature
\[ F_{ab}R_{cht} / (50th) \geq k \]  
(7.3.31-3)
Cross-sectional area of vertical or horizontal armature $F_{ab}$ may include cross-sectional area of vertical or horizontal stiffeners, respectively, assumed as uniformly distributed over the section.

7.3.32 Checking of strength of sides and longitudinal bulkheads for shear forces may be omitted, if the following condition is met:
\[ \tau \leq R_{p} / k_{1} \]  
(7.3.32)

Design characteristics of materials and formulae for determination of breaking forces and moments

7.3.33 Basic designations:

- $R_{ac}$ — tensile strength of concrete at axial compression (prism strength), MPa;
- $R_{at}$ — tensile strength of concrete at axial tension, MPa;
- $E_{c}$ — initial Young’s modulus of elasticity of concrete at compression and tension, MPa;
- $\sigma_{mt}$ — yield stress of compressed or the least tensioned armature, MPa; $\sigma_{cht}$ — yield stress of compressed or the least tensioned armature, MPa; $\sigma_{cht}$ — yield stress of compressed or the least tensioned armature, MPa; $\sigma_{cht}$ — yield stress of compressed or the least tensioned armature, MPa;
- $R_{cht}$ — material yield stress of bent rods located in one plane crossing the sloped section under consideration, MPa;
- $R_{cht}$ — material yield stress of bent rods located in one plane perpendicular to the element
axis and crossing the sloped section under consideration;

- $E_a$ — Young’s modulus of elasticity of armature, MPa;
- $M$ — bending moment due to design load in normal section of the element, kN·m;
- $M_n$ — design breaking moment in normal section of the element, kN·m;
- $N$ — longitudinal force due to design load, kN;
- $N_d$ — design longitudinal breaking force, kN;
- $Q$ — shear force due to design load, kN;
- $Q_d$ — design breaking shear force, kN;
- $Q_c$ — projection of limiting force in a concrete of sloped section of the element on a perpendicular to the element axis, kN;
- $q_\alpha$ — limiting force in transverse rods (loops) per unit of the element length, kN/m;
- $l_0$ — design length of the element, cm;
- $r$ — minimum radius of inertia of the element cross-sectional area, cm;
- $F$ — cross-sectional area of the whole element reduced to concrete, cm$^2$;
- $f_\alpha$ — cross-sectional area of the concrete, cm$^2$;
- $F_0$ — cross-sectional area of the whole longitudinal armature, cm$^2$;
- $F_a$ — cross-sectional area of the longitudinal armature, cm$^2$;

  for bent elements — armature within tensioned zone;

  for eccentrically compressed elements — armature located by the most distant section edge from a point of application of the longitudinal force $N$;

  for eccentrically tensioned elements — armature located by the most distant section edge from a point of application of the longitudinal force $N$;

- $F_{ben}$ — cross-sectional area of bent rods located in one plane crossing the sloped section under consideration, cm$^2$;
- $F_t$ — cross-sectional area of rods located in one plane perpendicular to the element axis and crossing the sloped section under consideration, cm$^2$;
- $f_\alpha$ — cross-sectional area of one branch of the loop, cm$^2$;
- $n$ — number of loop branches in one section of the element;
- $t$ — distance between transverse rods (loops) along the element length, cm;
- $a$ — angle of slope of the bent rods to the element axis, deg;
- $a^\prime$ — distance from the centre of gravity of armature $F$ to the nearest edge of the section, cm;
- $b$ — breadth of rectangular cross section; breadth of rib of T-section, cm;
- $h$ — total height of rectangular or T-section, cm;
- $h_0$ — effective height of the section equal to $h = a$, cm;
- $h_0'$ — effective height of the section equal to $h - a$, cm;
- $b_f$ — thickness of effective flange, cm;
- $z$ — height of compressed zone of concrete calculated with due regard to work of compressed armature, cm;
- $z_0$ — height of compressed zone of concrete calculated regardless of work of compressed armature, cm;
- $S_0$ — static moment of the whole cross-sectional area of concrete relative to an axis passing through the centre of gravity of cross-sectional area $F_a$ of the armature, cm$^3$;
- $S_0'$ — static moment of the compressed zone of concrete relative to an axis passing through the centre of gravity of cross-sectional area $F_a$ of the armature, cm$^3$.

\( e_0 \) — eccentricity of the longitudinal force, equal to \( 10^2 M/N \), cm;

\( e \) — distance between the line of action of the force \( N \) and the centre of gravity of cross-sectional area \( F_a \) of the armature, cm;

\( e' \) — distance between the line of action of the force \( N \) and the centre of gravity of cross-sectional area \( F_{a'} \) of the armature, cm;

\( c' \) — distance between the centre of gravity of the cross-sectional area and tensioned or the least compressed edge, cm.

7.3.34 Regulated strength characteristics of the hull structural concrete depending on concrete class are specified in Table 7.3.34-1, and the mechanical characteristics of armature — in Table 7.3.34-2.

The concrete strength characteristics against axial tension in cases where concrete strength against tension are not controlled on production, but taken by 2nd line of Table 7.3.34-1 depending on concrete class as per compressive strength.

7.3.35 The concrete density shall be determined experimentally in accordance with manufacture specifications.

Where experimental data are not available at design stage, density of heavy concrete may be taken equal to 2.40 to 2.45 t/m and that of light concrete — as per Table 7.3.35.

Density of reinforced-concrete shall be determined as sum of concrete and armature masses per unit of volume of the structure.

7.3.36 Design breaking forces in centrally compressed elements, kN, \( N_d = 0.1 \phi \left( R_{sh} F_c + R_{sh} F_a + R'_{sh} F_{a'} \right) \), (7.3.36) where \( R_{sh}, R'_{sh} \) — yield stress of armature of various classes; \( F_c, F_a \) — cross-sectional areas of armature of various classes; \( \phi \) — coefficient of longitudinal bending determined by Table 7.3.36.

If the armature of one class is used, the third term of expression within round brackets of the right part of the formula (7.3.36) is excluded.

Design length of the element \( l_0 \) is determined by means of multiplication of its geometrical length by coefficient depending on extent of constraining and mobility of element ends and taken equal to:

- at complete constraining of both ends 0.5
- at complete constraining of one end and hinged support of the other one 0.7
- at hinged support of both ends 1
- at completely constrained one end and free the other one 2
- at partly constraining of the ends and in frames with fixed junctions 0.7

7.3.37 Design breaking forces in centrally tensioned elements, kN.

</table>

$L_p = 0.1(R_{eh}F_a + R'_{eh}F'_a)$. (7.3.37)

If the armature of one class is used, the second term of expression within round brackets is excluded.

### 7.3.38 Design breaking moments in bending elements of rectangular section (Fig. 7.3.38), kNm:

$$M_d = \left[ R_{sh}bz(h_0 - z/2) + R'_{sh}F'_a(h_0 - a') \right] \cdot 10^3,$$

(7.3.38-1)

where

$$z = (R_{eh}F_a - R'_{eh}F'_a)/(R_{ac}b).$$

(7.3.38-2)

It is assumed here that value of $z$ calculated by the formula (7.3.38-2) meets the condition

$$2a' \leq z \leq 0.55h_0,$$

(7.3.38-3)

If

$$z < 2a' \leq z_0,$$

(7.3.38-4)

where

$$z_0 = R_{eh}F_a/(R_{ac}b),$$

(7.3.38-5)

then the design breaking moment is calculated by the formula (7.3.38-1) with an assumption that

$$z = 2a',$$

(7.3.38-6)

and

$$F'_a = (R_{eh}F_a - R_{ac}b2a')/R_{eh}.$$

(7.3.38-7)

If $z_0 < 2a'$, the design breaking moment is calculated by the formula (7.3.38-1) with an assumption that $F'_a = 0$.

### 7.3.39 Design breaking moments in bent elements of T-section including effective flange in tensioned zone are determined as for bending elements of rectangular section with a breadth equal to the stiffener breadth.

### 7.3.40 Design breaking moments, kN\cdot m, in bending elements of T-section including effective flange in compressed zone are calculated:

when

$$R_{eh}F_a \leq (R_{ac}h_1h_l + R'_{eh}F'_a)$$

(7.3.40-1)

by the formula (7.3.38-1) as for bending elements of rectangular section of $b_x \times h$ (Fig. 7.3.40-1);

![Fig. 7.3.40-1. Cross section of tee reinforced-concrete element](image)

at $R_{eh}F_a > (R_{ac}h_1h_l + R'_{eh}F'_a)$

(7.3.40-2)
by the formula

\[ M_p = \left[ R_{ac} b z \left( h_0 - z/2 \right) + 0.8 R_{ac} h_t \left( h_t - b \right) \times \left( h_0 - h_t / 2 \right) + F''_a R_{ch} \left( h_0 - a' \right) \right] \cdot 10^{-3}, \]

(7.3.40-3)

where

\[ z = \left[ \left( R_{ch} F_a - R_{ch}' F_a' \right) - 0.8 R_{ac} \left( h_t - b \right) h_t \right] / (R_{ac} b). \]

(7.3.40-4)

Here, the following condition shall be met (Fig. 7.3.40-2)

![Fig. 7.3.40-2. To calculation of static moments \( S_c \) and \( S_0 \)](image)

\[ S_c \leq 0.8 S_0. \]

(7.3.40-5)

**7.3.41** Design breaking forces \( N_b \) in eccentrically compressed elements of rectangular section (Fig. 7.3.41-1) meeting the condition

\[ 2a' \leq z \leq 0.55 h_0, \]

(7.3.41-1)

are determined by the formula, kN:

\[ N_p = 0.1 R_{ac} b z - (R_{ch} F_a - R_{ch}' F_a'), \]

(7.3.41-2)

where

\[ z = h_0 - e + \sqrt{\left( h_0 - e \right)^2 + 2 \left( R_{ch} F_a e + R_{ch}' F_a' e' \right) / (R_{ac} b)}, \]

(7.3.41-3)

Values of \( e \) and \( e' \) are calculated by the formulae

\[ e = 100 M / N + c - a'; \]

(7.3.41-4)

\[ e' = 100 M / N - c + a'; \]

(7.3.41-5)

at \( 100 M / N > c' - a' \),

(7.3.41-6)

and \( e' = c' - 100 M / N - a' \)

(7.3.41-7)

at \( 100 M / N \leq c' - a' \). (7.3.41-8)

In formula (7.3.41-3) sign of minus in the second term of the radicand is taken where the force \( N \) is applied outside the centre of gravity of armature \( F_a \) and \( F_a' \).

In elements of rectangular section meeting the condition

\[ z < 2a' \leq z_0, \]

(7.3.41-9)

where

\[ z_0 = h_0 - e + \sqrt{\left( h_0 - e \right)^2 + 2 \left( R_{ch} F_a e / (R_{ac} b) \right)}, \]

(7.3.41-10)

the design breaking forces are determined by the formula (7.3.41-2) with an assumption that

\[ 2a' \]

(7.3.41-11)

and

\[ F''_a = (R_{ch} F_a e - 2 R_{ac} ba' e') / (e' R_{ch}'), \]

(7.3.41-12)

At \( z_0 < 2a' \) the design breaking forces are determined by formula (7.3.41-2) regardless of compressed armature with an assumption that \( F''_a = 0 \).

In elements of rectangular section (Fig. 7.3.41-2) meeting the condition

\[ z > 0.55 h_0, \]

(7.3.41-13)
the design breaking forces are determined by the formula, kN:

\[
N_d = 0.1 \left[ R_{ch} F_a \left( h_0 - a' \right) + 0.5 R_{sc} b h_0^2 \right] / e .
\]  
(7.3.41-14)

Here, if the force \( N \) is applied between the centres of gravity of cross-sectional areas \( F_a \) and \( F_a' \) of the armature, the following condition shall be met

\[
N_d e' \leq 0.1 \left[ R_{ch} F_a \left( h_0 - a' \right) + 0.5 R_{sc} b h_0^2 \right] .
\]  
(7.3.41-15)

7.3.42 flange located in tensioned zone or in minor compressed zone are determined as for eccentrically compressed elements of rectangular section of breadth equal to breadth of the stiffener.

7.3.43 Design breaking forces in eccentrically compressed elements including effective flange located in compressed zone that meet the condition

\[
z \leq h_l ,
\]  
(7.3.43-1)
are determined as for eccentrically compressed elements of rectangular section of a breadth equal to width of effective flange, i.e. by formula (7.3.41-2) taking \( b = b_l \). If \( b = b_l \) at

\[
z > h_l ,
\]  
(7.3.43-2)
then the design breaking forces shall be determined by the following way:

1. height of a compressed zone, cm, is determined by the formula

\[
z = h_0 - e + \left( h_0 - e \right)^2 + 2 \left[ R_{ch} F_a e \pm R_{ch} F_a e' + R_{sc} h_l (h_0 - b) (h_0 - e - 0.5 h_l) / \sqrt{R_{sc} b} \right]^{0.5} .
\]  
(7.3.43.1)

A sign of minus in the second term of equation in square brackets is taken, where a point of application of the force \( N \) is outside the section part bounded by the centres of gravity of cross-sectional areas \( F_a \) and \( F_a' \) of the armature;

2. eccentric compression is considered by the following conditions:

\[
as at minor eccentricities
\]

\[
S_c > 0.8 S_0 ;
\]  
(7.3.43.2-1)

at major eccentricities

\[
N_d = 0.1 \left[ R_{ch} b z - (R_{ch} F_a - R_{ch} F_a') + R_{sc} (b_l - b) h_l \right] ;
\]  
(7.3.43.3)

If the whole section is compressed, the design breaking force found by the formula (7.3.43.4-1) is compared with the force \( N_c \), kN, calculated by the formula

\[
N_d = 0.1 \left[ R_{ch} F_a (h_0 - a' + 0.5 R_{sc} b h_0^2 + R_{sc} (h_l - b) h_l (h_0 - 0.5 h_l) / e .
\]  
(7.3.43.4-2)

For checking of strength the least of the breaking force values obtained from formulae (7.3.43.4-1) and (7.3.43.4-2) is taken.

7.3.44 Influence of flexibility on calculation of eccentrically compressed elements shall be accounted:

for rectangular sections at

\[
l_0 / b > 10 ;
\]  
(7.3.44-1)

for section of any shape at

\[
l_0 / r > 35 .
\]  
(7.3.44-2)

This influence is accounted by means of multiplication of value \( l_0 \) and coefficient \( \eta \) determined by the formulae:

for rectangular sections

\[
\eta = \left[ 1 - kN \left( l_0 / b \right)^2 / \left( 40 R_{sc} F \right) \right]^{-1} ;
\]  
(7.3.44-3)

for section of any shape

\[
\eta = \left[ 1 - kN \left( l_0 / r \right)^2 / \left( 480 R_{sc} F \right) \right]^{-1} ,
\]  
(7.3.44-4)

where \( k \) — safety factor taken according to Table 7.3.23.

7.3.45 If straining force is applied between centres of gravity of cross-sectional areas \( F_a \)
and $F'_a$ of the armature (Fig. 7.3.45), design breaking forces in eccentrically tensioned elements are determined by the formulae, kN:

$$N_d = 0.1F_a(\frac{h_0 - a'}{R_{ch}}/e')$$  \hspace{1cm} (7.3.45-1)

and

$$N_d = 0.1F'_a(\frac{h_0 - a'}{R_{ch}}/e),$$  \hspace{1cm} (7.3.45-2)

where $e$, $e'$ — parameters which values shall be determined by the formulae

$$e = c + 100M/N - a;$$ \hspace{1cm} (7.3.45-3)

$$e' = c' + 100M/N - a'.$$ \hspace{1cm} (7.3.45-4)

Here $c$ — distance between the centre of gravity of cross-sectional area of the whole armature and the most tensioned edge;

$c'$ — distance between the centre of gravity of cross-sectional area of the whole armature and the least tensioned edge.

For strength checking the least of obtained values of breaking force is taken.

7.3.46 Design breaking forces in eccentrically tensioned elements of rectangular section, when straining forces are applied outside centres of gravity of cross-sectional areas $F_a$ and $F'_a$ of armature cross-section

$$N_d = 0.1\left[\left(R_{ch}F_a - R'_{ch}F'_a - R_{ch}b'z\right)\right];$$ \hspace{1cm} (7.3.46-1)

where

$$z = h_0 + e - \sqrt{(h_0 + e)^2 - 2eF_aR_{ch}(\frac{1}{R_{ch}b})},$$ \hspace{1cm} (7.3.46-2)

where $e$, $e'$ — parameters which values shall be calculated by the formulae

$$e = 100M/N - c + a;$$ \hspace{1cm} (7.3.46-3)

and $F'_a$ of the armature (Fig. 7.3.45), design breaking forces in eccentrically tensioned elements are determined by the formulae, kN:

$$e' = c' + 100M/N - a'.$$ \hspace{1cm} (7.3.46-4)

where $c$ — distance between the centre of gravity of cross-sectional area of the element and tensioned edge;

$c'$ — distance between the centre of gravity of cross-sectional area of the element and compressed edge.

It is assumed here that height of the compressed zone of concrete meets the condition

$$2a' < z < 0.55h_0;$$ \hspace{1cm} (7.3.46-5)

If

$$z < 2a',$$ \hspace{1cm} (7.3.46-6)

the breaking force is determined by the formula (7.3.46-1) with an assumption that

$$2a' = 0.$$ \hspace{1cm} (7.3.46-8)

7.3.47 When the straining force is applied outside the centres of gravity of cross-sectional areas $F_a$ and $F'_a$ of the armature, design breaking forces in eccentrically tensioned elements of T-section including effective flange in the tensioned zone are determined as for eccentrically tensioned elements of a rectangular section of a breadth equal to breadth of the stiffener.
7.3.48 When the straining force is applied outside the centres of gravity of cross-sectional areas \( F_a \) and \( F_a' \) of the armature, design breaking forces in eccentrically tensioned elements of T-section including effective flange in the compressed zone, are determined by the following way:

at \( z < h_0 \), where \( z \) is calculated by the formula \((7.3.46-2)\) with an assumption that \( b = b_0 \), design breaking forces are determined as for elements of rectangular section of a breadth equal to width of effective flange;

at \( z > h_0 \) the design breaking forces \( N_c \) are determined by the formula, \( kN \):

\[
N_d = 0.1\left[ (R_{et} F_a - R_{et} F_a') - R_\infty b z - R_\infty (h_t - b) h_n \right],
\]

(7.3.48-1)

where

\[
z = h_0 + e - \left( h_0 + e \right)^2 + 2\left[ R_{et} F_a' - R_\infty e + R_\infty (h_t - b) h_t (h_0 + e - 0.5h_t) \right]/(R_\infty b)^{0.5}.
\]

(7.3.48-2)

7.3.49 Design breaking shear force in sloped section of element, \( kN \),

\[
N_d = 0.1 (R_{et} \sin a \cdot \sum F_{bent} + R_\infty \sum F_i + Q_e),
\]

(7.3.49-1)

where \( Q_e = 0.015 R_\infty b h_0^2 \). (7.3.49-2)

\( c_0 \) — design length of projection of the most unfavourable sloped section to the element axis, a length of which is got by increasing of loop pitches number up to the integer value \( c_0 \) equal to

\[
c_0 = \sqrt{0.015 R_\infty b h_0^2} \quad q_x,
\]

(7.3.49-3)

where \( q_x = 0.1 R_\infty e \). (7.3.49-4)

When bent rods are not available, the design breaking shear force, \( kN \), is determined as

\[
Q_d = \sqrt{0.06 R_\infty b h_0^2} - q_s t.
\]

(7.3.49-5)

7.3.50 Design breaking transverse force in elements subject to uniformly distributed load due to water pressure is determined in accordance with 7.3.49. Here, instead of value of \( q_s \), in calculating formulae \((7.3.49-3) - (7.3.49-5)\) the following shall be inserted

\[
q'_s = q_s + q,
\]

(7.3.50)

where \( q \) — design load due to water action per element length unit, \( kN/m \).

**Checking of hull elements for crack opening**

7.3.51 Basic designations:

- \( E_a \) — Young’s modulus of elasticity of armature, \( MPa \);
- \( M \) — bending moment, \( kNm \);
- \( N \) — longitudinal force, \( kN \);
- \( \sigma_a \) — stress in the armature due to longitudinal straining force, \( MPa \);
- \( \sigma_{ab} \) — stress in armature due to bending moment, \( MPa \);
- \( \sigma_i \) — initial tensile stress in armature due to concrete swelling, \( MPa \);
- \( a \) — distance from the centre of gravity of cross-section area of the most tensioned armature \( F_a \) to the nearest edge of the section, \( cm \);
- \( d \) — diameter of the most tensioned armature rods, \( mm \);
- \( a_c \) — design breadth of crack opening, \( mm \);
- \( l_{cr} \) — distance between cracks, \( cm \);
- \( F_0 \) — cross-sectional area of the whole longitudinal armature in the section under consideration, \( cm^2 \);
- \( F_a \) — cross-sectional area of tensioned armature in the element’s section under consideration, \( cm^2 \);
- \( b \) — breadth of rectangular cross section; breadth of rib of T-section, \( cm \);
- \( h \) — total height of rectangular or T-section, \( cm \);
- \( h_0 \) — effective height of the section equal to \( h - a \), \( cm \);
- \( t \) — distance between rods (pitch) of transverse armature, \( cm \).

7.3.52 All bending, centrally and eccentrically tensioned as well as eccentrically compressed hull elements, a strength of which is proved by calculation, shall be checked for
crack opening at action of constant or mutually applied constant and occasional loads.

7.3.53 Permissible width of crack openings for different reinforced-concrete elements and cases of loading shall be taken according to Table 7.3.53.

7.3.54 Design width of crack openings normal to axis of reinforced-concrete elements, mm

\[ \sigma_{cr} = (\phi_0 \sigma_{as} + \phi_b \sigma_{ab} - \sigma_{n}) l_{cr} / F_a , \]  

(7.3.54)

where \( \phi_{as}, \phi_b \) — coefficients to be taken by Table 7.3.54.

| Values of axial tension \( \phi_0 \) and bending \( \phi_b \) coefficients |
|-----------------|-----------------|
| Load type       | \( \phi_0 \)  | \( \phi_b \) |
| Random          | 0.65            | 0.8           |
| Constant        | 0.80            | 1.0           |
| Repeated, vibration | 0.95      | 1.2           |

For structures located in water \( \sigma = 20 \text{ MPa} \), for structures subject to prolonged drying \( \sigma = 0 \).

For eccentrically compressed elements action of normal compress force in calculation is not considered, it is taken as \( \sigma_{as} = 0 \).

7.3.55 Stresses in armature taken in calculation of crack opening are determined by the formulae:

1. due to longitudinal straining force, MPa,

\[ \sigma_{as} = 10N / F_b \]  

(7.3.55.1)

2. due to bending moment, MPa,

\[ \sigma_{ab} = 1000\Theta M / (F_a h_b \eta) \],  

(7.3.55.2)

where \( \Theta \) — coefficient taken equal to 1.0 in all cases except supporting sections of plates, for which \( \Theta \) is equal to 0.8;

\( \eta \) — coefficient taken equal to 0.85 for plates and T-profile girder with effective flange in the tensioned zone, and 0.90 — for T-profile girders with effective flange in the compressed zone.

7.3.56 Distance between cracks, mm, for bending, centrally and eccentrically tensioned and eccentrically compressed elements

\[ l_{cr} = 20\delta \rho (3.5 - 100 \mu) \frac{1}{\sqrt{d}} , \]  

(7.3.56-1)

where \( \delta \) — coefficient taken for centrally and eccentrically tensioned elements with minor eccentricity equal to 1.2, in other cases \( \delta = 1 \);

\( \rho \) — coefficient taken equal to 1.0 for rods of periodic profile and 1.3 — for smooth rods;

\( \mu \) — reinforcement coefficient of the section determined by the following formulae, but not more than 0.02;

for plates

\[ \mu = F_a / (bh_b) \]  

(7.3.56-2)

for girders with effective flange in the compressed zone

\[ \mu = F_a / (bh_b h) \]  

(7.3.56-3)

for girders with belt in the tensioned zone

\[ \mu = F_a / \left[ b_s h_s + b_t (h_0 - h_t) \right] \]  

(7.3.56-4)

where \( b_s \) — breadth of girder stiffener, cm;

\( b_t \) — width of effective flange, cm;

<table>
<thead>
<tr>
<th>Hull structural elements</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Deck plates in closed sections. Plates of bulkheads and framing girders in dry compartments</td>
</tr>
</tbody>
</table>
$h_s$ — beam height, cm.

Notes. 1. For girders with effective flange in tensioned zone the armature of a stiffener and a plate within width of effective flange shall be included into $F_a$.

2. At different diameters of tensioned armature an assumed value of diameter $d_c$ is being used in the calculation which is determined by the formula, mm,

$$d_c = (n_1d_1 + n_2d_2 + \ldots + n_id_i)/(n_1 + n_2 + \ldots + n_i),$$

where $n_i$ — number of rods of the given diameter $d_i$, mm, included into the tensioned armature;

3. In plates having in tensioned zone transverse armature of a diameter $d_1 > 0.07h_s$ arranged with a pitch $t$ and located parallel to the cracks a distance between the cracks is taken equal to $t$ on condition that $0.7l_{cr} \leq t \leq 1.3l_{cr}$.

**Calculation and designing of built-in parts**

7.3.57 Basic designations:

- $M$ — bending moment determined relative to an axis located in the outer edge plain of built-in part plate and passing through the centre of gravity of all the anchors, kNm;
- $N$ — normal force acting on a built-in part, kN;
- $Q$ — shear force acting on a built-in part, kN;
- $F_{an}$ — total cross-sectional area of anchors of the most stressed row, cm$^2$;
- $N_{an}$ — maximum tensile force in one anchor row, kN;
- $Q_{an}$ — shear force per one anchor row, kN;
- $R_{ch}$ — yield point of the anchor armature, MPa;
- $N_{an}'$ — maximum compression force in one anchor row, kN;
- $z$ — distance between edge anchor rows, cm;
- $f_{an}$ — area of anchor rod of the most stressed row, cm$^2$;
- $l$ — length of a built-in part’s anchors, mm;
- $d$ — diameter of a built-in part’s anchors, mm;
- $s$ — thickness of a built-in part’s plate, mm;
- $R_{pl}$ — yield stress of a built-in part’s plate, MPa.

7.3.58 The cross-sectional area of anchors butt-welded to flat elements of steel built-in parts during action of bending moments, normal and shear forces, shall be determined as per Fig. 7.3.58 and by the formula

$$F_{an} \geq 13 \sqrt{N_{an}^2 + \left(\frac{Q_{an}}{1.07} / (1.05)\right)^2 / R_{ch}^2},$$

where $N_{an} = 100 M/z + N/N_{an}$,

$Q_{an} = (Q - 0.3N_{an}')/N_{an}$,

$N_{an}' = 100 M/z - N/N_{an}$,

$n_{an}$ — number of anchors along the direction of shear force. If uniform transfer of shear force $Q$ to all anchor rows is not provided, when determining the shear force $Q_{an}$ not more than 4 rows shall be considered;

- $\lambda$ — parameter:
  $$\lambda = 6 \cdot \frac{3}{\sqrt{1 + \omega}} \{1 + 0.15 f_{an} / \sqrt{R_{ch}}\} \leq 0.7;$$

- $\delta$ — coefficient:
  $$\delta = \frac{1}{\sqrt{1 + \omega}} \geq 0.15;$$

- $\omega$ — pressure coefficient:
  $$\omega = \frac{0.3N_{an}/Q_{an}}{N_{an}' > 0} \text{ (there is pressure)};$$
  $$\omega = \frac{0.6N/Q}{N_{an}' \leq 0} \text{ (there is not pressure)}.$$

Fig. 7.3.58. To determination of cross-sectional area of the anchors.
If the anchors have not straining forces, coefficient $\delta$ is taken equal to unit.

Anchors cross-sectional area of the rest rows shall be taken equal to total cross-sectional area of anchors of the most stressed row.

Force $N$ is considered positive if it is directed from the build-in detail.

In case of forces $N_{an}$ and $Q_{an}$ calculated by the formulae (7.3.58-2) and (7.3.58-3) are negative, in the formula (7.3.58-1) they are taken equal to zero. If the force $N'_{an}$ calculated by the formula (7.3.58-4) is negative, in the formula (7.3.58-3) $N$ is taken instead of $N'_{an}$.

When placing a build-in detail on the upper (when concreting) surface of an item, the parameter $\lambda$ is decreased by 20% and value $N'_{an}$ is taken equal to zero.

7.3.59 The cross-sectional area of anchors welded to a plate by overlap under acting of shear force shall be determined as per Fig. 7.3.59 and by the formula

$$F_{an} \geq 12Q/R_{th} \quad (7.3.59)$$

Fig. 7.3.59. To determination of cross-sectional area of anchors welded to plate by overlap under acting of shear force

Shear force resistance of lap-welded anchors is considered at $Q > N$, where $N$ is tension force and anchor bend angle is from 15 to 30°. The butt-welded anchors shall be installed with sizes calculated by the formula (7.3.58-1) at $\delta = 1.0$ and $Q_{an}$ equal to 0.1 from the shear force determined by the formula (7.3.58-3).

7.3.60 The anchors length shall be not less than 15 times their diameters.

If this requirement can not be met, the length of anchors may be decreased to 3 times diameters providing that any of the following elements are welded perpendicularly to the anchor ends:

- square plates of not less than 5 mm thick with a square side not less than 4 times diameters of the anchor or 30 mm whichever is greater (Fig. 7.3.60, a);
- round washers of not less than 5 mm thick having the diameter of not less than three anchor diameters or 30 mm whichever is greater (Fig. 7.3.60, b);
- two transverse rods of the same diameter as the anchor with a length equal to 5 times diameters of the rod at $d \geq 12$ mm or one such rod at $d < 12$ mm (Fig. 7.3.60, c).

7.3.61 The thickness of build-in detail plates installed in an item plain shall correspond to the following condition:
\[ s = 0.5d_{\text{pl}} \frac{R_{\text{ct}}}{R_{\text{ci}}} \geq 5. \] (7.3.61)

### 7.4 Designing and Calculation of the Hull Made of Pre-Stressed Reinforced Concrete

#### General requirements

**7.4.1** Pre-tensioned reinforced concrete may be used for manufacturing the elements of ship hull and superstructure.

**7.4.2** When pre-stressed reinforced concrete is used, assemble or assemble-and-monolith methods shall be applied. Intersectonal connections are recommended to be made with cogging. Stressed joints may be used provided they are performed with relevant force.

#### Designing of connections

**7.4.3** General cogging of a hull shall be performed by means of preliminary stress of special armature rods or bunches located in longitudinal girders or strengthened elements of the hull (deck stringer, bilge, parts of longitudinal bulkheads adjacent to the bottom and the deck). Local cogging of the hull shall be carried out by means of pre-stressing of the armature of plates and framing girders.

**7.4.4** Pre-stressing of the armature shall be carried out by means of jacking on abutment or consolidated concrete. Thermal method of section armature jacking is allowed on condition that maximum temperature does not exceed 350°C for rod armature and 300°C for wire armature.

**7.4.5** Armature subject to pre-stressing shall be fastened in concrete by means of special anchors or by other way. When placing the armature in channels the latter shall be filled with cement grout.

**7.4.6** Ends of pre-stressed elements on sections of a length equal to two lengths of anchor devices and, if the anchors are not available, over a length of 10 rod diameters but at least 200 mm, shall be strengthened by weld lathings or closed loops. Here, the rod and loop diameters shall be not less than 6 mm.

**7.4.7** Thickness of the protection layer of the armature subjected to pre-stressing shall be equal to a rod diameter but not less than 10 mm.

When such armature is placed in channels or slots, the thickness of the protection layer shall be equal to diameter of the channel or half of the slot width respectively, but at least 20 mm.

Thickness of the protection layer of the armature not subject to pre-stressing shall be designated according to the requirements of 7.2.19.

#### Strength calculations

**7.4.8** Basic designations:

- \( R_{\text{ac}} \) — tensile strength of concrete at axial compression (prism strength), MPa;
- \( R_{\text{at}} \) — tensile strength of concrete at axial tension, MPa;
- \( N \) — longitudinal force due to design load, N;
- \( N_0 \) — longitudinal force decreasing stress in the concrete caused by its cogging, N;
- \( M \) — bending moment, N-cm;
- \( \sigma_{\text{as}} \) — design stresses in the armature due to longitudinal straining force, MPa;
- \( \sigma_{\text{ab}} \) — design stresses in armature due to bending moment, MPa;
- \( F_0 \) — cross-sectional area of the whole longitudinal armature, cm²;
- \( F_s \) — cross-sectional area of tensioned armature in the element's section under consideration, cm²;
- \( h \) — total height of rectangular or T-section, cm;
- \( h_0 \) — effective height of the section equal to \( h - a \), cm;
- \( e_0 \) — distance from the centre of gravity of cross-sectional area of the armature to the line of action of the force \( N_0 \), cm;
- \( \eta, \Theta \) — coefficients determined by the directions of 7.3.55.

**7.4.9** Hull elements fabricated of pre-stressed reinforced concrete shall be checked for crack resistance; for strength of compressed zone of the concrete; for strength
against breaking forces according to the requirements of the Rules. Elements of combined structures (consisting of pre-stressed and common reinforced concrete) as well as pre-stressed elements reinforced by hot-rolled rods and not contacting with water may be checked only for strength against breaking forces and crack resistance.

7.4.10 Calculation of pre-stressed structures is performed for affection of the following loads: design loads combined with preliminary cogging of the concrete, preliminary cogging of the concrete at a stage of the structure fabrication, forces arising during transportation and mounting of assembled elements in combination with preliminary cogging of the concrete.

7.4.11 Values of forces, moments and stresses arising in pre-stressed structures due to design loads shall be determined as for elastic systems according to the methods agreed with the River Register.

7.4.12 Safety factors in calculations of crack resistance and strength against breaking forces shall be not less than those indicated in Table 7.4.12.

7.4.13 Stresses in the compressed zone of the concrete due to mutual action of preliminary cogging and design load shall not exceed 0.6$R_{ac}$ in the hull elements subject to compression or both bending and compression, and 0.7$R_{ac}$ in elements subject to bending.

7.4.14 Pre-stressed elements shall be checked for main straining stresses, and elements with a wall thickness equal to or less than $h/15$ — also for main compression stresses.

### Table 7.4.12

<table>
<thead>
<tr>
<th>Design loads</th>

Here, value of the main straining stresses shall not exceed 0.8$R_{at}$, and of the main compression stresses — 0.5$R_{ac}$.

7.4.15 Crack resistance of pre-stressed structures, strength of which may be controlled by breaking forces, shall be checked in accordance with the directions of 7.3.51 to 7.3.56. Here, stresses in the armature shall be determined by the following formulae:

- due to action of axial straining force
  \[
  \sigma_{as} = 0.01 \left( N - N_0 \right) / F_0 ;
  \]  
  (7.4.15-1)

- due to action of bending moment
  \[
  \sigma_{ab} = 0.01 \left[ \Theta M + N_0 \left( e_s - k_0 \eta \right) \right] / ( F_0 h \eta ) .
  \]  
  (7.4.15-2)

7.4.16 Together with strength checking of the structure itself, strength of concrete under anchors shall be also checked. Values of local compression stresses of the concrete under the anchors shall not exceed 0.7$R_{ac}$. 
8 DESIGN OF GRP HULLS

8.1 GENERAL REQUIREMENTS

8.1.1 The requirements of present chapter apply to ships of all classes with GRP hulls.

8.2 DESIGNING OF CONNECTIONS

8.2.1 At the construction of ship’s hulls both monolith and sectional methods may be used.

At the sectional method of construction butts shall be located apart from each other for at least a length of the lining.

8.2.2 For quality control of glass-reinforced plastic when manufacturing shell and main bearing framing girders of ships more than 15 m in length a tolerance of sheets shall be provided and a length of one of the girders of the section shall be enlarged.

Properties of the material of other details may be determined on samples of the finished batch.

For ships up to 15 m in length and the ship hulls made by the monolith method simultaneously with a hull of the first ship of a series under the same conditions the control panels shall be formed, thickness and structure of which shall precisely correspond to a thickness and structure of the hull glass-reinforced plastic.

8.2.3 Rivets, bolts and screws applied for connections of structures made of glass-reinforced plastic shall be installed perpendicularly to the glass-reinforced plastic layers.

Places of the connections may be preliminary reinforced with metal plates.

8.2.4 Connection of the elements of structures made of hot hardening plastic with each other and with other materials (glass-reinforced plastics, metals) may be performed on connecting linings or kneepieces by means of glue, rivets, screws or bolts.

8.2.5 While manufacturing multi-layered structures (plating, members) using foamed plastics, honeycomb plastics or wood the tight filling of inner chambers and glue of the fillers to outer layers over the whole surface shall be ensured.

8.2.6 For ships over 15 m in length the longitudinal framing system shall be used for the bottom and decks, and the transverse framing system shall be used for sides. The other framing systems may be used meeting the requirements to hull strength specified in 8.3.

8.2.7 In forepeaks, the transverse framing system shall be applied.

8.2.8 For hulls of ships of P and JI classes over 15 m in length and ships up to 15 m in length of all classes, as well as for superstructures, wheelhouses, light bulkheads and enclosures of all ships, frameless or framed three-layered plating is allowed.

8.2.9 In case of the longitudinal framing system, the distance between longitudinal framing girders shall be taken not more than 250 mm.

8.2.10 Framing girders participating in global bending shall be continuous throughout the hull length without interruptions on transverse framing and bulkheads.

8.2.11 In case of the transverse framing system, spacing shall be taken 500 mm for ships of all the classes. Here, closed framing member rings shall be provided.

8.2.12 The distance between keelsons, m, shall be taken for basin category:

<table>
<thead>
<tr>
<th>Category</th>
<th>Distance (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>M-СП, M-ПР, М</td>
<td>1.00</td>
</tr>
<tr>

<td>1.5</td>
</tr>
</tbody>
</table>
8.2.13 Members shall be connected with the plating (Fig. 8.2.13) by means of double-sided symmetrical connecting angle bars of the same material as the elements to be connected. Dimensions of the angle bars are designated depending on the member dimensions and shall be substantiated. In all cases a width of the angle bar flange shall be not less than 30 mm, and thickness $t$ — not less than a girder web thickness.

Fig. 8.2.13. Connection of members with shell

8.2.14 Connection of framing member elements shall be carried out by means of double-sided symmetrical connecting linings; butt gaps shall not exceed 2 mm. The linings shall be made of glass-reinforced plastic of the same structure as the girder web. Dimensions of linings are defined by dimensions of the members and shall be substantiated. A length of the lining $l_1$ shall be not less than 1.5-fold profile depth, thickness $\delta_1$ — not less than a half of girder web thickness $t$ (Fig. 8.2.14). All gaps shall be filled with fiberglass impregnated by a resin.

8.2.15 For ships up to 10 m in length the bottom plating, the side plating and the deck plating may be made of mats, evaporated fibre or their compositions. For ships over 10 m in length, glass fabric or roving cloth with various reinforcement schemes shall be used.

8.2.16 If the connection of outer plating with a deck is performed by means of double-sided connecting angle bars, their sized shall be defined by the least thickness of the plates to be connected. The base in the angle bar layers shall be directed longitudinally.

8.2.17 Connection of the outer shell plating, the deck plating or bulkheads between each other shall be carried out by means of double-sided symmetrical linings. The length of the lining shall be not less than 200 mm and thickness — not less than 0.5 of thickness of plates to be connected. Butts shall be positioned in different longitudinal positions and be located, as far as possible, in the less stressed hull sections. The base in the lining layers shall be directed transversely to the butt.

8.2.18 Thickness of the outer shell plating and the deck plating is determined by a calculation on the conditions of global and local strength; thickness values shall not be less than specified in Table 8.2.18.

8.2.19 In the area of ends of strong superstructures in ships over 15 m in length reinforcement of the outer plating and the deck plating shall be provided.

8.2.20 For bulkheads in ships up to 15 m in length as well as of light bulkheads and enclosures in ships over 15 m in length frameless constructions with box and wave corrugates may be used.

For light bulkheads and enclosures finished three-layered panels may be used with outer layers made of hot hardening plastics.
8.2.18 Minimum thicknesses of outer shell and deck plating

<table>
<thead>

<td>Three-layered</td>
<td>2 / 2</td>
</tr>
</tbody>
</table>

8.2.21 Connection of bulkheads of glass-reinforced plastics with the hull shall be carried out by means of double-sided connecting angle bars of glass-reinforced plastic. Here, a width of the angle bar flanges for watertight bulkheads shall be not less than 60 mm.

Connection of panels between each other and with adjacent structures shall be carried out by means of metal, plastic or GRP angle-bars and beads with screws and glue.

8.2.22 Dimensions and choice of the bulkhead materials shall be substantiated. Here, thickness of watertight bulkhead plating shall be not less than, mm, at ship length, m:

<table>
<thead>
<tr>
<th>thickness</th>
<th>≤15</th>
<th>&gt;15</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

8.2.23 When choosing the framing system and designating the dimensions of strong superstructure members in ships over 15 m in length, the requirements for the main hull shall be considered. Light superstructures and wheelhouses in ships over 15 m in length and superstructures in ships up to 15 m in length may be of three-layered structure as well as with corrugated framing.

Thickness of walls and decks of light superstructures and wheelhouses shall be not less than specified in Table 8.2.23.

8.2.24 Connection of superstructure walls with a hull of glass-reinforced plastic shall be carried out by means of double-sided connecting angle bars of glass-reinforced plastic. Here, the angle bar flange for strong superstructures shall be not less than 90 mm and for light superstructures and wheelhouses — 60 mm.

8.2.25 Connection of superstructure walls made of GRP or plastic with decks made of other materials may be carried out by means of bolts, rivets, glue and combinations of glue and bolts (rivets). Here, fastening shall be carried out on metal coamings.

8.2.26 Design measures shall be provided to reduce the stress concentration at ends of strong superstructures extended from side to side.

8.2.27 In the base hull members all cutouts of dimensions over 20 thicknesses (except for openings in members where active stresses do not exceed 0.3 of the permissible ones) shall be reinforced.

All rectangular cutouts shall be rounded in corners by a radius of not less than 0.2 of the opening width.

8.2.28 Openings shall be reinforced by means of increase of the plate thickness or fitting linings over the cutout perimeter. Thickness of the lining (or enlarged plate thickness) for minor cutouts (of a width equal to or less than 50-fold thickness) may be taken equal to the plate thickness; at the greater openings (over 50-fold thickness) it is determined by the calculation.

8.2.29 Strength and rigidity of foundations and supports for engines, arrangements, as well as strength of fastening the engines and the arrangements to the foundations shall ensure the normal operation of the engines and the arrangements during the voyage.

8.3 STRENGTH AND BUCKLING CALCULATIONS

8.3.1 The following stresses are taken as unsafe normal stresses $\sigma_0$ and unsafe tangent stresses $\tau_0$, MPa:

$$\sigma_0 = k R_m; \quad (8.3.1-1)$$
$$\tau_0 = k \tau_m, \quad (8.3.1-2)$$

where $k$ — strength reduction coefficient of the material;

$R_m$ — tensile strength of the material at the corresponding type of deformation (as per laboratory tests of dry samples), MPa;

$\tau_m$ — shear ultimate strength of the material in the considered direction (as per laboratory tests of dry samples), MPa.

Strength reduction coefficients of the materials shall take into consideration the following:

1. difference of physical and mechanical properties of the material manufactured in plant conditions from those of laboratory samples;
2. change of the material properties due to moistening;
3. change of the material properties due to ageing in unloaded condition;
4. change of the material properties due to heating.

For structures not subject to constant loads, for glass-reinforced plastics with glass fillers treated by hydrophobic adhesive compositions (or similar materials) the coefficient $n$ may be taken equal to:

- for open deck platings: 0.50
- for platings of covered decks, platforms and bulkhead plating: 0.75
- for the bottom and side plating: 0.60
- for the deck, platform and bulkhead framing: 0.75
- for the bottom and side framing: 0.65

For hot-hardened plastics coefficient $n$ is taken equal to 0.80.

8.3.2 For structures subject to prolonged action of constant loads when calculating unsafe stresses the strength reduction coefficient $k$ shall be reduced and may be taken equal to 0.2.

8.3.3 For normal and tangent stresses that may lead to the buckling failure of the structure, Euler's normal stresses $\sigma_E$ and tangent stresses $\tau_E$ calculated with due regard to anisotropy for the plating and shear for the framing members are taken as unsafe stresses.

When calculating Euler's stresses design moduli shall be determined by the following expressions:

$$E_p = n E; \quad (8.3.3-1)$$

where $n$ — reduction coefficient of modulus of elongation of the material;

$E$ — modulus of elongation of the material (as per laboratory tests of dry samples);

shear modulus $G_p = n G, \quad (8.3.3-2)$

where $G$ — shear modulus deformation (as per laboratory tests of dry samples).

For glass-reinforced plastics with glass fillers treated by hydrophobic adhesive compositions (or similar materials) the coefficient $n$ may be taken equal to:

- for open deck platings: 0.50
- for platings of covered decks, platforms and bulkhead plating: 0.75
- for the bottom and side plating: 0.60
- for the deck, platform and bulkhead framing: 0.75
- for the bottom and side framing: 0.65

8.3.4 Values of unsafe stresses $\sigma'_0$ in the area of butt joints with two linings for glass-reinforced plastics shall be determined by the formula

$$\sigma'_0 = p R_t, \quad (8.3.4)$$

where $p = k$ — at bending and compression deformations ($k$ — see directions of 8.3.1 and 8.3.2) and $p = 0.8$ — at strain deformation.

Values of $R_t$ for glass-reinforced plastics based on glass fabric at bending deformations (at two linings) and compression deformations are taken equal to values of tensile strength of the material at the same deformation types. At strain deformation they shall be not less than $R_{t_re}$. Designated by Fig. 8.3.4 respectively for various thickness $t$, mm, of plates to be connected and lining lengths $l$.

8.3.5 Permissible stresses are determined in fractions of unsafe stresses.

At global strength calculations the permissible normal stresses are taken equal to 0.60 of $\sigma_0$ and tangent stresses — equal to 0.60 of $\tau_0$, where $\sigma_0$ and $\tau_0$ — see 8.3.1.
8 Design of GRP Hulls

Fig. 8.3.4 Values of $R_m$ depending on thickness of connected plates and lining length

At local strength calculations the permissible stresses are taken equal to 0.75 of $\sigma_0$ and tangent stresses — equal to 0.75 of $\tau_0$.

8.3.6 Euler’s normal stresses $\sigma_E$ of rigid hull members of ships of all classes calculated according to the requirements of 8.3.3 shall meet the condition

$$\frac{\sigma_E}{\sigma_0} \geq 0.95,$$  (8.3.6)

where $\sigma_0$ — see 8.3.1.

For ships over 15 m in length Euler’s stresses of grillages shall be defined with due regard to shear and anisotropy.

For ships up to 15 m in length the shear and anisotropy may be not considered.

8.3.7 Euler’s normal stresses $\sigma_E$ of the shell plating shall meet the condition

$$\frac{\sigma_E}{\sigma} \geq 1.5,$$  (8.3.7)

where $\sigma$ — design normal stresses due to global bending or total stresses.

8.3.8 In addition to the strength checking with regard to stresses, particular members and the hull in whole shall be checked with regard to value of deformations. Here, together with sagging due to bending for ships over 15 m in length and for particular members a sagging due to shear shall be also taken into account.

Permissible sags shall not exceed, mm:

1. due to global bending of the hull — $L/400$;
2. due to local loads for the base hull members:
   for framing girders — $l/100$;
   for plating — $l/50$.

Here, $L$ and $l$ — length (span) of the hull and particular members correspondingly, mm.

Note. At control measurements of span arrows the structures shall be loaded for at least 0.5 h.

8.3.9 For glued glass-reinforced plastic angle connections, i.e. a framing with a plating, a side with a deck and a strong superstructure with the hull made according to the directions of the present chapter, tangent stresses in the connection area shall not exceed 6.86 MPa.

When plucking loads are applied, value of stresses, MPa, at abruption shall not exceed the following, for the thickness of:

- $\geq 6$ mm — 5.88
- 3 mm — 2.94

For intermediate values of thickness from 6 to 3 mm the value of unsafe normal stresses is determined by linear interpolation.

Total thickness of connecting angle bars is taken for the design thickness.

8.3.10 Determination of design bending moments and shear forces at global bending and of loads at local strength calculation shall be carried out according to the requirements of the Rules specified for steel ships.

Here, for ships up to 15 m in length an influence of ship sagging on values of bending moments shall be taken into account.

Hull sagging shall be defined both due to bending and to shear having regard to directions of 8.3.3.

8.3.11 Calculation of hull girder elements is carried out for design cases of loading conditions and cross sections of the hull mentioned in Section 2.

8.3.12 At calculation of hull girder elements the hull members shall be included in the calculation with coefficients that consider:
- changes of the material properties (see 8.3.1 and 8.3.3);
difference of moduli of elasticity of the members as well as anisotropy of glass-reinforced plastics.

8.3.13 Flexible members are included in the hull girder with reduction coefficients. Parts of the plates adjacent to a rigid contour of a width equal to 1/6 of the shorter side of a bearing contour are not subject to reducing at all approximations during the calculation of the hull girder.

8.3.14 The reduction coefficients of the flexible hull members (plates) shall be determined by the method given in 2.2.38 and 2.2.39.

Euler's normal stresses $\sigma_E$ for plates of anisotropic glass-reinforced plastics shall be determined with due regard to anisotropy of elastic properties of the material, and for plates of glass mat they shall be determined with due regard to anisotropy of materials. Here, the requirements of 8.3.3 shall be considered.

8.3.15 Buckling strength of girders in ships over 15 m in length and of grillages in all ships shall be checked with due regard to shear.

8.3.16 Width of effective flange on the basis of fabric or mat at a parallel reinforcing structure shall be taken equal to the least of the values of a distance between the framing girders or 1/10 of the girder span. Width of effective flange on the basis of mat or evaporated glass-reinforced plastic shall be taken equal to a distance between the framing girders or 1/6 of the girder span, whichever is less.

Here, possible difference of moduli of elasticity of the plating and the framing members shall be regarded.

8.3.17 At local strength calculation of glass-reinforced plastic girders the same calculation schemes shall be used as for the calculation of girders made of isotropic materials with due regard to 8.3.16. Values of the section elements shall be designated with due regard to the directions of 8.3.16; here, the girder web area shall be taken regardless of connecting angle bars.

8.3.18 Girders shall be checked for the stability of flat bending shape.

8.3.19 Buckling strength of girders shall be calculated with due regard to requirements of 8.3.15 and 8.3.16.

8.3.20 Calculation of plates of anisotropic glass-reinforced plastics shall be carried out with due regard to anisotropy.

8.3.21 Calculation of three-layered plates with a light filler of rigid foam type shall be carried out with due regard to affection of shear deformations of the filler on outer layers.

8.3.22 At strength calculation of the framing members and plating joints and other similar connections the static moment and the moment of inertia shall be calculated with due regard to the area of connecting angle bars and the web thickness shall be taken equal to double thickness of the angle bar flange.
9 EQUIPMENT OF SHIP SPACES

9.1 GENERAL REQUIREMENTS

9.1.1 Requirements of the present Section apply to arrangement and equipment of accommodation and service spaces for the crew and passengers, wheelhouse, dry cargo holds, to passageways, doors, ladders and rescue manhole-sculltes.

9.1.2 Requirements of location and equipment of machinery spaces are specified in 1.8 to 1.10 Part IV of the Rules.

9.2 PASSAGEWAYS, DOORS, LADDERS

9.2.1 A width of the passageways shall not be less than:

.1 0.8 m in main corridors of common passenger spaces, corridors of passenger accommodation and public spaces as well deck passages of passenger ships leading to muster stations;

.2 0.6 m on decks between the bulwark and the wheelhouse for ships with power below 590 kW, or less than 25 m in length, or with a gross tonnage below 300 t, and 0.7 m for ships with greater power, length or gross tonnage values;

.3 0.7 m in the crew accommodation corridors;

.4 0.6 m in corridors of spaces in ships less than 25 m in length;

.5 0.5 m in corridors of spaces on dynamically supported craft less than 25 m in length;

.6 0.5 m on decks in places of installation of bollards, stanchions, hatchways.

9.2.2 Doors of superstructures and wheelhouses leading to the open deck shall be designed to open outwards.

Doors of public spaces (saloons, mess-rooms) shall be designed to open outwards or to either side. Cabin doors shall open inwards and be fitted with beat-out panels of 0.4×0.5 m in their lower part. On the cabin doors from the inner sides of those panels there shall be inscriptions “Emergency exit — beat out in case of emergency”.

Where cabins are fitted with scuttles or windows with clear dimensions of at least 400 mm, beat-out panels need not be fitted.

9.2.3 Passenger spaces located in superstructures of second and third tiers shall be fitted with at least two ladders located at the opposite ends of the superstructures.

9.2.4 In hold passenger spaces with a number of passengers less than 20 persons one ladder per each space may be provided.

9.2.5 When a number of passengers in the hold passenger space is 20 persons and more, there shall be two ladders located at the opposite ends of the space with one of them giving access to an open deck outside the deck structures as far as practicable.

9.2.6 When a number of passengers in the hold passenger space is from 20 to 50 persons inclusive, emergency ladder may be replaced by vertical ladder.

9.2.7 In addition to exits from hold spaces specified in 9.2.4 — 9.2.6, each space shall be fitted with rescue scuttles with one scuttle at each side according to 9.3.

9.2.8 Hold crew accommodation spaces for 20 persons and more shall be provided with at least two ladders located at the opposite ends of the space and giving access to the main deck; one of them (emergency ladder) shall be led to an open deck outside the deck structures or through insulated steel enclosure in the superstructure which provides safe exit to an open part of the main deck or deck overboard extension in the event of fire. Emer-
gency ladder may be replaced by vertical ladder.

9.2.9 Where hold spaces are intended for accommodation of 10 to 20 crew members and there is an exit giving access to an open deck, additional ladder need not be fitted provided that rescue scuttles are fitted at the side opposite to the main exit, with one scuttle at each side of the ship.

9.2.10 Where hold spaces are intended for accommodation of less than 10 crew members and there is an exit giving access directly to the main deck, additional ladder or rescue scuttles need not be fitted.

9.2.11 The ladders shall be arranged to provide free access of escape. Before entering / leaving a ladder as well as places where the next ladder builds on previous one shall be provided with free areas of a lengths not less than 0.8 m — for outer ladders and 0.6 m — for inner and vertical ladders, and a width not less than ladder width. The areas shall not have transverse coamings or shoulders. Angle of ladder slope to horizontal plain shall not exceed 50° — for accommodation and service spaces, and 55° — on decks and in machinery spaces. In order to access to equipment located in rooms and compartments of a ship the ladders with slope angle of 60° may be installed, and in periodically unattended machinery spaces where the ladders are difficult to install the stairways may be used.

9.2.12 Intermediate areas stated in 9.2.11 shall be arranged if the ladder length, mm, exceeds, for:

- inclined ladder 4000
- vertical ladder 9000

9.2.13 Ladder width for a number of passengers of 50 and less in the given space shall be at least 0.8 m. Ladder width shall be increased by 5 cm per each 10 passengers in excess of 50 persons. In crew spaces the stairway width shall be at least 0.8 m and in ships up to 25 m in length — not less than 0.65 m. In ships of a length up to 25 m the ladder width may be decreased up to 0.5 m if the requirement of present paragraph is not technically feasible.

9.2.14 Ladders with more than three steps shall be equipped with handrails or guardrail.

9.2.15 On hydrofoil craft and hovercraft each passenger mess-room intended for 20 persons and more shall be fitted with at least two exits located at the opposite sides of the mess-room. One of these exits may be an emergency exit.

9.3 SCUTTLES

9.3.1 The side scuttles shall be arranged to meet the requirements of 5.6.24 to 5.6.27 Part II of the Rules.

No scuttles are allowed in spaces intended for cargo carriage.

9.3.2 In hold spaces intended for passengers and crew as well as in engine room rescue scuttles shall be provided with a clear width of 400 mm.

Note. Rescue scuttles are required only in ships where a freeboard depth is sufficient for its free arrangement.

9.3.3 In hold spaces intended for passengers and crew rescue scuttles shall be located in common cabins or in corridors with one scuttle at each side of the ship.

9.3.4 In the machinery spaces one rescue scuttle shall be provided at each side of a ship. Where a door is arranged in the bulkhead separating the machinery space and the boiler room, at least one scuttle shall be provided in each of the spaces being located at the opposite ends of the space.

9.3.5 Where an emergency exit is provided in the hold space for passengers or crew as well as in the machinery space which gives access directly to the open main deck, rescue scuttles need not be fitted.

9.3.6 Lower edges of rescue scuttles shall not be located below the lower edges of ordinary side portholes.
9.3.7 Free access shall be provided to rescue scuttles. Hand irons shall be fitted in sides to facilitate the access to scuttles.

9.3.8 Frames of rescue scuttles shall be painted red and shall bear relevant inscriptions. Location indicators of rescue scuttles shall be placed on visible places.

9.3.9 On ships of М-СП, М-ПР, О-ПР, M, O and P classes the rescue scuttles located in spaces intended for passengers below the freeboard deck shall be fitted with automatic alarm led to the wheelhouse which warns that the rescue scuttles are open.

9.4 WHEELHOUSE

9.4.1 The wheelhouse shall be so arranged and equipped that the navigator can continuously and without unnecessary actions perform its functions.

9.4.2 The wheelhouse shall be provided with free vision in all directions.

The blind area for navigator before a ship for all the operating cases regardless of optical devices that can reduce the blind area shall be equal to double length of ship (convoy) but not more than 250 m.

The vision area from ordinary workplace of the navigator shall be a sector to the direction of horizon determined by angle not less than 240°. Not less than 140° of this angle shall be accounted for a half of round before a ship.

9.4.3 The direction of ordinary vision area of the navigator (in diametrical plane) shall be free from any superstructures. Masts, stays and other structures shall not occupy more than 1.0° of vision area in usual workplace of the navigator.

9.4.4 If free vision aftward is not provided, the mirrors, vision facilities and other auxiliary optical means may be installed in order to improve the vision.

9.4.5 The free vision through wheelhouse windows at any time shall be provided by means of lighting fixtures (spotlights).

9.4.6 Transparency of glasses used in wheelhouses shall be at least 75%.

9.4.7 The requirements to controls and automated system elements arranged in the wheelhouse are specified in 11.12 Part IV and 12 Part V of the Rules.

9.5 ACCOMMODATION AND SERVICE SPACES

9.5.1 When calculating passenger capacity of ships the following area shall not be included in the area for passenger accommodation:

1. the forepeak, the deck above the forepeak and the afterpeak;
2. mess-rooms, smoking saloons and other saloons, restaurants, canteens and similar spaces;
3. deck in the area of passages for boarding passengers, passages to lifeboats and embarkation ladders, as well as the deck not accessible for passengers;
4. deck area within 1 m apart from ship’s arrangements (steering gear, boat gear, cargo handling gear, mooring, towing, coupling and anchor arrangements);
5. cargo hatches, engine hatches, hatches of accommodation and service spaces.

On board inland navigation ships where the crew performs work, but accommodates ashore, the rooms listed in subparagraph 2 of this paragraph shall be included in the area for passenger accommodation when calculating the passenger capacity.

9.5.2 Ship spaces located on deck overboard extensions shall be located at least 300 mm apart from the extension edge. No berths may be arranged along the side bulkheads of superstructures or wheelhouses located on deck extensions.

9.5.3 Accommodation spaces and galleys as well as canteens used as recreation spaces may be located in the vicinity of tanks with fuel or above them only when a horizontal cofferdam at least 600 mm high or a vertical cofferdam of width equal to the spacing is provided.
Cofferdams shall be equipped with ventilation independent of the ventilation of accommodation spaces.

No cutouts for manholes or other cutouts are allowed in decks and bulkheads in way of the above spaces.

9.5.4 The following spaces shall not be used for the crew accommodation:
.1 the forepeak and the afterpeak spaces;
.2 spaces with cargo hatches not enclosed by trunks;
.3 machinery spaces and boiler rooms;
.4 accommodation spaces, public spaces, household, service and sanitary spaces;
.5 spaces with exits giving direct access through doors or manholes to spaces containing engines, boilers, pumps, or storage spaces for oil products, coal as well as paint stores and lamp stores;

9.5.5 In ships of M-СП, M-ПР, О-ПР, M, O classes equipment and furniture (cupboards, tables, sofas, pianos, chairs) shall be fastened.

9.5.6 Above the emergency exits there shall be provided illuminated inscription “Emergency exit”.

9.6 HALLS AND SPACES FOR MULTIMEDIA PRESENTATIONS

9.6.1 Halls and spaces equipped for multimedia presentations, film exhibition, etc. on passenger ships, living quarter barges, floating exhibitions shall be fitted with exits giving access directly to an open deck with one exit per 50 spectators, but at least two exits at the opposite ends of the space. Each exit shall be fitted with a door which opens outwards; minimal width of the door and the passage shall be not less than 1.1 m.

Above the each exit there shall be provided illuminated inscriptions “Exit” or “Emergency exit”.

Furniture in the halls shall be made of low flame-spreading materials (see 1.2.1.16 Part III of the Rules) and fastened.

No carpets and carpet strips may be used in the halls.

9.6.2 Film exhibition on non-self-propelled tankers is not allowed.

9.7 SPACES FOR ELECTRIC-GAS-WELDING OPERATIONS AND STORAGE OF RECEPTACLES

9.7.1 Storage places of oxygen and acetylene receptacles shall meet the requirements of 2.5.7 to 2.5.11 Part III of the Rules, and spaces for electric-gas-welding operations on board a ship – to 2.5.12 Part III of the Rules.

9.8 GALLEY ROOMS

9.8.1 Galley rooms shall meet the requirements of 4.1.1 and 4.1.2 Part III of the Rules.

9.8.2 Bulkheads and decks of the galley rooms shall be made of steel or another equivalent material.

Structures made of non-combustible materials near the cooking ranges shall meet the requirements of 2.3.3 Part III of the Rules.

9.9 SAUNAS

9.9.1 On ships fitted with saunas the following requirements shall be met:
.1 ceiling, walls and floor shall be plated with hard wood;
.2 door handles of sauna shall be made of poorly conducting material or covered with the same;
.3 sauna door shall open outwards by pushing; no shut-off devices are permitted on the door;
.4 distance of the lower edge of sauna door to floor plating shall be not less than 0.05 m;
.5 metal fittings of sauna lining boards, railings, grids shall be countersunk;
.6 all standard equipment of the sauna (beds, shelves, bowls, bailers) shall be made of wood or low-heat-conductivity materials and shall not have open thermally insulated parts;
.7 in order to control the temperature in sauna, the non-mercury thermometer shall be mounted;
.8 lamps, thermometers and other devices mounted in sauna shall have guards prevent-
ing the possibility their mechanical damage and therefore prevent burns from unintentional contact with them;

.9 electric fireplace shall be grounded and fitted with a fence not less than 1.2 high. The fence elements shall be made of thermally nonconductive material, and distance between elements shall not exceed 0.38 m;

.10 control switchboard of electric fireplace and switch of lighting in sauna shall be located outside the sauna. The electric fireplace shall be provided with a circuit breaker when the temperature reaches the limit;

.11 lighting fixtures shall be moisture-proof, and glass — heatproof;

.12 heating elements of the electric fireplace above shall be covered with rocks.

In addition, the saunas shall meet the requirements of 2.5.13 Part III of the Rules.
10 RAILING, HANDRAILS, GANGWAYS, COMPANIONWAYS

10.1 GENERAL REQUIREMENTS

10.1.1 Along the perimeter of open decks, bridges and superstructures as well as around the open areas and workplaces located at a height over 0.5 m, the bulwark and guard rails shall be provided. Openings and doorways in decks, sides, bulkheads, bulwark shall be provided with railings preventing the possible fall or injury of people while operating a ship.

10.1.2 Fixed railings (coamings, bulkwark, rails and guard rails) with regard to type, purpose and operating conditions of a ship shall minimize a risk of man-overboard, falls into machinery space trunk, opening in deck, from floating dock tower, from bridge wings, from maintenance area, from other workplaces.

In order to protect passengers and crew against overboard risk, ships are fitted with handrails, gangways, companionways in addition to the fixed railings.

Companion hatchways and other openings in decks, bulkheads, sides shall be equipped with movable or removable railings.

10.1.3 The railings shall withstand loads arising out during operation. Connections and fittings of railings shall be so designed that they are not reduced by vibration. Structural provisions shall be taken to prevent loss of fittings (bolts, nuts, pins).

10.1.4 Height of bulkwark or guard rail along a perimeter of decks and bridges as well as around the open areas located at a height more than 0.5 m above the deck shall be not less than 1100 mm, and the railings height inside rooms and compartments shall not be less than 1000 mm. Guard rail on the upper awnings may be omitted.

For ships less than 20 m in length the height of a bulwark or a guard rail may be reduced, but shall be not less than 900 mm when relevant grounds of adequate protection of the crew and passengers are submitted to the River Register.

10.1.5 Bulwark or guard rail shall be fitted on all open decks of the hull, superstructures and wheelhouses. On self-propelled ships up to 10 m in length handrail may be fitted along the perimeter of a superstructure or a deck.

10.1.6 On passenger ships of all classes railings on decks accessible for passengers shall be made as solid bulwark or guard rail with protective mesh screen.

10.1.7 In areas where bollards and fairleads are installed, the guard rail or bulkwark shall not have parts that require change of their position when operating with mooring lines.

10.1.8 In places where gangways are handled, the doors or removable, telescopic, hinged and similar types of railings shall be provided.

10.1.9 Removable railings shall have special safety hooks, design of which provides quick installation and ease removal of railings and prevents spontaneous release under the weight of falling person.

10.1.10 Decks of ferries and other ships intended for transportation of wheeled vehicles shall be fenced by fender beams with a height of at least 0.45 m.

10.2 BULWARK

10.2.1 Drainage cutouts shall be provided at each continuous section of the bulwark with the total area of not less than 10% of the area of continuous part of the bulwark.

10.2.2 Exit cutouts in the bulwark shall have folding doors which open inwards, or a removable railing.
10.2.3 A bulwark rail shall be fitted on the top of the bulwark.

10.3 GUARD RAIL

10.3.1 The distance between guard rail stanchions shall not exceed three spacings.

10.3.2 The guard rail of 1100 mm high shall be four-row, of 1000 mm high — three-row. The lower rail shall be located not higher than 230 mm above the deck. The distance between other rails shall not exceed 380 mm. The guard rail of decks accessible for passengers shall be fitted with protective screens. Side of screen cell shall not exceed 100 mm.

10.3.3 On non-self-propelled ships of all classes a handrail shall be provided in way of superstructures and wheelhouses, and on non-attended ships — in way of forecastle and poop.

On non-self-propelled ships of O, P and Â classes including non-attended ships the guard rail in the area of cargo hold and cargo bunker may be replaced by waist bar and handrail along the perimeter of cargo hatch coaming or the cargo bunker wall.

On flush deck barges without cargo bunker in the area of cargo platform a waist bar is to be installed.

On flush deck barges being unloaded by inclination or capsizing method a guard rail may be dispensed with provided that through passage is provided under the deck.

10.3.4 The upper edge of the waist bar shall be raised above the deck for at least 100 mm. The waist bar shall not impede water drainage from the deck.

10.3.5 In places of interruption of the bulwark and the guard rail (the deck machinery area, stairway flights etc.) removable chain rails shall be provided.

10.3.6 Clearances (gaps) between guard rails as well as between railings and other structures of a ship shall not exceed 150 mm.

10.3.7 Design of removable rigid or flexible guard rails shall provide their quick removal. In case of flexible guard rails (chain, rope) the possibility to tight rails shall be provided.

10.3.8 In people passages, the chain railings may be used only. Length of such railing (distance between stays) shall not exceed one meter. The maximum sagging of chain guard rail shall not exceed 40 mm.

10.4 HANDRAILS, GANGWAYS, COMPANIONWAYS

10.4.1 Ladders shall be fitted with railings and handrails of a height not less than required by the Rules.

10.4.2 Where a passage is provided along the deck extension, handrails shall be fitted on outer walls of the superstructures.

10.4.3 On oil tankers of M-СП, M-ПР, O-ПР, M and O classes between separate accommodation spaces and service spaces as well as in order to provide the crew with safe access to the afore part of the ship in any operating conditions gangways shall be provided raised above the deck. The gangways shall:

1. be at least 1 m wide and be located in way of the centre line;
2. be fitted with handrails at least 1.1 m high with stanchions not more than three spacings apart;
3. have side entries from the deck not more than 40 m apart from each other.

Be arranged by shelters of practicable design not more than 45 m apart from each other, when the open deck is extended for more than 70 m.

Each shelter shall be sufficient for at least one person and shall protect him against bad weather.

10.4.4 Pushboats and pushed vessels shall be fitted with gangways and stairways which provide safe passage of the crew from one ship to the other.
10.5 PASSENGER SPACES ON HIGH SPEED CRAFT

10.5.1 The high speed craft shall be fitted with seat for passengers in quantity corresponding to a ship passenger capacity.

10.5.2 Seats for passengers shall be fastened. Strength of seats fastening shall comply with the requirements of Appendix 10 "Criteria of test and assessment of seats for passengers and crew" of the International Code of Safety for High-Speed Craft (HSC Code).

10.5.3 Seats and their fastenings shall be designed to minimize the risk of injury of sitting passengers and to provide free exit of passengers, if required.
   Unless otherwise provided, the seats shall be fitted with life-saving appliances.

10.5.4 The seats shall be so installed that provide free exit and not to obstruct access to emergency equipment, life-saving appliances and escape routes.

10.5.5 Passenger seats shall be fitted with safety belts of design approved by the River Register.
STRENGTH CALCULATION METHOD OF JOINING STRUCTURES OF CATAMARAN HULL BODIES

1 In strength calculations of the bridge deck structure three basic deformations shall be considered: transverse bending, transverse twisting and unsymmetrical deformation caused by a vertical bend of hull bodies in the opposite directions.

The strength of the bridge deck members shall be checked at three wave-related positions of ship:

1. beam to sea (relative bearing \( \varphi = 90^\circ \)), when the transverse bending moment is maximal; the moment shall be calculated by formulae (A1.6-2) and (A1.7-1), and internal forces and stresses shall be calculated as per requirements of 16 of this Appendix;

2. quartering sea, when the transverse twisting occurs simultaneously with the transverse bending. To define maximum total stresses in the bridge deck member calculations shall be made for several values of \( \varphi \) nearly similar to the value of \( \varphi_1 \) determined by the formula (A1.8-10). The external forces shall be determined according to requirements of 8 and the internal forces — according to requirements of 17 and 19 of this Appendix;

3. quartering sea, when the hulls are bent in the opposite directions. To define maximum total stresses due to the deformation caused by the wave-induced bending of the hull bodies and due to the transverse bending in calm water, calculations shall be made for several values of \( \varphi \) nearly similar to the value of \( \varphi_2 \) defined by the formula (A1.9-7). The loads shall be determined according to requirements of 9 and the internal forces — according to requirements of 21 of this Appendix.

2 If the hull bodies have been joined with the help of a strength superstructure or a wheelhouse, it is sufficient to check the bridge deck strength at the transverse bending according to requirements of 10 of this Appendix.

3 The bridge deck strength shall be checked by calculations for the fully loaded condition and an emergency condition according to 2.2.7. For cargo ships the maximal non-uniformity of the cargo distribution over the ship’s breadth shall be considered as permitted by the Instruction on Loading and Unloading.

4 In calm water conditions the transverse bending moments shall be calculated in the same manner as the longitudinal moments: by integrating the loads considering not less than 21 ordinates. Two design values of the transverse bending moment in calm water shall be calculated by direct summing the moments of the weight forces and the supporting forces:

\[ M_1 \] in a plane section crossing an inner side amidships parallel to the centre line;

\[ M_2 \] in the centre line section.

If lines of submerged parts of the hull bodies are symmetric in relation to the centre plane of both hull bodies, and the weight load is symmetric in relation to the centre line of the catamaran body as a whole, then \( M_1 \) and \( M_2 \), kN·m, may be calculated by formulae
\[ M_1 = -0.5P_bB_h - P_hy_h; \quad (A1.4-1) \]
\[ M_2 = -B_c \left[ 0.5(B_h + c) - y_b \right] - P_hy_h, \quad (A1.4-2) \]

where \( P_b \) — weight of half of the bridge with cargo and other kinds of load (between a secant plane crossing the inner side amidships parallel to the centre plane and the centre plane of the whole ship), kN;

\( P_h \) — weight of one hull body and adjoining part of the bridge in the extremities together with the cargo, equipment, systems and other kinds of load up to the section crossing the inner side amidships parallel to the centre plane, kN;

\( y_h \) — distance between the centre of gravity of the weight \( P_h \) and the centre plane of the hull body; this distance is positive, when the centre of gravity is closer to the inner sides, m;

\( y_b \) — distance between the centre of gravity of the weight \( P_h \) and the centre plane of the whole ship, m.

5 Additional forces applied to the bridge deck at rough water may be calculated by the formulae given below. Design wave length included in these formulae shall be taken equal to: 40 m for ships of Ì-ÑÏ, Ì-ÏÐ and Ì classes, 20 m for ships of Î-ÏÐ and Î classes, 12 m for ships of P class and 6 m for ships of Ë class.

When the inequality is complied with
\[ \lambda \leq 2(c + B_h) \quad (A1.6-1) \]
the maximal additional transverse bending moment, kN\(\cdot\)m, occurring when a ship is abeam the waves, may be calculated by the formula:
\[ M'_3 = \pm 30.8hLBR_t m_1 \sin \left[ \frac{\pi(B_h + c)}{\lambda} \right] \times \left[ T(H_1 - T/2) m_b - B_c^2 m_2/12 \right]/\lambda, \quad (A1.6-2) \]

where \( T \) — draught amidships, m;

\( H_1 \) — distance from the neutral axis of a transverse member of the bridge to the base plane amidships (distance of the neutral axis of an hull girder of a superstructure or wheelhouse from the base plane, when the hull bodies are joined by strength superstructure or a wheelhouse), m;

\( m_1, m_b \) — coefficients taken from Table A1.6 depending on the actual waterline coefficient of one hull body \( \alpha \) and \( b_0 \) equal to \( b_0 = 0.5B_c/(B_h + c) \). (A1.6-3)

| Table A1.6 |
|---|---|---|---|---|
| \( \alpha \) | Coefficient \( m_1 \) at \( b_0 \) equal to | Coefficient \( m_b \) at \( b_0 \) equal to |
| 0.5 | 0.307 | 0.252 | 0.500 | 0.469 | 0.385 |
| 0.6 | 0.384 | 0.366 | 0.315 | 0.600 | 0.561 | 0.457 |
| 0.7 | 0.512 | 0.485 | 0.413 | 0.700 | 0.649 | 0.511 |
| 0.8 | 0.673 | 0.636 | 0.532 | 0.800 | 0.732 | 0.553 |
| 0.9 | 0.833 | 0.784 | 0.651 | 0.900 | 0.816 | 0.595 |
| 1.0 | 1.000 | 0.940 | 0.774 | 1.000 | 0.900 | 0.637 |

Simultaneously with moment \( M'_3 \), the bridge deck is subject to of either tension (positive) or compression (negative) force, kN,
\[ T'_{js} = \pm 30.8hLBR_t m_6 / \lambda. \quad (A1.6-4) \]

In formulae (A1.6-2) and (A1.6-4) either upper or lower signs shall be taken. The positive transverse bending moment causes tension of the top fibres of the bridge.

7 In case the inequality (A1.6-1) is not complied with, the maximal transverse bending moment which occurs when a ship is abeam the waves, kN\(\cdot\)m,
\[ M''_3 = \pm 30.8hLBR_t m_1 \sin \left[ \frac{\pi(B_h + c)}{\lambda} \right] \times \left[ T(H_1 - T/2) m_b - B_c^2 m_2/12 \right]/\lambda, \quad (A1.7-1) \]

where \( m_1, m_b \) shall be taken from Table A1.6 depending on the actual waterline coefficient of one hull body \( \alpha \) and \( b_0 \), which shall be assumed equal to
\[ b_0 = B_h / \lambda. \quad (A1.7-2) \]

Compression or tension force applied to the bridge, kN,
\[ T_{js}^* = \pm 30.8hLBR_t m_6 \sin \left[ \frac{\pi(B_h + c)}{\lambda} \right]/\lambda. \quad (A1.7-3) \]

8 In ship’s position at which the centre plane of a ship constitutes an angle \( \varphi \) relating to the wave propagation direction, the following forces are applied to the bridge:
additional transverse bending moment, kN-m,

\[ M_4 = \pm 30.8hL_B \sin \varphi \sin \varphi \times \left[ T \left( H_1 - 0.5T \right) m'_4 - B_5^m_4 \right] \lambda, \]

(A1.8-1)

torsion moment, kN-m,

\[ M_5 = \pm 1.23h_B L^2 h'_5 \sin \varphi, \]

(A1.8-2)

brings to the transverse axis pivot turn of the hull body relatively to the other one, and the compression or tension force, kN,

\[ T_{j\theta} = \pm (3.8hL_B T m'_4 \sin \varphi \sin \varphi) \lambda. \]

(A1.8-3)

Here:

\[ \varphi = \pi (B_h + \epsilon)(\sin \varphi)/\lambda; \]  

(A1.8-4)

\[ h_0 = B_6 \sin \varphi)/\lambda; \]

(A1.8-5)

\[ m'_2 = \left[ 1 - (0.57 + 0.33\alpha_1) h_0^2 \right] m_2; \]

(A1.8-6)

\[ m'_3 = \left[ 1 - 1.4 (\alpha_1 h_0)^2 \right] m_3; \]

(A1.8-7)

\[ m'_4 = m_4 - \left( 1.5 - 0.1\alpha_1^2 \right) h^2_0 m_2. \]

(A1.8-8)

Coefficient \( m_1 \) shall be taken from Table A1.8-1, coefficient \( m_2 \) from Table A1.8-2, coefficient \( m_3 \) from Table A1.8-3 depending on the actual waterline coefficient of one hull body \( \alpha_i \) and

\[ l_0 = L(\cos \varphi)/\lambda. \]

(A1.8-9)

</table>

Moment \( M_5 \) reaches the maximal value at an angle close to

\[ \varphi_1 = \arccos \left( 0.75\lambda/L \right) \]

(A1.8-10)

Vertical forces constraining either of the hull bodies in position at which the centre plane of the ship constitutes an angle \( \varphi \) in relation to the wave propagation direction are assumed to be distributed throughout the hull body full length under the law, kNm,
\[ q = \pm 9.81 B_0 h \left( b_1 \cos \left( \pi x/L \right) + b_2 \cos \left( 3\pi x/L \right) \right) \]

(A1.9-1)

when the point of origin is located amidships and axis \( x \) is directed forward.

The load applied to one hull body is assumed as of positive value while the other one is of negative value.

Coefficients \( b_1 \) and \( b_2 \)

\[ b_1 = 1.85 \left[ (1.212 - i_2 / \alpha_1 ) p - 4 m \sin \nu \right] \]

(A1.9-2)

\[ b_2 = 5.55 \left[ (0.363 - i_2 / \alpha_1 ) p - 4 m \sin \nu \right] \]

(A1.9-3)

where

\[ p = \left( i_1 m'_1 \sin \nu - \alpha_1 m'_1 \cos \nu \right) / \left( 6 \left[ 1 + c / (2 B_0) \right] \right)^2 \alpha_1 + 2 i_1 \]

(A1.9-4)

\[ m = -m'_2 \sin \nu / 8 + i_2 p / (4 \alpha_1 ) \]

(A1.9-5)

where

\[ m'_2 = m_5 \left( 1 - \left[ 1.45 - 2 \alpha_1 (1 - \alpha_1 ) \right] b_0^2 \right) \]

(A1.9-6)

Values of \( \nu \) shall be determined by the formula (A1.8-4), \( b_0 \) by the formula (A1.8-5), coefficients \( m_3 \) and \( m_4 \) by the formulae (A1.8-6) and (A1.8-8), coefficients \( i_1 \) and \( i_2 \) by Table A1.9-1 depending on the actual waterline coefficient of one hull body \( \alpha_1 \), coefficient \( m_5 \) by Table A1.9-2 depending on the actual waterline coefficient of one hull body \( \alpha_1 \) and \( b_0 \) calculated by the formula (A1.8-9).

Maximal loads take place at an angle \( \varphi \) close to the angle

\[ \varphi_2 = \arccos \left( \lambda / L \right) \]

(A1.9-7)

When the hull bodies are joined by a strength superstructure or a wheelhouse (see 4.1.5.1) the strength of the joint shall be checked at the transverse bending moment. Calculation shall be made in the same way as the calculation by the longitudinal bending moment. Stresses in two longitudinal sections shall be defined:

in a plane section crossing an inner side amidships parallel to the centre plane where the moment \( M_1 + M_2 \) is applied;

\[

</tr>
</tbody>
</table>

The following symbols are adopted in Table A1.11:

\( a \) — distance from the bulkhead end to the inner side (length of a bulkhead portion within the limits of either hull body), m;

\( l_b \) — length of a transverse bulkhead of the superstructure equal to its wall length, m.

The width of an effective flange shall not be more than the distance up to the next strength transverse bulkhead. For butt end bulkheads of the superstructure the width of an effective flange shall be assumed twice lesser than in the case when the flange is located to one side from the bulkhead.

12 Where the hull bodies are joined by a bridge, when determining stresses in the bridge members the catamaran shall be assumed as statically indeterminate system consisting of two longitudinal girders (hull bodies) connected with transverse girders and plates (the bridge deck and plating).

Hull bodies are subject to bending deformation in vertical and horizontal planes as well as twisting deformation; bridge transverse girders are subject to bending deformation (for shorter girders with a length less than 10 heights the shifting deformation shall be considered also); plates are in the flat stressed condition.

When meeting the requirements of 4.1.6, the conclusion on the bridge strength may be made on the basis of the rapid calculation method (see below) in which twisting of the hull bodies and connection between longitudinal deformations of the hull bodies via the bridge deck and plating are dispensed with.

13 For each transverse bridge girder the turn stiffness shall be calculated, which is assumed equal to the bending moment \( M_i \), kN·m, applied to that girder at symmetrical turning of the hull bodies at a unit angle. When the \( i \)th girder is located in the bulkhead of half-bulkhead plane of the hull, then

\[
M_i^* = 2EI_i/l_i^*,
\]

where \( E \), \( I \) — area moment of inertia and the length of the \( i \)th girder of the bridge, respectively.

For other girders the moment \( M_i^* \) shall be determined by the calculation of unloaded frames with the given shift of the junctions (with the given angles of turn of the straight bars joining the member ends).

14 Stresses in the bridge members due to local loading shall be determined.

The bar system consisting of the frame members of the bridge and the hull bodies shall be calculated, assuming that the hull bodies are fixed (do not turn in relation to one another). The transverse girders of the bridge in the plane of transverse bulkheads or half-bulkheads of a hull body are assumed to be rigidly fastened at the ends; the rest girders are shall be considered as a part of the framework with fixed junctions formed by the frames of the hulls and the transverse girder of the bridge. Local loading applied to transverse members of the bridge and the hull bodies shall be calculated for the given ship loading condition. For each \( i \)th girder, the bending
moments \( M'_i \) acting in the plane crossing the inner side amidships parallel to the centre plane shall be obtained as a result of calculation.

When determining stresses due to local bending loads, \( i \)-th transverse member of the bridge shall be assumed as a freely resting girder bearing the local load with two equal opposite moments applied to the ends, kNm:

\[
M_{ij} = M'_i - M'_i \sum M'_j / \sum M'_i.
\]  
(A1.14)

Values of \( \sum M'_i \) and \( \sum M'_i \) are determined by summing for all transverse girders.

15 Moments applied to the ends of \( i \)-transverse member at global transverse bending in calm water are, kNm:

\[
M_{i2} = M'_i M_1 / \sum M'_i.
\]  
(A1.15)

16 Additional waving moments applied to the ends of the bridge transverse members, when the ship is beam to the sea, are, kNm:

\[
M_{i3} = M'_i M_3 / \sum M'_i,
\]  
(A1.16-1)

where \( M_i \) shall be determined by the formula (A1.6-2) or (A1.7-1).

The force \( T_{ih} \) determined by the formula (1.6-4) or (A1.7-3) induces tension or compression stresses, MPa,

\[
\sigma_{WI} = T_{ih} \cdot 10^{-3} / \sum F_i,
\]  
(A1.16-2)

where \( F_i \) — cross-sectional area of \( i \)-th transverse member, m².

17 Additional transverse bending moment \( M_4 \) calculated by the formula (A1.8-1) that occurs in case of quartering sea and induces the following moments at the ends of \( i \)-th transverse member of the bridge, kNm:

\[
M_{i4} = M'_i M_4 / \sum M'_i,
\]  
(A1.17)

and the force \( T_{i4} \) calculated by the formula (A1.8-3), induces the stress \( \sigma_i \) determined by the formula (A1.16-2).

18 For each transverse member of the bridge its linear vertical shifting stiffness shall be calculated, i.e. the shearing force resulted from the movement of one hull body one unit upwards, and another — one unit downwards. This force is numerically equal to reaction \( R_i \) (Fig. A1.18). When \( i \)-th member is located in the hull half-bulkhead plane, then

\[
R_i = 24 E I_j / \left( f_j^3 + 31.2 I_j / f_j \right),
\]  
(A1.18)

where \( f_j \) — area of \( i \)-th member's web.

19 At the calculation of the bridge considering transverse torsion by moment \( M_5 \) the hull stiffness at bending and torsion shall be assumed as infinite large.

Shearing force, kN, acting in the transverse member, being located at the distance \( x_i \) from amidships (the axis \( x \) is directed forwards),

\[
N_{i5} = \left( c_1 + c_2 x_i / L \right) R_{i1},
\]  
(A1.19-1)

and bending moments at the ends, kN-m,

\[
M_{i5} = \pm 0.5 f / \left( c_1 + c_2 x_i / L \right) R_{i1},
\]  
(A1.19-2)

where \( c_1 \) and \( c_2 \) shall be found from the equations set:

\[
\begin{align*}
\sum R_1 & + \sum \left( R_1 x_i / L \right) = 0 \\
\sum \left( R_1 x_i / L \right) & + \sum \left[ R_1 \left( x_i / L \right)^2 \right] = M_5 / L.
\end{align*}
\]  
(A1.19-3)

20 When defining stresses in transverse members of the bridge due to bending of the hull bodies in the opposite directions, it may be assumed that the hull bodies are connected only by transverse girders which form the elastic base frame for the hull bodies. The influence of the bridge flooring and plating on this deformation shall be considered by introducing to the section of one of the hull bodies
the bridge longitudinal members located on one side from the centre plane of the ship. The loads applied to the hull bodies shall be determined by the formula (A1.9-1), and the forces in the bridge members — according to requirements of 21 of this Appendix; the angle \( \varphi \) shall be selected so that the stresses are maximal.

21 At bending of the hull bodies in the opposite directions in \( i \)th transverse member of the bridge the shearing force shall be determined by the formula, kN,

\[
N_{\varphi i} = R_1 (a_0 f_{0i} + a_1 f_{1i} + a_2 f_{2i} + a_3 f_{3i} + a_4 f_{4i}) h B_1 L
\]

(A1.21-1)

and bending moments at the ends, kN⋅m,

\[
M_{\varphi i} = \pm 0.5 N_{\varphi i} l_i
\]

(A1.21-2)

where \( R_1 \) — stiffness of \( i \)th member determined according to 18;

\[
\begin{align*}
 f_{0i} &= 1; \\
 f_{1i} &= x_i / L; \\
 f_{2i} &= \cos \left( \pi x_i / L \right); \\
 f_{3i} &= \sin \left( 2\pi x_i / L \right); \\
 f_{4i} &= \cos \left( 3\pi x_i / L \right).
\end{align*}
\]

(A1.21-3)

Here \( x_i \) — distance between the \( i \)th member and the midship (the axis \( x \) is directed forwards).

Coefficients \( a_0 \) to \( a_4 \) shall be determined from the equations set (A1.21-4), where \( I_b \) — area moment of inertia of one hull body and a half of the bridge (see par. 20) amidships, m\(^4\); \( p \), \( b_1 \), \( b_2 \) — the loading parameters determined by formulae (A1.9-2), (A1.9-3) and (A1.9-4) accordingly.

\[
\begin{align*}
\sum_{j=0}^{4} \left[ a_j \sum \left( R_{1j} f_{0j} f_{\varphi i} \right) \right] &= p \\
\sum_{j=0}^{4} \left[ a_j \sum \left( R_{1j} f_{1j} f_{\varphi i} \right) \right] &= 0 \\
\sum_{j=0}^{4} \left[ a_j \sum \left( R_{1j} f_{2j} f_{\varphi i} \right) \right] + (43.8a_2 + 49.6a_4) \times EI_b / L^3 &= 0.5b_1, \\
\sum_{j=0}^{4} \left[ a_j \sum \left( R_{1j} f_{3j} f_{\varphi i} \right) \right] + 370 a_3 EI_b / L^3 &= 0 \\
\sum_{j=0}^{4} \left[ a_j \sum \left( R_{1j} f_{4j} f_{\varphi i} \right) \right] + (49.6a_2 + 2942a_4) \times EI_b / L^3 &= 0.5b_2
\end{align*}
\]

(A1.21-4)

The summing shall be made for all bridge girders.

22 The width of an effective flange for the bridge transverse girders shall be assigned according to requirements of 2 and 3.

23 Superstructures (wheelhouses) of more than 0.15\( L \) long (see 4.1.5.2) when calculating the bridge strength shall be changed by transverse girders located in plain of transverse bulkheads of these superstructures (wheelhouses) structurally connected with hulls. Geometrical parameters of the girders shall be defined according to the requirements of 9.
Part II

STABILITY. FLOODABILITY. FREEBOARD. MANEUURABILITY
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 This Part of the Rules covers the following inland and river-sea navigation ships and their operating conditions:

.1 all the ships navigating in displacement mode;
.2 hydrofoil craft in operation and transient modes;
.3 hovercraft in operation mode.

1.1.2 The requirements of this Part of the Rules apply also to skimmers, sailing ships, captured air bubble craft, WIG craft and floating docks.

1.1.3 The requirements related to the river-sea navigation ships apply to the ships engaged on coastal voyages. For the ships engaged on international voyages and for the ships of Ì-ÑÍ 4.5 class irrespective of the type of their voyages (coastal or international voyages), the requirements of the International Convention for the Safety of Life at Sea 1974 as amended, International Code on Intact Stability for all types of ships 2008, and International Convention on Load Lines (ICLL 66/88) are mandatory as applicable to this Part of the Rules.

1.1.4 The requirements of the present part of the Rules apply to the designed ships and ships under construction if otherwise is stated in the corresponding clauses and chapters of the present part of the Rules.

1.2 TERMS AND DEFINITIONS

1.2.1 For the terms and definitions related to the Rules common terminology, see 2.1 and 2.2 Part 0 of the Rules. For the purpose of this Part of the Rules, the following definitions have been adopted:

.1 Damage waterline means waterline of a damaged ship with one or more compartments flooded;
.2 Roll amplitude means an assumed rated roll amplitude at irregular waves, whose intensity is set by the wave height in water basins of a given category;
.3 Weathertightness means a characteristic of the hull structural components and/or equipment that prevents water ingress inside the ship when watering by dissipated water jet perpendicular to the tested surface;
.4 Watertightness means a characteristic of the hull structural components and equipment that prevents water ingress inside the ship when affected by a water jet from an applicator with an outlet diameter of not less than 16 mm with water head of 10 m. The water jet shall be directed to the closing connection. A distance from the nozzle to the tested section shall not exceed 1.5 m, and applicator travel speed along the tested connection shall not exceed 0.2 m/s;
.5 Wave height means a rated height of wind waves with a probability of overtopping accepted for water basins of a given category;
.6 Freeboard means the distance between the upper edge of the deck line and the upper edge of the maximum draught line measured vertically on the side amidships;

1 It is defined according to Appendix 2 of Technical Regulations on Safety of Inland Marine Transport Facilities approved by Decree of the Government of the Russian Federation No. 623 dated 12.08.2010 depending on the basin category.
7. Wind pressure means an assumed rated wind pressure, either static or dynamic;

8. Ship length \( L \) means the distance between the perpendiculars laid from the outmost points of the hull at the level of the uppermost load waterline;

9. Closed ship means a ship with closures of the cargo and other hatches located on the open parts of the freeboard deck; the watertightness of those closures complies with the requirements of these Rules;

10. Closed openings means openings in the main deck or hull sides, as well as in the decks, sides and bulkheads of superstructures and wheelhouses, with strong watertight closures complying with the requirements in 5.6.

For the purposes of stability assessment by the main stability criterion (see 2.1), strong watertight opening type scuttles, hatches and doors shall be considered as closed openings.

When assigning a freeboard and assessing the floodability, the following openings shall be considered as closed:

- all hatches, trunks, access holes, doors, manholes and other openings fitted with strong watertight covers
- dead side and deck scuttles
- opening type scuttles with permanently attached storm shutters

11. Grain means seeds of cereal crops (wheat, rye, barley, oats, corn, rice, sorghum, etc.), leguminous plants (pea, bean, soybean, vetch, chick-pea, lentil, etc.) and processed forms thereof;

12. Volume permeability coefficient of a space \( k_v \) means the ratio of the volume within that space, which is assumed to be occupied by water in case of full flooding of the compartment, to the total theoretical volume of the space;

13. Surface permeability coefficient \( k_s \) shall be calculated by the following formula:

\[
k_s = \frac{S_s}{S}
\]

where \( S_s \) — the waterline area of the flooded compartment except for the areas of the cargo, machinery and equipment crossed by that waterline;

\( S \) — the waterline area of the flooded compartment;

14. Maximum draught line means the band whose upper edge defines the deepest draught of a ship when navigating in a basin of the relevant category;

15. Heeling moments mean the design values of static and dynamic heeling moments;

16. Maximum permissible moments mean design values of maximum permissible moments with due regard to the required parameters of the ship's stability at static or dynamic inclinations;

17. Draught \( T \) means a vertical distance from the baseline to a given load waterline;

18. Main stability criterion means the ratio between heeling moment due to gust wind pressure on a ship and the maximum permissible moment corresponding to the angle of capsizing or the angle of downflooding and is determined with or without due regard to rolling (depending on ship class);

19. Open ship means a ship without closures of the cargo or other hatches located on the open parts of the freeboard deck, or with closures on such hatches whose watertightness does not comply with the requirements of these Rules;

20. Free-flooding openings (for assessing stability) mean openings in the main deck or sides, as well in decks, sides and bulkheads of superstructures and wheelhouses not fitted with strong weathertight closures.

For the purposes of stability assessment by additional requirements (see 3 of this Part), opening type scuttles, hatches and doors shall be considered as free-flooding openings.

For the purposes of floodability assessment, openings in bulkheads, decks and sides through which water may penetrate and spread inside the hull, except those specified in 1.2.1.10, shall be considered as free-flooding openings;

21. Compartment means a part of inner volume of the hull limited by the bottom or inner bottom, sides or longitudinal bulkheads, freeboard deck (if available) or the
upper edge of the side (when there is no deck), and two adjacent transverse watertight bulkheads or a peak bulkhead and an extremity;

.22 **Freeboard deck** means the deck, from which the freeboard is measured. As a rule, it is a bulkhead deck, which limits the watertight bulkheads from above.

On ships with a designed trim or with stepped freeboard deck, the freeboard deck is the lowest part of the open deck or its extension parallel to the upper part of the deck in the area of the step;

.23 **Bulkhead deck** means the uppermost deck, up to which the transverse watertight bulkheads extend;

.24 **Deck line** means a horizontal strip at the mid-length of the ship marked on the side in such a manner that its upper edge coincides with the lowest point of the intersection line of the freeboard deck plating's upper surface with the outer surface of the side plating. Where marking the deck as specified above is not possible or practicable, it may be applied from another fixed point on the side of the ship with respective correction of the freeboard height;

.25 **Passenger spaces** mean spaces intended for accommodation and servicing of passengers, except for the luggage spaces, storerooms, provision stores and post rooms. Spaces located below the margin line and intended for accommodation and servicing of the crew shall be considered as passenger spaces;

.26 **Windage area** means the projected lateral area of the above-water portion of the ship on the centre line plane, when the ship is in the upright position with average draught to actual waterline;

.27 **Maximum length of flooding at the given point** means – for a ship with continuous bulkhead deck – the maximum length of an assumed compartment with the abscissa of its volume centre in the given point of the number axis along the ship’s length, after flooding of which with permeability coefficients indicated in 4.3.11, at the draught corresponding to the relevant subdivision load waterline and in the absence of initial trim, the emergency waterline is tangent to the margin line;

.28 **Margin line** means the intersection line of the freeboard deck plating's outer surface with the side plating's outer surface. For the ships with a rounded deck, it is the intersection line of the deck plating outer surface extension with the side plating outer surface extension;

.29 **Maximum angle of heel** means an angle of heel, which shall not be exceeded according to the present Rules;

.30 **Righting of a ship** means the process of eliminating or reducing heel or trim;

.31 **Angle of downflooding θ_{down}** means the minimum angle of heel, at which downflooding of inner spaces of a ship starts through the free-flooding openings;

.32 **Angle of capsizing θ_{caps}** means an angle of heel, at which a ship is capsized due to dynamically applied heeling moment;

.33 **Windage center** means the center of gravity of the windage area;

.34 **Ship breadth B** means the maximum breadth between the outer edges of the frames at the level of the assigned freeboard.

### 1.3 GENERAL REQUIREMENTS

1.3.1 Stability of ships depending on their type and class shall be assessed for all the loading conditions specified in 1.3.2 to 1.3.7. Where there are no requirements to a particular type or class of ships, stability shall be checked for the following loading conditions:

.1 ship at draught corresponding to the assigned freeboard;

.2 ship without cargo, with ballast and with 10% of stores and fuel.

1.3.2 Stability of passenger and other ships carrying people shall be assessed for the following loading conditions:

.1 ship in the fully loaded condition, with full stores and fuel, and the full number of cabin and deck passengers with their luggage;

.2 ship in the fully loaded condition, with 10% of stores and fuel, and the full number of cabin and deck passengers with their luggage;

.3 ship without cargo, but with 10% of stores and fuel, and the full number of cabin and deck passengers with their luggage;
.4 ship without cargo and passengers, but with 10% of stores and fuel;  
.5 ship without cargo, with full stores and fuel and with full number of cabin and deck passengers with their luggage (only for the ships of M-ClII class);  
.6 ship without cargo and passengers, with full stores and fuel (only for the ships of M-ClII class).

1.3.3 Stability of the dry cargo ships shall be checked for the following loading conditions:  
.1 ship with draught corresponding to the assigned freeboard, with fully homogeneous cargo equally distributed between the holds, with full stores;  
.2 ship with fully homogeneous cargo and 10% of stores;  
.3 ship without cargo, with ballast and full stores;  
.4 ship without cargo, with ballast and 10% of stores.

1.3.4 Stability of tankers shall be checked in the following loading conditions:  
.1 ship with draught corresponding to the assigned freeboard with full cargo and full stores;  
.2 ship with full cargo and 10% of stores;  
.3 ship without cargo, with ballast and full stores;  
.4 ship without cargo, with ballast and 10% of stores.

1.3.5 Stability of container ships shall be checked in the following loading conditions:  
.1 ship with maximum number of containers with the mass of each container with cargo being equal to the same part of the maximum gross weight for each type of containers with full stores and, where necessary, with liquid ballast at draught corresponding to the summer load line;  
.2 ship in the same loading condition as in 1.3.5.1, but with 10% of stores;  
.3 ship with maximum number of containers, each loaded container having the mass equal to 0.6 of the maximum gross mass for each type of containers, with full stores and, where necessary, with liquid ballast;  
.4 ship in the same loading condition as in 1.3.5.3, but with 10% of stores;  
.5 ship with maximum number of empty containers, with ballast and full stores;  
.6 ship in the same loading condition as in 1.3.5.5, but with 10% of stores.

1.3.6 Stability of the ships carrying timber cargoes on the deck shall be checked for the following loading conditions:  
.1 ship carrying timber cargo with specified stowage rate \( \mu \) (if the stowage rate is not specified, it is taken equal to \( \mu = 2.3 \, \text{m}^3/\text{t} \)) in the holds and on the deck, with full stores. If liquid ballast intake is provided at full load with timber in the holds and deck according to the handling instructions, the ballast shall be considered in calculations;  
.2 ship in the same loading condition as in 1.3.6.1, but with 10% of stores;  
.3 ship with timber cargo, having the greatest stowage rate specified, in holds and on the deck, with full stores;  
.4 ship in the same loading condition as in 1.3.6.3, but with 10% of stores.

1.3.7 Stability of the fishing ships shall be checked for the following loading conditions:  
.1 departure for fishing with full stores and fuel;  
.2 arriving at port from fishing with full catch in holds and on deck (if provision is made in the design for stowage of cargo on deck) and with 10% of stores and fuel;  
.3 arriving at port from fishing with no catch in holds but with cargo on deck (if provision is made in the design for stowage of nets, fish or other cargo on deck) and with 10% of stores and fuel.

1.3.8 If the loading conditions, according to the ship operational conditions, as regards stability are less favorable than those listed in 1.3.1 or specified in 1.3.2 to 1.3.7, stability shall be also checked for these conditions.

1.3.9 In the stability calculations, the free surface effect in ballast, fuel and other tanks may be omitted provided that the following condition is met:  
\[
\nu b y k \sqrt{\delta_{1} / D_{\text{light}}} \leq 0.01, \quad (1.3.9-1)
\]
where $v$ — the total volume of the tank, m$^3$

$b$ — the maximum breadth of the tank, m

$\gamma$ — liquid density, kN/m$^3$

$D_l$ — lightship displacement weight, kN

$\delta_1$ — block coefficient of the tank:

$$\delta_1 = \frac{v}{\gamma l b h}$$

$l$, $b$, $h$ — maximum length, breadth and height of the tank, m

$k$ — coefficient calculated by the formula:

$$k = 0.01 \left[ -0.817 + 6.694 \frac{b}{h} - 0.917 \left( \frac{b}{h} \right)^2 + 0.017 \left( \frac{b}{h} \right) \right]$$

(1.3.9-2)

or obtained from Table 1.3.9 depending on $b/h$.

1.3.10 Permissible angles of heel shall be determined at coextensive inclinations of the ship.

1.3.11 When using the tables given in this Part, intermediate values of the parameters shall be determined by linear interpolation.

**1.4 STABILITY CURVES**

1.4.1 Stability of a ship by the main criterion and additional requirements shall be assessed by the dynamic and static stability curves for corresponding loading conditions.

1.4.2 Stability curves shall be plotted considering the liquid cargo's free surfaces in all the cases when the condition specified in 1.3.9 is not met. The swash bulkheads shall be considered permeable. When assessing dynamic stability of a ship (by the main stability criterion), these bulkheads may be considered as watertight.

Stability curves for the ships of M-CPI class intended for operation at negative temperatures, as well as for the ice breakers, shall be plotted considering icing. The icing parameters shall be taken according to 1.7.2.

Correction to the metacentric height for liquid cargo's free surfaces in the tanks, where the mass of liquid is being changed during the ship operation, shall be taken according to the maximum value regardless of filling taken for calculation of weight loads. Correction to the metacentric height for liquid cargo's free surfaces in the tanks with constant filling level (ballast tanks, cargo tanks with liquid cargo) shall be taken according to actual filling of these tanks.

When calculating the ship's stability, residues of liquid cargoes in empty tanks may be omitted where their level does not exceed 5 cm.

1.4.3 Corrections to the metacentric height for liquid cargo are determined as a product of the liquid cargo densities and intrinsic transverse moments of inertia of free surfaces in the tanks calculated for the ship's upright position considering 1.4.2.

1.4.4 Corrections to the arms of the stability curves can be determined using one of the following methods:

1 by calculating actual heeling moment caused by motion of liquid in the tanks for each considered angle of heel;

2 by calculating intrinsic transverse moment of inertia of the liquid free surfaces in the tanks for the ship's upright position with further recalculation for each considered angle of heel by multiplying the received moment of inertia by sine of the angle of heel.

1.4.5 When plotting the stability curves, the influence of superstructures, wheelhouses and cargo hatch coamings may be considered when they are extended over at least 0.15 of the design hull length; in addition, those superstructures, wheelhouses and coamings as well as closures for openings and cutouts in them shall be strong and watertight.

1.4.6 When carrying timber cargo on the deck, additional righting moment caused by immersing the deck cargo shall be considered
by real geometric volume of cargo with the following permeability coefficients for timber:

- packaged 0.75
- round 0.60

**1.5 INFORMATION ON STABILITY AND FLOODABILITY**

1.5.1 Each ship shall be provided with a document named Information on Stability and Floodability prepared according to the Instructions on drawing up the Information on Stability and Floodability of Ship (Appendix 1). For the ships engaged on international voyages, the Information on Stability and Floodability shall be also prepared in English.

1.5.2 The Information on Stability and Floodability shall be prepared on the basis of stability and floodability calculation results according to the requirements of this Part of the Rules. It shall be amended on the basis of the inclining test results, with due regard to 1.6.2, when the deviations between the calculated results and experimental data exceed:

- ±2 % for lightship displacement;
- ±5 % for metacentric height;
- ± 0.01L for longitudinal center of gravity.

The Information on Stability and Floodability shall be prepared according to the Instructions on preparing the Information on Stability and Floodability of Ship (Appendix 1).

1.5.3 For the serial ships, the Information on Stability and Floodability shall be prepared on the basis of the inclining test results of the lead ship in the series.

1.5.4 The Information on Stability and Floodability for the floating cranes shall contain information on stability at various reaches and hook weights.

**1.6 INCLINING TEST**

1.6.1 The following ships shall undergo the inclining test to refine the position of the center of gravity:

- 1 the lead ship of each design;
- 2 a series ship with structural changes brought to essential changes of stability as compared to the first ship of the series exceeding the limits specified in 1.5.2. Such ship shall be considered as the first ship of a new series as regards stability;
- 3 ships after repair, conversion or modernization, if stability might be deteriorate;
- 4 ships, which have no information on stability.

1.6.2 It is allowed not to carry out the inclining test on a ship, which, as a result of modernization, conversion or repair, was subject to structural changes resulting in calculated change in lightship displacement by less than 2 %, in height of center of gravity by less than 4 cm, and in longitudinal center of gravity by less than 1 % of the ship length. The calculations of the lightship displacement and longitudinal center of gravity shall be confirmed by weighting according to 4.2 of Appendix 2.

1.6.3 The inclining test of a ship, except for a passenger ship, may be replaced by weighting, if the requirements of this Part of the Rules are met in case the center of gravity of a light ship is increased by 20 % as compared with the design value.

1.6.4 The inclining test shall be prepared and the results shall be processed according to the Instructions on Finding the Location of the Ship’s Center of Gravity from Experiment (Appendix 2).

**1.7 CONDITIONS OF SUFFICIENT STABILITY**

1.7.1 A ship is considered to be stable when, it complies, at all the loading conditions as specified in this Part of the Rules, with:

- 1 main stability criterion determined according to 2.1 to 2.4 depending on the ship’s class;
- 2 additional requirements to stability taken as in 3.1 to 3.9 depending on the ship’s type and purpose;
- 3 requirements to the static stability curve parameters according to 2.5;
- 4 requirement to initial stability, according to which the transverse initial metacentric
height shall be not less than 0.2 m with due regard to corrections for liquid cargo free surfaces for all the ships and also with due regard to icing for the ships of M-CHI class (see 1.4.2) and ice breakers.

Stability of the ships carrying hazardous goods shall also comply with the applicable requirements of Part IX of the Rules.

1.7.2 The initial metacentric height with due regard to icing shall be determined for the most unfavourable loading conditions for stability. Mass of ice per square meter of the total area of the open deck horizontal projection shall be taken equal to 15 kg. Mass of ice per square meter of the windage area shall be taken equal to 7.5 kg. The total horizontal projection of decks shall include the sum of horizontal projections of all exposed decks and gangways regardless of the availability of awnings.

The vertical moment due to this loading is determined for heights of the centres of gravity of the relevant areas of decks and gangways.

The deck machinery, arrangements, hatch covers and other objects installed on the decks are included in the projection of the decks and are not taken into account individually.

1.8 STABILITY CONTROL MEANS

1.8.1 The requirements of the present chapter apply to oil tankers operated in sea areas and BORO ships carrying oil and oil products.

The requirements of the present chapter apply to the designed ships, ships under construction and ships in service specified in the above paragraph of the present item. For the ships in service as well as for the ships under construction, the keel of which was laid down before 1 January 2016, the requirements of the present chapter shall be met at the earliest ordinary survey but not later than 1 January 2021.

1.8.2 All oil tankers and BORO ships of 24 m length and more carrying oil and oil products and operated in sea areas shall be equipped with stability control means which allow to evaluate ship’s compliance with intact stability and damaged stability requirements. Stability control means consist of software and hardware and allow to decide satisfiability of stability requirements specified for the given ship in the Information Stability and Floodability. The software shall be approved by the River Register.

The requirements for the stability control means software are specified in MSC.1/Circ.1461 "Guidelines for Verification of Damage Stability Requirements for Tankers", MSC.1/Circ.1229 "Guidelines for the Approval of Stability Instruments" and "International Code of Intact Stability 2008".

The Hardware (personal computer) of stability control means shall comply with the system requirements specified by the developer of the software.

The means shall comply with the requirements specified in 1.1.2 Part VI of the present Rules and shall be checked according to 8.1.3 of RTSC.
2 GENERAL REQUIREMENTS TO STABILITY

2.1 MAIN STABILITY CRITERION

2.1.1 Stability of a ship (except for the passenger ship of Ì-ÑÏ class) by the main criterion is considered to be sufficient when it withstands dynamically applied wind pressure on still water or at waves (according to the ship’s class), i.e. the following condition is met:

\[ M_{\text{heel}} < M_{\text{perm}} \quad \text{or} \quad K = \frac{M_{\text{perm}}}{M_{\text{heel}}} \geq 1 \]  \hspace{1cm} (2.1.1)

where \( M_{\text{heel}} \) — heeling moment due to the dynamic wind pressure, kN·m, determined as per 2.2

\( M_{\text{perm}} \) — maximum permissible moment at dynamic inclinations, kN·m, determined as per 2.3

2.1.2 Stability by the main criterion shall be checked for the ships of Ì-ÇП, Ì-ГП, Ì, Í-ГП and Í classes with due regard of roll (see 2.4) and for the ships of Ì and Ì class on still water.

2.1.3 Stability of the passenger ships of Ì-ÑÏ class is considered to be sufficient if the following condition is met:

\[ K = \frac{b}{a} \geq 1 \]  \hspace{1cm} (2.1.3)

where \( a \) and \( b \) are the areas determined from the static stability arm curve (see Fig. 2.1.3) when meeting the following conditions:

1. Ship is subject to a steady wind acting perpendicular to the centreline plane, this wind corresponds to the arm of wind heeling moment \( l_{w1} \);

2. Ship is inclined under the wave action to lee side from the static angle of heel \( \theta_0 \) (which shall not exceed 16°) caused by a steady wind action and corresponding to the first intersection point of the horizontal line \( l_{w1} \) and the righting arm curve \( l = f(\theta) \) to an angle equal to the roll amplitude \( \theta_{m1} \);

3. Inclined ship is subject to a dynamic gust of wind, which corresponds to the arm of heeling moment \( l_{w2} \);

4. To determine \( K \), areas \( a \) and \( b \) shaded in Fig. 2.1.3 shall be calculated and compared. The area \( b \) is limited by the righting arm curve \( l = f(\theta) \), the horizontal line at the level of the arm of heeling moment \( l_{w2} \) and the minimum angle of the following compared angles: angle of heel \( \theta_2 = 50° \); angle of downflooding \( \theta_{\text{down}} \) and angle of capsizing \( \theta_{\text{cap}} \). The area \( a \) is limited by the righting arm curve \( l = f(\theta) \), the horizontal line at the level of the arm of heeling moment \( l_{w2} \) and the angle of heel equal to \( \theta_0 - \theta_{m1} \);

5. The wind heeling lever \( l_{w1} \) is taken constant for all the angles and is calculated by the formula, m:

\[ l_{w1} = 0.001 p_s S z \left( g D \right) \]  \hspace{1cm} (2.1.3.5)

where \( p_s \) — rated static wind pressure, \( p_s = 252 \text{ Pa} \);

\( z \) — reduced heeling arm at simultaneous heel and lateral drift of ship determined according to the requirements in 2.2.5 and 2.2.6,

\( S \) — windage area of the ship at a draught with the checked loading condition, m²;
D — the displacement of the ship in the checked loading condition, t,

\[ g \] — acceleration of gravity, \( g = 9.81 \text{ m/s}^2 \);

The heeling arm \( l_{w3} \) is calculated by the formula

\[ l_{w3} = 1.5l_{w1} \, . \quad (2.1.3.6) \]

2.1.4 Roll amplitude \( \theta_m \) is determined according to the requirements in 2.4.10.

2.1.5 A gust speed limit is imposed on the ships depending on the ship class according to Table 2.1.5:

<table>
<thead>
<tr>
<th>Gust speed limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ship class</td>
</tr>
<tr>
<td>M-CP, M-IP, M</td>
</tr>
<tr>
<td>O-IP, O</td>

<tr>
<td>P, I</td>
</tr>
</tbody>
</table>

2.2 HEELING MOMENT DUE TO THE DYNAMIC WIND PRESSURE

2.2.1 The heeling moment applied to a ship due to the dynamic wind pressure is calculated by the formula, kN·m:

\[ M_{\text{heel}} = 0.001pS z \, , \quad (2.2.1) \]

where \( p \) — assumed rated gust wind pressure, Pa;

\( S \) — windage area of the ship at average draught to actual waterline, m\(^2\);

\( z \) — reduced heeling lever arm at simultaneous heel and lateral drift of the ship, m.

The values in the second member of the formula (2.2.1) shall be taken according to the requirements in 2.2.2 to 2.2.6.

2.2.2 The assumed design dynamic wind pressure shall be taken according to the ship class from Table 2.2.2 depending on the height of the windage center \( z_t \), m, above the actual waterline plane (at average draught \( T \)):

\[ z_t = z_w - T \, , \quad (2.2.2-1) \]

where \( z_w \) — the height of the windage center above the baseline of the ship, m.

The said assumed design dynamic wind pressure may be also determined by the following formulae for the ship classes:

\[
\begin{align*}
M-CP, & \quad p = 171(z_t + 0.6)^{0.34} \quad (2.2.2-2) \\
M-IP, M & \quad p = 151(z_t + 0.6)^{0.37} \quad (2.2.2-3) \\
O-IP, O & \quad p = 121(z_t + 0.6)^{0.44} \quad (2.2.2-4)
\end{align*}
\]

<table>

</tbody>
</table>

2.2.3 The windage area shall include the lateral planes of all continuous surfaces of the hull elements, superstructures and wheelhouses, mast, funnels, ventilators, boats and deck cargoes, as well as awnings which may be arranged in heavy weather.

Windage of discontinued surfaces of the hull elements like guardrails, crane trusses, rigging (except for masts), etc. may be approximately considered by increasing the total lateral area of continuous surfaces calculated for the minimum draught by 5 % and the static moment of this area with respect to the base plane by 10 %.

Windage of discontinued surfaces of the ship components in case of icing is considered by increase of the calculated total areas of the above said continuous surfaces for the minimum draught by 7.5 % and its static moment relative to the baseline of the ship by 15 %.

2.2.4 The approximate allowances for windage of the ship component discontinued surfaces specified in 2.2.3 may be disregarded, if the areas of all such surfaces and their static moments relative to the baseline are calculated individually. In this case, the windage area of discontinued surfaces shall include their overall areas multiplied by respective solidity coefficients, the values of which shall be taken for discontinued surfaces:
guard rails, covered with net, 0.6
not covered with net, 0.2
crane trusses, 0.5
spars and rigging, 0.6

Windage area of discontinued surfaces of the above mentioned elements, when they are calculated individually, shall be taken with a flow coefficient equal to 1.

Projected areas of the hull above the waterline, as well as superstructures and wheelhouses of general (not streamlined) type shall be taken with a flow coefficient equal to 1.

Projected areas of streamlined superstructures and wheelhouses may be taken with the flow coefficient of at least 0.6; however, it shall be proved by corresponding experimental and calculation data.

Projected areas of the ship’s elements located separately and having a streamlined shape (masts, funnels, ventilators, etc.) shall be taken with the flow coefficient equal to 0.6.

2.2.5 Reduced heeling arm due to the dynamic wind pressure, \( m \), is calculated by the formula

\[
\delta = z_c + a_1 a_2 T,
\]

where \( z_c \) — height of the windage center above the actual waterline plane (see 2.2.2), m;

\( a_1, a_2 \) — correction coefficients, see 2.2.6;

\( T \) — average draught of the ship at actual waterline, m.

2.2.6 Coefficient \( a_1 \), considering the influence of water resistance to lateral drift on heeling lever arm \( z \) shall be obtained from Table 2.2.6-1 depending on the ratio \( B/T \) (\( B \) and \( T \) are the breadth and the average draught of a ship at the actual waterline, m) or calculated by the formula:

\[
a_1 = 1.31 - 0.925e^{-0.00025(B/T)^4.33}.
\]

Coefficient \( a_2 \), considering the influence of inertia forces on the heeling lever arm \( z \) shall be obtained from Table 2.2.6-2 depending on the ratio \( z_g/B \) (\( z_g \) is the vertical distance from the centre of gravity to the base plane of the ship, m) or calculated by the formula:

\[
a_2 = \left[\frac{-6.2 + 0.75\left(z_g/B\right)^{-2.64}}{10.7 + \left(z_g/B\right)^{-2.64}}\right].
\]

\begin{table}[h!]

2.3 MAXIMUM PERMISSIBLE MOMENT FOR ASSESSING STABILITY BY MAIN CRITERION

2.3.1 Maximum permissible moment is determined by the maximum permissible angle of heel.

2.3.2 Maximum permissible angle of heel \( \theta_{perm} \) under dynamic effect of the heeling moment due to wind and waves shall be taken equal to either the angle of capsizing \( \theta_{caps} \) or the angle of downflooding \( \theta_{dnfl.} \), whichever is less.

2.3.3 Maximum permissible moment \( M_{perm} \) may be determined by the dynamic or static stability curves according to the requirements of this Section.

2.3.4 Maximum permissible moment \( M_{perm} \) for the ships of M-СП, M-ПР, M, O-ПР and O classes shall be determined by means of plotting performed with due regard to the roll effect.

When determining moment \( M_{perm} \) on the dynamic stability curve (curve of dynamic stability arms \( d \)) the latter is extended to negative area on a section equal to assumed design roll amplitude \( \theta_m \) calculated according to the requirements in 2.4.
The amplitude of roll is plotted to the left from the point of origin 0 (Fig. 2.3.4-1 and 2.3.4-2), and corresponding point A is fixed on the left leg of the curve; this point is further called the origin point.

When determining the maximum permissible moment using any of the described curves, the following typical cases are possible:

.1 For determination of the maximum permissible moment $M_{perm}$ corresponding to the angle of capsizing $\theta_{caps}$, tangent line $AK$ to the right leg of the curve of arms $d$ is drawn from the origin point $A$ (see Fig. 2.3.4-1). An abscissa of the point of contact $K$ defines, for this case, the angle of capsizing; a line parallel to abscissa axis is drawn via the origin point $A$, and segment $AB$ equal to 1 rad ($57.3^\circ$) is laid. A perpendicular is conducted from point $B$ up to intersecting tangent line $AK$ in a point $E$.

Further, a line parallel to abscissa axis is drawn via the origin point $A$, and segment $AB$ equal to 1 rad ($57.3^\circ$) is laid. A perpendicular is conducted from point $B$ up to intersecting tangent line $AK$ in a point $E$.

Segment $BE$ presents the numerical value of the arm $l_{perm1}$ of the maximum permissible moment corresponding to the angle of capsizing of the ship. In this case, the maximum permissible moment $M_{perm1}$, kN·m, shall be equal to $l_{perm1}$, m, multiplied by the weight of the ship $\Delta$, kN, at the draught, for which the stability curve is plotted, i.e.
For determination of the maximum permissible moment $M_{perm2}$ corresponding to the angle of downflooding $\theta_{dnfl.}$, a value of the angle of downflooding $\theta_{dnfl.}$ is plotted on the curve's X axis (see Fig. 2.3.4-2), and a perpendicular is drawn from the obtained point up to intersecting the curve of arms $d$ in a point $F$.

Further plotting on the curve are performed by the same way as stated above, except that instead of the tangent line to the curve, a secant line $AF$ is conducted to intersecting, in point $E$, perpendicular $BE$ constructed to segment $AB$ equal to 1 radian.

This segment $BE$, in this case, presents a numerical value of the arm $l_{perm2}$ of the sought maximum permissible moment corresponding to the angle of downflooding.

Maximum permissible moment $M_{perm2}$ is calculated by the formula, kN·m:

$$M_{perm2} = \Delta \cdot l_{perm2}, \quad (2.3.4-2)$$

where $l_{perm2}$ — arm of the maximum permissible moment, m;

$\Delta$ — weight of the ship, kN.

The maximum permissible moments $M_{perm1}$ and $M_{perm2}$ shall be determined according to the static stability curve as a result of plottings shown on Figs. 2.3.4-1 and 2.3.4-2.

On the static stability curves (the curve of arms $l$) straight lines $CN$ are chosen parallel to the abscissa axis so that shaded areas $S_1$ and $S_2$ are equal.

Segment $OC$ on the ordinate axis of the curve (see Fig. 2.3.4-1) presents a numerical value of the arm $l_{perm1}$ of the maximum permissible moment corresponding to the angle of capsizing, and the value of the moment $M_{perm1}$, kN·m, shall be calculated by formula (2.3.4-1). Similarly, segment $OC$ (see 2.3.4-2) presents a numerical value of the arm $l_{perm2}$ of the maximum permissible moment corresponding to the angle of downflooding, and the value of the moment $M_{perm2}$, kN·m, shall be calculated by formula (2.3.4-2).

2.3.5 Maximum permissible moment at dynamic inclinations — for the ships of P and I classes when assessing their stability by the main criterion (see 2.1) and for the ships of all the classes when assessing stability by additional requirements (see 3 of this Part) — shall be determined by the dynamic and static stability curves in the same order as specified in 2.3.4 regardless the roll effect (see Figs. 2.3.5-1 and 2.3.5-2), except for the stability assessment of tugboats of O-P1P, M-P1P and M-CIP classes for rope jerk carried out with due regard to rolling (see 3.3.14).
and without bilge keels (or bar keel) shall be taken from Table 2.4.1 depending on frequency \( m, \text{s}^{-1} \), which shall be calculated by the formula

\[
m = m_1 m_2 m_3, \quad (2.4.1-1)
\]

where \( m_1, m_2, m_3 \) are coefficients, see 2.4.3.

Notes. 1. When values \( m \) are greater than those specified in Table 2.4.1, the maximum design roll amplitude for the ships of this class shall be taken.

2. For the ships with bilge keels (or bar keel) the roll amplitude shall be determined according to 2.4.4 to 2.4.7.

</table>

The specified assumed design roll amplitude \( \theta_m \), deg., may be also determined by the following expressions for the ship classes:

- \( \text{M, M-P} \) \( \theta_m = 31 - 19.3e^{-1.9m^{2.9}} \) (2.4.1-2)
- \( \text{O, O-P} \) \( \theta_m = 24.4 - 15.9e^{-0.75m^{3.5}} \) (2.4.1-3)

2.4.2 For the ships with sharp bilges and paddle ships, the assumed design roll amplitudes shall be taken equal to 0.75 and 0.80, respectively, of the values taken from Table 2.4.1 or calculated by the formulae (2.4.1-2) and (2.4.1-3).

2.4.3 Coefficient \( m_1 \) that characterizes natural oscillation frequency of a ship (on still water) shall be defined by the formula, \( \text{s}^{-1} \):

\[
m_1 = m_0 / \sqrt{h_0}, \quad (2.4.3-1)
\]

where \( h_0 \) — metacentric height corresponding to the given loading condition of ship calculated regardless of the influence of free surface of liquid cargoes, \( m_0 \) — coefficient to be adopted from Table 2.4.3-1 or calculated by formula (2.4.3-3) depending on the parameter

\[
\eta_i = h_0 B / \left( \zeta_g \sqrt{V} \right), \quad (2.4.3-2)
\]

where \( V \) — volume displacement at mean draught \( T \) corresponding to actual waterline, \( m^3 \);

| Coefficient \( m_0 \) |
|-----------------|--------|--------|--------|
| \( \eta_i \) | \( m_0 \) | \( n_1 \) | \( n_2 \) |
| \leq 0.10 | 0.42 | 1.00 | 2.40 |
| 0.15 | 0.52 | 1.50 | 3.00 |
| 0.25 | 0.78 | 2.00 | 3.30 |
| 0.50 | 1.38 | 2.50 | 3.50 |
| 0.75 | 1.94 | \geq 3.00 | 3.60 |

\( z_g \) — height of centre of gravity above the baseline for the given loading condition, \( m \);

\( B \) — the ship’s breadth at the actual waterline, \( m \).

\[
m_0 = 3.66 - 3.43e^{-0.25}. \quad (2.4.3-3)
\]

Values of dimensionless coefficients \( m_2 \) and \( m_3 \), which consider the hull shape influence on the roll amplitude, shall be taken from Tables 2.4.3-2 and 2.4.3-3 or from expressions (2.4.3-4) and (2.4.3-5) depending on the \( B/T \) ratio and block coefficient \( \delta \).

2.4.3.1 The value of dimensionless coefficients \( m_2 \) and \( m_3 \) shall be taken from Tables 2.4.3-2 and 2.4.3-3 or from expressions (2.4.3-4) and (2.4.3-5) depending on the \( B/T \) ratio and block coefficient \( \delta \).

| Coefficient \( m_2 \) |
|-----------------|--------|--------|
| \( B/T \) | \( m_2 \) | \( B/T \) | \( m_2 \) |
| \leq 2.50 | 1.00 | 6.00 | 0.87 |
| 3.00 | 0.90 | 7.00 | 0.92 |
| 3.50 | 0.81 | 8.00 | 0.96 |
| 4.00 | 0.78 | 9.00 | 0.99 |
| 5.00 | 0.81 | \geq 10.00 | 1.00 |

2.4.3.2 For the ships with sharp bilges and paddle ships, the assumed design roll amplitudes shall be taken equal to 0.75 and 0.80, respectively, of the values taken from Table 2.4.1 or calculated by the formulae (2.4.1-2) and (2.4.1-3).

| Coefficient \( m_3 \) |
|-----------------|--------|--------|
| \( \delta \) | \( m_3 \) | \( \delta \) | \( m_3 \) |
| \leq 0.45 | 1.00 | 0.65 | 0.72 |
| 0.50 | 0.95 | 0.70 | 0.69 |
| 0.55 | 0.86 | 0.75 | 0.67 |
| 0.60 | 0.77 | \geq 0.80 | 0.66 |

\[
m_2 = 0.669 + 10.47(B/T) - 100.74(B/T)^2 + 327.36(B/T)^3 - 339.5(B/T)^4. \quad (2.4.3-4)
\]
$m_i = 1 - 0.358e^{-0.00758^{0.1}}$ \hfill (2.4.3-5)

2.4.4 Assumed design roll amplitudes $\theta_m'$, deg., for the ships with bilge keels (or bar keel)

$$\theta_m' = k \theta_m,$$ \hfill (2.4.4)

where $k$ — correction coefficient, see 2.4.5

$\theta_m$ — roll amplitude for ship without keels, see 2.4.1

2.4.5 Coefficient $k$ specifying the relative decrease of the roll amplitudes due to bilge or bar keels, shall be taken from Table 2.4.5 depending on

$$q = r \alpha \sqrt{B},$$ \hfill (2.4.5-1)

where $B$ — the ship breadth at the actual waterline, m

<table>
<thead>
<tr>

</table>

The said coefficient $k$ may be also determined by the expression:

$$k = 1 - 0.438q^{0.85} \left( \frac{7}{7 + q^{0.85}} \right).$$ \hfill (2.4.5-2)

2.4.6 Coefficient $r$ considering the increase of water resistance to roll due to bilge or bar keels shall be calculated by the formula:

$$r = (r_1 + r_2) r_3,$$ \hfill (2.4.6)

where $r_1$, $r_2$, $r_3$ are coefficients, see 2.4.7.

2.4.7 Coefficient $r_1$ considering the efficiency of bilge keels with the total area $S_k$, $m^2$, shall be taken from Table 2.4.7-1 depending on ratio $100S_k/(LB)$, % ($L$ and $B$ are the length and the breadth of the ship at actual waterline, m).

The said coefficient $r_1$ may be also determined by the expression:

$$r_1 = 47.8 \frac{S_k}{LB} - 0.241 at \quad r_1 = 1.66 \quad at \quad S_k/(LB) \leq 0.04$$

$$r_1 = 1.66 at \quad S_k/(LB) > 0.04$$ \hfill (2.4.7-1)

Coefficients $r_2$ and $r_3$ considering the influence of the hull shape on the efficiency of bilge keels shall be taken from Tables 2.4.7-2 and 2.4.7-3 accordingly depending on the block coefficient $\delta$ for keel area $S_k$ and ratio $B/T$ ($T$ is the mean draught of the ship at actual waterline, m).

Note: The requirements specified in 2.4.7 apply to the ships with bar keel too. In this case, $S_k$ is the keel’s lateral projection area, $m^2$.

The said coefficients $r_2$ and $r_3$ may be also determined by the expressions:

$$r_2 = \left(-0.116 + 0.25\delta\right)\left(1 - 2.7\delta + 2\delta^2\right),$$ \hfill (2.4.7-2)

$$r_3 = 1 + 0.166 \frac{B}{T}.$$ \hfill (2.4.7-3)

2.4.8 Roll amplitude $\theta_m$, deg., for the ships of M-CP class (except for passenger ships) with a rounded bilge and without bilge keels shall be calculated by the formula
$\theta_m = m_4 m_5 m_6$, \hspace{1cm} (2.4.8-1)

where $m_4$ — coefficient calculated by the formula:

$$m_4 = \left[ 1.103 - 0.5576 \frac{B}{T} + 0.0764 \left( \frac{B}{T} \right)^2 \right] / \left[ 1 - 0.4971 \frac{B}{T} + 0.0691 \left( \frac{B}{T} \right)^2 \right]$$ \hspace{1cm} (2.4.8-2)

or adopted from Table 2.4.8-1 depending on the ratio of the ship’s breadth $B$ to the draught $T$;

or adopted from Table 2.4.8-2 depending on the block coefficient $\delta$;

$$m_5 = 109.745 - 124.4 \delta + 52.94 \delta^2 - 41.68 \delta + 5.85 \delta^2$$ \hspace{1cm} (2.4.8-3)

or adopted from Table 2.4.8-2 depending on the block coefficient $\delta$;

or adopted from Table 2.4.9 depending on the ratio of the total area of bilge keels $S_k$, m$^2$, to the product $LB$.

2.4.9 If the ship of M-1 class (except passenger ships) has bilge keels, the roll amplitude shall be calculated by the formula

$$\theta_m = k \theta_m$$ \hspace{1cm} (2.4.9-1)

where coefficient $k$ depending on $\tilde{a} = 100 \frac{S_k}{LB}$ is calculated by the formula

$$k = \left[ 1 - 0.8554 \tilde{a} + 0.2522 \tilde{a}^2 - 0.0212 \tilde{a}^3 \right] / \left[ 1 - 0.8432 \tilde{a} + 0.2449 \tilde{a}^2 - 0.0184 \tilde{a}^3 \right]$$ \hspace{1cm} (2.4.9-2)

or adopted from Table 2.4.9 depending on the ratio of the total area of bilge keels $S_k$, m$^2$, to the product $LB$.

2.4.10 Roll amplitude $\theta_m$, deg., of the passenger ship of M-1 class with a rounded bilge shall be calculated by the formula:

$$\theta_m = 109 k x_1 m_5 \sqrt{r s}$$ \hspace{1cm} (2.4.10-1)

where $k$ — coefficient considering the influence of bilge keels taken from Table 2.4.9;

$x_1$ — dimensionless coefficient adopted from Table 2.4.10-1 depending on the breadth-to-draught ($B/T$) ratio or, within the $B/T$ range of 2.4 to 3.5, calculated by the formula:

$$x_1 = \sqrt{1.7645 - 0.3207 \frac{B}{T}}$$ \hspace{1cm} (2.4.10-2)

$m_5$ — dimensionless coefficient adopted from Table 2.4.8-2;

$r$ — parameter calculated by the formula:

$$r = 0.73 + 0.6 \left( \frac{z_g - T}{T} \right) / T \leq 1$$ \hspace{1cm} (2.4.10-3)
s — dimensionless coefficient taken from Table 2.4.10-2 depending on the roll period $\tau$ to be calculated by the formula, $s$:

$$ \tau = 2c \frac{B}{\sqrt{h}}. $$

(2.4.10-4)

To determine $s$ within the roll period range from 6 to 20 s, the following formula may be used instead of Table 2.4.10-2:

$$ s = 0.03 + 0.0439 \tau - 0.838 \cdot 10^{-3} \tau^2 + 0.536 \cdot 10^{-3} \tau^3 - 1.1399 \cdot 10^{-5} \tau^4; $$

$c$ — correction coefficient depending on the ship's dimensions:

$$ c = 0.373 + 0.023 \frac{B}{T} - 0.043 \cdot 10^{-2} \frac{L}{T}; $$

(2.4.10-6)

$h$ — corrected metacentric height, m (corrected for effect of free surfaces of liquid cargoes);

$L$ — ship's length, m.

The roll amplitude of a sharp-bilge ship shall be taken equal to 70% of the amplitude calculated by the formula (2.4.10-1).

The rated roll amplitude values shall be rounded to integer degrees.

2.4.11 Assumed design roll amplitude for the ships of M class. Roll amplitude $\theta_m$, deg., is calculated by the formula

$$ \theta_m = \frac{1}{2} \left( 0.1306 - 0.2584m + 0.2272m^2 - 0.0674m^3 \right) $$

(2.4.11)

or adopted from Table 2.4.11 depending on the parameter $m$.

2.5 REQUIREMENTS TO STATIC STABILITY CURVE PARAMETERS

2.5.1 For ships of M and M-III classes, the maximum righting arm of the static stability curve shall be at least 0.25 m for ships with a length of 80 m and less and at least 0.20 m for ships with a length of 105 m and more at an angle of heel $\theta \geq 25^\circ$. For ships with a length over 80 m but less than 105 m, righting arm $l_{\max}$ shall be obtained by linear interpolation of the data stated above. The angle of vanishing or the angle of downflooding of the static stability curve shall be at least 50°.

2.5.2 The static stability curve for the ships of M-III class (except for passenger ships) shall comply with the following requirements:

1. The maximum righting arm of the static stability curve shall be at least 0.25 m for ships with a length of 80 m and less and at least 0.20 m for ships with a length of 105 m and more at an angle of heel $\theta \geq 25^\circ$. For ships with a length over 80 m but less than 105 m, righting arm $l_{\max}$ shall be obtained by linear interpolation of the data stated above. For the ships with the $B/T \geq 2.5$, maximum arm may be decreased to 0.15 m if the area under the static stability curve within the angles of heel of $0^\circ$ to $15^\circ$ is at least 0.07 m rad;
2. The angle of vanishing or the angle of downflooding of the static stability curve shall be at least 50°;
3. The area under the righting lever curve shall not be less than, m-rad:
2.5.3 The static stability curve for the ships of M-CII class shall comply with the following requirements:

.1 The maximum righting arm \( l_{\text{max}} \) of the static stability curve shall be at least 0.25 m for ships with a length of 80 m and less and at least 0.20 m for ships with a length of 105 m and more at an angle of heel \( \theta \geq 30^\circ \). For intermediate values of the ship length, value \( l_{\text{max}} \) shall be determined by linear interpolation of the above data.

If the static stability curve has two maxima due to the influence of the superstructures or wheelhouses, the first maximum shall occur at the angle of heel not less than 25\(^\circ\);

.2 The limit of positive static stability (the angle of vanishing stability or the angle of downflooding) shall be at least 60\(^\circ\); however, this limit may be lowered down to 50\(^\circ\) provided that every lowering by 1 degree is accompanied by increase of the maximum arm \( l_{\text{max}} \) of the static stability curve by 0.01 m above the value specified according to 2.5.3.1;

.3 The area under the righting lever curve shall not be less than, m-rad:

3 ADDITIONAL STABILITY REQUIREMENTS
FOR VARIOUS SHIP TYPES

3.1 PASSENGER AND OTHER SHIPS
CARRYING PEOPLE

3.1.1 Stability of passenger ships by the
main criterion specified in 2.1 shall be as-
sessed for the loading conditions specified in
1.3.

When assessing stability by the main crite-
rion, cabin passengers shall be assumed to be
in their accommodation, deck passengers on
their decks and the cargo stowage in cargo
holds and on decks shall be assumed to com-
ply with the normal operating conditions of
the ship.

For the loading conditions in 1.3.2.1 to
1.3.2.3, stability of the ship shall be also
checked by additional requirements specified
in 3.1.2, 3.1.6, 3.1.10.

N o t e : Stability of a ship by additional re-
quirements shall be assessed also for non-full num-
ber of passengers, if such a loading condition may
be less favourable as regards stability than the worst
one of those listed above.

3.1.2 Stability of passenger ships shall be
sufficient in case of passenger crowding at one
side, i.e. the following condition shall be met:

\[ M_p < M_{perm}, \]  (3.1.2)

where \( M_p \) — heeling moment due to crowding
of passengers to one side, kN-m, see 3.1.3;

\( M_{perm} \) — maximum permissible moment at
static inclinations of the ship, kN-m, see 2.3.

3.1.3 Heeling moment \( M_p \) shall be deter-
mined by from the design scheme of crowding
the passengers at one side corresponding to
their most dangerous disposition possible in
normal operating conditions of the ship. In
this case, the distribution of passengers shall
be taken as at one side on deck areas free
from the equipment and arrangements, with
due regard to restrictions established for pas-
senger access to either part of the deck.

When determining heeling moment \( M_p \), the
passenger distribution density shall be taken as
follows: 4 persons per square meter of free
surface of decks on ships undertaking perma-
nent voyages longer than 24 hours; and 6 per-
sons per square meter on ships undertaking
voyages shorter than 24 hours.

Areas of outer passages in the vicinity of
bulwarks or guard rails shall be assumed with
a coefficient of 0.75, where the passage
breadth is over 0.7 m and with a coefficient of
0.50 where the breadth is \( \leq 0.7 \) m.

Areas of passages between sofas (benches,
armchairs), on which excessive passengers
may crowd in addition to the passengers oc-
cupying their seats, shall be assumed with a
coefficient of 0.5.

Mass of a passenger shall be taken equal to
75 kg and a centre of gravity located 1.1 m
above the deck.

3.1.4 As an ultimate permissible angle of
heel \( \theta_{perm} \), there shall be taken an angle equal
to 0.8\( \theta_{downfl} \), or an angle at which the deck
edge or upper edge of ship fender enters the
water, whichever is less. Value of \( \theta_{perm} \) shall
not exceed 10°, or 12° for ships of up to 30 m
in length.

3.1.5 Moment \( M_{perm} \) shall be defined from
the static stability curve depending on maxi-
mum permissible angles of heel \( \theta_{perm} \), deg.
(see 3.1.4). When assessing stability in case of
crowding passengers on one side, the effect of
free surfaces of liquid cargoes shall be consid-
ered according to 1.4.2.

3.1.6 Stability of passenger ships in case of
crowding passengers on side shall be sufficient
at the greatest dynamic heel arising at the
evolution period of turn, i.e. the following condition shall be met:

\[ M_{\text{turn}} < M'_{\text{perm}}, \] (3.1.6)

where \( M_{\text{turn}} \) — dynamically applied heeling moment, kN·m, arising in evolution period of ship turn and determined as in 3.1.7;

\( M'_{\text{perm}} \) — maximum permissible moment taken as in 3.1.9 when the ship is inclined in the evolution period of turn, having regard to initial heel due to crowding of passengers at one side, kN·m.

Note: If in any real loading condition of a serial passenger ship, condition \( M_{\text{turn}} \leq 0.8M'_{\text{perm}} \) is not met, her stability in the evolution period of turn shall be checked by means of specially conducted full-scale experiment performed on the lead ship of the series.

3.1.7 The dynamical heeling moment applied to ship in the evolution period of turn, kN·m, is:

\[ M_c = v_0^2 \Delta (z_g - a_1 T)/L, \] (3.1.7-1)

where \( c \) — coefficient depending on type of ship propulsor and equal to 0.029 for propeller and waterjet ships and 0.045 for paddle ships;

\( v_0 \) — ship speed before entering the turn, to be taken equal to 0.8 of full ahead speed on a straight course, m/s;

\( \Delta \) — weight of the ship corresponding to the draught up to actual waterline, kN;

\( z_g \) — height of centre of gravity above the baseline, m;

\( a_3 \) — coefficient considering vertical shift of lateral pressure centre when the ship is adrift; it is to be taken from Table 3.1.7 depending on the ratio \( B/T \) (\( B \) is the ship’s breadth at actual waterline);

<table>

<tr>
<td>6.00</td>
<td>-2.33</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

\( L \) and \( T \) — the ship’s length and the mean draught at actual waterline, respectively, m.

Coefficient \( a_3 \) may be also calculated within the range of \( 2.50 < B/T < 10.0 \) by the formula:

\[ a_3 = 0.015 (B/T)^3 - 0.282 (B/T)^2 + 0.662 B/T + 0.62. \] (3.1.7-2)

Note: Formula (3.1.7-1) is valid for displacement single-hull ships with length-based Froude number \( F_{Ll} = v/L \sqrt{g} \leq 0.36 \).

3.1.8 As the maximum permissible angle of heel \( \theta'_{\text{perm}} \), there shall be taken an angle equal to a deck entrance angle (regardless of fender entering the water) or an entrance angle of waterline being 75 mm below the edge of free-flooding openings, whichever is less.

3.1.9 Moment \( M'_{\text{perm}} \) shall be defined from the static stability curve depending on the maximum permissible angle of heel \( \theta'_{\text{perm}} \) (see 3.1.8) as a result of plotings shown on Fig. 3.1.9, where the point of origin is notionally carried to point \( \theta' \) on curve \( l \) corresponding to the static angle of heel due to crowding of passengers at one side \( \theta' \), arising due to action of static moment \( M_p \) calculated according to 3.1.3.

Moment \( M'_{\text{perm}} \) (or the arm of the permissible moment \( \theta'_{\text{perm}} \)) shall be determined from equality of the areas \( S_1 \) and \( S_2 \).

When assessing stability in the evolution period of turn, the effect of free surfaces of liquid cargoes shall be considered in accordance with 1.4.2.

3.1.10 Stability of passenger ships with the centre of windage located 2 m above the ac-
Additional Stability Requirements for Various Ship Types 239

... shall be sufficient at crowding of passengers at one side in case of static effect of wind, i.e. the following condition shall be met:

\[
\left( M_p + M_w \right) < M_{\text{perm}} ,
\]

where \( M_p \) — heeling moment due to passenger crowding at one side, kN·m, determined according to the instructions in 3.1.3;

\( M_w \) — heeling moment due to static effect of wind, kN·m, see 3.1.11;

\( M_{\text{perm}} \) — maximum permissible moment at static inclinations of a ship, kN·m, defined from the static stability curve depending on the value of angle \( \theta_{\text{perm}} \) (see 3.1.4), the value of angle \( \theta_{\text{perm}} \) being not limited by 10° or 12°.

3.1.11 The heeling moment due to static effect of wind, kN·m, is

\[
M_w = 0.001 p_s S \left( z_w - a_3 T \right) ,
\]

where \( p_s \) — assumed design static wind pressure, Pa, which shall be taken equal to 0.47 of the respective dynamic pressure from Table 2.2.2 depending on the ship class and the height of the windage center above the actual waterline plane;

\( S \) — windage area, m², see 2.2.3 and 2.2.4;

\( z_w \) — height of the centre of gravity above the base plane when the ship is the upright position, m;

\( a_3 \) — coefficient, see Table 3.1.7;

\( T \) — average draught of the ship at actual waterline, m.

3.1.12 Stability of crew boats, special purpose ships and non-passenger ships carrying organized groups of people shall comply with the requirements for stability of passenger ships with due regard to crowding of all people being on the ship (other than the crew members) at one side.

3.1.13 Carriage of people, towing (on a tow line or alongside towing) and industrial operations shall not be performed simultaneously. This fact shall be indicated in the Information on Stability and Floodability.

3.2 CARGO SHIPS

3.2.1 Stability of dry cargo ships shall be assessed by the main criterion specified in 2.1.1 at load according to 1.3.1, 1.3.3, 1.3.5, 1.3.6 and 1.3.8.

Cargo stowage shall correspond to normal conditions of ship’s service.

Stability of the tankers shall be checked at loading conditions according to 1.3.1, 1.3.4, 1.3.8 and, additionally, with 50 % filling of the tanks with full and 10 % stores. Stability of the refueling ships shall be checked at 25 %, 50 % and 75 % filling of the tanks with full and 10 % stores.

3.2.2 For all cargo ships with windage centre of 2 m above the actual waterline, stability at static wind effect shall be checked, i.e. the following condition shall be met:

\[
M_w < M_{\text{perm}} ,
\]

where \( M_w \) — heeling moment due to static effect of wind, kN·m, see 3.1.11;

\( M_{\text{perm}} \) — maximum permissible moment at static inclinations of a ship, kN·m, defined from the static stability curve depending on value of angle \( \theta_{\text{perm}} \) (see 3.2.3).

3.2.3 The maximum permissible angle of heel \( \theta_{\text{perm}} \) shall be taken equal to either 0.80\( \theta_{\text{down}} \) or deck edge entrance angle, whichever is less.

3.2.4 For all cargo ships with specific power capacity, i.e. \( P_e \), kW per unit of displacement \( V \), m³ such that \( P_e / V \geq 0.735 \), stability in the evolution period of turn shall be checked, i.e. the following condition shall be met:

\[
M_c < M_{\text{perm}} ,
\]

where \( M_c \) — dynamical heeling moment, kN·m, applied to a ship in the evolution period of turn, see 3.1.6;

\( M_{\text{perm}} \) — maximum permissible moment, kN·m, determined according to the statical or dynamical stability curves depending on the angle \( \theta'_{\text{perm}} \) (see 3.2.5).

3.2.5 The maximum permissible angle \( \theta'_{\text{perm}} \) shall be taken equal to deck entrance angle or entrance angle of waterline laying...
75 mm below the edges of free-flooding openings, whichever is less.

3.2.6 Stability of the ships of M-CPI class carrying bulk cargoes shall comply with the following requirements:

1. the calculated acceleration due to rolling (in fractions of $g$) $a_{cal}$ shall not exceed 0.3, i.e. the acceleration criterion

$$K^* = 0.3/a_{cal} \geq 1,$$

where $a_{cal} = 1.1 \times 10^{-3} \cdot B m_1 \theta_m$;

$B$ — ship’s breadth at the actual waterline;

$m_1$ — coefficient determined according to 2.4.3;

$\theta_m$ — roll amplitude determined according to 2.4.8 and 2.4.9;

2. when $K^* < 1$, permissible wave height of 3% probability of overtopping is taken from Table 3.2.6.

Table 3.2.6

<table>

</tbody>
</table>

3.2.7 The following additional requirements to stability of the ships of M-CPI class carrying timber cargoes on the deck shall be met:

1. Metacentric height with due regard to free surfaces shall be at least 0.20 m;

2. The maximal righting arm of the static stability curve shall be at least 0.25 m.

3.2.8 The following additional requirements to stability of the ships of M-CPI class carrying containers on the deck shall be met:

1. Metacentric height with due regard to free surfaces shall be at least 0.20 m;

2. The angle of heel on steady turning or under the effect of continuous beam wind as obtained from the stability curve shall not exceed half the angle, at which the freeboard deck immerses; in any case, the angle of heel shall not exceed 15°. Here, the heeling moment on steady turning shall be determined according to 3.1.7, and the heeling moment due to the static wind pressure shall be determined according to 3.1.11.

Where the containers are located only on cargo hatch covers, the angle, at which the hatch coaming edge is immersed, may be adopted instead of the angle, at which the upper deck edge is immersed.

3.2.9 The following additional requirements to the ships of M-IP and M-CPI classes carrying bulk grain shall be met:

1. The angle of heel due to the shift of grain shall not be greater than 12° or the angle, at which the upper deck edge is immersed, whichever is less;

2. In the statical stability diagram (see Fig. 3.2.9.2) the net of residual area between the heeling arm curve and the righting arm curve up to 40° angle of heel (which corresponds to the maximum difference between the ordinates of the two curves), or the angle of downflooding, whichever is the least, shall in all conditions of loading be not less than 0.075 m·rad;

3.2.10 For loading bulk grain, the following requirements shall be met:

1. All necessary trimming shall be performed to level all free grain surfaces and to
Additional Stability Requirements for Various Ship Types

minimize the effect of grain shifting; trimming means grain levelling in cargo holds and/or filling underdeck spaces in order to prevent uncontrolled shift of grain during transportation;

.2 In any filled compartment, trimmed, the bulk grain shall be trimmed so as to fill all spaces under the decks and hatch covers to the maximum extent possible;

.3 In any filled compartment, untrimmed, the bulk grain shall be filled to the maximum extent in way of the hatch opening but may be at its natural angle of repose outside the periphery of the hatch opening.

A filled compartment may comply with this category, if the compartment is considered specially suitable and the requirements to trimming are not applied because the underdeck void space shape resulting from free flowing grain into a compartment is taken into account when calculating the void space depth.

Specially suitable compartment refers to a cargo space, which is constructed with at least two vertical or sloping, longitudinal, grain-tight divisions which are coincident with the hatch side girders or are so positioned as to limit the effect of any transverse shift of grain. If sloping, the divisions shall have an inclination of not less than 30° to the horizontal;

.4 After loading, all free grain surfaces in partly filled compartments shall be leveled;

.5 Unless the account is taken of the adverse heeling effect due to the grain shift according to Appendix 3, free surface of the bulk grain in any partly filled compartment shall be secured by means of special arrangements as to prevent a grain shift;

.6 In filled compartments, trimmed, filled compartments, untrimmed, and partly filled compartments, longitudinal divisions may be installed as a mean to reduce the adverse heeling effect of grain shift provided that:

the division is grain-tight;

the division possesses adequate strength when being affected by pouring grain.

3.2.11 When meeting the requirements in 3.2.9 to 3.2.10, the River Register issues a Certificate of Fitness for Grain Carriage in Bulk.

The Certificate may be issued also if the Addendum to the Information on Stability and Floodbaility is available onboard the ship and includes:

.1 plans of grain stowage;

.2 curves or tables to determine the volume occupied by grain, vertical centre of gravity (height of centre of gravity), and assumed volumetric heeling moments. Such data shall be available for every compartment taking into account the influence of temporary appliances (shifters, shifting boards etc.) used for grain carriage;

.3 tables or curves of maximum permissible heeling moments for varying displacements and varying vertical centre of gravity to allow the master to demonstrate the compliance with the requirements of 3.2.9;

.4 brief loading instructions generalizing the requirements in 3.2.10;

.5 a specific example of calculations.

Note: It is recommended that loading conditions are provided for three representative stowage coefficients, e.g. 1.25, 1.50 and 1.75 m³/t.

3.3 TUGBOATS

3.3.1 Stability of tugboats shall be assessed by the main criterion given in 2.1 and by additional requirements in 3.3.2 to 3.3.11, 3.3.14 for the loading conditions specified in 1.3.1 and 1.3.8.

Note: Stability of the ships of other types fitted with towing arrangement shall be checked for all loading conditions according to 3.3.2 to 3.3.11.

3.3.2 Stability of all the tugboats shall be sufficient at static effect of the tow line, i.e. the following condition shall be met:

\[ M_s < M_{perm}' \]  

(3.3.2)

where \( M_s \) — heeling moment due to effect of statically strained tow line, kN·m, see 3.3.3;

\( M_{perm}' \) — maximum permissible moment at static inclinations of the ship, kN·m, see 3.3.6.

3.3.3 The heeling moment \( M_s \), kN·m, is calculated by the formula:
\[
M_s = F \left[ (z_h / B + f_1) f_2 f_3 + 0.65 h_0' / B \right],
\]

(3.3.3)

where \( F \) — coefficient taken equal to 1.12 \( P_e \) but not less than 0.17 \( V \);

\( z_h \) — vertical distance between a point of application of the tow line force and the base plane, m;

\( B \) — ship's breadth at actual waterline, m;

\( f_1, f_2, f_3 \) — coefficients, see. 3.3.4;

\( h_0' \) — small metacentric height calculated considering the correction to the influence of the liquid cargo's free surfaces (see 1.4.2), m.

Note: If a frame stop of a tow line is fitted, a distance \( z_h \), m, shall be taken equal to the greatest of the following values: elevation of a hook suspension point or elevation of a bottom edge of the frame stop.

3.3.4 Coefficients \( f_1 \) and \( f_2 \) shall be taken from Table 3.3.4 depending on the ratio of the ship breadth \( B \) to the draught \( T \) or by the following formulae, valid for the range of \( 2.25 < B/T < 8.0 \):

\[
f_1 = -0.0209 \left( B/T \right)^3 + 0.3767 \frac{B}{T} + 1.18;
\]

(3.3.4-1)

\[
f_1 = 0.0058 \left( B/T \right)^3 - 0.0904 \left( B/T \right)^2 + 0.3512 B/T + 0.3216.
\]

(3.3.4-2)

Table 3.3.4

</table>

The value of \( f_2 \) shall be taken equal to 1, when the distance between the point of applying the tow line force and the center of gravity, m, measured over a horizontal \( x''_h \leq 0.3L \); when \( x''_h > 0.3L \), then \( f_2 \) shall be taken equal to 0.85.

Note: If a frame stop of tow line is fitted, a value of \( x''_h \), m, shall be taken equal to a distance between the frame stop and the ship's centre of gravity.

3.3.5 Maximum permissible angle \( \theta'_{\text{perm}} \) shall be taken equal to 0.8 \( \theta_{\text{dnnl}} \) or deck edge entrance angle, whichever is less.

3.3.6 The maximum permissible moment \( M'_{\text{perm}} \) is determined by the formula, kN-m:

\[
M'_{\text{perm}} = Dl_{\text{perm}},
\]

(3.3.6)

where \( D \) — weight of the ship corresponding to the draught up to actual waterline, kN;

\( l_{\text{perm}} \) — heeling arm of the maximum permissible moment taken from the static stability curve at an angle of heel \( \theta'_{\text{perm}} \) (see 3.3.5), in m.

3.3.7 Stability of tugboats at \( z_h > 1.2z_g \) (\( z_g \) is the height of the ship’s centre of gravity above the base plane, m) shall be checked at tow line jerk, i.e. the following condition shall be met:

\[
M_p < M'_{\text{perm}},
\]

(3.3.7)

where \( M_p \) — heeling moment, kN-m, due to jerk effect of strained tow line, see 3.3.8;

\( M'_{\text{perm}} \) — maximum permissible moment, kN-m, characterizing the dynamical stability of a ship, see 3.3.10.

3.3.8 The heeling moment \( M_p \), kN-m, shall be calculated by the formula

\[
M_p = 1.85 w D \left( k_1 k_2 \right)^2,
\]

(3.3.8-1)

where \( w \) — coefficient depending on the ship's rated power \( P_e \), in kW, and adopted from Table 3.3.8-1 or calculated by the formula for the range of \( 400 < P_e < 1450 \):

\[
w = 1.31 \cdot 10^{-7} P_e^2 - 4.73 \cdot 10^{-5} P_e + 0.165;
\]

(3.3.8-2)

\[ x'_{\text{cargo}}/L \] — ratio, see 3.3.4.

3.3.9 Maximum permissible angle of heel \( \theta_{\text{perm}} \) shall be taken equal to the angle of capsize \( \theta_{\text{caps}} \) or the angle of downflooding \( \theta_{\text{dnfl}} \), whichever is less.

3.3.10 Maximum permissible moment, kN-m,

\[ M_{\text{perm}} = DI_{\text{perm}}, \]  

(3.3.10)

where \( D \) — weight of the ship corresponding to the draught up to actual waterline, kN;

\( I_{\text{perm}} \) — permissible moment arm determined by the dynamic stability curve according to the requirements in 2.3.4 or 2.3.5 at an angle of heel \( \theta_{\text{perm}} \) (cm. 3.3.9), m.

3.3.11 Stability of tugboats during the turning circle shall be checked according to the requirements in 3.2.4.

3.3.12 The Information on Stability and Floodability shall contain data on the flow speed \( v_{\text{flow}} \), above which the manoeuvring of the ship near a still barge without release of the tow line is assumed to be dangerous. A flow speed is calculated by the formula, km/h:

\[ v_{\text{flow}} = 4.8 \sqrt{M_{\text{perm}}/M_s}. \]  

(3.3.12)

The moments \( M_{\text{perm}} \) and \( M_s \) shall be calculated according to requirements given in 3.3.3 to 3.3.6.

3.3.13 Stability of tugboats of high power (over 6.6 kW/m³) shall be checked during trials of the lead ship of the series.

3.3.14 In addition to 3.3.7, stability at dynamic effect of the tow line considering the roll effect, shall be checked for the tugboats of O-P, M-P, M-PP and M-CT classes, if the heeling moment due to dynamic effect of the strained tow line, \( M_r \), determined according to 3.3.8 exceeds the heeling moment due to the dynamic wind pressure \( M_h \), i.e. the following condition shall be met:

\[ M_r < M_{\text{perm}} \]  

(3.3.14)

where \( M_h \) — heeling moment, kN-m, due to the dynamic effect of the strained tow line, determined according to the instructions in 3.3.8.

\( M_{\text{perm}} \) — maximum permissible moment at a dynamic inclination, kN-m, determined
according to 2.3.4 at design roll amplitude, deg, taken according to 2.4.1 to 2.4.7 for the tugboats of O-ПП and М-ПП classes and according to 2.4.8 and 2.4.9 for the tugboats of М-СП class.

To calculate \( M_{\text{perm}} \), the permissible heel angle shall be calculated in the same way as for stability assessment by the main criterion.

### 3.4 FISHING VESSELS

#### 3.4.1
For all the loading conditions, stability during the ship turning circle shall be also checked according to the requirements in 3.2.4.

#### 3.4.2
Where cells formed by filling boards, which prevent transverse and longitudinal shifting of fish, are not available, fish shall be considered as liquid cargo in stability calculations.

### 3.5 FLOATING CRANES, INDUSTRIAL SHIPS, LOADERS

#### 3.5.1
Stability of floating cranes shall be checked in the most unfavourable working condition with 10 % of water and fuel stores under the effect of dynamical wind pressure, i.e. the following condition shall be met:

\[
M_{\text{heel}} < M'_{\text{perm}},
\]

where \( M_{\text{heel}} \) — heeling moment due to dynamical wind pressure effect (see 3.5.2), kN·m;

\( M'_{\text{perm}} \) — maximum permissible moment, kN·m, determined with due regard of the initial heel due to a load on the hook according to 3.5.4.

**Note**: Floating full-turned cranes, in addition to the aforementioned requirement, shall have an angle of static heel at all possible boom lengths not exceeding 3°30’.

#### 3.5.2
The heeling moment due to the dynamic wind pressure when assessing stability of floating cranes in maximum loaded operating condition with a load on the hook shall be determined according to 2.2. The design wind pressure \( p \) for cranes of all classes shall be taken equal to 400 Pa regardless of the height of windage centre above the plane of actual waterline.

A design windage area of a crane with continuous walls shall be taken an area restricted by the crane contour, and for lattice structures — the same area with deduction of spans between the rods.

A design windage area of cranes consisting of several beams (continuous or lattice ones) of the same height located one after another shall be taken as (Fig. 3.5.2):

\[
\begin{align*}
S_{\text{all}} &= S + S_1 + S_2 + S_3 & a > h, \\
S_{\text{all}} &= S + 0.5(S_1 + S_2 + S_3) & h < a < 2h, \\
S_{\text{all}} &= S & a > h,
\end{align*}
\]

Fig. 3.5.2. Determination of the design windage area;

1. an area of the front girder, if a distance between the girders is less than the front beam height;
2. the total front girder area and 50 % of area of each girder, if a distance between the girders is equal to or exceeds the girder eight but less than double girder height;
3. the total girder area, if a distance between the girders is equal to or exceeds its double height.

Area of rear girders not covered by the front girder shall be entirely included to the windage area.

**Note**: Stability of floating cranes with turning boom shall be checked at the position of the boom turned to a side in the frame plane. Herewith, an effect of heeling moment due to gust wind effect shall be taken in the same direction as the heeling moment due to the turned boom and a load on hook.

#### 3.5.3
Maximum permissible angle of heel \( \theta'_{\text{perm}} \) shall be taken equal to one of the following angles, whichever is less, but not more than 6°:

- 1. deck entrance angle
- 2. angle determined at a waterline laying 75 mm bellow the edges of free-flooding openings maximum angle, at which operation of crane equipment is allowed.
3.5.4 When assessing stability of the floating cranes under the dynamic wind pressure at initial static heel due to the turned boom with a load on the hook, the maximum permissible moment is calculated by the formula, kN·m

\[ M_{\text{perm}}' = 0.0087 D \theta'_0 \left( \theta_{\text{perm}}' - \theta'_{\text{cargo}} \right), \]  

(3.5.4)

where \( D \) — weight of the ship corresponding to the draught up to actual waterline, kN;

\( \theta'_0 \) — metacentric height, m, calculated with due regard to correction for the effect of free surfaces of liquid cargoes according to 1.4.2;

\( \theta_{\text{perm}}' \) — maximum permissible angle of heel, deg., see 3.5.3;

\( \theta'_{\text{cargo}} \) — angle of heel due to turned boom with a load on hook, deg.

3.5.5 Design position of the center of gravity of the lifted load shall be taken in its suspension point to the boom.

3.5.6 Stability of the industrial ships (dredges, multi-bucket dredges, hydrographic and buoy vessels, anchor boats) by the main criterion (see 2.1) shall be checked for the following loading conditions:

.1 with full stores and fuel;
.2 with 10% of stores and fuel.

3.5.7 Stability of the loaders in working condition is checked with regard to the dynamic wind pressure, i.e. the following condition shall be met:

\[ M_{\text{heel}} < M_{\text{perm}}', \]  

(3.5.7)

where \( M_{\text{heel}} \) — heeling moment due to dynamic wind pressure, kN·m, determined according to 2.2, here the design wind pressure shall be taken equal to 400 Pa regardless of the ship’s class and the height of windage centre above the plane of actual waterline

\( M_{\text{perm}}' \) — maximum permissible moment, kN·m, determined with due regard to initial inclination \( \theta'_{\text{heel}} \) due to unsymmetrical loading in conveyers and cargo pipes by the formula (3.5.4), in which an angle \( \theta'_{\text{heel}} \) shall be taken instead of angle \( \theta'_{\text{cargo}} \).

3.6 HYDROFOIL CRAFT

3.6.1 This Chapter applies to hydrofoil craft of O-IIIP, O, P and J1 classes.

3.6.2 The requirements specified in 3.1.7, 3.1.10 and 3.1.11 do not apply to hydrofoil craft.

The other requirements of this Part of the Rules apply to hydrofoil craft when in displacement mode.

3.6.3 Stability shall be checked in loading conditions specified in 3.1.1 for the following modes:

.1 displacement mode;
.2 transition mode;
.3 operational mode.

Stability in displacement mode shall be checked by calculation method, and in transitional and operational modes – by model tests. Stability characteristics shall be finely adjusted: for the displacement mode, from the lead ship inclination test results, for the transitional and operational modes, from experimental investigations carried out during commissioning trials of the lead ship.

The test program, the test report, as well the Information on Stability and Floodability made up on the basis of calculations and experiments shall be submitted to the River Register for consideration.

3.6.4 Stability in the displacement mode shall be such that inclination of a ship from a horizontal does not exceed 8° in case of possible uncontrolled movements of passengers (i.e., where all free spaces accessible for passengers have been occupied) and angle of heel resulting from simultaneous effect of heeling moments due to crowding of passengers on one side and due to turn does not exceed 15°.

The heeling moment due to turning, kN·m, is calculated by the formula:

\[ M_w = 0.23 z_g D^2 \bar{D} / L, \]  

(3.6.4)

where \( z_g \) — height of the centre of gravity above the base line, m;
3.6.5 In transitional mode heel of a ship when moving at straight course in loading condition as in 1.3.2.2 and crowding of passengers on one side shall not exceed 15°.

3.6.6 In operational mode in loading condition as in 1.3.2.2, angle of heel when turning toward the heel due to passenger crowding at one side shall not exceed 10°.

3.7 HOVERCRAFT

General requirements

3.7.1 This Chapter applies to all hovercraft of O, P and J classes.

Requirements specified in 2.2.1, 2.2.5, 2.2.6, 2.3.4, 2.3.5, 2.4, 3.1.2, 3.1.5 to 3.1.7, 3.1.9 to 3.1.11, 3.1.13, 3.2.2, 3.2.4, 3.3 to 3.5 are not applicable for stability checking of hovercraft in air cushion mode.

3.7.2 Stability of hovercraft shall be substantiated by design-experiment way using the methods developed by the designer and approved by the River Register.

3.7.3 Experimental studies may be performed not in full or may be omitted, when, together with submitting the calculations to the River Register, the test results of the similar prototype ship prove the compliance with the requirements to stability properties which shall be determined experimentally.

3.7.4 Stability of hovercraft shall be checked for all the loading conditions specified in 1.3.1 for two modes:

1. navigation in displacement mode;

2. air cushion mode.

Stability characteristics shall be finely adjusted for displacement mode on the basis of inclination test, as well as speed and manoeuvring trials of the given hovercraft or the lead ship, and for air cushion mode – on the basis of experimental investigations under the most unfavourable operational conditions held during the commissioning trials of the hovercraft.

Note: Experimental stability testing of full-scale ships may be conducted for the most unfavourable loading condition only; this loading condition shall be determined according to the results of calculations or model tests. If the most unfavourable condition is minimum loading of the ship, the least heeling weights shall be used to induce the corresponding heeling moment.

3.7.5 Values of maximum permissible angles of heel shall be refined from experimental dependences of angle of heel vs. heeling moment, ship speed, and rudder angle.

Basic requirements for stability of skeg hovercraft

3.7.6 Heeling moment due to gust wind effect in air cushion mode, kN·m, is calculated by the formula:

\[ M_{heel} = 0.001kpS(z_w - 0.5T), \]  

(3.7.6)

where

\[ k \] — coefficient, see 3.7.7;

\[ p \] — assumed design dynamic wind pressure, Pa, determined according to 2.2.2;

\[ S \] — windage area of the ship at the draught corresponding to actual waterline, m², determined according to 2.2.3 and 2.2.4;

\[ z_w \] — height of the windage centre above the base plane of the ship at the level of lower skeg edges, m;

\[ T \] — average draught corresponding to actual waterline in air cushion mode, m.

3.7.7 Coefficient \( k \) considering the effect of the ship’s speed in air cushion mode on aerodynamic force is calculated by the formula:

\[ k = 1 + 0.711\sqrt{v}, \]  

(3.7.7)

where \( v \) — ship’s full speed, m/s.

3.7.8 Heeling moment due to gust wind effect in displacement mode shall be determined in accordance with 2.2; coefficient \( a_1 \) (formula (2.2.6-1)) shall be taken equal to unit regardless of the ratio \( B/T \).

3.7.9 Maximum permissible moment \( M_{perm} \) for ships of all classes regardless of values of \( M_{heel} \) shall be determined for air cushion mode according to the dynamic or static stability
Additional Stability Requirements for Various Ship Types

3.7.10 Maximum permissible moment \( M_{\text{perm}} \) for the ships of O-PIP and O classes shall be determined by means of plotting carried out considering roll, the design amplitude of which in air cushion and displacement modes shall be determined by model and full-scale tests.

**Note:** For stability calculations by the main criterion, the stability curve drawn up for air cushion hovering at-rest mode may be used.

3.7.11 Stability of passenger and cargo-and-passenger ships by the main criterion specified in 3.7.6 to 3.7.10 shall be checked for the loading conditions specified in 3.1.1.

3.7.12 Stability of passenger ships shall be sufficient when passengers are crowding at one side in all speed range in both air cushion and displacement modes. In air cushion mode, the following condition shall be met:

\[
\theta_p < \theta_{\text{perm}}, \quad (3.7.12)
\]

where \( \theta_p \) — angle of heel due to crowding of passengers on one side, deg., according to 3.1.3;

\( \theta_{\text{perm}} \) — maximum permissible angle of heel taken according to 3.1.4.

Angle of heel at the corresponding heeling moment and speed shall be taken equal to maximum angle of heel with due regard to experimental dependence of angle of heel upon the ship’s speed and the heeling moment (see 7.1 of Appendix 4).

For displacement mode stability of a hovercraft shall be checked according to 3.1.2 – 3.1.6.

3.7.13 Stability of passenger ships due to crowding of passengers at one side shall be sufficient at the maximum dynamic heel arising in the evolution period of turn in air cushion and displacement modes, i.e. the following condition shall be met:

\[
\theta_c < \theta_{\text{perm}}, \quad (3.7.13)
\]

where \( \theta_c \) — maximum angle of heel, deg., arising during the ship turning circle at passenger crowding at one side and determined experimentally (see 7.2 of Appendix 4)

\( \theta_{\text{perm}} \) — maximum permissible angle of heel, deg., taken according to 3.1.8.

3.7.14 Stability of passenger ships with a centre of windage located over 2 m above an actual waterline plane shall be sufficient at crowding of passengers on one side in case of static wind effect.

For air cushion mode, the following condition shall be met:

\[
\theta_{\text{wp}} < \theta_{\text{perm}} \quad (3.7.14)
\]

where \( \theta_{\text{wp}} \) — angle of heel (see 3.7.12) due to passenger crowding at the heeling moment (3.1.3) with simultaneous static wind pressure (see 3.7.15);

\( \theta_{\text{perm}} \) — maximum permissible angle of heel, determined according to 3.1.4, which is not limited here by 10° or 12°.

For displacement mode, stability shall be checked according to 3.1.10; coefficient \( a_3 \) necessary for determining the heeling moment \( M_w \) (see 3.1.11) shall be taken equal to zero regardless of the B/T ratio.

3.7.15 Heeling moment due to static wind effect in air cushion mode, kN·m:

\[
M_w = 0.001k\rho_pS_w(z_w - 0.5T), \quad (3.7.15)
\]

where \( k \) — coefficient determined according to 3.7.7 with replacing dynamic wind pressure \( \rho \) by static wind pressure \( \rho_p \) equal to 0.47 \( \rho \)

\( \rho_p \) — assumed design static wind pressure, Pa, which shall be taken equal to 0.47 of gust wind pressure adopted from Table 2.2.2 depending on the ship’s class and the height of the windage center above the actual waterline plane

3.7.16 Stability of cargo ships shall be checked by the main criterion according to 3.7.6 to 3.7.10 considering the requirements in 3.2.1.

3.7.17 For all cargo ships with centre of windage located over 2 m above the plane of actual waterline, stability shall be checked at static wind effect.
When a ship is moving on air cushion, the following condition shall be met:

\[ \theta_w < \theta_{perm}, \]  

(3.7.17)

where \( \theta_w \) — angle of heel due to static wind effect, deg., at heeling moment \( M_w \) calculated by the formula (3.7.15)

\[ \theta_{perm} \] — maximum permissible angle of heel, deg., see 3.2.3

For displacement mode, stability shall be checked according to 3.2.2 considering 3.7.14.

3.7.18 For all cargo ships in air cushion and displacement modes, stability shall be checked in the evolution period of turn, i.e. the following condition shall be met:

\[ \theta_{\text{turn}} < \theta_{\text{perm}}^{\text{\text{ turn}}}, \]  

(3.7.18)

where \( \theta_{\text{turn}} \) — maximum angle of heel, deg., arising in the evolution period of turn and obtained by experiment (see 7.2 of Appendix 4);

\[ \theta_{\text{perm}}^{\text{\text{ turn}}} \] — maximum permissible angle of heel, deg., see 3.2.5.

Additional requirements for stability of amphibian hovercraft

3.7.19 Stability in displacement mode shall be checked for all the loading conditions specified in 1.3.1 in the same way as for displacement ships considering the specifics of amphibian hovercraft.

3.7.20 Stability in air cushion mode shall be proved by results of experiments carried out during commissioning trials of the lead ship at the most unfavourable operating conditions according to the program developed by the designer and approved by the River Register.

3.8 HIGH SPEED DISPLACEMENT SHIPS

3.8.1 Stability of high speed displacement ships (with length-based Froude number \( \text{Fr}_L = \sqrt{gL} > 0.36 \)) shall be checked during the trials of the lead ship.

Stability shall be checked at turning in still water at consecutive stepped increase of the rudder angle including the hardover to a side contrary to crowding of passengers (for \( \backslash \) passenger ship), and at consecutive stepped increase of engine rpm up to the maximum one.

3.8.2 When trials of a passenger ship to ensure appropriate displacement, location of centre of gravity and initial angle of heel in case of crowding passengers on one side, a specially taken and lashed solid ballast shall be used.

3.8.3 During the trials, the following shall be contained in the test report:

- displacement;
- forward and aft draught;
- engine rpm and respective ship speed;
- water depth;
- weather conditions;
- initial angles of heel;
- angles of heel for each trial mode;
- rudder angles;
- water level on the ship sides at heel.

3.8.4 Angles of heel obtained during the trials shall be compared with the respective permissible angles of heel as per additional requirements to various types of ships (see 3.1 to 3.4).

3.8.5 On the basis of trials, necessary restrictions shall be entered in the Information on Stability and Flooding with regard to engine rpm and rudder angles.

3.8.6 The test program, the test report, as well the Information on Stability and Flooding made up on the basis of calculations and experiments are subject to special consideration by the River Register.

3.9 CATAMARANS

General requirements

3.9.1 Requirements of the present Chapter apply to catamarans of the M, O, P and \( \backslash \) classes, for which permissible angle of heel does not exceed the angle of coextensive inclination, when a waterline plane touches a bilge of exposed hull in the midship section.

Requirements in 2.2.5, 2.2.6, 2.4, 3.1.7, 3.1.11 do not apply to catamarans. The rest
requirements apply to catamarans as far as they are applicable and do not contradict with requirements of the present Chapter.

**Basic stability requirements for catamarans**

3.9.2 Reduced heeling arm for catamarans due to the dynamic wind pressure applied to the ship is calculated by the formula:

\[ z = z_w - 0.5T, \]  
(3.9.2)

where \( z_w \) — height of the centre of windage above the base plane of ship, m;

\( T \) — average draught of catamaran at actual waterline, m.

3.9.3 Design roll amplitude, deg, for catamarans of the respective class shall be taken from Table 3.9.3 depending on \( q_B \) and \( V/2L \) (where \( B, L \) and \( V \) are breadth, length and volume displacement of the catamaran respectively). Coefficient \( q, \text{s}^{-2} \), shall be calculated by the formula:

\[ q = \left( \frac{z_m - z_g}{i} \right), \]  
(3.9.3-1)

where \( z_m \) — height of transverse metacentre, m;

\( z_g \) — height of centre of gravity above the baseline, m;

\( i \) — relative moment of inertia of a mass including added mass of liquid, m·s²;

\[ i = \frac{z_g^2}{g} \left[ 5.79 B_{\text{hull}}^2 \left( \frac{z_g}{z_g + 0.61} \right)^2 + 1 \right] / (3g), \]  
(3.9.3-2)

\( B_{\text{hull}} \) — breadth of catamaran hull, m, amidships at a level of the actual waterline;

\( g \) — acceleration of gravity, m/s².

3.9.4 Height of transverse metacentre of the catamaran is calculated by the formula, m:

\[ z_m = \alpha B_{\text{hull}} b \left( \frac{\alpha}{11.4 + (\tau + 0.5)^2} + \delta \left[ \frac{b^2 (\alpha + \beta)}{\beta} \right] \right) / \delta, \]  
(3.9.4)

where \( \alpha \) — actual waterplane coefficient for actual waterline of catamaran hulls;

\( b \) — ratio of the hull breadth \( B_{\text{hull}} \) and the draught \( T \);

\( \delta \) — block coefficient of catamaran hulls;

\( \tau = C / (2B_{\text{hull}}) \) — relative horizontal clearance of catamaran hulls;

\( C \) — distance between inner sides of hulls at a level of actual waterline amidships, m.

**Additional stability requirements**

3.9.5 Dynamical heeling moment, kN, applied to a passenger catamaran in the evolution period of turn is calculated by the formula:

\[ M_{\text{turn}} = 0.03 \sqrt{v_0} D \left( \frac{z_g - 0.5T}{L} \right), \]  
(3.9.5)

where \( v_0 \) — catamaran speed before entering the turning taken equal to full straight ahead speed, m/s;

\( D \) — catamaran weight at draught according to actual waterline, kN;

\( z_g \) — see 3.9.3

\( L \) and \( T \) — catamaran’s length and average draught at actual waterline, m, respectively.

3.9.6 Heeling moment applied to passenger catamaran due to static wind effect, calculated by the formula, kN-m:

\[ M_w = 0.001 p_w S \left( z_w - 0.5T \right) \quad \text{(3.9.6)} \]

where \( p_w \) — assumed design static wind pressure, in Pa, which shall be taken equal to 0.47 of respective dynamic pressure according to Table 2.2.2 depending on the ship’s class and the height of the windage center above the actual waterline plane;

\( S \) — windage area calculated as per 2.2.3 and 2.2.4, \( m^2 \);

\( z_w \) — height of the centre of the windage area above the base plane when the ship is in upright position, m;

\( T \) — see 3.9.5.

3.9.7 When checking stability of a cargo catamaran by the formula (3.2.4), dynamic heeling moment \( M_t \) applied to the catamaran during the ship turning circle shall be calculated by the formula (3.9.5).

3.9.8 For catamaran tugboats, in formulae (3.3.3), (3.3.8-3), (3.3.8-4) and in Tables 3.3.4, 3.3.8-2 and 3.3.8-3, \( B \) shall be replaced by \( B_{\text{hull}} \), i.e. the total breadth of a catamaran tugboat at a design waterline, m.

3.9.9 When checking stability of catamaran tugboats, the heeling moment shall be calculated by formulae (3.3.3) and (3.3.8-1), and checked by the formula

\[ M_{\text{hull}} = 0.001 p_w S \left( z_w - 0.5T \right) + k \left( z_h - 0.5T \right) P_h \quad \text{(3.9.9)} \]

where \( p_w \) — assumed design dynamic wind pressure, Pa, taken according to the ship class as per Table 2.2.2;

\( S \) — windage area of the ship, \( m^2 \);

\( z_w \) — height of the centre of the windage area above the base plane, m;

\( T \) — average draught of the catamaran at actual waterline, m;

\( k \) — coefficient equal to 1.75 for catamarans of M class and 1.25 for catamarans of O, P and J classes;

\( z_h \) — height of the application point of pull force above the base plane of the ship, m;

\( P_h \) — pull force in the tow line, kN. If a value of the pull force is unknown, it shall be taken equal to 0.0163\( P_e \), \( P_e \) is rated output of main engines, kW.)
4 FLOODABILITY CRITERION

4.1 GENERAL REQUIREMENTS

4.1.1 Forepeak, afterpeak and engine room on all the ships shall be enclosed by watertight bulkheads.

4.1.2 For floodability calculations, the dimensions of the side and bottom damages shall be taken according to 4.1.3 to 4.1.6. A rectangular parallelepiped is assumed as a form of damage.

4.1.3 The dimensions of the hull side damages, except oil tankers and passenger ships of M-CPI class shall be taken as follows:

1. length of damage: 4 % of the ship’s length \( L \);
2. transverse extent measured from the inner surface of the outer plating at right angles to the centre plane: 0.075 \( B \) or 0.9 m whichever is less;
3. vertical extent: from the base line upwards without limit.

4.1.4 The following extent of side damage of oil tankers and passenger ships of M-CPI class shall be assumed:

1. length of damage: \( L^{2/3} / 3 \) for the oil tankers of M-CPI class and \( 3.0 + 0.03 \times L \) for the passenger ships of M-CPI class;
2. transverse extent measured from the inner surface of the outer plating at right angles to the centre plane at the level corresponding to summer freeboard, shall be \( B/5 \);
3. vertical extent: from the base line upwards without limit.

4.1.5 The following extent of bottom damage, except of oil tankers and passenger ships of M-CPI class, shall be assumed:

1. length of damage: 4 % of the ship’s length \( L \);
2. transverse extent: 0.1 \( B \);
3. vertical extent: 0.05 \( B \) or 0.8 m whichever is less.

4.1.6 The following extent of bottom damage of oil tankers and passenger ships of M-CPI class shall be assumed:

1. Longitudinal extent is \( L^{2/3} / 3 \) on the length equal to 0.3 \( L \) from the forward perpendicular and 5 m throughout the rest part of the bottom;
2. Transverse extent is \( B/6 \) or 5 m whichever is less;
3. Vertical extent is \( B/15 \) from the base line.

4.1.7 When ship’s damage of extent less than specified in 4.1.3 to 4.1.6 may worsen damage trim and/or damage stability, this variant of damage shall be considered when making checking calculations of floodability.

4.1.8 If the distance between two adjacent transverse watertight bulkheads is less than the dimensions of the damage specified in 4.1.3 to 4.1.6 or the transverse bulkhead of oil tanker of M-CPI class has a step of a length over 3.05 m within the area of assumed damage, then the respective compartment shall be added to any of the adjacent compartments at the option of the designer during the damage stability check.

Here, for all compartments of the hull the damage mid-length shall be assumed at the compartment mid-length. The forepeak and afterpeak shall be considered as separate compartments.

4.1.9 If there are any pipelines, channels or tunnels located within the area of assumed damage on the oil tanker of M-CPI class, their design shall prevent water from entering the compartments to be assumed to be non-flooded.

4.1.10 In checking calculations of floodability the design volume of flooded compartments shall be taken with due consideration of volume permeability coefficient of
each room of the compartment which shall be taken as equal to ships of all classes, except to passenger ships of M-CPI class:

- for double-side and double-bottom compartments, ballast tanks, empty non-refrigerated holds, free under-deck compartments of flush deck ships: 0.98
- for accommodation and passenger spaces, dry forepeak and afterpeak compartments, spaces occupied by empty vehicles: 0.95
- for empty refrigerated holds: 0.93
- for engine rooms of medium and large ships (L > 40 m): 0.85
- for engine rooms of small ships (L < 40 m): 0.80
- for spaces occupied by general cargoes, ship’s stores: 0.60
- for holds occupied by cargoes in bulk, including coal: 0.55
- for holds occupied by timber cargo: 0.35
- for holds occupied by flour or cement in bags: 0.25

4.1.11 Permeability coefficient of the tanks intended for liquid cargo transportation on oil tankers of M-CPI class shall be taken equal to:

- for the tanks intended for consumable liquids whichever results in more severe requirements: 0 or 0.95
- for the tanks intended for other liquids considering any possible liquid leakage from damaged tanks as well as the possibility of their partial filling: 0 to 0.95

4.1.12 For compartments that include spaces of different purpose, the volume permeability coefficient shall be calculated by the formula:

\[ k_v = \frac{k_{vi}V_i}{\sum V_i}, \]  

(4.1.12)

where \( V_i \) — total theoretical volume of separate rooms in the compartment

\( k_{vi} \) — volume permeability coefficient taken with due regard of the purpose of those rooms

4.1.13 The surface permeability coefficients \( k_s \) used when calculating the areas, static moments and inertia moments of the lost waterline area in flooded compartment for the purpose of taking into account the cargo, machinery, equipment etc., in way of the damaged waterline, shall generally be adopted equal to volume permeability coefficients as in 4.1.10. For rooms not occupied by any substantial quantities of cargo, machinery and equipment in way of the damaged waterline, the surface permeability coefficients shall be adopted equal to the arithmetic mean of unity and the volume permeability coefficient.

4.1.14 Covers of companion and light hatches, manholes, scuttles, glasses and outer doors shall meet the requirements of the national standards.

4.2 REQUIREMENTS FOR DAMAGE TRIM AND STABILITY AT FLOODING THE COMPARTMENTS

4.2.1 The requirements of this Chapter apply to all the ships, except passenger ships of M-CPI class, the requirements to which are specified in 4.3.

4.2.2 The requirements of the Rules to floodability of the ships shall be considered met, if at flooding the compartments specified in 4.2.3:

1. Margin line is not immersed;
2. Lower edges of free-flooding openings through which overboard water may spread to non-damaged compartments are located before righting above the damage waterline for:

- for the passenger ships, crew boats, special purpose ships and non-passenger ships carrying organized groups of people of M-CPI, M-P, M-O-P, O and P classes with a length of \( \geq 25 \text{ m} \) for the ships of M-CPI, M-P and M classes except those specified above, as well as passenger ships, crew boats, special purpose ships and non-passenger ships carrying organized groups of people of M-CPI, M-P, M-O-P and O classes with a length of < 25 m for the passenger ships, crew boats, special purpose ships and non-passenger ships carrying organized groups of people of P class with a length of < 25 m and for other ships

Floodability Criterion

.3 Angles of heel before and after righting do not exceed the values specified in 4.2.8 and 4.2.9;
.4 Damage stability complies with the requirements in 4.2.10 and 4.2.11.

4.2.3 The requirements to floodability shall be provided at flooding:
.1 the forepeak and afterpeak individually, for ships of all types and classes;
.2 each compartment individually, for oil tankers of M-СП class, for passenger ships and ships carrying organized groups of people and specific personnel of М-СП, М-ПП, М, О-ПП, О and Р classes (considering 4.2.1); ice breakers; self-propelled platform ships of M-СП, M-ПП, М, О-ПП and О classes; crewed reinforced concrete ships with a length over 25 m;
.3 the forepeak and afterpeak individually in one hull or both hulls, for catamarans;
.4 the forepeak and afterpeak individually in one skeg and in both skegs simultaneously, for skeg type for skeg type hovercraft;
.5 each two adjacent compartments adjoining to the board or transom, for all non-crewed reinforced concrete ships with a length of 25 m and more;
.6 each compartment individually in the dredge cut area, for bucket dredges of M-СП, М-ПП, М, О-ПП and О classes;
.7 each double bottom and/or double side compartment individually, for dry cargo ships of M-СП class.

Note: The requirement of 4.2.3.2 may be omitted for passenger spaces of hovercraft and hydrofoil craft; those ships shall keep positive buoyancy when these spaces are flooded.

4.2.4 At floodability calculations for the ships of all types and classes, flooding of the machinery space shall be taken into account irrespective of the requirement on providing floodability at flooding the machinery space.

4.2.5 When designing ships of all types and classes, the damage waterline and damage stability shall be checked by calculations at flooding of each compartment individually with submitting the calculations to the River Register. The results of the calculations shall be stated in the Information on Stability and Floodability.

4.2.6 When checking the ship's floodability at flooding the compartments, the parameters of damage trim and stability shall be determined by constant displacement method.

4.2.7 For passenger ships, damage stability shall be checked on the assumption that all the passengers are crowding on the uppermost decks they are permitted to be. The distribution of passengers shall be assumed according to 3.1.3.

4.2.8 In the final stage of unsymmetrical flooding before the righting measures, the angle of heel shall not exceed:
   for passenger ships 15°
   for non-passenger ships 20°

4.2.9 For unsymmetrical flooding after the righting measures, the angle of heel shall not exceed:
   for passenger ships 7°
   for non-passenger ships 12°

4.2.10 Transverse metacentric height determined by the constant displacement method shall be at least 0.05 m in the final stage of flooding for stable equilibrium state at unsymmetrical flooding and for non-inclined position at symmetrical flooding, before appropriate measures to increase metacentric height are taken.

4.2.11 The static stability curve of a damaged ship shall have a sufficient positive lever arm section. In the final stage of flooding and after righting, for all the ships other than flush deck ships, the following shall be provided:
   .1 the maximum lever arm of the static stability curve of not less than + 0.1 m;
   .2 the length of the positive arm section of the damage stability curve to the angle of downflooding is at least 30° at symmetrical flooding and at least 20° at unsymmetrical flooding.

For non-self-propelled flush deck ships, these norms are recommended.

4.2.12 Calculations to conform compliance to the requirements for damage trim and sta-
bility shall be made for such a number of loading conditions to be encountered in service and being the most unfavourable from the point of view of trim and stability, that, based on these calculations, one could assure that in all other cases the damaged ship would be in a better condition as regards damage trim and stability. Here, the following shall be considered: the actual configuration of damaged compartments, type of covers of openings, presence of longitudinal bulkheads and enclosures watertight sufficiently so that these structures render the flow of water through the ship completely or keep the tightness temporarily.

4.3 REQUIREMENTS TO SUBDIVISION, DAMAGE TRIM AND STABILITY AT FLOODING THE COMPARTMENTS OF THE PASSENGER SHIPS OF M-CII CLASS

Permissible length of compartments in passenger ships

4.3.1 The maximum permissible length of a compartment having its centre at any point in the ship’s length is obtained from the floodable length by multiplying the latter by an appropriate coefficient called the coefficient of subdivision.

When determining the floodable length \( l_{\text{lim}} \), the margin line may be immersed in the area of flooding.

4.3.2 For ship of a given length, appropriate coefficient of subdivision shall be determined by the criterion in service numeral \( C_S \) (hereinafter called the criterion numeral) depending on the parameters \( P \) and \( P_1 \), where \( P \) — the whole volume of the passenger spaces below the margin line, m³;

\[ P = N \times kN \]

\( k \) — passenger capacity

\( N \) — coefficient calculated by the formula:

\[ k = 0.056L \]  

\( L \) — ship’s length, m

The criterion numeral is calculated by the formulae at \( P_1 \):

\[ P_1 > P \quad C_s = \frac{72(M + 2R)}{(V + P_1 - P)} \]  

\[ P_1 \leq P \quad C_s = \frac{72(M + 2P)}{V} \]

where \( M \) — volume of the machinery space with addition of the volume of any permanent oil fuel tanks situated above the inner bottom and forward or abaft the machinery space, m³

\( V \) — whole volume of the ship below the margin line, m³

For ships without continuous bulkhead deck, the volumes of spaces shall be taken up to the actual margin lines used in determining the floodable lengths.

4.3.3 Forepeak or collision bulkhead shall be watertight up to the bulkhead deck; that bulkhead shall be located at least 5 % of the ship’s length clear of the forward perpendicular and not over 3 m with addition of 5 % of the ship’s length.

4.3.4 In ships with a length of 100 m and more, one of main transverse bulkheads abaft the collision bulkhead shall be located apart from the forward perpendicular at the distance not exceeding the permissible length of compartment.

4.3.5 The subdivision abaft the collision bulkhead of the ships with length of less than 131 m, but not less than 79 m having a criterion numeral equal to

\[ S = \left(3574 - 25L\right)/13, \]

shall be governed by the subdivision coefficient equal to 1;

with criterion numeral \( C_s = 123 \) and more — by subdivision coefficient equal to \( B \):

\[ B = 30.3/(L - 42) + 0.18 \]

with an intermediate criterion numeral between \( C_s = S \) and \( C_s = 123 \) — by subdivision coefficient equal to \( F \).
$$F = 1 - (1 - B)\left(C_s - S\right)/(123 - S).$$ \hspace{1cm} (4.3.5-3)

4.3.6 Subdivision abaft the collision bulkhead in ships less than 131 m but not less than 79 m in length, having a criterion numeral less than $S$, as well as ships less than 79 m in length, shall be governed by the subdivision coefficient equal to unit.

4.3.7 Requirement of 4.3.6 is applicable for ships of any length allowed for transportation of more than 12 passengers but not exceeding $L^2/60$ or 50, whichever is less.

4.3.8 Transverse bulkhead may be stepped provided that it meets one of the following conditions:

1. The combined length of the two compartments separated by the bulkhead in question does not exceed either 90% of the floodable length or twice the permissible length, except when in ships having a coefficient of subdivision greater than 0.9 the combined length of the two compartments in question shall not exceed the permissible length;

2. Additional subdivision is provided in way of the step to maintain the same measure of safety as that secured by a plane bulkhead;

3. The compartment, over which the step extends does not exceed, the permissible length corresponding to a margin line taken 76 mm below the step.

**Floodable length**

4.3.9 Calculations of the floodable length shall be made with due regard to the shape, draught and other characteristics of the ship in question.

4.3.10 In determining the floodable length, a uniform average permeability coefficient is applied throughout the whole length of each of the following portions of the ship below the margin line:

- engine room
- ship portion afore the machinery space
- ship portion abaft the machinery space

4.3.11 The average permeability coefficient $\mu$ throughout all machinery spaces shall be determined by the formula:

$$\mu = 0.85 + 0.1(a - c)/V,$$ \hspace{1cm} (4.3.11-1)

where $a$ — volume of the passenger spaces which are situated below the margin line within the limits of the machinery space, $m^3$  
$c$ — volume of between-deck spaces below the margin line within the limits of the engine room, which are intended for cargo or stores, $m^3$  
$V$ — whole volume of the engine room below the margin line, $m^3$

The average permeability coefficient $\mu$ of all the spaces located afore or abaft the machinery spaces shall be calculated by the formula:

$$\mu = 0.63 + 0.35a_1/V_1,$$ \hspace{1cm} (4.3.11-2)

where $a_1$ — volume of the passenger spaces which are situated below the margin line within the limits of forward of or abaft the engine room, $m^3$  
$V_1$ — whole volume of the part of the ship below the margin line within the limits of forward of or abaft the machinery space, $m^3$

**Damage stability**

4.3.12 Calculations confirming compliance of the requirements to damage stability shall be made for such a number of loading conditions to be encountered in service and being the most unfavourable from the point of view of trim and stability, that, based on these calculations, one could assure that in all other cases the damaged ship would be in a better condition as regards damage trim and stability.

4.3.13 At damage stability calculations, the design volume of the flooded compartments shall be calculated considering volume permeability coefficients of each compartment space, which shall be taken equal to:

- for the spaces occupied by the ship’s machinery and electrical equipment 0.85
- for the spaces occupied by stores and cargo 0.6
- for accommodation and passenger spaces, dry forepeak and afterpeak compartments, and empty cargo compartments 0.95
- for ballast tanks and other empty tanks 0.98
The permeability of tanks with liquid cargo shall be determined with due regard to replacement of cargo by outboard water.

4.3.14 Requirements to the ship’s stability are considered met if:

for the ship intended for carriage of less than 400 persons, at flooding of each separate compartment

or for the ships intended for carriage of 400 persons and more, at flooding a compartment or compartments (the number is determined depending on the damage location in any place along the ship length)

the trim parameters and stability elements of the damaged ship comply with the requirements in 4.3.15 to 4.3.21.

Requirements to trim and damage stability elements

4.3.15 In the final stage of flooding, the metacentric height of a ship determined by the constant displacement method shall be not less than 0.05 m.

4.3.16 The angle of heel at unsymmetrical flooding shall not exceed:

before the righting measures – 15°

after righting – 7° if one compartment is flooded and 12° if two adjacent compartments are flooded.

The righting time shall not exceed 15 minutes.

4.3.17 The margin line shall not be immersed; when closed openings are present through which outboard water may enter non-damaged compartments, the damage waterline shall be at least 0.3 m far apart of lower edges of such openings.

4.3.18 Damage stability curve of the damaged ship shall have a positive arm section to the angle of downflooding of at least 15°, measured from the balance position both before and after the righting measures of the ship or cross-flow actuation.

4.3.19 The area under the curve between the heeling angle corresponding to the equilibrium position of the ship and the least of the following values:

the angle, at which progressive flooding occurs

22° (from the initial point of the curve) if one compartment is flooded or 27° if two adjacent compartments are flooded simultaneously

shall be at least 0.015 m-rad

4.3.20 The residual positive righting arm within the damage stability curve section shall be determined considering the greatest of the following heeling moments:

.1 due to all passengers crowding at one side;

.2 due to launching all lifeboats and liferafts with their full complement of persons and outfit;

.3 due to wind pressure.

In this case, the maximum lever arm shall be equal to

\[ I_{\text{max}} = \frac{M_h}{D}, \]

where \( M_h \) — maximum heeling moment, kN-m

\( D \) — displacement, kN.

In all cases, this lever arm shall be not less than 0.1 m.

4.3.21 The heeling moments required for the determination of the residual righting lever arm shall be assumed on the basis of the following assumptions:

.1 When determining moments due to passengers crowding it is assumed that:

The density of distribution of passengers is assumed to be four persons per square metre.

The mass of each passenger is assumed to be 75 kg.

Passengers are crowing on free deck areas to one side on muster stations so that to provide the greatest heeling moment;

.2 When determining moments due to launching of all lifeboats and liferafts with their full complement of persons and outfit, it is assumed that:

All the lifeboats, rescue boats and liferafts of the one side to which the ship has got a
heel are assumed fully loaded, swung out and ready for launching.

Persons who are not in the life-saving appliances are not considered a source of additional heeling moment or righting moment.

Life-saving appliances at the opposite side are assumed to be stowed for sea;

When determining moments due to the wind pressure, the latter is assumed equal to $120 \text{ N/m}^2$, the design area is assumed equal to the windage area before damage and the lever arm equal to the vertical distance between the centre of effort and the point corresponding to half the mean draught of an intact ship.
5 FREEBOARD AND LOAD LINE

5.1 GENERAL REQUIREMENTS

5.1.1 The requirements of this Section apply to the inland and river-sea navigation ships engaged on coastal voyages.

On river-sea navigation ships engaged on international voyages, in addition to the load line marked according to the requirements of the International Convention on Load Line 66/88, the load line may be marked according to the requirements of this Section. The specified load line marked abaft the load line according to the International Convention on Load Line 66/88 in close proximity to the load line as far as practical.

5.1.2 Compliance with the requirements of the Rules as regards strength, stability and floodability of the ship is a necessary condition for assigning a freeboard.

5.1.3 For the wooden ships, composite ships or GRP ships, the freeboard height is assigned by the River Register if the designer submits the grounds and calculations made using the methods approved by the River Register.

5.1.4 The freeboard height assigned for the ship is fixed by marking a deck line and a load line on each side of the ship. On ships with a length of 10 m and less a freeboard marks may be omitted.

5.2 LOAD LINE MARKING FOR THE INLAND NAVIGATION SHIPS

5.2.1 The load line (Fig. 5.2.1-1) consists of a ring intersected by a horizontal line in the center and lines corresponding to maximum draughts.

A letter indicating the ship navigation area is marked above the horizontal line forward of the ring. Width of lines of the ring and all other load lines is 25 mm, the outer diameter of the ring is 250 mm, the length of the horizontal line which intersects the ring is 400 mm, the size of the letters is 100 × 60 mm with lines 15 mm wide.

If the freeboard height is less than 150 mm, the outer diameter of the ring of the load line may be decreased.

The upper edge of the horizontal line intersecting the ring shall pass through its centre; it is the line of the maximal draught for the class which is assigned to the given ship. The centre of the ring shall be placed on the same vertical with the centre of the deck line.

The deck line is usually applied so that its upper edge passes the intersection point of the outer surface of the freeboard deck and the outer surface of the side plating. The length of the deck line is 300 mm and width is 25 mm (see Fig. 5.2.1-1).

If the lowest side point of the upper surface of the freeboard deck is not located amidships, the deck line is applied amidships along the plane marked horizontally through the specified lowest side point.
If marking the deck line with the specified method is not possible, it may be applied from another fixed point on the side of the ship with respective correction of the freeboard height. The position of the specified point relative to the accepted deck of the freeboard shall be recorded in the load line certificate (see Fig. 5.2.1-2, distance \( a \)).

![Fig. 5.2.1-2 Position of the deck line for the ships with a rounded deck](image)

When a ship is intended for operation in water basins of different categories, then a vertical line and additional lines of maximum draughts 150 mm long shall be applied from the end of the ring’s horizontal line in the fore part of the mark (Figs. 5.2.1-3, 5.2.1-4, 5.2.1-5). The lines of maximum draughts of MC and OC ships on Fig. 5.2.1-5 are related to the inland navigation ships of M and O classes, which may operate in the areas with sea navigation conditions of respective categories.

![Fig. 5.2.1-3 Examples of the load lines of the ships of P and M classes](image)

Fig. 5.2.1-3 Examples of the load lines of the ships of P and M classes

The upper edges of the lines of maximum draughts shall comply with the ship’s freeboard height assigned for water basins of the respective categories.

![Fig. 5.2.1-4 Example of the load lines of the ships of O class](image)

**5.2.2** The load line and the deck line shall be applied on the plating amidships on each side.

On ships with side paddle wheels, two marks shall be placed on each side approximately 1/3 of the ship’s length apart from her extremities.

When the load lines are placed not amidships, the deck sheer shall be taken into account.

For sheered ships with the lowest deck point of the freeboard deck (zero ordinate of sheer) shifted abaft or ahead from the midship plane, the distance between the upper edge of the deck line and the upper edge of the maximum draught line which shall be placed amidships, shall be extended to the sheer ordinate in the midship section.

**5.2.3** Where the load line mark and subdivision load lines are places under the fender guard, the latter shall be cut so that its ends are clear of the load line mark and subdivision load lines for 100 mm.

**5.2.4** The load line shall be applied white or yellow on dark background or black on light background.

On steel ships, the load line shall be made of a steel sheet and welded or made by building-up fillets and painted according to the requirements of this Para.

On ships made of light alloys, horizontal lines of the load line shall be made of welded
or riveted strips of the same material as the hull; all the rest lines may be only punched and painted.

On ships with the hull made of GRP, the load line mark shall be made of plastic and glued.

On ships with wooden planking, the load line mark may be either cut and painted or only painted depending on the planking thickness.

5.2.5 For checking draughts and loading, in the fore and aft sections of the ship and for the ships with a length of more than 40 m and amidships, the draught marks (scales) shall be applied. When applying the draught scales amidships, they shall be located abaft the load line in close proximity to it. The manufacture, application and painting of the marks are made according to 5.2.4. For the ships with a length of less than 25 m, it is not required to meet this requirement.

5.3 LOAD LINE FOR THE RIVER-SEA NAVIGATION SHIPS

5.3.1 The load line, the general view and dimensions of which are specified on Fig. 5.3.1 shall be applied on board the ships of M-Ñ class.

5.3.2 The load line for the ships of M-Ñ class with a greater than minimum freeboard shall be applied according to Fig. 5.3.2.

The upper edge of the horizontal line intersecting the ring of the load mark shall be placed at a distance corresponding to a greater than minimum freeboard assigned measured downwards from the upper edge of the deck line.

Forward of the load line ring, the Fresh Water Load Line shall be applied at a distance calculated by the formula (5.3.2) considering actual salt water density in the sea navigation area:

\[ \Delta T = V (\gamma - 1)/q, \]

(5.3.2)

where \( \Delta T \) — distance between salt water and sea water load lines

\( \gamma \) — actual density of salt water in the navigation area, t/m³

\( V \) — volume displacement of the ship in salt water at a draught corresponding to the assigned freeboard, m³

\( q \) — weight of cargo, the acceptance or removal of which changes the ship draught by 1 cm in salt water with density \( \gamma \), t/cm

Forward of the load mark ring, the Fresh Water Load Line shall be applied at the distance corresponding to 1/48 of the draught above the centre of the ring. The distance may be specified taking into account the actual density of salt water in the area of navigation using the formula (5.3.2).

Abaft the load mark ring, the load lines shall be applied for navigation in inland water basins of categories M and O and in coastal sea areas with salt water where ships of classes M-ÏÐ and O-ÏÐ are allowed to operate.

5.3.3 Load line in ships of class M-Ñ with minimum freeboard assigned shall be applied according to Fig. 5.3.3.
Freeboard and Load Line

Fig. 5.3.3 Load line in ships of class M-ΠП assigned the minimum freeboard

The upper edge of the horizontal line of the ring shall be placed at a distance corresponding to the minimum summer freeboard measured downwards from the upper edge of the deck line.

Forward of the ring the following load lines shall be applied: the Summer Load Line (at the level of the load mark centre), the Fresh Water Load Line and the Winter Load Line for ships operating in the Baltic Sea, the Caspian Sea, the Black Sea and the Asov Sea.

For ships with a length over 100 m the Winter Load Line is omitted.

The Winter Load Line shall be applied under the Summer Load Line at the distance corresponding to 1/48 of the summer draught.

Abaft the ring, load lines shall be applied for navigation in basins of categories М and О and in coastal sea areas with salt water where ships of classes M-ΠП and O-ΠП are allowed to operate.

5.3.4 Periods, during which the Summer or Winter Load Lines are used for the ships of M-СП class with a length of up to 100 m, are specified in Table 5.3.4.

<table>

</tbody>
</table>

5.3.5 Load line for ships of class M-ΠП having an assigned freeboard (minimum or a greater than minimum) shall be applied as in Fig. 5.3.5.

The upper edge of the horizontal of the load mark ring shall be placed at a distance corresponding to the freeboard assigned measured downwards from the upper edge of the deck line.

Forward of the load mark ring, the Fresh Water Load Line shall be applied at the distance corresponding to 1/48 of the draught above the centre of the ring. This distance may be set by the formula (5.3.2) with due consideration of the water density in the sea navigation area.

Abaft the load mark ring, the load lines shall be applied for navigation in inland water basins of categories M, O and P and in coastal sea areas with salt water, where ships of class O-ΠП are allowed to operate.

The dimensions of the load line are taken according to Fig. 5.3.1.

5.3.6 Load line in ships of class O-ΠП with freeboard assigned shall be applied according to Fig. 5.3.6.

The upper edge of the horizontal of the load mark ring shall be placed at a distance corresponding to a greater than minimum freeboard assigned measured downwards from the upper edge of the deck line.

Forward of the load mark ring, the Fresh Water Load Line shall be applied at the distance corresponding to 1/48 of the draught above the centre of the ring. This distance may be calculated by formula (5.3.2) with due
Fig. 5.3.6 Load line in O-ΠP class ships

consideration of the water density in the navigation area.

Abaft the load mark ring, the load lines for navigation in inland water basins of categories O and P shall be applied.

The dimensions of the load line are taken according to Fig. 5.3.1.

5.4 MINIMUM FREEBOARD HEIGHT

5.4.1 Freeboard height for the ships with sheer taken according to Tables 5.5.2 and 5.5.4 and coaming heights taken according to Table 5.6.1 shall be set as follows:

.1 for the closed inland navigation ships according to Table 5.4.1-1 and Table 5.4.1-2.

<table>

</tbody>
</table>

For the passenger ships with a length of 100 m and more with enclosed first tier superstructure, the freeboard, \( m \), specified in Table 5.4.1-3 may be decreased by value \( \Delta F \) calculated by the formula:
\[
\Delta F = h_k l_a b_a / \left( 0.88 L_s B_s \right),
\]  
(5.4.1.4)

where \( h_k \) — the least of the following compared vertical dimensions, m:
- distances between the bulkhead deck and the lower edges of closed openings in outer walls of enclosed first tier superstructure;
- heights of coamings enclosing hatches in the freeboard deck

\( l_a, b_a \) — length and breadth, respectively, of the first tier superstructure, m

\( L_s \) — maximum length of the part of the ship below the margin line

\( B_s \) — maximum breadth of the part of the ship below the margin line

5.4.2 Minimum freeboard is determined by increasing the tabular freeboard determined according to 5.4.1 by the following corrections:

- For the closed inland navigation ships of Ë, Ð, Î and Ì classes and for the river-sea navigation ships of Î-ÏÐ and Ì-ÏÐ classes — according to the maximum values specified in 5.4.3;
- For the open inland navigation ships of Ë, Ð and Î classes and for the river-sea navigation ships of Ì-ÑÏ class — allowances determined according to 5.4.4 and 5.4.5 and considering deviation of the actual dimensions of the sheer, or the forecastle and poop, and coaming height from the dimensions specified in 5.5 and 5.6.

5.4.3 The freeboard height for the Ë, Ð, Î, Ì, Î-ÏÐ and Ì-ÏÐ class ships as obtained from Table 5.4.1-1 and 5.4.1-2 shall be corrected as follows:

- For the ships with the \( B/T < 4.5 \), the tabular freeboard height shall be increased by the correction value calculated by the formula, mm:

\[
\Delta H_{B/T} = 0.49 L (4.5 - B/T);
\]  
(5.4.3.1)

- For the ships with block coefficient \( \delta > 0.75 \), the freeboard height shall be increased by the correction value calculated by the formula, mm:

\[
\Delta H_{\delta} = \left[ 18.2 L + 17 \left( 4.5 - B/T \right) \right] \cdot (\delta - 0.75) .
\]  
(5.4.3.2)

If \( B/T \geq 4.5 \), in the formula (5.4.3.2) the \( B/T \) ratio shall be taken equal to 4.5;

- For the ships with the length to breadth ratio \( L/B < 5.5 \), the tabular freeboard height shall be increased by the correction value calculated by the formula, mm:

\[
\Delta H_{L/B} = 6.7 L (5.5 - L/B) .
\]  
(5.4.3.3)

5.4.4 If the sheer or dimensions of the forecastle and poop are different from the values specified in 5.5, the freeboard height shall be increased by a value that provides the two following conditions met:

- Buoyancy reserve shall be not less than one determined for the ships with the sheer specified according to 5.5 or with the forecastle and poop;

- The static moments of the volumes, which result from the extended freeboard height relative to the midship plane, shall be not less than the static moments of the volumes for the ships with the sheer determined according to 5.5 or with forecastle and poop.

5.4.5 If the coaming height is less than that specified in the requirements in 5.6, the minimum freeboard height shall be increased by the difference between the tabular and the actual coaming heights.

The minimum height of coaming of hatches located on the open decks shall be at least 100 mm for ships of all classes.

Decrease of the freeboard height as compared with the value stated in Table 5.4.2 due to the increase of the coaming height is not allowed.
The coaming’s heights of other hatches may be less than tabular heights without correction of the freeboard height, if the hatch covers comply with the requirements in 1.2.1.10.

5.4.6 The minimum freeboard height of the closed inland navigation ships of Ë and Ð classes shall be not less than:
   For all the ships, except the tankers and platform ships:
   Ë class — 150 mm;
   Ð class — 250 mm;
   For tankers and platform ships:
   Ë class — 90 mm;
   Ð class — 160 mm.

5.4.7 The cargo platform guard of the platform ship shall be designed to prevent washing of the bulk cargo. The sum of the guard height and the freeboard height shall be at least one half of the wave height corresponding to the basin category where the ship operates.

5.4.8 For the awning barges of O, P and Ë classes carrying cargo in the holds, the minimum freeboard height may be assigned same as for the dry cargo decked ships (see Table 5.4.1-1) provided that the awning and its gates are weathertight and the gate coaming height is not less than that provided for cargo holds (see 5.6.1).

Note: Awning is a light structure on the freeboard deck for cargo and passenger protection in bad weather conditions. Awnings gates are enclosure of an opening in the awning wall for cargo handling.

When these conditions are not met, the minimum freeboard height shall be assigned the same as for open ships.

5.4.9 For the dredgers, landing stages, guard ships and floating docks, the freeboard height shall be taken same as for the closed ships.

5.4.10 For the cargo ships loaded by hydromechanization means, the freeboard height shall be calculated in the same manner as for the tankers. While substantiating the possibility of transporting other types of cargo on these ships the freeboard height shall be assigned as for the open ships.

5.4.11 The freeboard height for skeg-type hovercraft shall be calculated as for the displacement ships.

Here, the freeboard is the distance to the upper edge of the deck line and, in the absence of the freeboard deck, the distance to the lower edge of openings, through which water may come inside the ship but not above the lower edge of window openings.

5.4.12 The freeboard of amphibian-type hovercraft with such design and shape of the hull, which differ from ordinary displacement ships, shall be assigned on condition that buoyancy reserve corresponding to at least 100 % of maximal mass displacement is provided.

5.5 SHEER, FORECASTLE AND POOP

5.5.1 On the ships of M-СІІ, M-ПП and M classes with the freeboard height to the forecastle deck in the fore perpendicular area (and in absence of the forecastle, to the freeboard deck) less than the sum of the minimum freeboard height amidships and sheer, the ordinate values of which are specified in this Section, it is recommended to fit the bulkwark in the bow.

5.5.2 For sheer line of ships without forecastle and poop shall be taken a broken line with ordinates on fore and aft perpendiculars taken according to Table 5.5.2 (except the ships of M-СІІ class) and ordinates at points located 0.15 of the ship’s length apart from the fore perpendicular and 0.07 of the ship’s length apart from the aft perpendicular being equal to 0.

</table>

Notes.
1. Sheer ordinates for the tankers are taken according to this Table with lowering the class, i.e. for the ships of M class, ordinates of the ships of O class are taken, for the ships of O class – ordinates of the ships of P class.
2. The sheer is not required for all the ships of Л class and for the tankers of P class.

The sheer ordinates shall be measured from a horizontal line coinciding with the upper edge of the deck line marked according to 5.2.

5.5.3 The sheer specified in 5.5.2 is not required for the ships of M-ПП, М, О-ПП, О and П classes, if the following conditions are met:

1. The forecastle height above the deck shall be at least: for the ships of М-ПП and М classes – 1000 mm, for the ships of О-ПП and О classes – 900 mm and for the ships of П class – 500 mm;

2. The forecastle length not less than 0.07 of the ship’s length for the ships of all classes;

3. The poop height above the deck not less than one half of the forecastle height for the ships of all classes;

4. The poop length not less than 0.03 of the ship’s length but not less than 2 m for the ships of all classes.

The ships of М-ПП and М classes with the sheer without the forecastle, in the bow extremity there shall be fitted with a bulwark with a length equal to the length of the forecastle determined according to 5.5.3.2.

Ships of М, О and П classes without sheer and the poop in the aft shall be fitted with a bulwark of the same length, but not less than 2 m.

5.5.4 The sheer ordinates $S$ for the closed ships of М-ПП class are regulated in Table 5.5.4.

<table>

They may be also calculated by the formulae:

for the bow
$$S = 1695 - 0.711L + 0.0127L^2 - 20595/L;$$

(5.5.4-1)

for the stern
$$S = 766 + 0.6L + 0.305 \cdot 10^{-2} L^2 - 8639/L,$$

(5.5.4-2)

where $L$ — ship length, m.

The sheer ordinates for the tankers of М-ПП class are determined according to Table 5.5.2 as for the tankers of М class.

5.5.5 The forecastle and poop dimensions for the ships of М-ПП class shall comply with the following requirements:

The forecastle height above the deck at least 1500 mm.

The forecastle length at least 0.07 of the ship’s length and at least half the ship breadth.

The poop height above the deck shall be at least half the forecastle height.

The poop length shall be at least 0.03 of the ship’s length but not less than 2 m.

5.6 ARRANGEMENT OF OPENINGS AND COAMINGS

5.6.1 For all the ships, except the ships of М-ПП class, the height of coamings from the upper edge of the deck plating of cargo and other hatches located on the freeboard deck and not protected by the superstructures or wheelhouses shall be not less than specified in Table 5.1.6.

* Other hatches include trunks, access holes, non-cargo holds, outer exits to the superstructures and wheelhouses, awnings.

For the ships of M-CP class, the height of the cargo hatch coamings shall be not less than 450 mm and for other hatches according to the requirements in 5.6.1 for the ships of M and M-IP classes.

5.6.2 The height of the cargo hatch coamings for the open ships of O, P and J classes shall be assigned according to the requirements in 5.4.1.2.

The coaming’s height of hatches in passenger ships where passengers are located in the hull’s compartments not closed by a deck or superstructure, shall be not less than the coaming’s height on open cargo ships.

5.6.3 Where the hatches are located inside the superstructures fitted with the closures as specified in this Chapter, the height of the hatch coamings may be taken as 75 mm for the ships of all classes.

5.6.4 Coamings of companion hatchways of M-CP class ships shall be at least 450 mm high when located on the open deck and at least 380 mm high when located on decks of the superstructures.

5.6.5 For the ships of M-CP class, coamings of doors leading to the open deck shall be at least 380 mm high, and coamings of doors leading to the superstructure deck at least 280 mm high.

5.6.6 The thickness of vertical plating of the companion hatchway coamings specified in 5.6.4 shall be equal to the thickness of the deck where the companion hatchways are located but not more than 8 mm.

5.6.7 The companion hatchway covers and all the outer doors of the superstructures, wheelhouses and lobbies for the ships of M-CP class shall be permanently attached and watertight. They shall be made of steel or material with fire-retardant properties not lower than wood impregnated with fire-proof substance (see 1.2.1.20, Part III of the Rules). Quick-action arrangements shall be provided for opening, closing and tightening the covers and doors which shall be capable of being used from both sides.

For passenger ships the requirements of the present paragraph apply only to covers of companion hatchways and outer doors of superstructures, wheelhouses and lobbies located on the freeboard deck.

5.6.8 The thickness of flat steel companion hatchway covers for the ships of M-CP class shall be not less than that of the shell or plating, on which they are fitted, but not more than 10 mm.

5.6.9 Cargo and other hatches located on the open areas of the freeboard deck for the closed ships of M-CP, M-IP, M, O-IP and O classes shall be fitted with watertight closures, and for the ships of P and J classes with weathertight closures.

Cargo hatches of class O ships may be fitted with weathertight closures, when the sum of the assigned freeboard height and the cargo hatch coaming is not less than 1200 mm.

Closures of the cargo hatches for the ships of M, O, P and J classes shall be rated for loading by the cargo weight which is assumed to be stowed on those closures, but the design load shall not be less than 2.45 kPa.

5.6.10 The requirements in 5.6.11 to 5.6.17 related to the closures are specified for steel machine-driven closures on the ships of M-CP class with weather-tightness secured by means of gaskets and batten-down devices.

5.6.11 The closures shall be rated for the weight loads from the cargo which is assumed to be stowed on those closures. However, in all the cases the minimum load depending on the ship’s length shall be assumed as linearly increased from 7.35 kPa at the ship’s length of 24 m up to 12.15 kPa at the ship’s length of 100 m. For the ships less than 24 m and more
100 m in length the weight load shall be taken as not dependent on the ship’s length and equal to the above limit values of 7.35 kPa and 12.15 kPa accordingly.

For the ships of M-Ç II 4.5 class, the minimum loads on hatch covers (except for the area at a distance of 25 % of the ship’s length abaft the bow perpendicular) are taken as equally distributed along the length and equal to 7.84 kPa at the ship’s length of 24 m and equal to 13.37 kPa at the ship’s length of 100 m. For the area at a distance of 25 % of the ship’s length abaft the fore perpendicular, the minimum load on hatch covers is taken changing by linear dependence from 8.33 kPa at the ship’s length of 24 m and from 14.59 kPa at the ship’s length of 100 m on bow perpendicular to 7.84 kPa at the ship’s length of 24 m and to 13.37 kPa at the ship’s length of 100 m on the aft border of the area. At the ship’s length above 24 m but less 100 m, the minimum loads on hatch covers are determined by means of linear interpolation.

5.6.12 When the rated load (see 5.6.11) is applied to closures, the stress in the closure components shall not exceed 0.4 of the yield point or 0.235 of the ultimate strength of the material, whichever is less.

5.6.13 A deflection of hatchway covers shall not exceed 0.0028/l (l — span of beams or bearing stiffeners of the cover).

5.6.14 Thickness of steel plating of hatchway covers shall not be less than 0.01 of the spacing of stiffeners or 6 mm, whichever is greater.

5.6.15 Parts of a driving unit of hatchway covers shall ensure the normal operation at ambient temperatures from −25 °C to +50 °C, heel up to 5° and the maximum trim by bow or stern due to full loading of one of the end holds.

5.6.16 Hatchway covers of cargo compartments in oil tankers shall be permanently attached and, when battened down, be water/gas-tight under inner carried liquid vapour pressure at least 24.5 kPa.

5.6.17 The steel plates of hatchway covers of cargo compartments in oil tankers shall be at least 8 mm thick and covers made of light alloys at least 10 mm thick. At every 400 mm of the cover length stiffeners made of strip of thickness equal to that of the cover and with a height of at least 80 mm shall be provided.

5.6.18 Cargo hatchway covers in ships of class M-Ç II shall be rated for the weight loads from the cargo, which is assumed to be stowed on those covers. The specific minimum load on the cargo hatch covers depending on the ship’s length shall be assumed as linearly increased from 4.90 kPa at the ship’s length of 24 m up to 9.81 kPa at the ship’s length of 100 m. For the ships less than 24 m and more 100 m in length the specific weight load shall be taken as not dependent on the ship’s length and equal to the above limit values of 4.90 kPa and 9.81 kPa accordingly.

5.6.19 Cargo hatchway covers and closures of other hatches and openings on open parts on the weather deck, lobbies, entrances and other openings in the superstructure on the main deck of class O-Ç ships as regards strength and weathertightness shall meet the requirements for class M ships; here, cargo hatchway covers shall be rated for the weight loads from the cargo which is assumed to be stowed on those covers. The minimum specific load on the cargo hatch covers depending on the ship’s length shall be assumed as linearly increased from 2.45 kPa at the ship’s length of 24 m up to 5.40 kPa at the ship’s length of 100 m. For the ships less than 24 m and more 100 m in length the specific weight load shall be taken as not dependent on the ship’s length and equal to the above limit values of 2.45 kPa and 5.40 kPa accordingly.

5.6.20 Ventilation heads located on the open parts of the freeboard deck shall have strong steel coaming with the height for the ships of M-Ç II class being not less than 760 mm and for the ships of other classes being not less than that required for coamings of the cargo hatches. Ventilation openings on all the ships, except P and JI classes shall be fitted with tight closures. Coamings of portable ven-
tilation heads shall be fitted with covers or similar closing means.

5.6.21 Outlet openings of piping when located in sides below the freeboard deck shall be arranged according to the requirements of Section 10.4 Part IV of the Rules.

5.6.22 All outer doors and windows of the superstructures, wheelhouses and lobbies located on the freeboard deck shall be watertight for the ships of all classes, except for the cases specified in 5.6.23.

5.6.23 Outer doors may be weathertight when its lower edge is clear of the maximum draught plane on at least a length stated in Table 5.6.23.

</tbody>
</table>

Doors of the closed spaces (e.g., store-rooms, boatswain's stores) located on the freeboard, forecastle and poop decks, may be weathertight.

5.6.24 Scuttles in the outer shell plating below the freeboard deck, in frontal bulkheads of closed superstructures and wheelhouses of the first level as well as in frontal bulkheads of closed superstructures and wheelhouses of the second level on 0.25 of the ship’s length from the forward perpendicular shall be supplied with storm shutters permanently attached to the hull structures. The thickness of the scuttle glasses shall comply with the requirements in 2.7.24, Part III of the Rules.

5.6.25 Scuttles in superstructures of the first and the second levels, located outside the areas and structures stated in 5.6.24, shall be supplied with permanently attached storm shutters and the thickness of glass shall be at least 8 mm at clear diameter of 250 mm or less and at least 12 mm at clear diameter of 350 mm or more. Clear diameter shall not exceed 400 mm.

5.6.26 On the class M and O ships, the side scuttles located in spaces below the freeboard deck shall be fitted with permanently attached storm shutters; here, the scuttle glass thickness shall be at least 8 mm at a clear diameter up to 250 mm inclusive and at least 12 mm at a clear diameter of 350 mm and more. However, the clear diameter shall not exceed 450 mm. For intermediate clear diameters the glass thickness is determined by linear interpolation.

On the class P and I ships, the glass thickness for scuttles may be at least 6 mm at a clear diameter of 250 mm and below and at least 10 mm at a clear diameter of 400 mm and more.

The lower edge of side scuttles of ships of all classes shall be clear of the maximum draught line on at least 150 mm. On the class P ships, where the storm shutters are not available on the scuttles, the specified distance shall be not less than the freeboard height according to Tables 5.4.1.

Side scuttles of class M-PIP and M passenger ships located less than 2.5 % of the ship’s breadth apart from the maximum draught line shall be dead.

On the class M-PIP and M ships, in the superstructures located on the freeboard deck and extended from side to side, the scuttles shall be fitted with storm shutters. In superstructure spaces located on the freeboard deck and not being extended to the sides may be fitted with watertight with heavy glass (at least 10 mm).

On the passenger ships of M-CPI, M-PIP, O-PIP, M, O and P classes, the side scuttles located in the spaces below the freeboard deck, except rescue scuttles, shall be non-opening or to have a structure allowing to open them only by the crew members. The scuttles, except for the non-opening ones, located below the freeboard deck, including rescue scuttles, shall be equipped with automatic alarm on their opening led to the wheelhouse.

5.6.27 Side scuttles of M-CPI class passenger ships shall be so located that no scuttle sill is below a line parallel to the freeboard deck.
at side and having its lowest point \(0.025B\) above the summer load line or 500 mm, whichever is greater.

5.6.28 Covers on outboard water inlet and ice boxes shall be watertight.

The upper edge of openings shall be above the maximum draught line by at least 150 mm.

5.6.29 On oil tankers and flush deck ships, the following requirements shall be met:

1. All openings in the freeboard deck shall be fitted with strong watertight closures;
2. Manholes, doors of lobbies and other openings of ships of O, P and \(\Omega\) classes located on the forecastle or poop may be weathertight.
6 MANOEUVRABILITY OF SHIPS

6.1 SCOPE OF APPLICATION

6.1.1 This Section contains the manoeuvrability requirements to the displacement ships and convoys, which apply to:

.1 self-propelled cargo ships with a length of 40 m or more;
.2 displacement passenger ships, special purpose ships and crew boats with a length of 20 m or more.

6.1.2 The requirements of this Section do not apply to pushed convoys, ship formations, catamarans or ships with waterjets, rotating-blade propulsors or paddle wheels.

6.2 DEFINITIONS AND EXPLANATIONS

6.2.1 The following terms are used in this Section:

.1 propulsion and steering unit (PSU) means propulsor and its steering devices (rudders and/or nozzles);
.2 ship propulsion and steering system (PSS) means all the PSUs that are present on the ship and ensure its longitudinal movement and manoeuvrability;
.3 turning capability means the ship’s ability to turn within a minimum radius of curvature;
.4 directional stability means the ship’s ability to maintain the chosen straight course in deep\(^1\) still water;
.5 manoeuvrability under wind conditions means ship’s ability to:
   maintain any chosen straight course while all propulsors are rotating at rated speed and
   turn on the spot in the chosen direction under wind conditions by simultaneously operating the main controls and the bow steering device;
.6 manoeuvrability with propulsors not in operation means ship’s ability to mechanically maintain a straight course under her own momentum, to turn in the chosen direction and to invert the direction of the turn;
.7 emergency stopping means quickly changing the operating mode of all the propulsors from full speed ahead to full speed astern in deep still water, when loaded as indicated in 6.3.2.

6.3 GENERAL REQUIREMENTS TO SETTING MANOEUVRABILITY STANDARDS

6.3.1 A ship is considered to meet the manoeuvrability requirements specified in this Section if, when loaded according to 6.3.2, the following requirements are met:

.1 turning capability (see 6.5);
.2 directional stability (see 6.6);
.3 manoeuvrability with propulsors not in operation (see 6.7);
.4 emergency stopping (see 6.8);
.5 manoeuvrability under wind conditions (see 6.9).

6.3.2 The manoeuvrability test shall be conducted when the ship is in fully loaded condition, with an even keel trim and with the full stores and fuel.

Manoeuvrability tests for cargo ships under wind conditions in accordance with 6.9 shall be conducted only for ships in ballast, without cargo, and with 10% of stores and fuel.

Manoeuvrability tests for passenger ships under wind conditions in accordance with 6.9

\(^{1}\) Deep water means that depth \(H\) of a water body does not affect propulsion performance of the ship and complies with condition \(H \geq 4T + 3V^2/g\), where \(T\) — ship draught, m; \(V\) — ship velocity, m/s; \(g\) — acceleration of gravity, m/s\(^2\).
shall be conducted only for ships without cargo or passengers, and with 10 % of stores and fuel.

6.3.3 The ship manoeuvrability criteria specified in 6.3.1 apply to the ships with the following types of ship propulsion and steering systems:

.1 propellers in steering nozzles;
.2 propellers in steering nozzles with a centre rudder;
.3 rudders behind open propellers;
.4 rudders behind nozzle propellers including independent nozzles.

Manoeuvrability criteria values for the ships with the above types of the PSSs are calculated according to the instructions of Appendix 5.

6.3.4 For the ships with the PSS types not specified in 6.3.3, the manoeuvrability criteria determination methods are specified according to the methods developed by the designer and approved by the River Register.

6.3.5 The criteria for assessing ship’s turning capability, directional stability and manoeuvrability with propulsors not in operation may also be determined by:

.1 testing an autonomous self-propelled ship model which is geometrically similar to the ship;
.2 full-scale tests.

In these cases, the criteria values do not have to be calculated.

6.4 TABLE OF MANOEUVRABILITY CHARACTERISTICS

6.4.1 To facilitate speedy reference, a table of each ship’s manoeuvrability characteristics shall be posted in a visible place in the wheelhouse.

6.4.2 The table shall be drawn up by the design organization and the results of the calculations shall be supplemented or corrected on the basis of data from full-scale tests and tests with self-propelled models.

6.4.3 For the form of the table, see Appendix 5.

6.5 TURNING CAPABILITY

6.5.1 The criterion for measuring turning capability is the minimum relative mean steady turning diameter \((D/L)_m\), measured from the centre of gravity, that is, the ratio between the diameter \(D\) of the smallest possible turn which the ship can make in deep still water and the length \(L\) of the ship at the design waterline, where the speed of rotation of all the propellers is the same prior to the commencement of the manoeuvre and is not subsequently regulated.

\[ \frac{D_t}{L} \leq 2. \] (6.5.2)

6.6 DIRECTIONAL STABILITY

6.6.1 The criterion for measuring directional stability is the minimum relative mean steady turning diameter, measured from the center of gravity of the ship in deep still water with the rudder angle at zero and all the propellers rotating at the same speed.

6.6.2 The ship’s directional stability is considered to satisfy the requirements of in the Rules if the steady turning diameter is 10 or more times the ship’s length, and also if the ship continues to move on a straight course without turning, with the rudder angle at zero.

6.7 MANOEUVRABILITY WITH PROPULSORS NOT IN OPERATION

6.7.1 The criterion for measuring manoeuvrability with propulsors not in operation is the ship’s capacity to come out of a steady turn, made with the rudder at a 20° angle, after the main propellers have stopped, without using the side thruster.

6.7.2 The ship is considered to meet the requirements of these Rules if it can be taken out of a steady turn, made with the rudder at a 20° angle, after the main propellers have stopped, by operating the main controls, without using the side thruster.
6.8 EMERGENCY STOPPING CAPACITY

6.8.1 The criterion for measuring emergency stopping capacity is the ship’s stopping course $S_{AT}$ the distance, m, which the ship travels relative to the water from the moment when the order to make an emergency stop is given to the moment when the ship has come to a complete stop relative to the water.

6.8.2 The ship is considered to meet the requirements of the present Rules, if the stopping course $S_{AT}$ does not exceed the value calculated by the formula, m,

$$S_{AT} = 30.7 \sqrt{V} + 1.28 L,$$  \hspace{1cm} (6.8.2)

where $V$ — displacement of the ship, m$^3$;
$L$ — ship’s length, m.

6.9 MANOEUVRABILITY UNDER WIND CONDITIONS

6.9.1 The criteria for measuring manoeuvrability under wind conditions are:

.1 Wind velocity in navigational zone, m/s, which allows the ship to move along any chosen straight course with all propulsors rotating at the rated speed;

.2 The specific thrust of the side thruster, kN/m$^2$, required for the ship to turn on the spot using the main controls and the side thruster.

The specific thrust of the side thruster of a cargo ship is the ratio between the thrust of the side thruster $T_T$, kN, and the product of the length of the ship at the design waterline $L$ and the full load draught $T$. The specific thrust of the side thruster of a passenger ship is the ratio $T_T/S$ between the thrust of the side thruster $T_T$, kN, and the windage area $S$, m$^2$.

6.9.2 The ship’s manoeuvrability under wind conditions (criterion 6.9.1.1) is considered to meet the requirements of the Rules if the wind velocity in the navigation area which still allows the ship to move on any chosen straight course with all the propulsors rotating at rated speed is:

- for class M and O ships — no less than 19 m/s;
- for class P and J ships — no less than 14 m/s.

6.9.3 Specific thrust of the bow thruster (criterion 6.9.1.2) meets the requirements of the Rules, if it is not less than:

$$T_T/(LT) = 0.03 \text{ for cargo ships; }$$
$$T_T/S = 0.04 \text{ for passenger ships with } SL \geq 20\,000\,m^3.$$  \hspace{1cm} (6.9.3)

6.10 FULL-SCALE TRIALS

6.10.1 Full-scale trials of the ships and convoys intended to determine the ship’s manoeuvrability compliance with the requirements of the Rules, confirmation of the calculation or full-scale trial results, as well as additions and corrections to the table of manoeuvrability characteristics, shall be carried out together with commissioning trials in the following cases:

.1 on the lead ships in the series;
.2 on the single built ships;
.3 on ships after repair, refitting or modernization, if their manoeuvrability is affected.

6.10.2 The full-scale trials are carried out at ship loading according to 6.3.2. Deviations with regard to draught shall not exceed 10%.

6.10.3 Full-scale manoeuvrability trials are carried out in deep still water, with waves no greater than 1 to 2 points according to the scale of the Central Hydrometeorological Department of the Russian Federation, and wind velocity no greater than 3 to 4 m/s.

6.10.4 Full-scale manoeuvrability trials shall be carried out using the program drawn up according to the requirements in Appendix 5 and RTSC.
INSTRUCTION ON DRAWING UP INFORMATION ON STABILITY AND FLOODABILITY OF SHIP

1 This Appendix contains general instructions on drawing up the Information on Stability and Floodability (hereinafter referred to as the Information). The Information shall include all the ship features determining its stability and floodability.

2 The Information is intended to assist the master in preparing and introducing measures to provide adequate stability and floodability of the ship in operation.

3 The Information shall contain references to the documents used for its drawing up.

4 The system of physical units shall be the same for the entire document. Symbolic notations of the units shall be accompanied with explanations.

5 The Information shall contain the general particulars of the ship including the following:
   .1 name of the ship, design No. and the year of construction;
   .2 registry number;
   .3 type of ship;
   .4 purpose of the ship (kinds of cargoes, which the ship is intended for);
   .5 ship class;
   .6 navigation areas of the ship and restrictions imposed;
   .7 main dimensions of the ship (length, breadth, depth, draught up to summer load line and the relevant displacement and deadweight);
   .8 speed of the ship in deep still water;
   .9 bilge keel area, if any;

10 inclining test data including the place of tests, the date, the test results (weight displacement in lightship condition, abscissa and applicata of the ship's centre of gravity), the Inspection office of the River Register who has approved the inclining test results;

11 other data at the option of the Information developer.

6 The Information shall contain the data proving that the ship meets the stability criteria which are developed for typical loading conditions and include:
   .1 plan of location of tanks with stores and ballast, cargo spaces, engine room;
   .2 tables showing the distribution of stores and ballast among the tanks in typical loading conditions with the indication of weight and coordinates of the centre of gravity and the relevant moments.

The calculations for typical loading conditions shall contain the following data:
   a text description of the loading condition; a drawing of the ship showing the location of the main loading components to be included in the displacement, a plan of the deck cargo stowage;
   tables for calculation of the ship’s weight, position of the centre of gravity, moments of separate loading components and of the light ship, and, in the event of icing of the ship, with due regard to the ice weight;
   corrections for the free surface effect of liquid cargoes and ballast;
   the value of initial metacentric height and the static stability curve with due regard to the free surface effect;
values of the stability criteria required by the Rules for the given loading condition and the results of checking how these requirements are met;

.3 a summary table of typical loading conditions including:
  denomination of the loading condition;
  displacement;
  ship trim parameters;
  vertical centre of gravity and longitudinal centre of gravity;
  corrections for the free surface effect;
  the initial metacentric height of the ship with due regard to the free surface effect;
  permissible values of the initial metacentric height or position of the centre of gravity;
  values of normed parameters, stability criteria and their permissible values;
  the angle of downflooding.

7 The Information shall contain materials for the stability estimation when the loading conditions vary from the typical ones. Those materials shall enable the master to determine, with sufficient accuracy and without undue loss of time, whether the ship stability meets the Rules.

The materials under consideration shall include:

.1 stability check diagrams containing the curves of permissible heights of the centre of gravity depending on the ship’s displacement. The diagram may comprise several curves for different loading conditions (i.e., for the ship without deck cargo, with timber cargo, in conditions of icing etc.);

.2 data for determining the weight and position of the centre of gravity of liquid cargoes;

.3 tables for determining corrections for the free surface effect;

.4 data for determining the weight and position of the centre of gravity of cargoes carried by the ship.

For carriage of containers and timber cargoes recommended plans of its stowage on the deck shall be provided;

.5 data for calculation of the trim and heel;

.6 a diagram (or a table) enabling to determine the mean draught of the ship by her displacement (the displacement curve);

.7 method of using the contents of .1 to .6 for estimating the ship’s stability at calculations of a loading condition other than the typical ones. An example of the calculations shall be also given on the form used for typical loading conditions of the ship;

.8 blank forms on which the master could make independent calculations.

8 The Information shall contain also the data on the ship’s floodability including the description of floodability requirements as applied to the ship concerned, as well as results of floodability calculations and damage stability criteria. Calculations for symmetrical and unsymmetrical flooding shall be given on separate sheets where the following shall be provided:

a sketch of the ship’s inboard profile with the indication of flooded compartment and position of the emergency waterline;

static stability curve of a damaged ship.

Floodability calculation results shall be presented in a tabular form that shall contain the data on emergency trim and heel, transverse metacentric height and normed parameters of damage stability. The table shall contain also the similar data on intact stability.

On the basis of the floodability calculation results for the river-sea navigation ships, a curve on the permissible position of the ship’s center of gravity considering the requirements to damage stability shall be provided.

9 The Information shall also contain the materials required to enable more precise estimation of the ship stability when any of the criteria are met without any reserve being ensured. Such materials include:

.1 a diagram of permissible moments including resultant curves for each criterion;

.2 curves or tables of the form-stability arms which allow plotting of precise static and dynamic stability curves for each non-typical loading conditions;

.3 materials necessary for calculation of stability criteria using the static stability curve;
dependence of the angle of downflooding on the draught or displacement of the ship;
other materials at the designer's option and the information for the determination of the limiting criterion;
the method of using the materials specified in 9.1 to 9.5 with a numerical example of the stability calculation.

A separate section of the Information shall contain the directions for the master on restrictions which follow from the provisions of the Rules, and the recommendations for ensuring stability in service with due regard to the ship's particulars including:

the information on the criteria limiting the ship's stability;

an indication that the stability criteria do not take into account the possible shifting of cargo and, in order to prevent the shifting one should be guided by the documents stating the cargo securing and stowage;
the information on restrictions imposed on the ship's loading, the information of stowage of the deck cargo;
instructions on the order of consumption of liquid cargoes and ship's ballasting during the voyage;
the list of openings which shall be closed during the operation to prevent flooding. At the option of the designer, the plan of location of these openings may be included;
recommendations on checking the ship stability during handling operations;
other information at the designer's option.

This Section may also contain the roll calculation results in the wave height range corresponding to the navigation area at different direction towards the ship's course with the respective recommendations for the master.
INSTRUCTION ON DETERMINING THE LOCATION OF SHIP’S CENTRE OF GRAVITY FROM EXPERIMENT (INSTRUCTION ON INCLINING TEST OF SHIPS)

1 GENERAL PROVISIONS

1.1 The inclining test of ships is required for final checking of the loading and initial stability calculation results by experimental determination of position of the centre of gravity. Inclining test is carried out according to the present Instructions and is attended by the expert.

1.2 A group of specialists headed by the inclining test manager is appointed for carrying out the inclining test.

1.3 The inclining test manager is responsible for the quality and reliability of the test results. His demands are obligatory for all specialists involved in carrying out and supporting the inclining test.

1.4 All deviations from the Instructions occurred at the inclining test shall be indicated and grounded in the inclining test report drawn up on the spot during the test.

2 PLACE OF CONDUCTING THE TEST (WATER AREA) AND WEATHER CONDITIONS

2.1 The inclining test shall be conducted in the still water area protected against current, waves and wind.

2.2 The water depth on the spot of test shall be such as to provide at least 1 m depth under the bottom (or under the hydrofoil for hydrofoil craft) at the maximal inclination of the ship.

2.3 The water area shall be free of objects hindering free inclination of the ship and movements around the ship while measuring operations. Water area shall be sufficiently distant away from passing ships or protected against waves created by passing ships.

3 PREPARATION

3.1 Ship

3.1.1 The ship shall be oriented towards the direction of the wind or current.

3.1.2 The ship shall be fixed in the center plane by longitudinal mooring ropes of maximum possible length connected together below the anchor hawseholes. The number of mooring ropes to be used shall be not more than four. Special devices for ship holding during inclining test having the River Register’s Compliance Certificate may be used.

3.1.3 The initial angle of ship heel shall be not more than 0.5°.

3.1.4 Loading condition shall be as close as possible to light ship displacement. The mass of missing loads is permitted to be not more than 2 % of light ship displacement, the mass of excessive loads including the test weight — not more than 5 % without regard to the ballast as per 3.1.9 of this Instruction.

3.1.5 All objects shall be secured in their proper locations. Movable objects shall be also secured.
3.1.6 Liquid loads shall be removed excepting liquid media in engines, systems and pipelines to ensure their operational condition.

The following liquids may not be removed:
.1 fresh water and lubricating oil stores;
.2 residuals of liquid cargoes and stores in daily tanks not influencing the quality of the test. The tanks containing stores other than daily tanks shall be pressurized until the liquid appears in the air pipes subject to measures preventing air pockets, the valves of service lines shall be shut off and sealed. Plots or tables for determining the weight and coordinates of the centre of gravity of the remaining cargoes shall be available.

3.1.7 On refrigerating ships, it shall be assured that no water is present under insulation in the holds.

3.1.8 Foreign objects, cargo residuals, scaffolding, garbage, snow shall be removed from the ship.

No icing of external and internal surfaces including the underwater part of the ship is allowed.

3.1.9 Metacentric height shall be not less than 0.2\text{m}. The necessary ballast may be taken onboard to provide this value.

3.1.10 The only persons present onboard shall be the personnel carrying out the inclining test.

3.1.11 Machinery and equipment which are in operation shall be stopped. In particular cases operation of the machinery or equipment not affecting the inclining test quality may be allowed.

3.1.12 It is necessary to establish the signals “Prepare for measurements”, “Start measurements”, “Finish measurements”, to instruct the participants of the inclining test and to establish method of communication.

3.1.13 Immediately prior to the inclining test it is necessary to check the presence of liquid loads and excessive cargoes, correspondence of missing loads to the record, stowage and securing of removable loads. It is necessary to prepare test weight, inclinographs, fittings, tools, reporting and technical documentation. Condition of the ship shall undergo random inspection after the test has been finished.

3.1.14 For ships less than 12\text{m} in length the ship prepared for the test shall be weighed prior to the test.

3.2 Test weights

3.2.1 Solid test weights shall be used for the inclining test. The inclining test may be carried out using a method whereby groups of persons move from side to side.

3.2.2 If all the test weight is located on one side, the ship's heel shall be provided: 2 - 4° – by solid test weight or 1.5 - 2° – by moving groups of persons from side to side. For catamarans and floating cranes a heel of at least 1° shall be ensured.

3.2.3 The test weights shall be of such design and shape as to ensure its precise fixation and determination of its center of gravity.

3.2.4 The test weights shall be divided into equal groups. When using solid test weights, the number of groups shall be two or more, the number of groups of persons – one or more.

3.2.5 The weight of the test weights shall be determined using weigh scales.

Weigh scales and weights which have not undergone the certification according to the laws of Russian Federation cannot be used. All solid test weights shall be marked.

It is not allowed to determine the mass of the whole group by mass of one or several weights.

3.2.6 The test weights shall be placed on the weather deck in the places easily accessible for its moving and changing the arms. The places where the test weights are located shall be fixed.

3.3 INSTRUMENTS

3.3.1 The following instruments shall be used for measuring the heeling angles:
.1 pendulums, water levels, inclinographs – if heeled by the solid test weights;
.2 inclinographs – if heeled by moving groups of persons from side to side.

3.3.2 One of the three following variants shall be used for measuring the heeling angles:
.1 pendulums (water levels) – three off and more;
.2 inclinographs – two off and more;
.3 inclinographs and pendulums (water levels) – two off.
For ships less than 30 m in length two pendulums (water levels) or one measuring device and one pendulum may be used.

3.3.3 Pendulums (water levels) shall be placed in different places along the ship length and prepared for operation according to the Instruction for use.

3.3.4 Length of pendulum thread shall be sufficient to provide a deflection of at least 150 mm across the measuring scale with the test weight at one side.

Pendulums with a thread length less than 3 m on ships having a length of 30 m and more, and pendulums with a thread length less than 2 m on ships less than 30 m in length, are not allowed.

3.3.5 The pendulum shall be made of flexible wire up to 0.3 mm in diameter and a billet (weight). For fast oscillation damping, two mutually perpendicular plates shall be attached to the weight and immersed into the receptacle filled with water or lube oil.

For measuring the weight deflection a measuring rod with a paper strip or measuring scale firmly attached to the hull shall be provided. Prior to beginning the test the weight thread shall be stretched by hanging the weight.

3.3.6 When determining the ship’s heeling angles by means of water levels (communicating vessels), two glass tubes with a length of approximately 1 to 1.2 m and diameter of 10 to 20 mm shall be connected with a rubber hose.

The tubes shall be mounted at the sides in the same framing plane at equal distance from the deck. After the tubes are fixed, one of them shall be filled with coloured water in a such amount that the water level reaches approximately half a length of the tubes. When determining the ship’s heel angle, the distance between the tubes is taken as the pendulum length and changes of the water level in the tubes as regarding the initial water level as the deflections.

It is necessary to check during the test that the rubber hose is filled with water along the whole length and is free of air bubbles which may impair the test results.

3.3.7 Calibration data of inclinographs to be used for the inclining test shall be submitted.

4 INCLINING TEST

4.1 Measurements

4.1.1 The heel angles shall be measured since the moment of “Start measurement” signal till the moment of “Finish measurement” signal.

4.1.2 A steel tape is required for measuring distances up to 20 m.

4.1.3 The measurements shall be performed with the following accuracy:
.1 the length of pendulums – 5 mm;
.2 the draught and freeboard height – 10 mm;
.3 test weight transfer arms – 10 mm;
.4 the pendulum deflections – 1 mm;
.5 deflections of inclinograms – 0.2 mm;
.6 mass of the test weights – 1 %;
.7 time – 0.1 s.

4.2 Draught

4.2.1 The draught shall be measured at the beginning and at the end of the inclining test by the draught marks and measurements of the freeboard height at three points along the ship’s length, as a minimum.

For the purpose of on-line measurements quality, specially prepared Profile Views scaled up by the height, Bonjean diagram, or lines drawing with indicated draft marks shall be used. Waterlines shall be drawn by draught
and freeboard height measurement points. In case of significant deviations of some points additional measurements shall be made.

4.2.2 The measurements shall be made on both sides. In order to measure draught values at waves it is recommended to use a glass tube open at the both ends with a hose of 1 to 2 m in length; one end of the tube with the hose attached shall be immersed in water at the depth of 0.1 m or below a plywood sheet freely floating on the water surface.

4.2.3 Draught of tugboats and ships less than 30 m in length may be measured also by means of a wooden frame consisting of a horizontal bar with a length exceeding the maximal ship breadth by 1 to 1.5 m and two vertical struts scaled in centimeters. The frame may be of swing-up type, where the bar and the struts are connected by steel hinges and crossbeams. For better immersing of the frame into the water it is recommended to bind the bar at the bottom by a steel strip 8 to 10 mm thick.

For measuring the ship’s draught the frame shall be placed from the bow or stern and pulled to the plane of one of the frames in a such manner as the water level at the struts corresponds to the same scales.

When performing measurements in the flat bottom area of ships with initial heel angle the draught is determined as a half-sum of the scales fixed at port and starboard struts provided that the struts are symmetric as regards the centre plane of the ship.

After the draught measurements in that frame plane are finished, the frame shall be moved using the struts aftward or forward, and the draught is measured in other frame plane in the same manner.

4.3 Test weight transfer

4.3.1 Procedure and sequence of transfer of the test weight groups is determined by the inclining test manager according to recommended type diagrams (Table A2.4.3.1).

4.3.2 The arm of solid test weight transfer shall be measured from the transfer of its center of gravity.

</table>

Note: Figures 1 to 6 specify the test weight group number, 0 means empty space where the symmetric test weight group may be transferred from the other side; the number of the test weight group transferred at the given measurement is underlined.

The arm of the groups of persons transfer is the distance between the guide lines along which the persons are lined up, reduced by 20 cm.

If indirect measuring of the arms is applied, the reason for this and the used measuring method shall be indicated.

4.3.3 The persons shall transfer according to the designated signal, stand in alignment, without bending or resting on something, faced towards the centre plane, with the heels touching the guide lines.

4.3.4 The number of transfers of the test weight and measurements shall be not less than eight.

4.3.5 The center of gravity of the group of persons over the height shall be assumed at the deck level.

4.4 Angle of heel

4.4.1 One measurement of the heeling angle and one value of the metacentric height correspond to each transfer of the test weight.
4.4.2 At each measurement the following shall be taken into account:

1. A deflection of the pendulum shall be measured for at least 5 sequential swings (distances between extreme positions of the pendulums) after the swing becomes less than 15 mm;

2. If determining the heeling angle by water levels, the procedure of measuring the water level in the tubes is the same as for pendulum method;

3. The inclinograms shall be recorded by the inclinograph for at least five full free inclinations of the ship according to the Instructions for inclinograph use. The device recording scale shall be at least 15 mm/degree.

4.5 Period of rolling

4.5.1 If the inclining test is performed using the inclinographs allowing to measure free inclination period of the ship, the period of rolling shall be determined for all ships of M-III, M-IIP, M, O-IIP and O classes (see also 4.5.2 of this Appendix).

At each transfer of the test weights the total time required for five or six free sequential inclinations of the ship shall be measured by a stop-watch timer. Here, for the reference points shall be taken the most clearly expressed inclinogram peaks. The period of rolling shall be determined with due regard to the inclinograph time scale coefficient.

4.5.2 In cases not stipulated in 4.5.1 of this Appendix and for ships with excessive stability the inclining test manager decides whether it is necessary to determine the period of rolling. The swinging of the ship is performed by means of transferring the solid weights or by moving of the group of people from side to side at least three times; at each swinging, the time required for five or six free sequential inclinations of the ship shall be measured by at least two stop-watch timers.

5 INCLINING TEST REPORT

5.1 The results of the inclining test are fixed in the inclining test report and the reports 1–5 which are integral parts of the inclining test report (see Section 8 of the present Appendix). The inclining test report is signed by all participants of the inclining test, and the reports — by responsible performers appointed by the inclining test manager.

5.2 The expert who attends the inclining test signs the following documents:

1. inclining experiment report;

2. the inclinogram or records of the pendulum deflections.

6 PROCESSING OF INCLINING TEST RESULTS

6.1 Input data

6.1.1 The inclining test report and the ship’s report documents documentation are assumed as the initial data in the processing of the inclining test results. These materials shall be processed according to the requirements given in 6.2 – 6.8 of the present Appendix.

6.2 The inclining test materials

6.2.1 The inclining materials shall comprise the calculations of the displacement, coordinates of the ship’s center of gravity in lightship condition and the ship’s inertial coefficient at inclining (if the period of rolling has been determined, see 4.5 of the present Appendix).

6.2.2 The inclining test materials are drawn up by the designer as the report documents.

6.2.3 The inclining test materials are submitted in three copies to the River Register for approval.

6.3 Sagging

6.3.1 The ship’s sagging shall be taken into account at the calculations of the displacement and the Z-coordinate of the ship’s center of gravity using any reasonably precise method.

6.4 Displacement and coordinates of the ship’s center of gravity
6.4.1 The weight of the ship $D$, kN, and coordinates of the centre of gravity $z_c$, $x_c$, m, shall be determined using the following formula:

1. at trim < 0.005$L$, m:

$$D = pgV; \quad (A2.6.4.1.1-1)$$

$$z_g = r + z_c - h_t; \quad (A2.6.4.1.1-2)$$

$$x_g = x_c - R \psi \varphi. \quad (A2.6.4.1.1-3)$$

Theoretical elements $V$, $z$, $r$, $x$, and $R$ shall be determined using the curves of the lines drawing;

2. at trim ≥ 0.005$L$, m:

$$D = pgV; \quad (A2.6.4.1.2-1)$$

$$z_g = z_c + (r - h_t) \cos \psi; \quad (A2.6.4.1.2-2)$$

$$x_g = x_c - (r - h_t) \sin \psi. \quad (A2.6.4.1.2-3)$$

Theoretical elements $V$, $z$, $r$, and $x$ are determined using any reasonably precise method at corresponding bow and stern draughts.

6.5 Metacentric height

6.5.1 The metacentric height according to the results of particular measurements shall be calculated in the Table A2.6.5.1.

6.5.2 The metacentric height at the inclining test $h_t$ shall be determined using the formula (see also 6.6.4), m,

$$h_t = \Sigma i/n, \quad (A2.6.5.2)$$

where $n$ — number of observations (measurements).

6.6 Inclining test quality

6.6.1 Quality of the inclining test is considered satisfactory, if the relative confidence accuracy of the test calculated according to 6.6.2 at the confidence coefficient of 0.98 does not exceed 5%.

6.6.2 Quality of the inclining test shall be assessed as the following:

1. the root mean square deviation of the metacentric height values, m,

$$\sigma_h = \sqrt{\frac{\sum (h_i - h_\bar{h})^2}{n(n-1)}} = \sqrt{\frac{\Sigma_6}{n(n-1)}}, \quad (A2.6.6.2.1)$$

2. the confidence accuracy of the test, m,

$$\varepsilon = t_{0.98} \sigma_h, \quad (A2.6.6.2.2)$$

where $t_{0.98}$ — coefficient to be determined as regards the number of considered measurements according to the Table A2.6.6.2.2.

<table>

</table>

3 Relative confidence accuracy of the test, %

$$\tau = 100\varepsilon/h_t. \quad (A2.6.6.2.3)$$

6.6.3 On-line control of the inclining procedure shall be performed for each pendulum (water level, inclinograph) by the plots (Fig. A2.6.6.3-1) or the type of inclinograms (Fig. A2.6.6.3-2).

The total ship’s heeling angle (or its tangent) calculated from the initial position (before moving test weights) is plotted along the abscissa axis (see Fig. A2.6.6.3-1), the total heeling moment induced by all test weight transferred since the beginning of the inclining procedure is plotted along the ordinate axis. Each measurement corresponds to a particular point on the plot. All points marked on the plot shall be approximately on the same straight line passing through the origin of coordinates. The points distant from this line are assumed as uncertain, they shall be controlled during the inclining procedure and the relevant inclining shall be repeated.

6.6.4 If it is discovered from a single measurement result that value of metacentric height \( h \) could be obtained only as a result of an accidental error (e.g., the person carrying out observations has made a mistake while recording the readings, the ship has touched an obstacle, etc.), this individual measurement may be discarded.

6.7 Inertial coefficient

6.7.1 The ship’s inertial coefficient at inclining shall be determined using the formula, \( m^{1.5} \): \[
C = \tau \sqrt{h_g / B},
\]

(A2.6.7.1)

where \( \tau \) — period of ship’s rolling, s.

6.8 Light ship

6.8.1 The displacement of the light ship include the weight of a ship in full ready condition without deadweight and liquid ballast.

6.8.2 The deadweight includes the following loads:

1. the loads transported by the ship, other than “dead” liquid loads;
2. the crew and passengers with their luggage, food stores including packing and fresh water;
3. fuel, water and lubricating oil stores for ship operation, other than liquid loads;
4. consumables;
variable set of changeable fishery equipment of fishing vessels;
fishery production and components for its treatment, packing and packaging materials on fishing vessels.

Note: “Dead” liquid loads mean residuals of liquid loads in the hull, which cannot be removed by ordinary onboard facilities from the tanks, draining bilges, bilge sumps etc.

6.8.3 The deadweight does not include the following loads:
1 supply and belongings;
2 spare parts;
3 liquids media in engines, apparatus, installations, systems and pipelines to ensure their operational condition;
4 water in swimming pools;
5 solid and liquid ballast.

6.8.4 Weight and coordinates of the center of gravity of the light ship shall be determined according to Table A2.6.8.4.

7 CALCULATION RESULTS
7.1 The light ship elements obtained from the inclining data shall be presented in comparison with the design data (Table A2.7.1).

Weather conditions
Wind 1 to 1.5 m/s
Waves calm, calm weather
Ambient air temperature + 10 °C

List of the test committee
Inclining test manager

(name and surname, position, organization)
Members of the committee:

The test was attended by the representative of Branch Office of the River Register.

Notes
(The ship’s position relatively to the wind and waves, initial heeling angle, the water level in boilers etc.)

Ship’s draught during the test (from the base plane)
At the fore perpendicular \(T_f = 2.42\) m
At the aft perpendicular \(T_a = 2.62\) m
Average \(T_{av} = 2.52\) m
Trim \(\varphi = (T_f - T_a)/L = - 0.0081\)
Draught measurement error \(\Delta T = \pm 0.005\) m

The diagram indicating the ship position, mooring, the direction of the wind and waves etc.

The draughts were measured according to the draught marks from the boat and according to the freeboard height (see Draught Measurement Report).

Initial trim — 0°.

Ship’s loading condition
The ship was brought to a loading condition equal to the lightship displacement with tolerance given in 3.1.4 of the present Appendix.

The forepeak and afterpeak tanks are drained and stripped. The lubricating oil tank is pressurized.

Missing loads are given in Table 1, excessive loads — in Table 2 and in records of loads which are missing or excessive as regards the lightship condition.

Test weight and transfer arms
Iron castings were used as test weights. Prior to the test the ballast weights were weighed, marked, divided into four groups and stowed on the deck.

Weight of test weight groups and their transfer arms are specified in Table 3.

The total weight of the test weights is 1544 kN.
The weight error of test weight groups does not exceed 1 %.

The transfer arms were measured by the metal tape.

### Statement No. 1

**Ship draughts measurement**

The ship draughts measured by the draught marks from the boat and freeboard height measured by wooden gauge rod from the upper deck are specified below. Given below:

<table>
<thead>
<tr>
<th>Draught by the draught marks, m:</th>
<th>Starboard</th>
<th>Port</th>
</tr>
</thead>
<tbody>

9 EXAMPLE OF PROCESSING THE RESULTS OF DETERMINING THE LOCATION OF SHIP’S CENTRE OF GRAVITY FROM THE INCLINING TEST

Calculation of the ship’s displacement and coordinates of the centre of gravity in test conditions (Table A2.9-1)

Calculation data

The ship’s draught at the perpendiculars from the base plane during in test conditions:

$T_f = 2.42$ m; $T_a = 2.62$ m.

Station spacing $\Delta L = 1.234$ m.

Displacement volume regardless of protruding parts

$V = \Delta L \Sigma_2 = 1.234 \cdot 123.7 = 152.5$ m$^3$.

The ship’s weight in test conditions including protruding parts

$D = KpgV = 1 \cdot 1.006 \cdot 9.81 \cdot 152.5 = 1504.5$ kN.

X-coordinate of the centre of buoyancy

$x_{cv} = \Delta L \Sigma_4 / \Sigma_2 = -1.234 \cdot 14.58 / 123.7 = -0.15$ m.

Z-coordinate of the centre of buoyancy

$z_{cv} = \Sigma_5 / \Sigma_2 = 195.3 / 123.7 = 1.58$ m.

Metacentric radius

$r = 2 \Sigma_7 / (3 \Sigma_2) = 2 \cdot 234.0 / (3 \cdot 123.7) = 1.26$ m.

Calculation of metacentric height in test conditions A2.9-2 – A2.9-4)

Metacentric height in test conditions

$h_{it} = \Sigma_4 / 8 = 2.944 / 8 = 0.368$ m.

### Calculation of coordinates of the ship's centre of gravity in test conditions

X-coordinate of the centre of gravity (from amidship):

\[ x_g = x_{cv} - \left( r_{yy} - h_c \right) \sin \psi = -0.15 -\]
\[ - \left( 1.26 - 0.368 \right) \cdot 0.008 = -0.16 \text{ m}. \]

Z-coordinate of the center of gravity (from the base plane):

\[ z_g = z_{cv} + \left( r_{yy} - h_c \right) \cos \psi =\]
\[ = 1.58 + \left( 1.26 - 0.368 \right) \cdot 1 = 2.47 \text{ m}. \]

### Root mean square deviation

\[ \sigma_h = \sqrt{\sum \left( h_i - h_b \right)^2 / (n(n-1))} =\]
\[ = \sqrt{\sum h_i \cdot 10^{-4} / (n(n-1))} =\]
\[ = \sqrt{10.14 \cdot 10^{-4} / (8 \cdot 7)} = 0.00426 \text{ m}. \]

CALCULATION OF ASSUMED HEELING MOMENT
FOR BULK GRAIN CARRIAGE

1 General assumptions

1.1 When calculating the adverse heeling moment due to a shift of cargo surface in ships carrying bulk grain it shall be assumed that:

.1 In filled compartments, which have been trimmed according to 3.2.10 of the present part of the Rules, a void exists under all boundary surfaces having an inclination to the horizontal less than 30° and that the void is parallel to the boundary surface having an average depth \( h_v \), mm, calculated by the formula:

\[
h_v = h_{sv} + 0.75 \left( h - 600 \right),
\]

where \( h_{sv} \) — standard void depth taken from Table A3.1.1.1, mm;

</table>

\( h \) — depth of the hatch girder (under-deck section of coaming) mm, which is taken equal to the depth of longitudinal girder of the hatch or hatch-end beam, whichever is less.

Value of \( h_v \) shall be taken not less than 100 mm;

.2 Within filled hatchways and in addition to any open void within the hatch cover, there is a void of average depth of 150 mm measured down to the surface of the grain from the lowest part of the hatch cover or the top of the hatch-side coaming, if it is located below the indicated part of the hatch cover;

.3 In a filled compartment which is exempted from trimming outside the hatchway according to 3.2.10.3 of the present Part of the Rules, it shall be assumed that the surface of grain after loading will slope into the void space underdeck, in all directions, at the angle of 30° to the horizontal from the edge of the opening which establishes the void;

**Note**: A distance from the hatch end or hatch side to boundary of the compartment (i.e. boundary surfaces) in the corner area shall be taken equal to the perpendicular distance from the line of the longitudinal hatch girder or the line of the hatch-end beam up to the boundary surfaces of the compartment, whichever is greater;

.4 In a filled compartment which is exempted from trimming in the ends of compartment and being considered as specially suitable according to 3.2.10.3 of the present Part of the Rules, it shall be assumed that the surface of grain after loading will slope in all directions away from the filling area at the angle of 30° to the horizontal from the lower edge of the hatch-end beam.
1.2 For ensuring the stability characteristics according to 3.2.9 of the present Part of the Rules the stability calculations shall be based upon the assumption that the center of gravity of cargo in a filled compartment, trimmed, is at the volumetric center of the whole cargo space. When it is permitted to take into account the effect of assumed underdeck voids on the vertical position of the center of gravity of the cargo in filled compartments, trimmed, it will be necessary to compensate for the adverse effect of the vertical shift of the surface of grain by increasing the assumed transverse heeling moment due to the transverse shift of grain according to 2.2 of the present Appendix.

In all cases the weight of cargo in a filled compartment, trimmed, shall be the volume of the whole cargo space divided by the stowage coefficient of grain.

1.3 The centre of gravity of grain in a filled compartment, untrimmed, shall be taken to be the volumetric centre of the whole cargo compartment without regard to voids. In all cases the weight of cargo shall be the volume of the cargo (resulting from the assumptions stated in 1.1.3 or 1.1.4) divided by the specific stowage coefficient of grain.

1.4 In partly filled compartments the adverse effect of the vertical shift of grain surfaces shall be taken into account by means of increasing the assumed volumetric heeling moment according to 2.2 of the present Appendix.

1.5 In calculating the maximum void area that can be formed against a longitudinal structural member, the effects of any horizontal surfaces, e.g. flanges or faces, shall be ignored.

1.6 The total areas of the initial and final voids shall be equal.

1.7 Longitudinal structural members, which are grain-tight, may be considered effective over their full depth except where they are provided as a device to reduce the adverse effect of grain shift. In the latter case the provisions of 3.2.10.6 of the present Part of the Rules shall apply.

1.8 After the assumed shift of grain the final void pattern in cross-sectional plane of the compartments shall be:

1 according to Fig. A3.1.8-1 when the compartment section within the length of hatch openings has no longitudinal division;

![Fig. A3.1.8-1](image1)

Notes. 1. If the maximum void area which can be formed under \(AB\) after grain shifting is less than the initial void area under \(AB\), i.e. the area \(AB\ h\), than the excess area \(AB\ h\) shall be added to the area of void formed under \(CD\) in the hatchway opening.

2. If the maximum void area which can be formed under \(CD\) after grain shifting is less than the initial void area under \(CD\), than the excess initial void area under \(CD\) shall be added to the area of void formed at the elevated side;

2 according to Fig. A3.1.8-2, if longitudinal bulkhead is present.

![Fig. A3.1.8-2](image2)

Notes. 1. If the maximum void area, which can be formed under \(AB\) after grain shifting, is less than the initial void area \(AB\ h\), than the excess area \(AB\ h\) shall be added to the area of void formed in the low half of the hatchway opening, i.e. under \(CD\).

2. If a centreline division is the division mentioned in 3.2.10.6 of the present Part of the Rules,
it shall extend to at least 0.6 m downwards the edge of point H or J, whichever gives the greater depth.

1.9 For filled compartments which are exempted from trimming outside the periphery of the hatchway according to 3.2.10.3 of the present Part of the Rules the following shall be assumed:

1. The resulting grain surface after shifting is sloped at an angle of 25° to the horizontal. However, if in any section of the compartment, forward, aft or abreast of the hatchway the mean transverse cross sectional area of that part of the compartment not filled with grain is equal to or less than the area which could be obtained by application of 1.1, then the angle of grain surface after shifting in that section shall be assumed to be 15° to the horizontal;

2. The cross sectional area of any part of the compartment the void area not filled with grain shall be assumed to be the same both before and after the grain shift.

1.10 For specially suitable filled compartments which are exempted from trimming forward and aft of the hatchway according to 3.2.10.3 of the present Part of the Rules the following shall be assumed:

1. The resulting grain surface after shifting is sloped at an angle of 15° to the horizontal;

2. The resulting grain surface forward and aft of the hatchway after shifting shall be assumed to be at an angle of 25° to the horizontal.

1.11 For partly filled compartments the resulting grain surface after shifting shall be assumed to be at an angle of 25° to the horizontal.

1.12 Bulkhead fitted in partly filled compartment shall be raised above the surface of the grain for 1/8 of the maximum breadth of the compartment and extended downwards the surface of the grain for the same distance.

1.13 When the longitudinal divisions fitted in the compartment do not reach its transverse boundaries or are made of several parts separated from each other by free spans, then such divisions or their parts may be considered as the effective means to prevent full width shifts of grain surfaces only for the length equal to the actual length of the division or its continuous portion less 2/7 of the greater of the transverse distances between the division and ship’s side.

2 Calculation of the heeling moment arms due to transverse shift of grain

2.1 The design heeling moment arm \( l_0 \) shall be determined by the formula, m:

\[
l_0 = \frac{M_{qy}}{\mu \Delta},
\]

where \( M_{qy} \) — assumed volumetric heeling moment, m^4;

\( \mu \) — volume of unit of the cargo (grain) weight, m^3/t;

\( \Delta \) — ship displacement, t.

2.2 Assumed volumetric heeling moment \( M_{qy} \) is calculated by the formula, m^4:

\[
M_{qy} = C_{vsc} M_{qyi}^L,
\]

where \( S_{vsc} \) — coefficient taking into account the adverse effect of vertical shift of the grain surface on the stability:

for filled compartments, trimmed 1.06
for partly filled compartments 1.12

\( M_{qyi}^L \) — total design volumetric heeling moment, m^4:

\[
M_{qyi}^L = \sum_{i=1}^{n} M_{qyi}^L,
\]

where \( n \) — number of compartments;

\( M_{qyi}^L \) — design heeling moment due to horizontal shift of cargo (grain) in \( i \)-th compartment \((i=1, 2...n)\), m^4:

\[
M_{qyi}^L = F_i y_i L_i,
\]

\( F_i \) — cross-sectional area of the compartment, m^2, filled with cargo; it is assumed that at the grain shift the area \( F_i \) is not changed, the trace of the resulting grain surface on the cross-section area of the compartment after
shift is a straight line inclined at 15° to the horizontal for filled compartments, trimmed and 25° for filled compartments, untrimmed and partly filled compartments;

\( y_i \) — value of horizontal shift, m, of the centre of gravity of the compartment cross-section area \( F_i \) at the grain shift (changing of the section configuration);

\( l_i \) — length of \( i \)-th hold.

2.3 Design heeling moment arm \( l_40 \), m:

\[ l_{40} = 0,8l_0. \]
REQUIREMENTS FOR FULL-SCALE TRIALS AND EXPERIMENTAL DATA TO CONFIRM STABILITY OF HOVERCRAFT

1. Trials shall be carried out on the lead ships which have undergone the inclining test according to the Instructions for Finding the Location of Ship’s Center of Gravity from Experiment given in Appendix 2.

2. The purpose of the trials is full-scale determination of heeling angles at inclining loads provided by 3.7 of the present Part of the Rules and different speed values.

3. When checking stability in hovering mode, the trials are carried out with the main blowers operating in full-load mode regardless of the ship’s speed.

4. The trials are conducted in the water area free of current, waves and wind. In case of current with permanent velocity and direction, the trials shall be conducted twice at each running mode, upstream and downstream.

5. For a single-propeller ship, the load required for inducing the design inclining moment shall be located to the side opposite to the direction of the propeller rotation.

6. Cargo shifting along the ship during the trials is prohibited.

7. The following shall be checked during the trials:
   .1 running the straight course at five or six values of the running speed from zero to the maximal speed at design inclining moments provided by 3.7 of the present Part of the Rules with continuous recording of the heeling angles;
   .2 turning at the maximum speed and speeds corresponding to the maximal heel on the straight course, at three values of rudder shifting angle including hardover positions, from zero position to port and starboard with continuous recording of the heeling angles. The rudder shall be reversed as quick as possible. Initial trim due to crowding of passengers shall be to the side external relatively to the turning centre.

8. The following shall be submitted to the River Register:
   .1 inclining test report;
   .2 trials report containing the data on the ship’s weight during the trials, forward and aft draught, position of the centre of gravity along the ship’s height and length, initial metacentric height, water depth, presence of current and weather conditions during the trials, data on records and measurements done according to the program;
   .3 processed measurement results as the heeling angle versus straight ahead speed graph at inclining moments provided by 3.7 of the present Part of the Rules and the maximum heeling angle at turning versus the rudder angle and initial turning speed graph at inclining moments provided by 3.7 of the present Part of the Rules.
MANEUVRABILITY CALCULATIONS AND FULLSCALE MANEUVRABILITY TRIALS OF INLAND AND RIVER-SEA NAVIGATION SHIPS

1 General provisions

1.1 The present Appendix shall be used for calculation of criteria regulating the ships manoeuvrability and for full-scale manoeuvrability trials according to requirements given in 6 of the present Part of the Rules.

2 Terms and definitions

2.1 The following designations have been adopted in the present Appendix:

- $A_0$ — propeller disc area, m$^2$; $A_0 = \pi D^2/4$;
- $A_e$ — propeller disc expanded area, m$^2$;
- $A_r$ — rudder blade area, m$^2$;
- $A'_r$ — part of the rudder blade area located within the propeller jet, m$^2$;
- $A''_r$ — part of the rudder blade area located outside the propeller jet, m$^2$;
- $B$ — ship’s breadth, m;
- $C_b$ — block coefficient of the ship hull;
- $C_{TT0}$, $C_{T0}$ — load coefficients at nominal running mode (at $v_0$ and $n_0$);
- $C_k$ — the characteristic of the hull;
- $D$ — propeller diameter, mm;
- $D_1$ — steady turning diameter, m;
- $D/L = 2/\Omega$: relative steady turning diameter;
- $k_v$ — speed increasing coefficient near the PSU at a nonlinear motion of the ship;
- $L$ — ship length, m;
- $l_a$ — nozzle length, m;
- $l'_a$ — relative nozzle length: $l'_a = l_a/D$;
- $m$ — ship mass, t;
- $n$ and $n_m$ — rotation frequency of the propeller, s$^{-1}$ and min$^{-1}$, respectively;
- $n_0$ — rated rotation frequency of the propeller, s$^{-1}$;
- $R$ — water resistance to the ship’s motion, N;
- $R_0$ — water resistance to the ship’s motion at $v_0$, N;
- $P$ — propeller pitch, m;
- $S$ — windage area, m$^2$;
- $T$ — ship draught, m;
- $t$ — time, s;
- $v$ and $v_s$ — ship speed, m/s and km/h, respectively;
- $v'$ — ship speed droop at a nonlinear motion;
- $v_0$ — ship speed at rated rotation frequency of all propellers, m/s;
- $V_a$ — wind velocity in navigational zone, m/s;
- $v_a$ — PSU inflow velocity, m/s;
- $w$ — wake coefficient at the straight course motion of the ship;
- $w'$ — wake coefficient at a nonlinear motion of the ship;
- $x_r$, $x'_r = x_r/D$ — distance, m, and a relative distance of rudder profile leading edge from the plane of open propeller disc, or from nozzle trailing edge, measured along the propeller axis;
- $z$ — number of PSUs in the ship PSS;
- $\delta$ — propeller jet angle at a nozzle angle $\delta$, degrees;
- $\lambda$ — aspect ratio of a rudder blade;
\( \lambda'_r \) — aspect ratio of a rudder blade located within the propeller jet;
\( \lambda''_r \) — aspect ratio of a rudder blade located outside the propeller jet;
\( \rho \) — water density, kg/m³.

2.2 The terms used in this Appendix should be understood as follows:

1. Non-dimensional lateral force of the PSU \( C_y \) means lateral force of the PSU \( Y_r, N \), related to \( \rho v_a^2 A_0/2 \);
2. Non-dimensional rate of turn of the ship \( \Omega \) means ratio between the ship's rate of turn, \( \omega, \) degree/s, and the value 57,3 \( \times v/L \);
3. Damping force means an anti-rotation force dependent on the ship's rate of turn;
4. Propeller thrust loading coefficient \( C_{\ominus} \) means propeller thrust \( \Theta, N \), related to \( \rho v_a^2 A_0/2 \);
5. PSU "propeller in nozzle" loading coefficient \( \Psi \) means thrust \( T_e, N \), related to \( \rho v_a^2 A_0/2 \);
6. Advance ratio \( J_p \) of propeller (PSU "propeller in nozzle") means ratio between the PSU water inflow speed \( v_a, m/s \) and the product of propeller rotation frequency \( n, s^{-1} \), with the propeller diameter \( D, m \);
7. Aspect ratio of a rudder blade (a part of a rudder blade) means ratio between the depth of the rudder or its part (nozzle stabilizer or its part) to the relevant chord; for the complex planeform means ratio between the planeform area and the squared chord, or ratio between the squared depth and the planeform area;
8. Positional force means force dependent on a drift angle (ship), a rudder angle (steering equipment);
9. Ship's rate of turn \( \alpha \) means ratio of the course angle deviation to its deviation time, degree/s;
10. Drift angle \( \beta \) means angle between the centre line and speed direction in the center of gravity of the ship, degrees;
11. Drift angle \( \beta_{\text{ash}} \) means drift angle in aft part of the ship (angle of PSU water inflow), degrees;
12. Rudder angle \( \delta \) means steering equipment angle as related to the centre line, degrees;
13. Propeller thrust \( T_p \) means force generated by the propeller along the centre line and applied to thrust bearing, N;
14. PSU "propeller in nozzle" thrust \( T_e \) means total force generated by the nozzle propeller along the centre line, N.

3 General instructions on manoeuvrability calculation

3.1 The present Appendix provides for calculation of manoeuvrability criteria values for the following types of the PSSs:
1. propellers in steering nozzles;
2. propellers in steering nozzles with a centre rudder;
3. rudders behind open propellers;
4. rudders behind nozzle propellers.

3.2 When using tables, diagrams and charts of the present Appendix, intermediate values of initial characteristics shall be determined by means of linear interpolation.

4 Turning capability

4.1 Minimum relative steady turning diameter \( (D_1/L)_{\text{min}} = 2/\Omega_{\text{max}} \) shall be determined by finding \( \Omega_{\text{max}} \) x-coordinate of intersection of curves \( C_{\Theta}(\Omega) \) and \( C_{\Theta}(\Omega) \), built on the same diagram as a function of non-dimensional rate of turn of the ship \( \Omega \) (Fig. A5.4.1).

4.2 Characteristics of the hull \( C_{\Theta}(\Omega) \) and characteristics of hull/PSU interaction (wake coefficient \( w', \) speed droop \( v'' \), coefficient of increasing PSU inflow speed \( k_v \)) shall be calculated according to Table A5.4.2:
1. for each drift angle specified in Table A5.4.2, values \( \Omega \) and \( C_{\Theta} \) shall be determined by using known values \( \beta B/T, T/L \) (and \( C_{\Theta} — \) for passenger ships) and basing on a chosen diagram (Fig. A5.4.2-1 – A5.4.2-4). The dia-
grams shown on Fig. A5.4.2-1 – A5.4.2-4, shall be used for tracing hull performance curve $C_{yk}(\Omega)$ when calculating turning capability, directional stability and manoeuvrability with propulsors not in operation. Each diagram (Fig. A5.4.2-1 for cargo ships, Fig. A5.4.2-2 – A5.4.2-4 for passenger ships with various block coefficients $C_b$) is subdivided into five subdiagrams conforming to values $B/T$: 3.5; 4.5; 5.5; 6.5; 7.5. Each diagram has a grid of curves $T/L$ within the range of values from 0.02 to 0.04 and that of curves within the range of values from 5° to 40°.

Calculation of characteristics of the hull $C_{yk}(\Omega)$ provides that a necessary diagram is selected basing on the ship type and block coefficient $C_b$, a subdiagram and a relevant curve thereof are selected basing on the ratio $B/T$. Non-dimensional rate of turn of the ship $\Omega (X$-axis) and characteristics of the hull $C_{yk}(\Omega)$ (Y-axis) shall be determined by given values of drift angles $\beta$ (subdiagram curves). It shall be noted that each subdiagram has its own Y-axis;

2 angle PSU water inflow $\beta_{stem}$ at the stern, degrees, shall be calculated by the formula:

$$\beta_{stem} = \chi \arctan (\tan \beta + 0.475 \Omega / \cos \beta),$$  

(A5.4.2.2)

where $\chi = 1.0$ for stern PSU; $\chi = 0.8$ for center line PSU;

3 wake coefficient $w'$ for single- and double-propeller ships shall be calculated by the formula:

$$w' = \begin{cases} w_p \left[ 1 - \left( \frac{\beta}{45} \right)^6 \right] & \text{if } \beta < 45^\circ \\ w_p & \text{if } \beta \geq 45^\circ \end{cases}$$  

(A5.4.2.3-1)

where $w_p$ — wake coefficient by calculation of the ship's propulsion performance.

4 the ship speed droop $v'$ on steady turning shall be calculated by the formula:

$$v' = \Omega + 2.61 - 0.70 \tan \Omega,$$  

(A5.4.2.4)

5 coefficient of increase of PSU water inflow $k_v$ shall be calculated by the formula:

$$k_v = \frac{\cos \beta}{\cos \beta_{stem}}.$$  

(A5.4.2.5)

6 auxiliary coefficient $\varphi$ shall be calculated by the formula:

$$\varphi = \pi \rho D^2 (1 - w')^2 / (4LT).$$  

(A5.4.2.6)

4.3 Nondimensional lateral force of the PSS of any type shall be calculated using Tables A5.4.4, A5.4.7, A5.4.9, A5.5.4, A5.5.7, A5.5.9.

4.4 Nondimensional lateral force of PSS "propellers in steerable nozzles" and "propellers in steerable nozzles + center rudder" shall be calculated according to Table A5.4.4. Angle $\delta_m = 32^\circ$ shall be taken as the maximum nozzle angle. Propeller thrust increasing coefficient $q_t$ at nozzle deflection shall be taken equal to 1.40.

Calculation at drift angles $\beta = 5^\circ$, $10^\circ$, $15^\circ$ may be omitted.

4.5 Initial values for calculation of PSU "propeller in nozzle" performance according to Table A5.4.4, shall be calculated by the following formulas and Tables:

1. Angle of propeller jet deflection by steerable nozzle $\delta^*$ – by the formula for nozzles:
   - without stabilizer $\delta^* = 28.0 - 30.5(\ell_0 - 0.6)$
   - with stabilizer $\delta^* = 32.0 - 15.0(\ell_0 - 0.6)$
   (A5.4.5.1);

2. PSU thrust decreasing coefficient $q_{TT}$ by the formula for nozzles:
   - without stabilizer $q_{TT} = 0.75 - 0.25(\ell_0 - 0.6)$
   - with stabilizer $q_{TT} = 0.70 - 0.07(\ell_0 - 0.6)$
   (A5.4.5.2);

3. Coefficient of lift force of steerable nozzle as foil ring – by the formula:
   $$\mu = 1.67 + 4.11\ell_0' - 1.11(\ell_0')^2.$$
   (A5.4.5.3)

4.6 The values included in Table A5.4.4, shall be calculated using data of Table A5.4.2 by the following formulas, tables and diagrams:

1. Propeller advance ratio $J_p$ – by the formula:
   $$J_p = v_0v'(1 - \varphi)k_c/(D\ell_0);$$
   (II5.4.6.1)

2. PSU "propeller in nozzle" thrust loading coefficient $C_{TT}$ – from diagram (Fig. A5.4.6.2);

3. Propeller thrust loading coefficient $C_T$ – by the diagram (Fig. A5.4.6.3);

4. Auxiliary value $A_y$ – by the formula:
Fig. A5.4.6.3. Propeller in nozzle thrust loading coefficient

\[ A_y = q_{TT} C_{TT} \left( \sqrt{1 + q_T C_T \cos \delta^* - \cos \beta_{stem}} \right), \]

where \( \beta_{stem} \) shall be calculated by the formula (A5.4.6.4);

5 auxilary coefficient \( k_{\delta} \) – from Table A5.4.6.5;

6 positional component of non-dimensional lateral force of the PSU \( B_y \) – by the formula:

\[ B_y = \left( A_y \sqrt{1 + q_T C_T^2 + \mu \cos \beta_{stem}} \right) \cdot k_{\delta} \sin \delta^*; \]

(A5.4.6.6)

7 auxiliary coefficient \( k_{\beta} \) – from Table A5.4.6.7;

8 damping component of nondimensional lateral force of the PSU \( D_y \) – by the formula:

\[ D_y = \left( A_y + \mu \cos \delta^* \right) \cdot k_{\beta} \sin \beta_{stem}; \]

(A5.4.6.8)

9 if the nozzle stabilizer has a section with area \( A_{stab}' \), m², and aspect ratio (ratio of the average depth of this stabilizer section to its length) \( \lambda_{stab}' \), which is projected upward from the propeller jet, an additional nondimensional damping lateral force \( \Delta C_{stab} \) by the formula:

\[ \Delta C_{stab} = 0.143 \lambda_{stab}' A_{stab}^* \left( 32 - \beta_{stem} \right) \cos \beta_{stem} / \left( 1 + \lambda_{stab}' \cdot D^2 \right) ; \]

(A5.4.6.9)

</tbody>
</table>
if a double-propeller ship fitted with propellers in nozzles has an additional centre rudder with area $A_r$ and aspect ratio $\lambda_r$, which is deflected at angle $\kappa$ times more than the nozzle angle, an additional non-dimensional lateral force $C_y$ shall be calculated by the formula:

$$
C_p = \begin{cases} 
0.140 \lambda_p A_p \left( \frac{32 \kappa - \beta_{stem}}{2 + \lambda_p} \right) & \text{if } \kappa < 1.5 \\
0 & \text{if } \kappa \geq 1.5
\end{cases}
$$

(A5.4.6.10)

where $\beta_{stem}$ shall be calculated by the formula (A5.4.2.2) for centerline PSU.

If the PSS does not include a centre rudder, $C_y = 0$;

11 non-dimensional lateral force $C_y$ of PSU "propeller in steerable nozzles" and "propellers in steerable nozzles + centre rudder" shall be calculated by the formula:

$$
C_y = \phi \left[ 0.81 \left( B_y + D_y \right) + \Delta C_{stab} + 0.5 C_{pr} \right].
$$

(A5.4.6.11)

4.7 Nondimensional lateral force of PSS "rudders behind open propellers" shall be calculated according to Table A5.4.7. Angle $\delta_{m} = 35^\circ$ shall be taken as the maximum possible rudder angle $\delta$.

Calculation at drift angles $\beta = 5^\circ$, $10^\circ$, $15^\circ$ may be omitted.

4.8 The values included in Table A5.4.7, shall be calculated using data given in respective columns of Table A5.4.2 by the following formulas, tables and diagrams:

1. propeller advance ratio $J_p$ by the formula (A5.4.6.1);
2. propeller thrust loading coefficient $C_T$ by the diagram on Fig. A5.4.8;
3. lateral force PSU loading coefficient derivative with respect to deflection angle $C_y$ – from Table A5.4.8.3;
4. upwash coefficient $k_\beta$ – from Table A5.4.8.4;
5. coefficient $k_p$ – from Table A5.4.8.5 in relation to $C_T$.

Note: $x_p'=x_p/D$ — relative distance of the rudder profile leading edge from the plane of the propeller disc measured along the propeller axis.

If the rudder section projected from the propeller jet has aspect ratio $\lambda_\sigma^* \leq 0.1$, $k_\sigma = 1.0$ shall be taken;

Coefficient $a_\sigma$ for a value correction $\lambda_\sigma^*$ from 1.0, – by the formula:

$$ a_\sigma = (2\lambda_\sigma^* + \lambda_\sigma^* - 1)(4\lambda_\sigma^* k_{\lambda_\sigma} - 3\lambda_\sigma^* - 4k_{\lambda_\sigma} + 6)/\left[\lambda_\sigma^*(\lambda_\sigma^* + 1)(\lambda_\sigma^* + 2)\right]; $$

(A5.4.8.6)

Coefficient $b_\sigma$ for an effect of the rudder section projected from the propeller jet – by the formula:

$$ b_\sigma = 8\lambda_\sigma^* A_y \left[ (1 + \lambda_\sigma^*) D^2 \right]; $$

(A5.4.8.7)

Non-dimensional lateral force $A_y$ generated by the rudder section located within the propeller jet – by the formula:

$$ A_y = 0.0175 a_\sigma C_T \left( \delta - k_{\lambda_\sigma} \beta_{\text{stern}} \right); $$

(A5.4.8.8)

Non-dimensional lateral force $B_y$ generated by the rudder section located within the propeller jet – by the formula:

$$ B_y = 0.0175 b_\sigma \left( \delta - \beta_{\text{stern}} \right); $$

(A5.4.8.9)

Non-dimensional damping force $C_{pr}$ generated on the propeller – by the formula:

$$ C_{pr} = -0.0175 \left( k_{\lambda_\sigma} + k_{2y} \sqrt{C_T} \right) \beta_{\text{stern}}; $$

(A5.4.8.10)

where $k_{\lambda_\sigma} = 0.177 P/D + 0.087 \left( A_y / A_0 - 0.55 \right)$

$K_{2y} = \left[ 0.257 + 0.233 \left( A_y / A_0 - 0.55 \right) \right] \cdot (P/D)^2 +$

$\left[ 0.067 - 0.018 \left( A_y / A_0 - 0.55 \right) \right];$

(A5.4.8.11)

Coefficient of PSU/hull dynamic interaction $k_y$ – by the formula:

$$ k_y = 1 - a \left( \delta - 11.5 \right), $$

where $a$ is taken as follows for the following ships:
double-propeller 0.022
single- and three-propeller 0

.12 nondimensional lateral force $C_y$ of PSS "rudders behind open propellers" – by the formula:

$$C_y = \varphi \left( A_y + B_y \right) + k_y + C_{pr}$$  \hspace{1cm} (A5.4.8.12)

4.9 Nondimensional lateral force of PSS "rudders behind propellers in nozzles" shall be calculated using Table A5.4.9. Angle $\delta_m = 35^\circ$ shall be taken as the maximum possible rudder angle $\delta$.

</tbody>
</table>

Note: \( x_p' = x_p / D \) — a relative distance of the rudder profile leading edge from the nozzle trailing edge, measured along the propeller axis.

\[
C_{pr} = -k_y \left( C_{TT} / \left( \sqrt{1 + C_T} - \cos \beta_{\text{stern}} \right) + \mu \right) \times \sin \beta_{\text{stern}},
\]

(A5.4.10.12)

where coefficient \( \mu \) shall be calculated by the formula (A5.4.5.3);

.13 coefficient of PSU/hull dynamic interaction \( k_y \) by the formula:

\[
k_y = 1 - 0.011(\delta - 11.5); \quad (A5.4.10.13)
\]

.14 non-dimensional lateral force \( C_{yr} \) of PSS "rudders behind propellers in nozzle" shall be calculated by the formula (A5.4.8.12).

5 Directional stability

5.1 Relative steady turning diameter with the rudders angle \( D_{\text{turn}} / L \) at zero shall be determined by finding a zero x-coordinate \( \Omega_0 \) of intersection of curves \( C_{ik}(\Omega) \) and \( C_{yr}(\Omega) \), built on the same diagram as a function of nondimensional rate of turn of the ship \( \Omega \)(see Fig. A5.5.1). If curves \( C_{ik}(\Omega) \) and \( C_{yr}(\Omega) \) do not intersect, the ship is considered as straight course stable, relative diameter of her steady turning with the rudders angle at zero \( D_{\text{turn}} / L \) = \( \infty \), nondimensional rate of turn \( \Omega_0 = 0 \).

5.2 Characteristics of the hull \( C_{ik}(\Omega) \) calculated according to A5.4.2 may be used as characteristics of the hull \( C_{ik}(\Omega) \), for calculating directional stability.

5.3 Nondimensional lateral force of PSS of any type shall be calculated using Tables A5.5.4, A5.5.7, A5.5.9. The rudder angle \( \beta \) is taken equal to zero. Calculations only at drift angles \( \beta = 5°, 10°, 15° \) will be sufficient.

5.4 Non-dimensional lateral force of PSS "propellers in steerable nozzles" and "propellers in steerable nozzle + centre rudder" shall be calculated according to Table A5.5.4.

5.5 Values \( \mu \) for calculation of non-dimensional lateral force of PSS "propellers in steerable nozzles" according to Table A5.5.4 shall be calculated by the formula (A5.4.5.3).
For calculating nondimensional lateral force of PSS "propellers in steerable nozzles" and "propellers in steerable nozzle + centre rudder".

5.6 The values included in Table A.5.5.4 shall be calculated using data of Table A.5.4.2 by the following formulas, tables and diagrams:

1. Propeller advance ratio \( J_p \) - by the formula (A.5.4.6.1);

2. PSU "propeller in nozzle" thrust loading coefficient \( C_T \) - by the diagram on Fig. A.5.4.6.1;

3. Propeller thrust loading coefficient \( C_T \) - by the diagram on Fig. A.5.4.6.2;

4. Auxiliary value \( A_y \) - by the formula:

\[ A_y = C_{TT} \left( \sqrt{1 + C_{TT}} - \cos \beta_{stern} \right) \]  \hspace{2cm} (A.5.5.6.4)

where \( \beta_{stern} \) shall be calculated by the formula (A.4.2.2);

5. Auxiliary coefficient \( k_\beta \) - from Table A.5.4.6.7;

6. Damping component of nondimensional lateral force of the PSU \( D_y \) - by the formula:

\[ D_y = -\left( A_y + \mu \right) k_\beta \sin \beta_{stern} \]  \hspace{2cm} (A.5.5.6.6)

If the nozzle stabilizer has a section with area \( A_{stab} \), \( m^2 \), and aspect ratio (ratio of the average depth of this stabilizer section to its length) \( \lambda_{stab} \), which is projected upward from the propeller jet, an additional nondimensional damping lateral force \( \Delta C_{stab} \) shall be calculated by the formula:

\[ \Delta C_{stab} = -0.14 \lambda_{stab} A_{stab} \cos \beta_{stern} \int \left( 1 + \lambda_{stab} \right)^{-2} \right] \]  \hspace{2cm} (A.5.5.6.7)

8. If a double-propeller ship fitted with nozzle propellers has an additional centre rudder with area \( A_r \) and aspect ratio \( \lambda_r \), an additional non-dimensional damping lateral force \( C_r \) shall be calculated by the formula:

\[ C_r = -0.14 \lambda_r A_r \cos \beta_{stern} \int \left( 2 + \lambda_r \right)^{-2} \right] \]  \hspace{2cm} (A.5.5.6.8)

where \( \beta_r \) shall be calculated by the formula (A.4.2.2) for centerline PSU.

If the PSS does not include the centre rudder, \( C_r = 0 \);  

9. Non-dimensional lateral force \( C_\eta \) of PSS "rudders behind open propellers" shall be found from Table A.5.5.7. The rudder angle \( \delta \) shall be taken \( \delta = 0^\circ \). Calculation at drift angles \( \beta = 20^\circ, 25^\circ, 30^\circ, 35^\circ, 40^\circ \) may be omitted.

5.8 The values included in Table A.5.5.7 shall be calculated using data of Table A.5.4.2 by the following formulas, tables and diagrams:

1. Propeller advance ratio \( J_p \) - by the formula (A.5.4.6.1);

2. Propeller thrust loading coefficient \( C_T \) - by the diagram on Fig. A.5.4.8;

3. PSU loading derivative with respect to lateral force \( C_\eta \) - from Table A.5.4.8.3;

4. Upwash coefficient \( k_\beta \) - from Table A.5.4.8.4;

5. Coefficient \( k_\alpha \) - from Table A.5.4.8.5;

6. Coefficient \( a_r \) for a value correction \( \lambda_r \) from 1.0. - by the formula (A.5.4.8.6);

Note: $x_p = x_p/D$ — relative distance of rudder profile leading edge from nozzle trailing edge measured along the propeller axis.

0.8 coefficient $h_i$ for an effect of the rudder section projected from the propeller jet – by the formula (A5.4.8.7);

0.9 non-dimensional lateral force $A_y$ generated by the rudder section located within the propeller jet – by the formula:

$$A_y = -0.0175a_i k_\beta \beta_{\text{stern}},$$  (A5.5.10.9)

10 non-dimensional lateral force $B_y$ generated by the rudder section projected from the propeller jet – by the formula:

$$B_y = -0.0175b_i \beta_{\text{stern}},$$  (A5.5.10.10)

11 non-dimensional damping lateral force $C_{py}$ generated on the PSU “propeller in nozzle” – by the formula:

$$C_{py} = -0.0175k_\beta \left[C_T \left(\frac{1}{1+C_T} - 1\right) + \mu \right] \beta_{\text{stern}},$$  (A5.5.10.11)

where the coefficient $k_\beta$ shall be taken from Table A5.5.10.5;

coefficient $\mu$ – by the formula (A5.4.5.3);

12 non-dimensional lateral force $C_{yr}$ of PSS “rudders behind propellers in nozzles” – by the formula:

$$C_{yr} = \phi \left(A_y + B_y + C_{py}\right).$$  (A5.5.10.12)

6 Manoeuvrability with propulsors not in operation

6.1 The ship’s capacity to come out of any steady turn, after the main engines have stopped, shall be determined by comparing the maximum absolute negative value $\left(C_{yr}\right)_{\text{min}}$ of hull performance curve $C_{y\alpha}(\Omega)$, plotted according to 4.2 of the present Appendix, and values of nondimensional lateral force $\left(C_{yr}\right)_{\text{min}}$, generated by main steering equipment of the ship with propulsors not in operation (see Fig. A5.6.1). The ship is considered as capable to come out of any steady turn with propulsors not in operation, if $\left|\left(C_{yr}\right)_{\text{min}}\right| \geq \left|\left(C_{yr}\right)_{\text{min}}\right|$, i.e. if the value $\left(C_{yr}\right)_{\text{min}}$ lies below the minimum point of hull performance curve $C_{y\alpha}(\Omega)$.

Fig. A5.6.1. Diagram for calculating the ship’s capacity to come out of any steady turn after the main engines have stopped

6.2 Nondimensional lateral force $\left(C_{yr}\right)_{\text{min}}$ generated by main steering equipment of the ship with main engines not in operation shall be taken as follows:

- with single steering nozzle $-1.1$
- for single rudder behind open propeller $-0.75a_i A_i/A_0$
- for single rudder behind propeller in nozzle $-0.65a_i A_i/A_0$
- for centre rudder of the double-propeller ship $-\phi A_i(z_{pr} A_0)$

7 Emergency stopping capacity

7.1 When determining stopway the procedure of emergency stopping is considered to include two phases:

1 The first phase – from the moment when the order to make an emergency stop is
given to the moment when all propulsors start running at full astern;

7.2 The second phase – from the moment when all propulsors start running at full astern to the moment when the ship has come to a complete stop.

7.2 Emergency stopway $S_{st}$, m, shall be calculated by the formula

$$S_{st} = S_1 + S_2,$$  \hspace{1cm} (A5.7.2.1)

where $S_1$ — way, which the ship travels within the first phase, m, to be determined according to 7.3 of the present Appendix.

$S_2$ — way, which the ship travels within the second phase, m, to be determined according to 7.6 of the present Appendix.

7.3 The way $S_1$, m, which the ship travels within the first phase of emergency stopping, shall be calculated by the formula:

$$S_1 = \ln \left(1 + C v_1 t_1 \right)/C,$$  \hspace{1cm} (A5.7.3.1)

where $t_1$ — time of the first phase at emergency stopping, s, to be determined according to 7.4 of the present Appendix.

The value $C$, m$^{-1}$, included in the expression (A5.7.3.1), shall be calculated by the formula:

$$C = (R_0 - \sum T_{el} \right)/\left(1.05m v_0^2 \right),$$  \hspace{1cm} (A5.7.3.2)

where $m$ — ship mass, t.

$R_0$ — water resistance to the ship’s motion at $v_0$, kN, to be determined by calculation of propulsion performance.

$\sum T_{el}$ — average total thrust of the PSS within the first phase of emergency stopping, kN, to be calculated by the formula:

$$\sum T_{el} = 0.5pv_0^2 \times \sum_{i=1}^{z_p} \left[k_{Ki}D_i^2 \left(1 - w_i \right)^2 + C_{hi}D_iP_i \right],$$  \hspace{1cm} (A5.7.3.3)

where $z_p$ — number of PSUs

$i$ — number of PSU within PSS;

$K_{Ki}$ — coefficient taken equal to:

0.4 — for open propellers;

0.5 — for propellers in nozzles;

$w_i$ — wake coefficient for the $i$-th PSU by calculation of propulsion performance;

$D_i$ — diameter of the $i$-th propeller, m;

$P_i$ — pitch of the $i$-th propeller, m;

$C_{hi}$ — correction coefficient, m$^{-1}$, to be calculated by formula:

$$C_{hi} = \left(1 - w_i \right)(\lambda_i - \Delta\lambda_i) / \left[P_i\sqrt{1 - (\lambda_i - \Delta\lambda_i)^2} \right],$$  \hspace{1cm} (A5.7.3.4)

where $i$ — shall be taken as:

for open propellers 0.675

for propellers in nozzles 0.70

$\Delta\lambda_i$ shall be taken as:

if reversible gear is available 0.5

when the engine directly drives the propeller 0.3

7.4 Unless otherwise noted, time of the first phase of emergency stopping $t_1$ shall be taken equal to 25 s according to 6 of the present Part of the Rules. Time of the first phase of emergency stopping less than 25 s shall be approved by the engine manufacturer.

7.5 The ship speed $v_1$ at the end of the first phase of emergency stopping, m/s, shall be calculated by the formula:

$$v_1 = v_0 / \left(1 + C v_0 t_1 \right),$$  \hspace{1cm} (A5.7.5)

where $C$ — coefficient, m$^{-1}$, to be calculated by the formula (A5.7.3.2);

$t_1$ — time of the first phase of emergency stopping, s, to be determined according to 7.4 of the present Appendix.

7.6 The way, which the ship travels within the second phase of emergency stopping, m, shall be calculated by the formula:

$$S_2 = 0.5 v_1 \ln \left(1 + a^2 \right)/\left(ab \right),$$  \hspace{1cm} (A5.7.6.1)

where $v_1$ — ship speed at the end of the first phase of active stopping to be determined according to 7.5 of the present Appendix.

The values $a$ and $b$ shall be calculated by formulas, s$^{-1}$:

$$a = (v_1 / v_0) \sqrt{R_0 / \sum T_{el} \right},$$  \hspace{1cm} (A5.7.6.2)

$$b = \sqrt{R_0 \sum T_{el} / \left(1,05m v_0 \right) \right},$$  \hspace{1cm} (A5.7.6.3)
where \( \sum T_{e2} \) — average total thrust of the PSS within the second phase of emergency stopping, kN, to be calculated by formula:

\[
\sum T_{e2} = 0.5 \sum_{i=1}^{z} \left[ m_i k_{K2} P_{d_i}/(\pi n_{i0} P_i) \right],
\]

(A5.7.6.4)

where \( m_i \) — capacity ratio of the \( i \)-th engine at astern running, to be taken equal to 0.85 for reversing engines. In installations with reverse gear \( m_z \) shall be taken equal to reverse gear ratio at ahead and astern running;

\( K_{K2} \) — coefficient taken equal to:
- for open propellers 6.00
- for PSU "propeller in nozzle" 6.25

\( P_{d_i} \) — power to the \( i \)-th propulsor at ahead running, kW;

\( n_{i0} \) — rotation speed of the \( i \)-th propeller at ahead running, s\(^{-1}\);

\( D_n, P_r \) — see 7.3 of the present Appendix;

\( m \) — see 2.2 of the present Appendix.

8 Maneuverability under wind conditions

8.1 Wind velocity \( V_a \), m/s, which the ship move along any chosen straight course with all propellers rotating at the rated speed of all propulsors, shall be calculated by the formula:

\[
V_a = 0.75 V_0 \times \sqrt{[0.35 (a_i + 2.10 b_i)/c + 0.12 a_2/c^2]} / P_{a_2} + 1.0,
\]

(A5.8.1)

where \( c \) — coefficient to be determined according to 8.8.2.

The values \( P_{a_2}, a_i, b_i, a_2 \) included in the formula (A5.8.1), shall be calculated by the following formulas:

.1 auxiliary coefficient \( P_{a_2} \) — by the formula:

\[
P_{a_2} = 0.001225 S/\left( LT \right).
\]

(A5.8.1.1)

.2 coefficient of positional force on hull \( a_i \) — by the formula for:

- cargo ships \( a_i = 3.7 T / L \)
- passenger ships \( a_i = 4.2 T / L \)

(A5.8.1.2)

.3 coefficient of positional force on hull \( a_2 \) for cargo ships — from Table A5.8.1.3:

</table>

.5 coefficient of positional moment on hull \( b_1 \) shall be calculated by the formula:

for cargo ships

\[
b_1 = \left[ 0.101 + 0.00174 (L/B - 8.17) \right] \times \left( 21.07T/L + 0.285 \right),
\]

(A5.8.1.5-1)

for passenger ships:

\[
b_1 = \left[ 0.109 + 0.00189 (L/B - 8.17) \right] \times \left( 22.05T/L + 0.299 \right).
\]

(A5.8.1.5-2)

8.2 The coefficient included in the formula (A5.8.1) shall be calculated by the formula:

\[
c = (\rho D^5 + 0.037 h)/\left( \rho B^5 \right),
\]

(A15.8.2)

where values \( B^5, D^5 \) for various types of PSU shall be determined according to 8.3 and 8.4 of the present Appendix, value \( \rho \) shall be determined by the formula (A5.4.2.6), value \( w' \) included in this formula shall be determined by formulas (A5.4.2.3-1), (A5.4.2.3-2) at \( \beta_{stern} = 10^\circ \).
8.3 Values $B_y^\delta$, $D_y^\delta$ included in formula (A5.8.2) for PSS "propellers in steerable nozzles" and "propellers in steerable nozzles + centre rudder" shall be calculated by the following formulas:

$$B_y^\delta = 0.0175k_\delta \times$$
$$\left[ q_{TT}C_{CT0}\sqrt{1 + q_{TT}C_{CT0}/(1 + q_{TT}C_{CT0} - 1) + \mu} \right].$$

$$D_y^\delta = -0.0175k_\delta \left[ q_{TT}C_{CT0}/(1 + q_{TT}C_{CT0} - 1) + \mu \right] -$$
$$-0.14 \left[ \lambda_u^* A_u^*/(1 + \lambda_u^*) + \lambda_p A_p/(2 + \lambda_p) \right]/D_t.$$  

(A5.8.3.1)

(A5.8.3.2)

The values included in the formulas (A5.8.3.1) and (A5.8.3.2) shall be determined by formulas and tables given in 4.4 and 4.6 of the present Appendix. If no section of nozzle stabilizers is projected from the propeller jet, $A_u^* = 0$. If the PSS does not include the centre rudder, $A_p = 0$.

8.4 The values $B_y^\delta$, $D_y^\delta$ included in the formula (A5.8.2) for PSS "rudders behind open propellers" shall be calculated by the following formulas:

$$B_y^\delta = 0.0175 \left( a_\gamma C_y^\delta + b_1 \right),$$

$$D_y^\delta = -0.0175 \left( a_\gamma C_y^\delta k_\beta + b_1 \right).$$

(A5.8.4.1)

(A5.8.4.2)

where values, included in formulas (A5.8.4.1) and (A5.8.4.2), shall be determined by formulas and tables given in 4.8 of the present Appendix.

8.5 Values $B_y^\delta$, $D_y^\delta$ included in formula (A5.8.2) for PSS "rudders behind propellers in nozzles" shall be calculated by the following formulas:

$$B_y^\delta = 0.0175 \left( a_\gamma C_y^\delta + b_1 \right),$$

$$D_y^\delta = -0.0175 \left( a_\gamma C_y^\delta k_\beta + b_1 \right).$$

(A5.8.5.1)

(A5.8.5.2)

where values, included in formulas (A5.8.5.1) and (A5.8.5.2), shall be determined by formulas and tables given in 4.10 of the present Appendix.

9 Instructions on full-scale trials

9.1 The program of full-scale manoeuvrability trials shall be developed by the designer and shall include turning-circle trial, spiral trial, $10^\circ/10^\circ$, $20^\circ/20^\circ$, $30^\circ/30^\circ$, zigzag trial, stop-inertia trial, ship’s emergency stopping and astern steering trial.

9.2 Turning circle trials shall be carried out by circling at rudder angles $\delta = 10^\circ, 20^\circ, 35^\circ$ on either side, for ships with the maximum rudder angles exceeding $35^\circ$, and at high rudder angles. Turns shall be carried out in deep still water, where all propellers turn at any rotation speed, which is the same prior to the commencement of the manoeuvre and is not subsequently adjusted. The trials include measurements of steady-turning diameters $D_t$. The trials shall result in plotting the diagram of $\Omega = 2L/D_t$ or $D_t/L$ against the rudder angle (diagram of ship manoeuvrability). The section of the ship manoeuvrability diagram within the range of rudder angles $-5^\circ \leq \delta \leq +5^\circ$ shall be plotted upon results of spiral manoeuvre according to 9.3 of the present Appendix. The average value of $2L/D_t$ on either side at the maximum rudder angles shall be considered as a criterion of the ship's turning capability according to 6.5.2 of the present Part of the Rules.

9.3 The spiral manoeuvre shall be carried out as a continuous sequence of steady turns at rudder angles $\delta$ within the range of $+5^\circ$ to $-5^\circ$. To carry out this manoeuvre the ship shall enter into the turn at the rudder angle $\delta = +5^\circ$ at any fixed motion speed $v_0$, where the speed of rotation of all propellers is the same prior to the commencement of the manoeuvre and is not subsequently regulated. After a steady rate of turn is obtained, a rudder angle shall be gradually decreased to $+3^\circ$, $+2^\circ$, $+1^\circ$, $+0^\circ$. A steady rate of turn shall be obtained on each phase. If at $\delta = 0^\circ$ the ship stops turning and gets on a straight course, the manoeuvre is over. If at $\delta = 0^\circ$ the ship keeps turning to starboard, the rudder shall be sequentially moved aport at small angles ($\delta = -0.5^\circ, -1^\circ, -1.5^\circ, -2^\circ$) to set such rudder angle to port, at
which the ship starts turning to port after achieving a steady rate of turn (critical rudder angle \( \delta_{cr} \)). After steady rates of turn are obtained, the rudder shall be sequentially moved to \(-3^\circ\) and \(-5^\circ\). Here the whole procedure shall be carried out again from \( \delta = -5^\circ \) to \( \delta = +5^\circ \). The ship's rate of turn \( \omega \), deg/s, shall be measured on each area after steady turning is obtained.

The manoeuvre results shall be processed by the formula:

\[
\Omega = \omega L / (57.3 v' v') = 2L / D_{\text{turn}}, \quad (A5.9.3.1)
\]

where \( v' \) shall be calculated by the formula (A5.4.2.4) using the method of successive approximations, starting at \( v' = 1.0 \). Processing results shall be applied on the ship manoeuvrability diagram obtained in 9.2 of the present Appendix.

9.4 If the ship manoeuvrability diagram, plotted according to 9.2 and 9.3 of the present Appendix, is symmetric with respect to axis \( \delta = 0^\circ \), this axis represents the true zero rudder angle, and the average value on this axis on either side \( \Omega = \Omega_{0} \) or the value \( D_{\text{turn}} / L = 2 / \Omega_{0} \) shall be considered as a criterion of straight course stability according to 6 of the present Part of the Rules.

If the ship manoeuvrability diagram, plotted according to 9.2 and 9.3 of the present Appendix, is not symmetric with respect to axis \( \delta = 0^\circ \), the axis of true zero rudder angle shall be drawn through the point \( \delta_{0} = 0.5 (\delta_{cr\text{,abs}} + \delta_{cr\text{,port}}) \) on this axis. In this case the criterion of straight course stability according to 6.6.1 of the present Part of the Rules shall be the average value \( \Omega_{0} \) \( \Omega \) on either side on the axis of true zero rudder angle or the value \( D_{\text{turn}} / L = 2 / \Omega_{0} \).

9.5 The \( 10^\circ/10^\circ, 20^\circ/20^\circ, 30^\circ/30^\circ \) zigzag trials shall be carried out by gradual deflection of the rudder at the same angle \( \delta \) on either side at the moments, when the ship sets off a straight course to the opposite side at the angle \( \Theta = -\delta \) (Fig. A5.9.5). Zigzag trials shall be carried out at the ship speed on the initial straight course \( v = 0.8v_{0} \). The following shall be tested: ship's overshoot angle \( \Theta_{1} \) (angle of ship's turn from the beginning of rudder moving to pullout to the moment of rotation stop) and pullout time \( t_{1} \) (from the beginning of rudder moving for pullout to the moment of rotation stop). Each manoeuvre shall consist of three semi-periods to measure respectively \( \Theta_{11}, \Theta_{12}, \Theta_{13} \) and \( t_{11}, t_{12}, t_{13} \).

9.6 Stop-inertia trials shall be carried out by entering into a steady turning at the rudder angle \( \delta = 20^\circ \) with stopping the ship's propulsors and subsequent rudder moving at the angle \( \delta = 30^\circ \) to the opposite side. The trials shall include recording of the ship's rotation stop and transition to its rotation to the opposite side or her failure to pull out of turn.

9.7 Emergency stopping shall be carried out at the straight course motion of the ship at a speed conforming to a rated rotation speed of propellers by quickly changing the operating mode of propulsors to full speed astern. The following shall be recorded during trials:

1. The ship's stopway path from the moment when the command "stop - full astern" is given to the moment when the ship has come to a complete stop relative to the water;
2. Time from the moment when the command "stop - full astern" is given to the moment when propellers start running astern;
3. Ratio of the course angle deviation to the initial one at the end of manoeuvre.
9.8 Astern steering trials shall be carried out at the ship moving astern by her straight course keeping without manoeuvring on main engines.

10 Table of manoeuvrability characteristics

10.1 Table of manoeuvrability characteristics shall be placed in a conspicuous position in the wheelhouse. The recommended form of Table of manoeuvrability characteristics is given on Fig. A5.10.1.

Table of manoeuvrability characteristics

10.2 Table of manoeuvrability characteristics shall be developed by the ship’s designer basing on calculations with subsequent supplementing and correction upon full-scale trial results.

10.3 Table of manoeuvrability characteristics shall include the following components:

1. Table of characteristics of ship, ship power installation and steering equipment main dimensions, load and ballast draught; main engine capacity, rated and critical rotation speed of main engines; type and sizes of rudders (parameters of steerable nozzles and steerable pods), thruster capacity and thrust.

2. Table of characteristics of ship, ship power installation and steering equipment may be developed in any form;

3. The ship speed performance as a diagram of the ship speed \( v \), km/h, on a straight course in deep still water against propellers rotation speed \( n_p \), min\(^{-1}\), in fully loaded and ballast conditions (Fig. A5.10.3-1).

4. Performance of fully loaded ship turning quality as a board presenting time-dependent motion path at different rudder angles \( \delta \) (Fig. A5.10.3-2).

5. Inertial properties of the ship as a diagram of motion speed \( v \), km/h, and way, which she travels \( S_n \), m, against time and initial speed \( v_0 \), km/h (initial rotation speed of
propellers $n_0$, min$^{-1}$), at emergency stopping (Fig. A5.10.3-3);

Fig. A5.10.3-3. Diagram of ship speed and the way, which she travels, against time and initial motion speed at emergency;

.5 pullout performances according to Table A5.10.3.5, which contains pullout time $t_1$, s, and overshoot angle $\theta_1$ at pullout of a steady turn of a fully loaded ship moving fully ahead at the rudder angle $\delta_0$ by moving rudders at the maximum angle to the opposite side;

Note: Numerals of parameters on Fig. A5.10.1 and A5.10.3-1 – A5.10.3-3 and in Table A5.10.3.5 – A5.10.3.7 are given for reference only and do not apply to a particular ship.
Part III

FIRE PROTECTION
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 This Part of the Rules establishes requirements for structural fire protection of ships, fire extinguishing systems and stations, fire protection outfit, fire safety of domestic and general service systems, fire alarm system, spare parts and tools for fire extinguishing systems.

1.1.2 Elements of structural fire protection, fire extinguishing systems and fire alarm system shall comply with the requirements of the corresponding Parts of the Rules.

Fire extinguishing means (fire extinguishing medium, fire-fighting equipment, fire extinguishers, fire-fighting tools included in fire protection outfit, spare parts, tools, etc.) and personal protective equipment (fireman’s outfit included in fire protection outfit, emergency escape breathing devices), regarding fire safety requirements, shall comply with the requirements established by the Federal Law No. 123-ФЗ dated 22 July 2008 “Technical Regulations on Fire Safety Requirements” that shall be approved by declarations or certificates confirming the production compliance with the specified Federal Law requirements, drawn by the bodies, accredited according to the legislation of the Russian Federation on accreditation in the national accreditation system.

1.1.3 Requirements of this Part are not applied to fire extinguishing systems and equipment fitted on special fire-fighting ships, as well as to their fire protection outfit, spare parts and tools.

1.1.4 Tugboats and pushboats intended for operation with oil tankers are covered by the requirements related to oil tankers.

1.2 TERMS AND DEFINITIONS

1.2.1 Terms related to the Rules common terminology and their definitions are stated in 2.1 and 2.2 Part 0 of the Rules. The following terms are used in these Rules:

- **Cargo zone** means a totality of spaces and areas connected with cargo storage and transportation.

Cargo zone of ships intended for storage and transportation of inflammable liquids in bulk and liquefied gases consists of the following spaces and areas:

- compartments and tanks for inflammable liquids and gases and adjacent spaces;
- rooms containing pumps and compressors for pumping inflammable liquids and gases;
- storage rooms for cargo hoses;
- spaces in which cargo system pipelines are led;
- spaces above the pump rooms and vertical cofferdams adjacent to the compartments and tanks for inflammable liquids and gases;
- spaces above the cargo tank deck at the distance of less than 2.4 m in the vertical and less than 3 m in the horizontal directions from the cargo tanks;
- spaces located less than 3 m in any horizontal direction and less than 2.4 m in the vertical direction from closed tanks, receptacles, measuring tanks;
- spaces located less than 3 m in any direction from gas ventilation outlets and similar arrangements;
- spaces in which pipelines for inflammable liquids and gases are led, within 3 m from those pipelines in any direction;
- spaces connected with the above-mentioned spaces by openings or exits.

Cargo zone of other ships consists of the following spaces and areas:

- holds and spaces for cargo stowage;
spaces at the distance less than 3 m in any direction from the gas ventilation outlets of the cargo hold intended for any kind of stowage of inflammable and highly inflammable materials and substances as well as other spaces connected with the above-mentioned spaces by openings or exits;

2 Cargo spaces means the spaces which include:
   cargo tanks intended for cargo carriage including discharge tanks;
   spaces for dry goods not being ship stores, dry cargo and refrigerated holds and spaces between decks intended also for carriage of containers and removable tanks as well as motor vehicles without fuel in their tanks;
   closed ro-ro cargo spaces extending to 1/3 length or the entire length of the ship;
   open ro-ro cargo spaces extending to 1/3 length or the entire length of the ship, opened on both sides or on the one side and having ventilation providing the absence of trapped zones over the entire length of the space through permanent openings distributed in the side plating or deckhead or from above, having a total area of at least 10% of the total area of the space sides;
   weather deck is a deck that is totally exposed to environment from above and at least from two sides;

3 Length of a ship means the overall length of a ship;

4 Inflammable liquids — see the definition in 2.2.14 Part 0 of the Rules;

5 Confined space means the space having any of the characteristics mentioned below:
   confined entry and exit openings;
   insufficient ventilation and;
   not intended for continuous operation;
   and includes (but it is not limited to the listed), cargo spaces, double bottom, fuel tanks, ballast tanks, cargo pump rooms, compressor rooms, cofferdams, chain lockers, empty spaces, box-shaped keels, separating spaces, boilers, engine crankcases, engine air inlets, fecal tanks and adjacent rooms. The list is not exhaustive and for confined spaces it shall be made with regard to features of particular ships;

6 Closed method of loading and unloading oil products means a method of performing cargo handling operations by both coastal and onboard facilities by means of sealed piping system ensuring communication of the oil compartments with the atmosphere only through the gas outlet system;

7 Structural fire protection means a set of passive structural protection means aimed at:
   prevention of fire risk;
   restriction of spreading fire and smoke along the ship;
   arrangement of conditions for safe evacuation of people out of the ship spaces and from the ship as well as for fire extinguishing;

8 Vertical fire-resistant zones means the hull, superstructure and deckhouse spaces formed by transverse fire-proof or fire-retardant divisions;

9 Divisions of type A, or fireproof divisions means those divisions formed by bulkheads or decks which shall be:
   made of steel or equivalent fire resistant material;
   constructed to prevent the passage of smoke and flame to the end of the one-hour standard fire test (see 1.2.1.35).

The divisions have the following designations depending on the time t within which the surface temperature of the unexposed side will not rise more than 140 °C above the original temperature nor will the temperature at any one point, including any joint, rise more than 180 °C above the original temperature:

\[
\begin{array}{c|c}
 t \text{ (min)} & \text{Division}\n \hline
 0 & A-0 \\
 15 & A-15 \\
 30 & A-30 \\
 60 & A-60 \\
\end{array}
\]

10 Divisions of type B or fire-retardant divisions means

---

1 According to GOST 1062.
2 The definition was given by the IMO Resolution A.1050 (27).
those divisions formed by bulkheads, decks, ceilings or linings made of non-combustible materials and being flame-tight within the 30-minute standard fire test. The divisions have the following designations depending on the time $t$ within which the surface temperature of the unexposed side will not rise more than 140 °C above the original temperature nor will the temperature at any one point, including any joint, rise more than 225 °C above the original temperature:

<table>
<thead>
<tr>
<th>$t$ (min)</th>
<th>B-15</th>
<th>0</th>
<th>B-0</th>
</tr>
</thead>
</table>

11 Divisions of type C means those divisions made of non-combustible materials for which the requirements for smoke and fire penetration prevention as well as observance of the temperature rise are not applied;

12 Foam expansion ratio means the ratio of the volume of foam produced to the volume of foaming agent aqueous solution supplied;

13 Material equivalent to steel means a non-combustible material which, by itself or due to insulation provided, has structural and integrity properties equivalent to steel at the end of the applicable exposure to the standard fire test;

14 Machinery spaces – see the definition in 2.2.25 Part 0 of the Rules;

15 Machinery spaces of A category means the spaces, containing internal combustion engines, boilers or other power plants working on liquid fuel, as well as trunks of these spaces;

16 Low flame spread means that the surface will adequately restrict the spread of flame, this being determined in accordance with national standards;

17 Stairways means inner ladders, elevators and moving stairways;

18 Continuous B type ceilings and linings means B class ceilings and linings of terminating either at an A or B type divisions or at outer surfaces of a ship;

19 Standard fire test specimen means a bulkhead (a deck) specimen with the heating area of at least 4.65 m² and the height (the deck length) of 2.44 m, which corresponds with the intended structure and comprises insulation joints, if they are present on the intended structure;

20 Fire-resistant material means a material keeping sufficient heat-insulating capacity in the event of fire or by fire heat, that is determined according to national standards;

21 Protected space means a space equipped with one of fire-fighting systems and automatic fire detection system;

22 Accommodation spaces means cabins for the crew, passengers, special personnel, lounges, mess-rooms, restaurants, canteens, sport halls, offices, hair-dressing saloons, sanitary compartments, as well as corridors, lobbies and companions adjoining to these compartments;

23 Pump rooms means cargo pump rooms in tankers;

24 Semi-closed spaces means partially closed spaces with natural ventilation, which are located on ships in the explosive zone at distance up to 3 m from cargo tanks, tanks for combustible liquids with flash point of max. 60 °C or spaces with cargo pumps, pipelines of combustible liquids, hoses;

25 Adjacent spaces means spaces separated from each other with a bulkhead, deck or similar fixed structure without openings or with permanently closed openings.

Spaces separated from each other with detachable structures or having non-closing openings in separating bulkhead or deck shall be considered as one common space;

26 Service spaces means utility spaces; boatswain stores, paint stores; machine and electric shops, not being a part of machinery spaces, radio room;

27 Utility spaces means galleys, dishwashing, preparation rooms; rooms for

1 GOST 12.1.044, GOST 53327, GOST R 51032, GOST 30444.

2 GOST 53299, GOST 30247.0, GOST 53310, GOST R 56076.
water heaters, ironing rooms, saunas and similar spaces intended for household needs which contain oil fuel, solid fuel or gaseous fuel burning units or are fitted with electrical heaters; storerooms for ship’s stores; adjacent corridors;

28 **Fire station** means the place where start-up devices of fire extinguishing systems, fire appliances or fire alarm detectors for a particular part of a ship (a compartment or separate spaces) are located;

29 **Central fire control station** means a fire control station, where fire detection stations and remote starting devices of fire-fighting systems, if any, are centralized. The room in which the central fire control station is located and which is not a wheelhouse, shall have direct communication with the wheelhouse or round-the-clock watch while the ship is under way;

30 **Fixed fire-fighting systems** means systems intended to supply fire extinguishing agent to protected spaces or directly into them and structurally connected with the hull;

31 **Discharge tank** means a tank intended for collecting water used for washing cargo tanks and contaminated ballast water;

32 **Fire protection outfit** means portable active fire-fighting means (apparatuses, appliances and expenditure materials) intended for:

- fire suppression;
- provision of actions of the crew while extinguishing a fire;

provision of fire extinguishing systems with substances required for their operation when extinguishing a fire;

33 **Method of spaces’ protection** 1C means that all inner division bulkheads are of classes B or C and that the fixed alarm fire detection system is fitted and meets the requirements of the Rules. Automatic smoke detectors and manual detectors of this system shall be located so as to provide fire detection throughout all corridors, all ladders and escape routes within accommodation spaces;

34 **Combustible mediums** means inflammable liquids, gases, solid combustible materials and substances;

35 **A standard fire test** means the determination of the specimen’s resistance to heating from any of the sides depending on the time of heating in a test furnace up to the following temperatures counted off from the initial furnace temperature, °C:

<table>
<thead>
<tr>
<th>end of minute</th>
<th>5</th>
<th>10</th>
<th>15</th>
<th>30</th>
<th>60</th>
</tr>
</thead>
<tbody>
<tr>
<td>temperature</td>
<td>556</td>
<td>659</td>
<td>718</td>
<td>821</td>
<td>925</td>
</tr>
</tbody>
</table>

36 **Fixed deck coatings** means all deck coatings applied directly to metal deck including anti-corrosion coating and glue, but not including finish coatings (linoleum, carpet, etc.);

37 **Passenger ship** – see the definition in 2.2.40 Part 0 of the Rules. Coastal ships intended for accommodation of more than 12 passengers are considered in the present Part of the Rules as passenger vessels;

38 **Crude oil** means any oil occurring naturally in the earth whether or not treated to render it suitable for transportation and includes crude oil where certain distillate fractions may have been removed from or added to;

39 **Flash point** means the minimum temperature at which vapour formed on the surface of inflammable liquid forms a mixture with the ambient air capable of igniting when an open flame has been brought to it. Flash point shall be determined using the closed cup test;

40 **Fire smothering** means a method of fighting a fire by filling the protected space with vapours of non-inflammable liquids or non-inflammable gases which form the environment which does not sustain combustion;

41 **Surface fire-fighting** means a method of fighting a fire by cooling, damping or restricting access of oxygen to burning surfaces, e.g. by water or foam;

42 **Fuel oil and lubricating oil storages** means main storage tanks, daily service tanks, discharge, settling, sediment and other tanks;

43 **Crew** – see the definition in 2.2.76 Part 0 of the Rules.
1.3 FIRE PROTECTION PLANS

1.3.1 On every self-propelled ship with a length of 25 m or more the diagrams shall be arranged in the central control station, the wheelhouse or at visible places in corridors, indicating the following:

1. location of control stations;
2. location of the spaces protected by fixed fire extinguishing systems with the indication of their control devices and arrangements;
3. location of fire-retardant and fire-resistant divisions;
4. location of fire protection outfit;
5. means of access to compartments, on decks etc. with the indication of escape routes, corridors and doors (for ships fitted with cabins);
6. location of fire hydrants;
7. the ventilation system diagram including the central control of fans, with the indication of fan shutters and fans servicing all the ship zones;
8. locations for remote closing of fuel tank pipelines.

1.4 CLASSIFICATION OF EXPLOSION-HAZARDOUS ZONES AND SPACES

1.4.1 For classification of explosion-hazardous zones, see Table 1.4.1.

1.4.2 Fire-risk rooms and spaces are the following:

first category:

1. tanks and cargo tanks for inflammable liquids and liquefied gases;
2. cofferdams separating the tanks stated in 1.4.2.1 from adjacent spaces, and spaces adjacent to them which are not separated by cofferdams and not having forced ventilation;
3. cargo holds intended for transportation of inflammable liquids and liquefied gases;

second category:

4. pump rooms for inflammable liquids and compressor rooms for liquefied gases;
5. closed / semi-closed spaces for storing cargo hoses used for pumping inflammable liquids and liquefied gases;
6. closed / semi-closed spaces in which pipelines for inflammable liquids and liquefied gases are led;
7. spaces adjacent to the tanks stated in 1.4.2.1, not separated by cofferdams but having forced ventilation;
8. spaces above the pump rooms and vertical cofferdams adjacent to the tanks stated in 1.4.2.1;
9. spaces above the cargo tank decks and cofferdams at the distance of less than 2.4 m in the vertical and less than 3 m in the horizontal directions from the cargo tanks;
10. spaces located closer than 3 m in any horizontal direction and no less than 2.4 m in the vertical direction above closed tanks, receptacles, measuring tanks and similar capacities;
11. spaces located closer than 3 m in any direction from gas ventilation outlets and similar arrangements;
12. semi-closed spaces adjacent to the tanks stated in 1.4.2.1, as well as spaces, through which spaces in which pipelines for inflammable liquids and liquefied gases are led, within 3 m from those pipelines in any direction.

1.4.3 Rooms and spaces onboard the oil tankers designed for carrying inflammable liquids and liquefied gases with flash point up to 60 °C inclusive or for operating with them are subdivided into explosive (see 1.4.1) and explosion-proof ones, and with vapor flash point more than 60 °C — fire-hazardous (see 1.4.2) and fire-proof ones.
### Classification of explosion-hazardous zones

<table>
<thead>
<tr>
<th>Designation of hazardous zone</th>
<th>Classification of explosion-hazardous zones</th>
<th>Rooms and spaces included in this zone</th>
</tr>
</thead>
</table>
| 0                            | Zone, where explosive mixture of air and gas may be present permanently or for long periods of time | 1. Inner spaces of cargo compartments and tanks, tanks for combustible liquids; cargo holds for transportation of combustible liquids in containers; cargo pipelines.  
2. Open spaces up to 1 m high from the water surface covered with oil products. |
| 1                            | Zone, where explosive mixture of air and gas may be present under normal operating conditions | 1. Pump and compressor rooms for pumping inflammable liquids.  
2. Cofferdams separating compartments and tanks belonging to zone 0 from adjacent spaces and spaces adjacent to those belonging to zone 0, not separated by cofferdams and not having forced ventilation.  
3. Storage rooms for cargo hoses for pumping inflammable liquids.  
4. Spaces above the cargo tank deck at the distance of less than 2.4 m in the vertical and less than 3 m in the horizontal directions from the cargo tanks.  
5. Spaces and semi-closed rooms on the open deck in a radius of 3 m from the openings which are not ventilating, filling openings and hatches of cargo tanks, pump rooms and cofferdams adjacent to cargo tanks.  
6. Laying areas for pipelines with combustible liquids on the open deck – up to 3 m in any direction.  
7. Spaces located closer than 3 m in any direction from gas ventilation outlets.  
8. Open spaces located within 3 m vertically and horizontally from devices for emission from safety and breathing valves of containers with inflammable liquids and combustible gases. |
| 2                            | Zone with low chance of presence of explosive mixture of air and gas, and in case if this mixture appears it is present for short periods of time | 1. Closed / semi-closed spaces in which pipelines for combustible liquids and liquefied gases are led.  
2. Spaces adjacent to those in zone 0, not separated by cofferdams but having forced ventilation.  
3. Inner spaces of cargo compartments and tanks, cargo pipelines, for combustible liquids with flash point of max. 60 °C and their ventilation system. |
2 STRUCTURAL FIRE PROTECTION

2.1 SUBDIVISION OF MATERIALS DUE TO COMBUSTIBILITY, FLAME SPREADING AND INFLAMMABILITY

2.1.1 Materials used for ships construction shall undergo tests for assessing combustibility, flame spreading, inflammability of deck coverings, degree of integrity and inflammability of textiles.

For the test methods established by normative documents on fire safety, see Appendices 1 to 5 Part X of the Rules.

Proceeding from the test results the grades of materials are determined according to 2.1.2–2.1.4.

2.1.2 Materials, except for textiles, are divided into:

1. non-combustible materials – materials, whose combustibility parameters at 30 minute-tests in the furnace are the following:
   - temperature increase – max. 50 ºC;
   - sample weight loss – max. 50 %;
   - steady flame burning – max. 10 s;

2. combustible materials – materials not complying with at least one of the parameters stated in 2.1.2.1.

2.1.3 Classifications of materials according to flame spreading are based on flame spreading index value $I$ – dimensionless reference indicator, characterizing the capability of materials or substances to inflame, to spread flame on the surface and to release heat. Combustible materials and compositions undergo tests for flame spreading and are assessed as follows:

1. low flame-spreading materials – materials and compositions which are relatively high resistant to flame spreading along the surface and are characterized by flame spreading index $I \leq 20$;

2. rapid flame-spreading materials are the materials and compositions which spread flame along the surface and are characterized by flame spreading index $I > 20$.

2.1.4 Fixed deck coverings with a thickness 5 mm and more are subject to ignitability tests and are assessed according to Appendix 3 Part X of the Rules or according to GOST 30402 as follows:

1. hardly inflammable deck coverings – fixed deck coverings with critical surface density of heat flow exceeding 35 kW/m²;

2. medium inflammable deck coverings – fixed deck coverings with critical surface density of heat flow in range from 20 to 35 kW/m²;

3. highly inflammable deck coverings – fixed deck coverings with critical surface density of heat flow exceeding 20 kW/m².

2.2 REQUIREMENTS FOR MATERIALS

2.2.1 Structural bulkheads, decks and trunks of machinery spaces shall be made of steel; otherwise their structure shall be equivalent to steel structure due to the fire safety.

2.2.2 No combustible materials for structure elements in the machinery spaces are allowed.

2.2.3 Insulation of the ship spaces shall be as follows:

1. For the ship's sides, decks, bulkheads, partitions and other divisions it shall be made of non-combustible materials;
2. Heat and noise insulation of the ship’s sides, bulkheads, decks and trunks off machinery spaces and boiler rooms shall be made of non-combustible materials. The insulation surface shall be protected against ingress of fuel, oil and their vapours.

Bulkheads and decks separating machinery spaces from adjacent accommodation and household spaces shall be made of at least A-30 type divisions.

If spaces adjacent to the machinery spaces are completely free from combustible materials, their divisions may be of A-0 type.

2.2.4 At control stations, in accommodation and household spaces including related corridors, fixed deck coverings of a thickness 5 mm and more shall be hardly inflammable as per 2.1.4.1 and shall not release toxic or explosive gases.

Outer surfaces of corridors and partitions of the ladders from the control stations, accommodation and household spaces as well as concealed or non-accessible surfaces in those spaces (beyond panels, linings, etc.) shall be made of low flame-spreading materials.

Facing of outer surfaces in accommodation and household spaces may be made of combustible materials with a thickness not exceeding 2 mm, when the latter are not adjacent to the machinery spaces. If low flame-spreading materials are used, facing may be more than 2 mm thick.

2.2.5 Mass of combustible materials used for inner bulkheads, furring, insulation, lining, finishing, furniture and other equipment of control stations, accommodation and household spaces excepting cooled spaces, where this Part of the Rules allows its application, shall be not more than 45 kg per 1 m² of the deck area where the given space is located.

The area of a space formed by non-vertical structures is calculated on the basis of plan area of this space at the middle of its height between the floor and the top ceiling.

Wood for furring, covering of inner decks and platforms, bulkheads, insulation lining shall be impregnated by fireproof composition or treated in other equivalent way.

In case of fire or heating the materials shall not release toxic or explosive gases in hazardous concentrations.

In all cases surface of the material shall be low flame-spreading.

2.2.6 No varnishes, paints on nitrate base or any other combustible base shall be used for inner finishing of the ship’s spaces.

Finishing coatings shall not release toxic substances in dangerous concentrations when burning (class of hazard — not higher than moderately hazardous according to GOST 12.1.044).

No aluminium paints shall be used on oil tankers in cargo compartments, cofferdams, pump rooms, cargo deck area and other spaces where explosive vapours may be present.

2.2.7 Textiles for draperies, curtains etc., as well as furniture covers and mattresses shall not spread flame more rapidly than woollen cloth of relative mass 0.8 kg/m².

Carpets and similar coverings shall not spread flame more rapidly than woollen products used for the same purpose.

No combustible materials with rapid flame propagation shall be used as padding for mattresses and pillows.

2.2.8 All capacities intended for collection of combustible wastes shall be made of non-combustible materials and shall have no openings in walls or the bottom.

2.2.9 Materials used for equipment included in fire extinguishing systems shall be non-combustible and resistant to fire extinguishing agents. Gaskets and flexible hoses (see 10.2.22 Part IV of the Rules) used in joints of fire extinguishing systems shall be made of materials resistant to fire extinguishing agents, water (sea water for M-СП, М-ПП and О-ПП class ships) and moist air.

2.2.10 Deck coverings inside explosive rooms and spaces shall prevent the risk of spark formation.

1 GOST R 50810.
2.3 USE OF COMBUSTIBLE MATERIALS

General provisions

2.3.1 On passenger ships, A, B or C type divisions in accommodation and service spaces which are faced with combustible materials, facings, moldings, decorations and veneers shall comply with the provisions of 2.2.4, 2.2.6, 2.3.4 – 2.3.6.

2.3.2 On non-passenger ships, non-combustible bulkheads, ceilings and linings fitted in accommodation and service spaces may be faced with combustible materials, facings, moldings, decorations and veneers provided such spaces are bounded by non-combustible bulkheads, ceilings and linings in accordance with the provisions of 2.2.4, 2.2.6, 2.3.4 – 2.3.6.

2.3.3 Structures of combustible materials near galley ovens shall be covered with heat insulation of non-combustible material, faced with steel plates which shall be extended over the overall oven dimensions for at least 500 mm.

Maximum heat of combustion for combustible materials

2.3.4 Combustible materials used on the surfaces and linings shall have a heat of combustion not exceeding 45 MJ/m², with regard to their thickness. The requirements of this paragraph are not applicable to the surfaces of furniture fixed to linings or bulkheads.

Heat of combustion with regard to facing material is determined by the following formula (MJ/m²):

$$ Q = q_s ps $$

(2.3.4)

where $q_s$ – specific heat of combustion for the material, determined according to GOST R 56025 (MJ/kg);

$p$ – material density (kg/m³);

$s$ – material thickness (m).

2.3.5 The total volume of combustible facings, moldings, decorations and veneers meeting the requirements of 2.3.1 and 2.3.2 in accommodation and service spaces shall not exceed a volume equivalent to 2.5 millimeters veneer on the combined area of the walls and ceiling linings. Furniture fixed to linings, bulkheads or decks need not be included in the calculation of the total volume of combustible materials.

2.3.6 The following surfaces shall have low flame-spread characteristics;

1. on passenger ships:
   - outer surfaces in corridors and ladder enclosures, and bulkhead and ceiling linings in accommodation and service spaces (except saunas) and control stations;
   - surfaces and grounds in concealed or inaccessible spaces in accommodation and service spaces and control stations;

2. for non-passenger ships:
   - outer surfaces in corridors and ladder enclosures and of ceilings in accommodation and service spaces (except saunas) and control stations;
   - surfaces and grounds in concealed or inaccessible spaces in accommodation and service spaces and control stations.

2.4 LADDERS, TRUNKS. REQUIREMENTS FOR DRAUGHT RESTRICTION AND PENETRATION OF SMOKE AND FLAME

2.4.1 Exits from spaces, ladders, doors and rescue scuttles shall be made according to the requirements of 1.8 Part IV and 9 – 10 Part I of the Rules. In addition to the requirement of 1.8.4 Part IV of the Rules for ships of 85 m in length, light hatch may be used as a second exit. It shall be opened from inside.

2.4.2 Ladders shall be made of steel or other equivalent material. Ladders passing through a single deck shall be enclosed on either of two decks by fire-retardant divisions and self-closing doors.

Ladders passing through more than one deck shall be enclosed on all decks by fire-retardant divisions and self-closing doors; exits shall be provided from ladder enclosures to the open deck or to the corridors giving access to the open deck.

2.4.3 In ladder enclosures of passenger ships, each deck shall be provided with max.
six seats. Seats shall be fixed and shall not restrict the passenger escape route. Furniture shall not be permitted in passenger and crew corridors forming escape routes in cabin areas.

2.4.4 Elevators and lifts shall be located within trunks made of steel or equivalent material which shall prevent smoke and flame penetration from one space between decks to another one. Closing arrangements restricting draught and smoke penetration shall be provided.

2.4.5 Air spaces located beyond the lining of ladders, trunks and similar vertical enclosures as well as deck penetrations for pipes and cables shall be sealed with a non-combustible material at every deck.

2.4.6 Protection of ladders and elevator trunks in the accommodation, service spaces and control stations of M-CTI class ships shall be provided as follows:

.1 Ladders passing through one deck only shall be protected at least at one level by at least B-0 type divisions and self-closing doors. Elevators passing through one deck only shall be enclosed by A-0 type divisions with steel doors at both levels. Ladders and elevator trunks which penetrate more than a single deck shall be surrounded by at least A-0 type divisions and be protected by self-closing doors at all levels;

.2 Ladders and elevator trunks may be protected by B-0 type divisions on ships with the accommodation spaces intended for 12 passengers or less, ladders passing through more than one deck and at least two exits to an open deck available at each accommodation spaces’ level;

.3 One of the ladders of the machinery spaces which comply with the requirements of 1.8.3 Part IV of the Rules, throughout the escape route shall have continuous fire protection by means of separation by A-15 type divisions;

.4 Elevator trunks shall be so arranged that to prevent from penetration of smoke and flame from one tween-deck space to another;

.5 Where hold-back arrangement is provided, it shall comply with the requirements of 2.6.3.

2.5 FIRE-HAZARDOUS MATERIAL STORAGE, WELDING ROOMS AND SAUNAS

Storerooms for highly inflammable materials and substances

2.5.1 Storerooms for highly inflammable materials and substances as well as combustible materials shall not be adjacent to the accommodation spaces, machinery spaces, fuel and lubricating oil storages. Structures of bulkheads and decks of the storerooms shall be made of steel or another equivalent material.

Where the hull, superstructures and deck-houses are made of other materials, structures of bulkheads and decks of the storerooms shall be of type B-15.

2.5.2 Storerooms for highly inflammable materials and substances shall comply with the following requirements:

.1 Storerooms shall have separated exits to an open deck. One exit to an open deck may be arranged from the lamp rooms and paint stores located in adjacent spaces through a common lobby isolated from other spaces provided that each store room has individual closable exit to that lobby;

.2 Equipment shall be made of non-combustible materials;

.3 Stores shall be provided with natural plenum-exhaust ventilation. Outlet openings of vent pipes from the mentioned spaces shall be fitted with flame arresting fittings;

.4 Inflammable liquids of ship supply with a flash point lower than 43 °C inside the storerooms shall be stored in special steel tanks with air ducts led to the outside and fitted with flame arresting fittings;

.5 Storeroom doors shall open toward the open deck and be provided with an inscription “Fire danger!”

2.5.3 Where a separate storeroom for easily inflammable liquids is impracticable, they may be stored in steel lockers or boxes complying with the following requirements:

.1 The lockers and boxes shall be fitted with tightly closing doors or covers with locks and vent ducts fitted with flame arresting fittings. The lockers and boxes shall not be adja-
cent to the accommodation spaces. Doors or cover in places of contact with the case shall be faced with materials preventing spark formation. Where the lockers or boxes are fitted on the deck made of combustible material, the latter shall be insulated by steel above non-combustible heat-insulating material 5 mm thick along the locker or box surfaces. Instead of deck insulation the locker or the box may be fitted on legs at least 50 mm high.

2. Inside the lockers or boxes inflammable liquids may be stored in not more than two tightly closed cans. Steel cans shall be secured in pockets faced with non-combustible material preventing spark formation. The can capacity for inflammable liquids shall not exceed 20 L. No cans made of synthetic materials may be used.

2.5.4 Store of rags and used rags shall be kept in storerooms outside the machinery spaces. Service store of rugs is allowed to be kept in the machinery spaces in individual closed steel boxes.

Ship’s pyrotechnical means

2.5.5 Ship pyrotechnic means other than those for lifeboats and liferafts shall be kept in tightly closed metal lockers.

2.5.6 Lockers for storing pyrotechnic signal means shall be impenetrable and made of steel or its equivalent fire-resistant material, fitted with tight doors, located on the open deck, at least 100 mm above the deck and at minimum distance of 100 mm from external bulkheads of the superstructure / wheelhouse, next to which they are mounted, or integrated in the wheelhouse. In the latter case, their doors shall be arranged to open outwards (to the deck).

Lockers shall be provided with shelves excluding friction and shocks of rockets, their displacement under heel conditions.

If the locker is subject to direct sunlight, it shall be provided with a sun visor.

The following inscriptions shall be applied on the lockers (boxes):

“Pyrotechnics
No open flame”.

Storage rooms for oxygen and acetylene cylinders

2.5.7 Storage rooms for oxygen and acetylene cylinders shall be at least 2 m clear of the accommodation spaces and control stations and at least 4 m clear of spaces containing inflammable substances and fuel or essential onboard equipment.

2.5.8 The storage room for acetylene cylinders shall be separate from the storage room for oxygen cylinders.

2.5.9 Rooms for storing cylinders shall be separated from adjacent rooms by A-60 type divisions and have an entrance directly from the open deck.

2.5.10 Storage spaces for oxygen and acetylene cylinders shall be equipped with regard to the following requirements:

1. Oxygen and acetylene cylinders shall be kept in vertical position in special closed spaces with natural ventilation or on open decks;

2. Storage spaces for the cylinders shall be fitted with uprights with sockets, clamps or other devices which provide reliable fastening and release of the cylinders;

3. Storage spaces for the cylinders on the open deck shall be selected to avoid accidental mechanical damage of the cylinders and access of unauthorized personnel;

4. Cylinders shall be protected against direct sunlight;

5. Warning inscriptions “Acetylene” “Explosive” and “No smoking” shall be provided on the fence of the area with acetylene cylinders; warning inscriptions “Oxygen”, “No oil inside” and “No smoking” shall be provided on the fence of the area with oxygen cylinders;

6. Cylinders shall not be fastened on bulkheads of accommodation spaces;
.7 Laying and placement of foreign equipment, cables and pipelines in cylinder rooms is not allowed.

2.5.11 Doors of spaces shall open outward, shall have locks and inscriptions as stated in 2.5.10.5.

**Spaces for electric-gas-welding operations**

2.5.12 Space for electric-gas-welding operations shall comply with the following requirements:

1. The space shall be located to the aft from cargo tanks (in oil tankers), discharge tanks and cofferdams protecting them, shall be separated from adjacent rooms by A-60 type divisions and have an exit to the open deck;

2. The space shall not be located in machinery spaces of A category, as well as at distance less than 5 m from the rooms intended for storing and transporting explosive and fire-risk materials;

3. The distance from the room to gas ports of cargo compartments and discharge tanks shall be min. 9 m;

4. The space shall be fitted with forced ventilation which provides 20 air exchanges per hour;

5. The welding current source shall be fitted with a blocking device preventing from its activation when entrance door is open and forced ventilation is not in operation;

6. The door shall have a lock, the outer door shall be provided with lighting panel “Keep out! Welding in progress!”.

**Saunas**

2.5.13 Saunas shall comply with the requirements of 9.9 Part I of the Rules and with the following requirements:

1. The sauna perimeter shall be fitted with A-60 type divisions, except those inside the perimeter;

2. Saunas shall include changing rooms, showers and toilets. If there is an entrance from the bathroom to the sauna, then the door between them may not comply with fire safety requirements, but in this case the bathroom shall comply with the requirements for saunas according to the present Rules;

3. Wooden benches and wooden linings on bulkheads and ceilings are permitted in saunas and in this case the requirements of 2.3.4, 2.3.5 are not applied. The ceiling above the oven shall be lined with a non-combustible plate with an air gap of at least 30 mm.

The distance from the hot surfaces to combustible materials shall be at least 500 mm, or the combustible materials shall be protected (e.g., non-combustible plate with an air gap of at least 30 mm).

2.6 **REQUIREMENTS FOR STRUCTURAL FIRE PROTECTION OF VARIOUS SHIP TYPES**

**Passenger ships**

2.6.1 On passenger ships the following structural elements shall be fireproof inside the hull and superstructures:

- trunks of machinery spaces and boiler rooms
- enclosures of ladders
- bulkheads and decks separating the control stations from adjacent spaces
- bulkheads and decks separating the accommodation spaces from the household, machinery spaces and boiler rooms as well as the cargo holds and fuel storerooms
- bulkheads and decks of storerooms for highly inflammable and combustible materials as well as galleys and all other spaces where fuel is stored or used
- bulkheads and deck of the passages used as escape routes for passengers and crew

The stated structural elements shall be designed as per Tables 2.6.1-1 and 2.6.1-2.

When using Tables 2.6.1-1 and 2.6.1-2, the following shall be considered:

1. Bulkheads between cabins, between cabins and corridors, vertical bulkheads
- bulkheads separating lounges according to 2.6.2, bulkheads of spaces with pressure sprinkler system shall comply with B-0 type;
### Table 2.6.1-1

1. The type of bulkheads for mustering stations is specified as follows: in the numerator – inside the ship, in the denominator – in open spaces.
2. The type of bulkheads between lounges and mustering stations is specified as follows: in the numerator – inside the ship, in the denominator – in open spaces.
3, 4 Type of bulkhead shall be selected with regard to the requirements of 2.6.1.1 and 2.6.1.2, respectively.
5 The type of bulkheads is specified as follows: in the denominator – bulkheads separating galleys and refrigerated chambers or provision rooms, in the numerator – other bulkheads.

1–4 See the corresponding footnotes for Tables 2.6.1-1.

...
tor of the door position (“O p e n” – “C l o s e d ”).

Self-closing doors, which remain open during the normal operation, shall be closed from the place permanently manned by crew members. After the door is closed, it shall remain available for local closing and opening.

Other openings in the bulkhead shall be sealed by non-combustible material in a such way that the bulkhead integrity is not disturbed.

Closing devices of the openings in other fire-retardant divisions shall be so sealed that to retain the integrity.

2.6.4 Air spaces beyond the ceiling, panels or lining shall be separated by tightly fit sealings without gaps made of non-combustible materials preventing from draught and located at the distance not exceeding 14 m apart.

2.6.5 Structural fire protection of passenger ferries shall be executed in the same way as on passenger ships.

Ships and ferries intended for transportation of motor vehicles and other vehicles with filled fuel tanks shall comply with the following requirements:

1. Accommodation, service and machinery spaces shall be separated from cargo decks and holds by fireproof divisions of type A;
2. Closed spaces (holds) shall be fitted with forced ventilation.

Oil tankers. General requirements

2.6.6 Portholes and windows in bulkheads of superstructures and deckhouses faced to the cargo tanks or measuring tanks as well as in outer bulkheads adjacent to a superstructure at the distance within 3 m shall be of blind (non-opening) type. No doors are allowed in the mentioned areas.

This requirement does not apply to cargo handling control stations having no direct connections with the accommodation and service spaces, and the wheelhouse.

In addition to the above mentioned, the requirements of 5.6.2 Part IX of the Rules shall be met.

2.6.7 For heating the ship’s cargo or spaces, the machinery space or special compartment from the deck or from the machinery space, boilers working on liquid fuel with flash point of over 60 °C, may be fitted. The doors in machinery space trucks shall be of self-closing type. The doors shall be closed in normal position.

2.6.8 No wood or other combustible materials may be used in bulk cargo tanks, cofferdams and pump rooms.

2.6.9 Bulk cargo / discharge tanks shall be separated from the machinery spaces by cofferdams.

2.6.10 Cofferdams shall be of a length equal to one spacing but not less than 0.5 m. By-pass gate valves in cofferdam bulkheads are not allowed.

2.6.11 When the pump room is adjacent to the machinery space, no cofferdam is required.

2.6.12 Pump rooms shall be separated from the machinery spaces and cofferdams by gastight bulkheads.

Pump rooms shall have separate exits to the open deck fitted with gas-tight closures.

Direct connection between the pump rooms and the machinery spaces is not allowed.

2.6.13 On the deck of bulk cargo tanks hollow (tubular) details in the structure of ladders, enclosures and other structures are permitted, if natural ventilation of their inner cavities is provided. No hollow details are permitted in bulk cargo tanks and pump rooms of oil tankers.

The requirement does not cover pipelines of the cargo heating system.

2.6.14 Structure of hatch covers fitted in spaces and areas with risk of explosion shall prevent spark formation when they are being opened or closed. Hatch covers shall be gastight.

2.6.15 Accommodation spaces shall be located in the superstructures of the after part of a ship made of steel or other equivalent
material. Where the accommodation spaces are located above the pump rooms, cofferdams or cargo compartments, the deck of the mentioned spaces shall be raised for 0.5 m above the ship’s deck.

2.6.16 The space between the ship’s deck and the raised superstructure shall be open. The raised deck shall be gas-tight and be made of steel or other equivalent material.

2.6.17 The superstructure containing the accommodation spaces shall have two exits on the open deck, one from each side.

2.6.18 On self-propelled oil tankers a smoking room shall be provided in the superstructure, with equipment and lining made of non-combustible materials. Exit from the smoking room shall lead to a corridor, the portholes shall be of blind (non-opening) type.

2.6.19 On oil tankers and ships carrying hazardous chemicals in bulk, cofferdams, ballast tanks, cargo reservoirs and other spaces in the cargo zone shall be accessed directly from the open parts of the deck. Double bottom space may be accessed through other spaces.

2.6.20 Ships stated in 2.6.19, shall be provided with two independent exits in the cargo zone which are located as far as possible from each other. Minimum free dimensions of exits shall be the following:

- \((600 \times 600)\) mm – for exits through horizontal openings, manholes, hatches
- \((600 \times 800)\) mm – for exits through vertical openings, manholes and hatches. If the lower edge of an exit is located 600 mm above the floor level, it shall be provided with steps.

Requirements for oil tankers intended for transportation, pumping and storage of liquids with a flash point of max. 60 °C.

2.6.21 Peaks shall be separated from cargo zone and fuel tanks by cofferdams. Machinery spaces shall be separated from cargo zone by cofferdams, cargo pump rooms or isolated ballast tanks. The cofferdams shall be fitted with water or inert gas filling system.

Accommodation spaces shall be located above dry compartments in superstructures of the after part of a ship made of steel or other equivalent material. The first tier of the aft superstructure shall extend from side to side. The fore bulkhead of that tier shall be tight and have no doors, necks and opening portholes.

Placement or overhanging of accommodation spaces and the wheelhouse above the pump room and cargo tanks on self-propelled tankers is not permitted. On non-self-propelled ships those spaces may be located amidships above the cofferdams, pump rooms and cargo compartments, when the deck of those spaces is raised above the ship’s deck by 2 m; here, the requirement of 2.6.16 shall be complied with.

2.6.22 In the pump room (see 2.6.11 and 2.6.12), the first floor from the machinery space bulkhead shall be gas-tight.

2.6.23 The structure and material of the deck machinery elements (locking devices, brake blocks etc.) fitted in spaces and areas with risk of explosion, shall prevent spark formation.

Chain lockers (if located in the mentioned spaces and areas) shall be gas-tight and fitted with arrangements for water filling.

2.6.24 Mooring and towing bollards shall be arranged on foundations which design shall provide for free air circulation beneath the bollards.

In spaces and areas with risk of explosion no steel towing or mooring ropes may be used or stored.

2.6.25 The structure and material of guard rails located in explosive cargo zone shall prevent formation of sparks as a result of impact.

2.6.26 Working spaces decks (near the onboard arrangements and the deck machinery) shall be covered with wooden grating or insulated by non-slip mastic. Grating shall have no steel fastenings.

Requirements for oil stations

2.6.27 On oil stations working with inflammable liquids with a flash point of max.
60 °C no accommodation or other spaces may be located except for pump rooms, machinery spaces, control stations and service spaces (offices, washrooms, shower rooms and lavatories).

2.6.28 No control stations or service spaces may be located in the ship’s hull.

2.6.29 Machinery spaces of all stations as well as boiler rooms of stripping stations working with inflammable liquids with a flash point below 60 °C, shall comply with the following requirements:
- The deck of machinery spaces located above the cargo tanks shall be raised over the cargo tank deck by at least 0.7 m;
- Machinery spaces located inside the hull shall be separated from the cargo tanks by cofferdams of at least 0.5 m width.

2.6.30 In oil stations working with inflammable liquids with a flash point of over 60 °C, the machinery spaces may be located either inside the hull or above the cargo tank deck.

- The deck of machinery spaces located above the cargo tanks shall be raised over the cargo tank deck by at least 0.5 m.
- Machinery spaces located inside the hull shall be separated from cargo tanks by a cofferdam.

- In oil stations intended for operation with inflammable liquids with a vapour flash point above 120 °C, no raise of the machinery space deck over the cargo tank deck is required.

2.6.31 In oil stations working with inflammable liquids with a vapour flash point below 60 °C entries to the machinery spaces shall be arranged from the deck of superstructure or entrance deckhouse arranged at the height of at least 2 m from the main deck.

2.6.32 Pump rooms, machinery spaces and entrance deckhouses shall have blank (non-opening) side scuttles, tight bulkheads and divisions and separate exits to open decks with tight closures.

Requirements for oil tanker service ships

2.6.33 Port ships, which service oil tankers carrying oil goods with vapour flash point of max. 60 °C, including auxiliary ships, fuelers, floating stores shall comply with the requirements of 2.1 – 2.5, and with the following:
1. Fender guards shall be either made of materials preventing spark formation or faced with such materials. Guard rails shall not be fastened to the hull by driftbolts;
2. Fenders with outer surfaces made of spark-forming materials are not permitted;
3. Detachable elements of guard rails, mooring and towing ropes, closures of bulwarks and fender suspensions shall be made of materials preventing spark formation;
4. Design of the doors and hatch covers located in the cargo zone of an oil tanker during mooring operations, shall prevent spark formation when they are being opened (closed);
5. Fuelers being oil tankers shall also comply with the requirements of 2.6.6 – 2.6.32 with due regard of the vapour flash point of the cargo being transported.

Requirements for ships less than 25 m in length

2.6.34 The requirements of 2.1 – 2.5 apply to ships less than 25 m in length, unless specified otherwise in 2.6.35 – 2.6.37.

2.6.35 On wooden and composite ships wood may be used without fireproof impregnation for inner bulkheads, divisions, decks except for wooden divisions in spaces containing internal combustion engines.

- Ceilings, sides and bulkheads of the machinery space shall be either impregnated with fireproof composition or plated with steel above the layer of non-combustible material not less than 5 mm thick.

2.6.36 Heat insulation of the deck above the fuel tank compartment shall be made of non-combustible material.

2.6.37 On ships without continuous deck tight bulkheads are not required for enclosing spaces of engines.

Requirements for floating objects with wooden superstructures

2.6.38 Wood may be used as structural material for superstructures of inland navigation
floating objects with the reinforced concrete hull, operated in close proximity to the coast and moored to it, if the requirements of 2.1 – 2.5 and the following requirements are complied with:

1. Superstructures shall be made of timber impregnated by fireproof composition;
2. There shall be maximum three superstructure tiers;
3. It is necessary to take measures to minimize the amount of combustible materials onboard the floating object (non-combustible materials shall be used for isolation, finishing and furniture);
4. All spaces shall be protected by a fire detection and alarm system;
5. When selecting and fitting ship’s technical facilities, elements of systems and electric equipment, the fire risk arising from superstructure material properties shall be considered;
6. Floating object shall be equipped with fire extinguishers, whose number shall exceed that stated in 6.1.8 at least by two times;
7. Smoking shall be forbidden on board the floating object;
8. At least two (main and reserve) evacuation routes from each room and from the floating object shall be provided. The reserve route may be provided by means of portable (folding or rope) ladders through windows and portholes.

2.7 STRUCTURAL FIRE PROTECTION OF M-CII CLASS SHIPS

General requirements

2.7.1 In places where A type metal divisions are adjacent to metal decks, bulkheads and sides as well as in places where piping, cables and air ducts penetrate through A type metal divisions, those structures adjacent to as well as penetrating through A type divisions shall be insulated by non-combustible materials. The total length of the insulated section shall be at least 500 mm regardless of the insulation availability at one side or both sides from the A type division. The length of the insulated section may be reduced if the reduced insulation length is proved sufficient by the standard fire testing (see 1.2.1.35).

2.7.2 The A type divisions separating two adjacent rooms, one of which is completely free from combustible medium (inflammable liquids, inflammable compressed, liquefied gases and gases dissolved under pressure, inflammable solid combustible materials and substances), or being the outer surfaces of superstructures and deckhouses, due to their fire resistance properties shall meet the requirements for A-0 type divisions.

2.7.3 Continuous B type ceilings and linings (ceilings and linings terminating either at an A or B type division or at outer surfaces of a ship) together with related decks and bulkheads may be approved as completely or partially complying with the requirements to insulation and fire resistance of A type divisions stated in relevant fire resistance tables (see Tables 2.7.18-1, 2.7.18-2, 2.7.22-1, 2.7.22-2).

2.7.4 B type bulkheads shall extend from deck to deck and to outer plating or other boundaries. However, when such a boundary is protected by a continuous B type ceiling or lining extending to both sides from the bulkhead, the latter may terminate near such continuous ceiling or lining.

2.7.5 Closures of openings in A and B type divisions shall be of the same type as the divisions themselves.

Closures of openings in A type divisions shall be smoke- and fire-tight within 60 min of standard fire resistance test and be made of steel or equivalent material.

Closures of openings in B type divisions shall be fire-tight within 30 min of standard fire resistance test and be made of non-combustible material.

B type doors may be used in corridor A-0 type bulkheads.

All windows and portholes in bulkheads inside the accommodation and service spaces shall be arranged in such a way that they do to impose the fire-resistance properties of the bulkhead. This requirement does not apply to glassed bulkheads, windows and portholes in the outer plating of the hull, bulkheads and deckhouses, and outer doors in superstructures and deckhouses.
2.7.6 Fire-fighting doors in bulkheads of vertical fire zones and in ladder enclosures as well as doors leading to machinery spaces of A category, except for mechanically driven watertight doors, outer and normally locked doors, shall be self-closing. Those doors shall close at the inclination angle up to 3.5° to the side opposite to the closing direction. The doors shall be supplied with a hold-back arrangement keeping them in the open position and releasing them either by the remote control or directly from the places arranged on both sides of the door. The hold-back arrangement shall be designed in such a way that the doors could be closed automatically if the remote control system is damaged.

2.7.7 In the lower corner of the doors located in fire-resistant bulkheads (except for doors in the main fire-resistant bulkheads) there may be an opening with self-closing device for fire hose. The diameter of the opening shall allow free pass of fire hose connections used onboard the ship and provide the doors with possibility to close with a fire hose passing through them.

2.7.8 No air ducts or gratings may be arranged in A type doors.

2.7.9 Air ducts may be arranged either in the lower half of doors of corridor bulkheads, cabins or public spaces or under doors except for the doors in ladder enclosures. The total net area of such openings shall not exceed 0.05 m²; they shall be fitted with a mesh made of non-combustible material.

2.7.10 Upper parts of B type doors may be glassed by special heat-resistant glass or glass wired with reinforcing wire mesh. Frames for glass fixation shall be made of steel or other non-combustible material. Construction of glassed doors shall comply with all requirements to B type divisions; this shall be proved by the results of testing specimens of such doors for fire resistance.

2.7.11 Hinges of A and B class doors shall be made of materials with melting point not less than 950 °C.

2.7.12 Where openings for cables, piping, trunks, air ducts or ventilation system assemblies, lightning fixtures etc. are arranged in A and B type divisions, the measures shall be taken against loss of fire resistance properties of the latter.

2.7.13 Doorways of all doors, air ducts, ring spaces around smoke pipes, light hatchways of machinery spaces, boiler and pump rooms shall be supplied with closing devices. Those devices shall be manufactured in such a way that they could be controlled from the open deck in the event of fire. The requirement for the control of closing devices from the open deck does not apply to doors that can be closed from outside the spaces listed above.

2.7.14 In light hatchways of machinery spaces and boiler rooms no glass panels shall be fitted. Portholes arranged in the light hatchways shall have glass wired with reinforcing wire mesh.

Requirements for passenger ships

2.7.15 Structural fire protection of passenger vessels regardless of the voyage patterns shall correspond with the requirements of the International Convention for the Safety of Life at Sea, 1974, as amended. The requirement applies to passenger ships of M-IIP and O-IIP classes.

Requirements for cargo ships

2.7.16 The requirements of 2.7.17 – 2.7.20 are additional to the requirements of 2.7.1 – 2.7.14 and apply to cargo ships of gross tonnage 500 and over.

2.7.17 Accommodation and service spaces shall be protected by 1C protection method which specifies that all inner bulkheads shall be made of non-combustible B and C type divisions.

2.7.18 The minimum fire resistance of bulkheads and decks separating adjacent spaces shall comply with the requirements of 2.7.18-1 and 2.7.18-2 respectively, which divide those spaces into the following categories proceeding from the risk of fire:

1. Bulkheads which separate wheelhouse, chart house and radio room, may be of B-0 type.
2. To determine the type of bulkheads see 2.4.6 and 2.7.20.
3. Doors from cabins to inner individual lavatories may be made of combustible materials.
4. Where transport of hazardous goods is not provided, A-0 type bulkheads may be used.
5. When spaces are used for the same purpose, bulkheads between them may be dispensed with.

**Note.** “*” — divisions made of steel or other equivalent material, which may be not of A type.

**Note.** See footnotes and Note to Table 2.7.18-1.

1 – control stations;
2 – corridors, lobbies and companions;
3 – accommodation spaces according to 1.2.1.22 except for corridors, lobbies and companions;
4 – inner ladders and elevators except for those entirely located within the machinery spaces as well as their enclosures. A ladder enclosed only in one tween-deck space is to be considered as a part of the space from which it is not separated by fire-fighting door;
5 – service spaces (with low risk of fire): storerooms of combustible materials with area less than 2 m², storerooms of non-combustible materials, drying rooms and laundries;
6 – machinery spaces of A category;
7 – other machinery spaces: machinery spaces except for those of category 6, and special electrical spaces;
8 – cargo spaces according to 1.2.1.2;
9 – service spaces (with high risk of fire) according to 1.2.1.26 except for those listed in category 5;
10 – open decks: open deck spaces and closed promenade decks having no risk of fire as well as air spaces outside the superstructures and deckhouses;
11 – ro-ro cargo spaces according to 1.2.1.2.

Openings in bulkheads and decks between ro-ro cargo spaces shall have fire- and smoke-tight covers.

Where a deck marked with * in Table 2.7.18-2, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations should be made tight to prevent the passage of flame and smoke.

2.7.19 At the control stations, in accommodation and service spaces all ceilings and linings, draught stops and relevant framing shall be made of non-combustible material.

2.7.20 Bulkheads in accommodation and service spaces, which are not required to be made as A or B type divisions, shall be made as at least C type divisions.

Requirements for oil tankers

2.7.21 The requirements of 2.7.22 – 2.7.33 are additional to those stated in 2.7.1 – 2.7.14 and apply to oil tankers of gross tonnage 500 and over, which are intended for transportation of crude oil and oil products with a flash point of max. 60 °C. Ships intended for transportation of oil products with a flash point exceeding 60 °C shall comply with the requirements of 2.7.16 – 2.7.20.

Ships of gross tonnage up to 500 shall comply with the requirements of 2.6.6 – 2.6.26.

2.7.22 The minimum fire resistance of bulkheads and decks separating adjacent spaces shall comply with the requirements of 2.7.22-1 and 2.7.22-2, which divide those spaces into the following categories proceeding from the risk of fire:

<table>
<thead>
<tr>

</table>

**Note.** See footnotes to Table 2.7.22-1.

1 — control stations
2 — lobbies, corridors and companions
3 — accommodation spaces excepting lobbies, corridors and companions
4 — stairways (inner ladders and elevators)
5 — service spaces (with low risk of fire): storerooms of combustible materials with area less than 2 m², storerooms of non-combustible materials, drying rooms and laundries
6 — machinery spaces of A category
7 — other machinery spaces
8 — cargo pump rooms
9 — service spaces (with high risk of fire) according to 1.2.1.26 excepting those stated in category 5 as well as control stations of cargo operations and incinerator rooms
10 — open decks means open deck areas without any risk of fire and air spaces outside the superstructures and deckhouses

Sealings of shafting and cables piercing the bulkhead between the machinery spaces of A category and other machinery spaces shall not disturb the bulkhead integrity.

Where a deck, except for an open deck, marked with * in Table 2.7.22-2, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations should be made tight to prevent the passage of flame and smoke.

However, where a deck, except for an open deck, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations should be made tight to prevent the passage of flame and smoke.

2.7.23 External boundaries of superstructures and deckhouses which enclose the accommodation spaces (including shelter decks on which these spaces are situated), facing cargo zone along the full height, as well as adjacent side boundaries along 3 m at the height of three levels from the deck shall have insulation which corresponds to A-60 type divisions.

2.7.24 Windows and portholes in external boundaries facing cargo zone as well as in the adjacent side boundaries of superstructures and deckhouses, at the height of three levels from the deck along the distance of 4 % of the ship’s length, but not less than 3 m, and not over 5 m from the end of the superstructure or deckhouse facing cargo zone, shall be of closed (non-opening) type.

The requirement does not apply to wheelhouse windows which may allow opening, but they shall provide tightness in closed position.

The mentioned portholes in frontal bulkheads of the first level shall be supplied with...
dead covers permanently attached to their casings. Casing, frame, dead cover and glass-fixing ring shall be made of steel or other equivalent material. Porthole glass shall be tempered and have the following minimum thickness (mm):

<table>
<thead>
<tr>
<th>clear diameter (mm)</th>
<th>thickness (mm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 and less</td>
<td>10</td>
</tr>
<tr>
<td>300 to 350</td>
<td>15</td>
</tr>
<tr>
<td>400</td>
<td>19</td>
</tr>
</tbody>
</table>

Clear diameter shall not exceed 400 mm. For intermediate clear diameters (from 200 to 300 mm and from 350 to 400 mm) the glass thickness shall be determined by means of linear interpolation.

2.7.25 In boundaries mentioned in 2.7.24 no doors are permitted excepting for doors to control stations of cargo operations, provision and other stores not connected with other spaces. Bulkheads separating such stations and stores shall be of class À-60.

This requirement does not apply to wheelhouse doors. These doors shall provide the wheelhouse tightness when closed.

In boundaries mentioned in 2.7.24 detachable plates may be attached by bolts to close openings for transportation of dismantled equipment.

2.7.26 Machinery spaces, control stations, cargo operations control stations, accommodation and household spaces (excluding isolated cargo handling gear lockers) shall be situated aft of cargo tanks, discharge tanks, pump rooms and cofferdams.

Machinery spaces other than category A, control stations, accommodation and service spaces may be situated to the bow from cargo zone provided that they are separated from cargo tanks and discharge tanks by cofferdams, pump rooms or isolated ballast tanks and the adequate safety level is reached if compared with location of those spaces aft from cargo tanks, discharge tanks, pump rooms and cofferdams.

2.7.27 In the accommodation area closed spaces for smoking (smoking rooms) shall be provided. Those spaces shall be formed by B-15 type divisions, and their finishing shall be made of low-flame-spread materials.

2.7.28 Cargo pumps shall be located in separate rooms enclosed by gas-tight bulkheads. Openings in boundaries separating pump rooms from the machinery spaces for pass of cargo pump shafts, electric cables, etc. shall be equipped with sealings which do not disturb the bulkhead integrity.

In bulkheads and decks which separate the pump rooms from other spaces, fixed gas-tight light enclosures may be allowed, provided that they do not impose fire integrity of those divisions.

The bearing structures of deck light hatches for cargo pump compartments shall be made of steel. These hatches shall close from the outside of the pump room.

Pump room bulkhead may be designed with a recess which butts into the machinery space with the height not exceeding one-half of the design depth.

2.7.29 Machinery spaces shall be separated from cargo tanks and discharge tanks by cofferdams, cargo pump rooms, fuel tanks or isolated ballast tanks.

Cargo tank or discharge tank adjacent to the machinery space by their corner shall be separated by a corner cofferdam.

Corner cofferdams not accessible for visual examination are to be filled with a composition suitable for this purpose.

Spaces for pumps and related equipment for ballasting compartments adjacent to cargo tanks and discharge tanks as well as spaces for fuel pumps may be used for separation of the machinery spaces from cargo tanks and discharge tanks provided those spaces have the fire safety level required for cargo pump rooms.

2.7.30 On the upper deck a continuous coaming extending from side to side with the height of at least 150 mm shall be provided at a distance about 2 m from the superstructure where accommodation and service spaces are located.

2.7.31 No coal-fueled cooking ranges or any other coal-fueled equipment are permitted.
2.7.32 Intake ventilation openings of accommodation and service spaces as well as control stations shall be located either on the outer walls of superstructures or deckhouses not facing cargo zone or on the side wall of a superstructure or a deckhouse at a distance of at least 4% of the ship length but not less than 3 m and not exceeding 5 m from the end of the superstructure or the deckhouse facing cargo tanks.

Air duct openings of the machinery spaces shall be located as far as possible from the cargo zone.

2.7.33 In combination carriers the following requirements shall be also complied with:

1. Discharge tanks shall be surrounded with cofferdams except for cases when shell plating, deck plating, pump room bulkhead or fuel tank wall performs function of a discharge tank boundary. Those cofferdams shall be separated from all enclosed (closed) spaces including double bottom space and trunks for pump room piping by tight structures. Means shall be provided for filling the cofferdams with water and for draining them.

When bulkhead of the cargo pump room serves as a boundary of the discharge tank, the latter shall be separated from double bottom space, pump room piping or other enclosed (closed) spaces by tight divisions. Openings with gas-tight bolted covers are permitted.

2. Means shall be provided for isolating the piping connecting the pump room with discharge tanks. The means of isolation shall consist of a valve followed by a spectacle flange or a spool piece with blank flanges. The means of piping isolation shall be located near discharge tanks. Such means may be arranged in the pump room directly at the bulkhead in the place where the pumps penetrates it.

In addition to existing onboard cargo and drainage systems, independent pumps and piping shall be provided on the open deck for discharging the contents of discharge tanks;

3. Access for discharge tank cleaning is allowed only from the open deck. Hatches shall be provided with gas-tight covers. Those covers shall be provided with locking arrangements preventing their unauthorised opening;

4. All cargo spaces and adjacent spaces shall be provided with forced ventilation. Forced ventilation may be provided by portable fans.

Cargo pump rooms, pumping trunks and cofferdams adjacent to discharge tanks stated in 2.7.33.1 shall be fitted with an alarm and monitoring system for inflammable vapours.

Provision shall be made for measuring vapour concentration in all other spaces located within cargo zone, which allows measuring from the open deck or accessible places;

5. Precaution instructions for operations with dry goods when oil residue is present in discharge tanks shall be provided in a visible place.
3 FIRE-EXTINGUISHING SYSTEMS

3.1 GENERAL PROVISIONS

General requirements

3.1.1 Requirements of the present Section apply to fire extinguishing systems and stations intended for fire protection of ships.

3.1.2 If a ship is equipped with fire extinguishing equipment and systems in addition to those stated in this Section, they shall comply with the requirements of the present Section of the Rules.

3.1.3 Fire extinguishing systems and stations shall be intended to ensure their reliability and readiness for use under all conditions of operation.

3.1.4 In addition to the requirements of this Section, elements of fire alarm systems (pumps, filters, pipelines, fittings, etc.) shall comply with the applicable requirements of 7, 8, 10 and 11 Part IV of the Rules.

3.1.5 Storage reservoirs for extinguishing medium, pneumohydraulic tanks, vessels for compressed gases used in fire extinguishing systems shall comply with the requirements for pressure vessels stated in 8 Part IV of the Rules.

Fire-extinguishing systems.

General requirements

3.1.6 On ships with the main engines of total capacity exceeding 220 kW as well as in floating workshops, passenger ships, crew boats, special purpose ships, loaders of inflammable substances or liquids and pump stations regardless of the engines capacity spaces proceeding from their purpose shall be equipped with fixed fire extinguishing systems according to Table 3.1.6 with regard to the following:

1. Automatic sprinkler or water spray system shall be fitted:

   In passenger ships carrying more than 36 passengers in control stations, accommodation and service spaces, including corridors and ladders. Control stations, where water may cause damage to essential equipment, may be fitted with fixed fire-extinguishing system of another type. Spaces having little or no fire risk such as voids, public toilets, carbon dioxide rooms and similar spaces need not be fitted with this system.

   In passenger ships carrying not more than 36 passengers, where fixed smoke detection and alarm system shall be fitted only in corridors, ladders and escape routes within accommodation spaces, in accommodation and service spaces and in control stations, except those containing no significant fire risk, such as voids, lavatories, etc.

   In cargo ships in accommodation spaces, galleys and other spaces (except those containing no significant fire risk) equipped with fire detection and alarm system where restrictions to types of bulkhead structure are not applied;

2. Lamp rooms, paint stores, storerooms for inflammable liquids, liquefied and compressed gases may be not fitted with fixed fire extinguishing system if the volume of each storeroom does not exceed 3 m³ or if the deck area of the storeroom without access to accommodation spaces is less than 4 m²;

3. Fire extinguishing systems for protection of cargo container spaces in ships of gross tonnage 2000 and more;

4. Dry cargo spaces (10 of Table 3.1.6) are not fitted with fire extinguishing systems in the following cases:

   In cargo ships with gross tonnage less than 2000 not suitable for transportation of hazardous goods.

1 Medium expansion foam extinguishing system shall be used.
2 The system is used on ships intended for special purposes, such as automobile or railroad car ferries, where the provision of vertical fire zone bulkheads would defeat the purpose for which the ship is intended, in addition to water-sprinkling, foam fire extinguishing and gas fire extinguishing.
3 High expansion foam extinguishing system shall be used.
4 They shall be fitted only in the rooms, which may be closed from outside the rooms.
5 See 3.1.7.
6 Dry cargo and refrigerated holds and spaces between decks intended also for carriage of containers and removable tanks as well as motor vehicles without fuel in their tanks.
7 See 3.1.6.3 to 3.1.6.4.
8 It shall not be used to protect cargo container spaces.
9 See 3.8.25.

**Note.** Symbols: O – rooms are protected by the stated system; + – spaces are protected by one of the systems marked with this symbol.

If holds are intended only for transportation of ore, coal, grain, non-dried timber, non-combustible goods and goods with low fire risk; the holds shall be fitted with steel hatch covers and means of covering vent outlets and other openings leading to the holds.

Dry cargo spaces (10 of Table 3.1.6) of passenger ships with gross tonnage 1000 and more shall be protected with fixed gas fire extinguishing system or fixed foam fire extinguishing system with foam expansion ratio 1000:1.

6 Gas fire extinguishing system shall be fitted in rooms for muffler spark arresters of internal combustion engines, waste-heat boilers, flues and steam boilers onboard the ships: carrying inflammable liquids and their tenders;

carrying dry goods, regardless of their gross tonnage;
carrying highly inflammable dry goods, regardless of their gross tonnage;
with the total capacity of the main and auxiliary engines exceeding 350 kW;
7 If machinery spaces of A category and attended machinery spaces are protected with foam extinguishing system, the portable foam generator shall be provided;
8 Floating objects with wooden bulkheads shall be equipped with water, foam and carbon dioxide extinguishing systems.

3.1.7 Inert gas fire extinguishing system may be used for oil tankers during unloading operations to prevent the fire by creating and maintaining the medium not sustaining combustion in the cargo tanks by means of inert gas;
On oil tankers of gross tonnage 5000 and more the system is fitted at the ship owner's discretion.

3.1.8 Tugboats and pushboats intended for service ships carrying inflammable substances and liquids as well as motor transport having fuel in tanks shall be equipped with foam or water extinguishing system.

3.1.9 On ships with crew consisting of less than three persons (see 3.1.8), fixed water / foam extinguishing system may be dispensed with.

3.1.10 On non-self-propelled ships operating without a crew, fire-fighting equipment and fire extinguishing systems are not required. Tugboats and pushboats intended for operation with these ships shall be equipped with fixed fire extinguishing systems with manifolds with quick-closing nuts located on the open deck and intended for delivering water or water solution of foam-forming agent to the ships being towed or pushed.

3.1.11 If in the space protected by gas or aerosol fire extinguishing system air receivers with a capacity of 30% of this space are provided, the quantity of fire extinguishing agent is determined according to the design volume of the space to be protected and according to the excess of compressed air free volume. Such increase in quantity of fire extinguishing agent may be not provided, if the air is discharged outside the protected space by safety valves and safety fusions of air receivers.

3.1.12 Overpressure or depression as a result of extinguishing medium dispersion shall not cause damage to structural elements of the protected room. It shall be possible to provide safe pressure equalizing.

3.1.13 Protected rooms shall be provided with possibility to remove fire extinguishing agent. If corresponding suction devices are fitted for this purpose, they shall not operate during fire extinguishing.

3.1.14 Divisions which separate the spaces protected by fire smothering system from the adjacent spaces shall be water-tight.

3.1.15 Air ventilation openings of the spaces protected by fire smothering systems shall be fitted with closing devices from outside of the spaces.

3.1.16 Fire extinguishing systems shall be subject to hydraulic tests according to 6.2.58 RTSC.

Additional requirements for fire extinguishing systems of M-CII class ships

3.1.17 Where two or several adjacent ship spaces with risk of fire are not separated from each other by gas- or water-tight bulkheads or decks, fire extinguishing agent and corresponding fire extinguishing system are chosen proceeding from the space possessing the highest risk of fire, and the necessary amount of fire extinguishing agent and its flow rate are calculated using the corresponding total area or volume of all spaces connected with each other. Total number of extinguishing aerosol generators for these rooms shall be determined by summing the number of generators, intended individually for each room.

If protected spaces are not connected with each other, the necessary quantity of fire extinguishing agent shall be calculated for one space which is the largest.

3.1.18 Water- and gas-tight doors may be considered as enclosures in a bulkhead sepa-
rating adjacent machinery spaces only if they are remotely driven and fire stations which can release the fire-extinguishing agent are fitted with alarm reporting the full closing of these doors. If such alarm is not available, the amount of fire extinguishing agent is calculated and delivered proceeding from the necessity to provide fire extinguishing means for the total volume (area) of adjacent spaces.

In order to prevent excessive pressure in spaces fitted with fire smothering systems during release of fire extinguishing agent either valves shall be provided or the available means shall be used (e.g. air ducts or ventilation pipes).

3.1.19 When calculating the amount and the flow rate of fire extinguishing agent, the total net volume (area) of storage tanks for substances with fire risk located in that space shall be added to the design volume (or the intended area accordingly) of the protected space, excepting the volume (the area) of tanks contained in double bottom.

If protected space is a machinery space of A category, then volume of fuel and oil tanks located inside the space or adjacent to it shall be added to the design volume, excepting tanks contained in the double bottom. Here, the volume of the largest tank of separate tanks or two adjacent tanks shall be added to the design volume (the greatest volume shall be chosen).

3.1.20 Fire extinguishing systems shall be so designed that fire extinguishing agent shall be delivered to all areas of the protected space including enclosed sections therein (e.g. control stations, workshops in the machinery spaces, etc.).

Piping and valves

3.1.21 When laying pipelines the following requirements shall be met:

.1 Fire smothering systems extinguishing agent shall be delivered to each of protected spaces by a separate pipe; check valves shall be fitted in the space of the fire extinguishing station.

This requirement is not applied to foam extinguishing systems intended for delivering foam outside the cargo tanks by means of high-pressure monitors and portable air-foam hoses or by means of medium-expansion foam generators.

One delivery pipeline is permitted for a group of small spaces of the same type (e.g. lamp room and paint store room);

.2 Piping of fire extinguishing systems shall not be led in fuel and lubricating oil stores and cooled spaces for all ships and in pump rooms for tankers. Pressure piping of fire extinguishing systems shall not be led in accommodation spaces;

.3 Piping of gas fire extinguishing systems may be laid via accommodation and service spaces, when piping throughout its length inside those spaces has no plug connections and is designed for pressure stated in Table 6.2.58 RTSC;

.4 All fire extinguishing systems shall be so designed that to ensure periodical inspections in process of operation. For checking pipes of gas fire extinguishing systems, compressed air shall be supplied to the manifold. Compressed air line shall be fitted with a stop-check valve.

Systems equipped with pipelines and nozzles for supplying extinguishing media, shall have devices for their operation testing by compressed air.

Aerosol fire extinguishing systems shall be so designed that to ensure periodical inspections by starting them with the help of simulators of fire extinguishing aerosol generators, whose electric characteristics shall comply with characteristics of generators starting devices.

3.1.22 In fire extinguishing system seamless steel pipes shall be used. Copper, copper-nickel and bimetallic tubes (where one layer is made of steel or copper) may be used as equivalent to steel tubes and pipes.

Steel tubes shall have anti-corrosion coating on the inner and the outer surfaces.

Hydrants, other equipment and fittings of fire extinguishing systems which provide working and safe condition of those systems,
shall be made of materials resistant to fire extinguishing agents and water (sea water for ships of Р-П, Р-ПП and О-ПП classes).

3.1.23 The system shall be activated without additional switches at the station, shall operate under any working conditions of the ship, including at temperatures below 0 °C and in case of fire.

3.1.24 The fire extinguishing system shall be activated at the control station located outside the protected space.

3.1.25 If the fire extinguishing system is intended for protection of several rooms, it shall be equipped with a separate marked activation device for each room.

3.1.26 In the immediate proximity to each activation device, there shall be operating instructions written with non-erasable text and hanged in a visible place. It shall contain the instructions on:

1. activating the fire-extinguishing system;
2. ensuring that no persons are present in the protected space;
3. the crew’s actions for activating the system;
4. the crew’s actions in case of fire extinguishing system failure.

3.1.27 In any service conditions the systems shall be prevented from spontaneous start-up, except for the sprinkler and aerosol fire extinguishing systems in case of temperature increase in the protected space up to the values stated in 3.4.15 and 3.9.11, respectively. All devices shall be protected from mechanical damage. Start-up handles of foam extinguishing and fire smothering systems shall be sealed.

3.1.28 Regardless of the availability of remote activation the system shall be provided with local control directly from the fire extinguishing station and that for the pump – from the place of its location.

For aerosol fire extinguishing systems local control may be dispensed with.

3.1.29 Remote activation systems (using air, nitrogen, carbon dioxide etc.) shall have two starting reservoirs, each of them capable of performing a single full start of extinguishing system.

3.1.30 Remote activation devices shall be controlled by means of handwheels or levers rigidly connected with rods or rollers.

3.2 FIRE EXTINGUISHING STATIONS

General requirements

3.2.1 Equipment of all fire extinguishing systems except for water and aerosol extinguishing systems shall be located outside the spaces protected by the system and at fire extinguishing stations, with regard to 3.2.3.

If those systems operate in conjunction with the fire pumps, on passenger vessels more than 65 m long, self-propelled dry cargo ships and oil tankers with cargo-carrying capacity over 1500 t, fire pumps, driving motors as well as their controls shall be located outside protected spaces.

Fixed emergency fire pump shall comply with the requirements of 3.3.17.

3.2.2 Foam extinguishing stations and fire smothering stations shall comply with the following:

1. All fire extinguishing stations excepting that for machinery spaces shall be located on open deck or directly under it with direct access to the decks.

Fire extinguishing station for machinery spaces may have no direct access to open deck only if remote extinguishing medium release device is accessible from the wheelhouse or other space having direct access to the open deck;

2. Stations shall be located in tight enclosures or lockers. Bulkheads and decks separating the station from protected spaces shall be type A divisions (see 1.2.1.9);

3. If the station requires temperatures above zero for operation, the station room shall be fitted with heat insulation and heating;

4. To monitor the ambient temperature the station room shall be fitted with a ther-
mometer visible from inside the station and from outside via a porthole. The ambient temperature in the space shall not exceed 40 °C.

Readings of press-gauges on air reservoirs shall be visible from inside the station and from outside via a porthole.

The station shall have natural or artificial illumination; electric power to lamps shall be supplied from both the main network and the emergency lighting network.

The station shall be permanently locked by a lock with two keys, one of which shall be kept in a locked box with a glassed wall near the lock, and the other – in the wheelhouse.

The diagram of the fire extinguishing station showing activation devices and protected spaces as well as brief manual on starting the system shall be located in the station room in a visible place.

All valves and devices shall be supplied with nameplates bearing inscriptions and indications: “Open”, “Closed”;

Stations shall be fitted with independent exhaust ventilation which provides 12 air exchanges per hour.

3.2.3 If the amount of fire extinguishing agent supplied to the protected space does not exceed 125 kg, local fire extinguishing stations may be provided with max. 5 vessels.

Inside the machinery spaces, reservoirs with fire extinguishing agent may be fitted for the protection of crank cases, mufflers of internal combustion engines, smoke pipes and other closed volumes located within the machinery space.

Additional requirements for fire extinguishing stations of M-CII class ships

3.2.4 On M-CII class ships with a gross tonnage less than 150, where the location of fire extinguishing station outside the protected space is impracticable, as well as in particular cases in other ships where the total volume of protected spaces does not exceed 100 m³, reservoirs with fire extinguishing agent and pressure vessels may be located inside the protected spaces provided that they are fitted by remote activation device for immediate system actuation from the outside of the protected space; here, the location of remote activation drive shall be indicated and illuminated from both the ship’s general network and the emergency network.

Reservoirs containing fire extinguishing agent with toxic properties which are located inside permanently attended spaces, shall be enclosed in steel gas-tight partitions fitted with independent ventilation.

3.3 WATER EXTINGUISHING SYSTEM

Fire pumps

3.3.1 Pumps of water extinguishing systems shall be operated by electric power. The number of fixed main and emergency fire pumps shall be not less than stated in Table 3.3.1. The total capacity of the main fire pumps shall be the maximum one of those specified according to the requirements of 3.3.3 and 3.3.4.

</tbody>
</table>

Fire pumps may be driven from the main engine provided that the structure “engine – shafting – propeller” enables the operation of the fire pump when the ship is at anchorage and provides for switching-off the pump when the ship is in motion.

3.3.2 Emergency fire pump may be dispensed with, if fire pumps and power sources
for their drive are located in different compartments having not more than one adjacent steel decks or bulkheads so that in the event of fire pumps located in another (other) compartment (compartments) shall provide the water delivery to the fire main.

3.3.3 The total capacity of the main fire pumps shall be determined proceeding from the condition of simultaneous supply of 15% of all hydrants available on a ship but not less than three of them, and for ships with total engine capacity of 220 kW and less — not less than two pumps capable of feeding jets of maximal capacity used on a ship. Here, the requirements of 3.3.19 shall be complied with.

Every fixed fire pump shall be rated for a supply of at least two water jets by the maximal diameter of nozzles used in a ship. Every fixed fire pump excepting emergency pump shall additionally have supply of not less than 80% of the total required supply divided by required number of fire pumps, but at least 25 m³/h.

3.3.4 The total supply of fixed fire pumps shall be at least (m³/h):

\[ Q = K \left(1.68 \sqrt{L(B+H)} + 25\right)^2, \quad (3.3.4) \]

where \( K \) — coefficient: for passenger ships \( K = 0.012 \) and \( K = 0.008 \) for cargo ships;

\( L, B, H \) — main dimensions of a ship (m).

The supply \( Q \) may not exceed 180 m³/h, if greater supply is not required for proper simultaneous functioning of other water consuming systems.

When determining the total supply of fire pumps neither pumps fitted in the fore part of oil tankers nor the emergency pump shall be taken into account.

3.3.5 Head in the system shall be sufficient to provide for simultaneous operation of systems stated in 3.3.3; pressure at hydrants shall be at least 0.25 MPa.

3.3.6 If a ship is fitted with alternative systems which consume water from fixed fire pumps, the latter shall supply water in quantity sufficient for operation of water extinguishing system with a supply of min. 50% of that stated in 3.3.3 and 3.3.4 and parallel operation of one of other systems consuming the greatest amount of water. In this case, the water supply for water extinguishing system shall be sufficient for at least two water jets by the greatest nozzles. Possible increase of water supply should be considered due to the pressure rise in the pipelines necessary for operation of other fire extinguishing systems; the requirement of 3.3.5 shall also be considered.

3.3.7 Water quantity for fire extinguishing systems, except for water fire extinguishing system, shall be determined according to the requirements of 3.4, 3.5 and 3.7.

3.3.8 As fixed fire pumps sanitary, ballast, drainage and other outboard water pumps may be used provided that its supply and head comply with the requirements of 3.3.5, 3.3.6. They shall also meet the requirements of 3.3.9.

3.3.9 Fire pumps located outside the machinery spaces of A category shall have a separate sea valve in each compartment containing them.

3.3.10 All fire pumps including the emergency pump shall be located in spaces with temperature above zero.

3.3.11 In cargo and passenger ships with not permanently attended spaces of fire pumps or permanently attended with one person, remote start-up of one of the pumps shall be provided from the wheelhouse and the area permanently attended when the ship is at anchor; water shall be supplied to the fire main without opening of valves in the pump room. The location of the pump remote start-up device shall be fitted with an indicator of the water pressure in the fire main.

3.3.12 Onboard energy sources shall provide for operation of fire pumps in any service conditions including the anchorage.

3.3.13 Fixed fire pumps may be used for other ship purposes when the ship is fitted with at least two independently driven pumps, one of which is permanently ready for immediate operation according to the main pur-
pose. If a ship is fitted with one fire pump, its short-term use is allowed for other purposes (e.g. for washing a deck, hawses etc.).

3.3.14 Fire pumps and pipelines shall be used neither for pumping of oil products, lubricating oil and other inflammable fluids nor as ballast pumps for tanks filled in turn by fuel and ballast.

3.3.15 On discharge line a pressure gauge shall be fitted prior to isolating valve.

Pumps charging pressure in fire piping over the permissible value shall be supplied with overflow valves for removing water from a discharge line to a filling line.

Overflow valves shall be adjusted on a pressure exceeding the working pressure by not more than 10%.

3.3.16 Fixed fire pumps and relevant outboard valves shall be fitted below the light-draft water-line. If a pump is located above the mentioned water-line, self-suction devices shall be provided.

Provision should be made for the delivery of water by fire pumps from two outboard valves located on both sides of a ship. On ships with ice strengthening, one of the sea inlets shall be further equipped for efficient ice removal, air removal and shall be heated.

3.3.17 Emergency fixed fire pump shall comply with the following:

1. The pump shall be driven from a diesel engine or an electrical motor supplied with power both by main or emergency diesel generator. If a diesel engine is fitted to drive the pump, the emergency fire pump room shall be fitted with a daily fuel tank of capacity sufficient to enable operation of the pump for at least 3 hours; and for M-СП, M-ПП and M class ships – for at least 6 hours;

2. The pump shall be connected to water extinguishing system of a ship;

3. The pump supply shall be sufficient for simultaneous operation of two hand fire nozzles with maximal jet diameter applied on a ship at the design pressure. If the pump may be used also for other water or foam extinguishing systems, its supply shall be increased accordingly to comply with the requirements of 3.3.3;

4. The pump, power sources for its drive and outboard water intake valves shall be so located as in the event of fire in the main fire pump room, they cannot be out of operation;

5. The entrance to the emergency pump room shall be independent of the main fire pump room. The pump shall not be located forward of the fore peak bulkhead;

6. The pump shall comply with the requirements of 3.3.15, 3.3.16; any of the outboard valves required by 3.3.16 may be used as the second outboard valve, if a slide gate on filling pipeline from that outboard valve is located in the emergency pump room.

3.3.18 On non-self-propelled ships with a minimum crew of 3 persons, fitted with electric power sources, portable diesel-pump set may be used as a fire pump and shall meet the following requirements of 3.15.2.

Piping

3.3.19 Diameter of fire main of water extinguishing system and water service pipes shall be sufficient for supplying the maximum required discharge from two fire pumps working simultaneously. In this case, the water velocity in all areas shall not exceed 4 m/s as per 3.3.4.

Pressure in the fire main shall not exceed 1 MPa.

3.3.20 Fire piping led via non-heated spaces and open decks shall be fitted with check valves to disconnect it from piping led via heated spaces, and with drainage arrangements.

3.3.21 Filling and discharge lines of each fire pump shall be fitted with check valves; filling pipes may be fitted with slide valves; if there are two or more rotary pumps, discharge lines of each of them shall be fitted with check stop valves.

3.3.22 Fire main piping shall be fitted with drainage arrangements.

The arrangement of pipes and hydrants shall be such as to avoid the possibility of freezing.
3.3.23 On ships carrying deck cargo, the pipelines shall be arranged as far as practicable to avoid risk of damage by such cargo.

3.3.24 On ships with a length of 50 m and more fire mains with linear piping shall be fitted with check valves on at least each section 30 m long in accessible places.

Hydrants

3.3.25 Each hydrant shall be provided with fire hose coupling, providing fast, tight and reliable connection of the hydrant with fire hose, as well as connection of fire hoses between them and with other fire-fighting equipment.

Hydrants located on the open deck shall be also provided with blank cap.

3.3.26 Hydrants shall be so located to provide two water jets by two hydrants simultaneously, one of which shall be supplied to the hose of length stated in 3.3.33 to any place of the ship.

3.3.27 Hydrants shall be located:
1. on the open deck – in the exit area of superstructures and trunks as well as near cargo hatches;
2. inside the spaces – in corridors and lobbies, in the machinery spaces.

Hydrants shall be located at the distance not more than 1.35 m from the deck or planking.

Hydrants in the inside spaces shall be located not more than 20 m far apart from each other.

Outer hydrants (on decks) shall be located not more than 40 m far apart from each other.

Between two nearby stop valves double hydrants shall be fitted.

3.3.28 On ships carrying deck goods hydrants shall be protected from damage by cargo and located in easily accessible places.

3.3.29 Machinery spaces, where engines and boilers working on fuel oil are fitted, shall provide at least two hydrants located at the port and starboard; on ships with capacity up to 750 kW for this purpose the hydrant located directly near the fire pump (between the pump and the stop valve) may be used.

Machinery spaces of ships with total capacity less than 220 kW may be fitted with one hydrant located directly near the fire pump (between the pump and the check valve).

3.3.30 On passenger ships, the number and arrangement of hydrants in accommodation, service and machinery spaces shall comply with the requirements of 3.3.26 with all watertight doors closed and all doors in bulkheads of vertical fire zones closed.

3.3.31 Tugboats, push-tugboats, icebreakers, rescue boats and floating docks shall be fitted with manifolds with quick-closing nuts located on the open deck and intended for water delivery to other vessels.

3.3.32 All onboard hydrants shall be painted red and numbered.

Fire hoses and nozzles

3.3.33 Fire hoses shall satisfy the following:
1. A hose length for hydrants located on the open deck shall be not less than 10 m and not more than 20 m; for hydrants located in the ship spaces – at least 10 m, but not more than 15 m;
2. Hoses shall be made of low-flame-spread materials.

3.3.34 The number of fire hoses used for the purposes of extinguishing fires or testing the fire-extinguishing apparatus at fire drills and surveys shall be at least equal to the number of onboard hydrants.

3.3.35 Each fire hose assembled with a nozzle shall be located near the relevant hydrant. In interior locations in passenger ships carrying more than 36 passengers fire hoses shall be connected to the hydrants at all times.

Fire hoses shall be stored in separate non-locking cabinets or on hose reels; cabinets shall be marked with subscription ПР (FH – “fire hose”) or with corresponding pictograph.

3.3.36 Nozzles shall be of a dual purpose type, i.e. jet/spray type.
3.3.37 Standard nozzle diameters shall be 12, 16 and 19 mm.

For accommodation and service spaces, a nozzle size shall be max. 12 mm.

In machinery spaces and on open decks of ships with carrying capacity of 1000 t and over, on passenger ships 50 m long and over, technical fleet vessels and on floating docks, nozzle diameter of hand hoses shall be such as to obtain the maximum discharge possible from two jets at the pressure stated in Table 3.3.1 from the smallest pump, provided that the nozzle diameter is 16 to 19 mm.

In tugboats and pushboats with total capacity of the main engines less than 900 kW hand hoses with nozzle diameter of 12 mm may be used on the open deck, if operation of a foam extinguishing system is provided by means of a fire pump.

In tugboats and pushboats with minimum total capacity of the main engines 900 kW, nozzle diameter of 16 and 19 mm may be used.

Isolating valves and relief valves

3.3.38 Shut-off valves shall be provided to separate the fire main within the machinery space containing the main fire pump or pump(s) from the rest of the fire main. These valves are to be fitted in accessible place outside the machinery space. The fire main shall be so arranged that all the hydrants on the ship, except those in the machinery space referred to above, can be supplied with water by another fire pump, including an emergency fire pump, provided that the isolating valves are shut.

3.4 SPRINKLER SYSTEM

General provisions

3.4.1 Sprinkler system shall spray the water of 5 L/min per 1 m² of the largest protected space.

The system tubes shall be constantly filled with water, except for small outer sections, which may not be filled, if it is necessary preventive measure. In the sprinkler system part filled with water, the necessary pressure shall be maintained. Any system parts subjected to low temperatures shall be adequately protected from freezing.

3.4.2 Sprinklers shall be activated automatically in case of increase in temperature in the protected space up to the values stated in 3.4.15.

3.4.3 Sprinkler system shall be equipped with pneumohydraulic tank, alarm control valves, automatically activated pump and air compressor and cylinder maintaining the working pressure in the system and immediate water supply to opening sprinklers.

3.4.4 The air cylinder, compressor, pump and pipes of the sprinkler system, except for the pipeline connecting the sprinkler system with water extinguishing system, shall be independent from other systems.

3.4.5 The sprinkler pump and pneumohydraulic tank shall be fitted outside the machinery spaces as per 3.2. The central control station shall be fitted with pressure gauge connected to the fire main piping.

Sprinkler system pumps

3.4.6 The pump shall be activated automatically in case of the system pressure drop and shall supply the water before all the water in the pneumohydraulic tank is used.

Automatic activation means shall be provided for the pump in case of the pressure drop.

3.4.7 The pipeline pump and system shall maintain the necessary pressure at the level of the highest sprinkler to supply the maximum discharge for simultaneous operation area of the greatest protected space for the parameter stated in 3.4.14.

3.4.8 The delivery side of the pump shall be fitted with a sampling cock with a open-ended discharge tube. The cross-sectional area of the valve and tube shall be sufficient for passing the water in the amount equal to the pump supply with the pressure stated in 3.4.7.

3.4.9 The pump shall have a sea valve located in the pump room and arranged in such
a way to preclude the need for shutting off
the seawater delivered to the pump for any
reason, except for the pump inspection and
repair.

3.4.10 The feed line shall be connected to
the suction line of the water extinguishing
system of a ship. The connecting pipeline
shall be fitted with lockable stop-check valve.

Pneumohydraulic tank

3.4.11 The pneumohydraulic tank shall be
fitted with the following instruments and de-
vices:

1 device for automatic pressure mainte-
nance;
2 device for water level check and alarm
warning on the water/pressure level in the
tank lower than the specified one, led to a
permanently attended place: to the wheel-
house; to the central control station (if any);
in the machinery space (permanently at-
tended) or near the attendant’s place (if any);
3 pressure relief valve;
4 pressure gauge.

3.4.12 The pneumohydraulic tank shall
permanently store the fresh water in amount
equal to the sprinkler pump supply per 1 min.
Tank capacity shall be minimum doubled
water-supply stated above.
The tank shall maintain the air pressure to
have the pressure not lower than the working
one of the sprinkler plus hydrostatic pressure
from the tank bottom to the highest sprinkler
after using the full reserve of the fresh water.

3.4.13 Structure of pneumohydraulic tanks
shall comply with 8.17 and 8.18 Part IV of the
Rules for pressure vessels.

Sprinklers

3.4.14 Sprinklers shall be fitted in the up-
per part of the protected space and spaced to
supply the medium discharge of min. 5 L/min
per 1 m² of the protected space area.

3.4.15 Sprinklers in accommodation and
service spaces shall be actuated within the
temperature range of 68 to 79 °C. On passen-
ger ships they shall be actuated within the
temperature range of 57 to 68 °C. For sprin-
klers fitted in drying rooms and galleys, the
response temperature shall be max. 30 °C
higher than the air temperature near the ceil-
ing.

3.4.16 Sprinklers shall be made of material
resistant to corrosion. The sprinklers of galva-
nized steel shall not be used.

Alarm and monitoring device

3.4.17 Alarm and monitoring device sen-
sors shall be fitted on the feed line of each
section of the sprinkler system and:

1 supply the signal to activate the water
supply sources when opening any sprinkler
fitted in the section;
2 give visual and audible alarm when
opening any sprinkler fitted in the section;
3 transmit the information on the fire
break-out in the group of spaces served by the
system.

3.4.18 Alarm and monitoring devices shall
be fitted in metal lockers outside machinery
spaces in permanently attended places and in
other places, where the crew can receive the
fire alarm.

Places of alarm and monitoring devices in-
stallation shall be accessible, lighted and
closed with glassed doors for monitoring con-
dition of the devices and pressure gauges.

Each alarm and monitoring device shall
provide the list of protected spaces or plan of
the protected spaces served by each section.
The ship shall provide the instructions for
checking and maintaining the system.

3.4.19 One of the alarm and monitoring
devices shall have switches, allowing to check
the alarm response and operation of indicators
of each section for sprinklers.

Piping

3.4.20 Sprinkler systems shall be separated
by sections. One section shall provide for
max. 50 sprinklers. One section may not be
located in different vertical fire zones. One
section shall service maximum two decks.
Each section shall provide for devices to blow the pipelines with compressed air or to wash them with water.

3.4.21 Each section shall be deactivated by only one stop valve with a pressure gauge behind it.

The stop valve of each section shall be available, and its location shall be marked.

To verify correct operation of the system, a sampling cock shall be fitted near the stop valve of each section with cross sectional area equal to that of the sprinkler.

3.4.22 Diameters of the sprinkler system pipelines shall provide the operation of sprinklers with pressure and water consumption stated in 3.4.1 and 3.4.14.

The sprinkler system pipelines shall be fitted with stop-check valves, preventing the ingress of outboard water inside the tank and water leakage from the tank and system.

The intake of the pump feeding the sprinkler system shall be fitted with a filter.

3.5 WATER-SPRAYING SYSTEM

3.5.1 The water-spraying system in machinery spaces of A category and in pump rooms shall be constantly filled with water and shall be pressurized. This system shall be supplied from the water extinguishing system line and from the independent pump, activating automatically in case of the system pressure drop. The pipeline providing connection with the fire main of water extinguishing system shall be fitted with stop-check valve.

In other protected spaces the system may be supplied only from the water extinguishing system line.

Pump and its controls shall be located outside the spaces protected by the system.

3.5.2 The pump supply and head shall be determined with regard to features and number of sprayers fitted in the largest protected space and intensity of water supply, which shall be at least:

- 0.85 L/min per 1 m² of the deck area on ships intended for carriage of hazardous goods in bulk;
- 5 L/min per 1 m² of the fuel spillage area, or of the cargo space area;
- 20 L/min per 1 m² for front parts and surfaces of boilers, fuel oil units, centrifugal separators (but not bilge water separators) and fuel purifiers;
- 10 L/min per 1 m² for heated fuel pipelines, located near exhaust pipes or similar hot surfaces of main and auxiliary engines.

3.5.3 The intake of the pump feeding the system, and the pipeline providing connection with the fire main of water extinguishing system shall be fitted with filters, preventing the blockage of the system and sprayers.

3.5.4 The distribution valves shall be located in accessible places outside the protected space.

Permanently attended spaces shall provide for remote control of the distribution valves from these spaces.

3.5.5 Sprayers in the protected spaces shall be located in the following places:

- 1 under the space ceiling;
- 2 above the equipment and facilities, whose operation is connected with using fuel oil or other inflammable liquids;
- 3 above the surfaces for possible spillage of fuel oil or inflammable liquids.

Sprayers in the protected spaces shall be located in such a way that the working area of any sprayer could overlap the working area of adjacent sprayers.

3.6 DRENCHING AND WATER SCREEN SYSTEM

3.6.1 The drenching system shall be supplied from the pump located outside the protected spaces.

3.6.2 The system shall be started outside the protected space.

Automatic systems actuated in case of inadmissible increase of the room temperature may be fitted.

3.6.3 The capacity of pumps serving the drenching system shall be at least 24 L/min per 1 m² of the total area of the protected space.
3.6.4 The drenching system may be used to protect the superstructures of the ship extinguishing the fire on other ships. In this case, intensity of water supply on the protected surface shall be min. 10 L/min on 1 m² of the tier length and can be reduced to 5 L/min provided that the protected surfaces have isolation of A-60 type. System sections shall be located on each tier, and the nozzle location shall provide for even water supply on the protected outer surface.

3.6.5 Water screen system shall be supplied from the water extinguishing system main. The calculated capacity of pumps serving the water screen system is min. 70 L/min per 1 m of the screen length.

3.6.6 Screens for protection of doorways shall be located and controlled from the side of the corridor.

3.7 FOAM EXTINGUISHING SYSTEM

General provisions

3.7.1 In a foam extinguishing system foam of the following expansion ratios may be produced as an extinguishing medium:
.1 low expansion – around 20:1;
.2 medium expansion – from 20:1 to 200:1;
.3 high expansion – around 200:1.

3.7.2 Foam-forming medium for producing low and medium expansion foam for M-СП, M-ПР and О-ПР class ships shall be capable of working both on fresh water and sea water.

3.7.3 Output of foam extinguishing system and the quantity of foam-forming medium shall be calculated proceeding from the foam expansion ratio, the flow rate of the medium and the working period of the system stated in Table 3.7.3.

When using the data in Table 3.7.3, the following shall be considered:
.1 Output of foam extinguishing system in the case marked with footnote 1 in Table 3.7.3 is selected when multiplying the relative feeding values specified under the footnote sign by the area specified below:
   for relative feeding of 0.36 m³/h per 1 m² of the greatest horizontal cross-section area of a tank;
   for relative feeding of 0.036 m³/h per 1 m² of the area of cargo tank deck which is determined as the product of the maximal ship breadth and the length of cargo tank deck;

¹ See 3.7.3.1.  
² Horizontal cross-section area of the largest protected space shall be taken for a rated area.  
³ See 3.7.3.3.
for relative feeding of \(0.18 \text{ m}^3/\text{h per 1 m}^2\) of the area protected by high-pressure monitor of the maximal supply and fully located forwards to it, but not less than \(75 \text{ m}^3/\text{h}\).

The output of foam extinguishing system is the maximum calculated value;

2. The minimum quantity of foam-forming medium shall be calculated by multiplying the system capacity by the design time of its continuous operation stated in Table 3.7.3;

3. For oil tankers equipped with inert gas system, in cargo tank spaces for inflammable liquids with vapour flash point of max. 60°C and decks for these tanks, the design time of continuous operation shall be 20 min.

3.7.4 Foam-forming medium reservoirs shall be fitted with filling and discharging facilities, liquid level detector and cleaning facilities. Capacity of the reservoirs shall be sufficient for storage of the entire reserve of foam-forming medium.

Where excessive pressure is not allowed when the system is in operation, non-return valves shall be provided between the reservoirs and the main pipeline.

Where in ships intended for operation entering areas of salt water a foam-forming medium for fresh water is provided in high expansion foam extinguishing system, foam reserve shall be provided in a reservoir of foam extinguishing station which is sufficient for at least single filling of a space to be protected. The rest water may be supplied from the ship store.

3.7.5 The calculation of foam extinguishing system output shall include technical evaluation of the mixer type selection for obtaining water solution of foam-forming medium of the required concentration, steam generators and air-foam hoses.

Rated discharge of foam-forming medium of the mixer shall be sufficient for operation of nozzles / foam generators working simultaneously.

3.7.6 The foam extinguishing system main control station shall be located at the fire extinguishing station located outside the cargo area, near the accommodation spaces, be accessible and provide control over the system in case of fire in the protected areas and spaces. A sampling device for determining the foam-forming medium percentage in the solution shall be provided at the fire extinguishing station on the main at the maximum distance from the mixers, the pipeline feeding the system with water shall be fitted with a pressure gauge.

The main equipment of the system (tanks with foam-forming medium, pumps, mixers, etc.) may be located in the machinery space, if the system does not serve it.

**Low / medium foam extinguishing system**

3.7.7 Low-expansion foam fire extinguishing system shall produce foam with expansion ratio not exceeding 20:1. If actual expansion ratio is more than 20:1, the quantity of foam-forming medium is calculated as for the system with expansion ratio 20:1. If actual expansion ratio is less than 20:1, the amount of foam-forming medium shall be proportionally increased.

3.7.8 Foam extinguishing system shall be able to deliver foam to any tank located on the deck which is opened, and to any area of the cargo tanks. Foam thereto shall be delivered by high-pressure monitors and portable arrangements (air-foam hoses or foam generators).

3.7.9 Air-foam nozzle used in ship spaces shall provide foam supply of not less than \(120 \text{ m}^3/\text{h}\).

3.7.10 The number and location of monitors shall comply with the requirements of 3.7.8, 3.7.12. Each high-pressure monitor shall supply foam solution with intensity at least 50% of that stated in footnote 1 of Table 3.7.3.

3.7.11 High-pressure monitor shall be fitted with switchover device for alternate delivery of water and foam. Branches of the water main and the foam solution main shall be connected to this device.

Check valves may be provided instead of switchover device, if their interlock is provided.
3.7.12 A distance from high-pressure moni-
tor to the most distant boundary of the pro-
tected area located forward to the monitor
shall not exceed 75 % of monitor jet length
under conditions of calm weather.

3.7.13 To provide the integrity of the fire
main in case of fire or explosion on the foam
main in accessible and protected places at
poop front and on the deck of cargo tanks
shut-off valves shall be fitted approximately
in each 30-40 m of the length. Each valve
shall be fitted with a plate with inscription
notifying that in normal operating conditions
it shall be permanently open.

In front of each shut-off valve, the main
shall be fitted with doubled fire nozzles of
diameter 70 mm for connection of air-foam
hoses at the distance which provides fulfill-
ment of the requirements of 3.3.25 and
3.3.27.

Branches of the water and foam mains for
high-pressure monitors connection shall be
also located in front of shut-off valves.

In ships where medium expansion foam is
applied, instead of doubled fire nozzles valve
boxes shall be fitted with the number of fire
nozzles equal to 50 % of the design number of
foam generators.

3.7.14 Portable medium-expansion air-
mecanical foam generator shall comply with
the following requirements:

.1 design flow on foam-forming medium
solution at pressure about 0.6 MPa in front of
the foam generator shall be not less than
21.6 m³/h;

.2 length of the foam jet shall be at least
8 m;

.3 design number of the foam generators
or combined foam units shall be:

\[ N = \frac{Q}{q} \]  (3.7.14.3)

where \( Q \) – the system productivity regarding
the solution (m³/h);

\( q \) – foam generator or combined foam
unit productivity regarding the solution
(m³/h).

3.7.15 Fixed foam extinguishing system of
spaces for dry hazardous goods shall comply
with the following requirements:

.1 Check valve shall be fitted in front of
the place where system main crosses the open
deck;

.2 The main shall be fitted with a valve
box with hydrants at both port and starboard
sides. The distance between the valve boxes at
both sides shall be not more than 40 m. The
number of hydrants in each valve box shall be
equal to 50 % of the design number of foam
generators.

3.7.16 Foam extinguishing system in tug-
boats and pushboats intended for operation
with non-self-propelled ships carrying in-
flammable liquids or dry hazardous goods
shall be designed for fire extinguishing on the
ships being under service. The system produc-
tivity and store of foam-forming medium are
defined according to 3.7.3; here, cargo tanks
and holds of a non-self-propelled ship are
taken as cargo tanks and holds.

Foam extinguishing unit shall be fitted with
flow-line hoses, foam nozzles with foam
pourers or foam generators with extenders.

For fire protection of tugboats and
pushboats other fire extinguishing systems
may be used.

3.7.17 When a ship is equipped with low /
medium expansion foam extinguishing system,
the solution main lines shall be arranged to
the entrance area of the machinery spaces
from the upper deck as well as to the areas of
the fuel delivery to the ship. Each of those
lines shall be fitted with two hydrants for the
connection to fire hoses with air-foam nozzles
or foam generators.

3.7.18 On ships using the medium-
expansion air- mechanical foam, the solution
pipeline shall be connected to the water ex-
tinguishing system main for using foam from
this main for extinguishing fires in accommo-
dation and service spaces. For this purpose,
hydrants in accommodation, service and ma-
chinery spaces shall provide for corresponding
number of foam generators.

3.7.19 Instead of monitors and foam gen-
erators, fixed or portable combined foam units
may be used.
High expansion foam extinguishing system

3.7.20 Spaces protected by high expansion foam system shall be fitted with air outlets in the upper part of a side opposite to foam entrance which shall comply with the requirements of 10.4, 10.12 Part IV and 4.2.2.2 Part II of the Rules.

3.7.21 Cross-sectional area of foam lines shall be not less than that of foam generator outlets. Foam lines shall be so arranged that to reduce the head loss to a minimum and the outlets shall be so located as to avoid any obstacles to free delivery of foam to a protected space.

3.7.22 Foam generator or foam line outlets in places where they go outside the boundaries of the station shall be fitted with a closing device. That device shall be opened automatically simultaneously with the start of the system.

The device shall be controlled manually and fitted with the “Open” and “Closed” positions indicators.

3.7.23 A switchover device shall be provided for supplying the foam to the protected space or to the open deck during the test of the system. The device shall be sealed in a position which ensure delivery of the foam to a protected space.

3.7.24 Equipment ensuring generators operation shall be fed by the main and emergency power sources.

3.8 GAS FIRE EXTINGUISHING SYSTEM

General requirements

3.8.1 The gas fire extinguishing system may use the following fire extinguishing agents:

- CO₂ – carbon dioxide;
- inergen (IG-541) – gas containing 52 % of nitrogen, 40 % of argon, 8 % of carbon dioxide;
- gas fire-extinguishing media, complying with the requirements of the Russian Federation legislation in fire safety area.

3.8.2 The total open flow area of mains as well as the open flow area of the supply manifold shall not exceed the total open flow area of valves of reservoirs opened simultaneously for the largest protected space.

3.8.3 The open flow area of supply manifolds for protected spaces shall not exceed the total open flow area of valves of reservoirs opened simultaneously for the given space. The total open flow area of outlet discharge pipelines shall not exceed the open flow area of the supply manifold.

3.8.4 The amount of 85 % of the design quantity of carbon dioxide shall be delivered within at least (min):

- for machinery spaces, emergency diesel generator rooms, fire pump rooms and other spaces where liquid fuel or other flammable liquids are applied 2
- for spaces where no liquid fuel or other inflammable liquids are transported or applied. 10

3.8.5 For gas delivery to the protected spaces the upper part of the latter shall be fitted with nozzles.

Where floor plating of the machinery spaces is located at the height over 1 m from the bottom (inner bottom), then the part of nozzles (min. 15 %) shall be located at the upper part of the space under the plating.

3.8.6 The total area of nozzle outlets of this space shall not exceed 85 % of the total open flow area of the supply manifold.

3.8.7 In silencers, exhaust gas boilers and funnels perforated pipes may be used instead of the nozzles.

The total area of the pipe perforations shall be 10 % less than its cross-sectional area.

3.8.8 Gas fire extinguishing station shall be fitted with a device for weighing reservoirs or measuring their liquid level.

Carbon dioxide fire extinguishing system

3.8.9 Amount of carbon dioxide shall be determined by the formula (kg):

\[ G = 1.79V\varphi \]  

(3.8.9)

where \( V \) – the design volume of the largest protected space (m³)

\( \varphi \) – the factor equal to:
for dry cargo holds and other spaces excepting those stated below for machinery spaces which design volume is calculated taking into account the overall volume of trunks; for machinery spaces which design volume is calculated without taking into account the volume of trunks from the level where horizontal cross-sectional area of trunks is max. 40 % of the machinery spaces area

The factor $\varphi$ for which the $G$ value is greater is taken for machinery spaces.

On ships with gross tonnage less than 2000 register tons, excepting passenger ships, factors 0.35 and 0.4 may be reduced to 0.3 and 0.35 accordingly.

3.8.10 The number of carbon dioxide storage reservoirs is determined proceeding from the extent of filling (the amount of carbon dioxide per 1 m$^3$ of the capacity) which shall not exceed either 675 kg/m$^3$ at the design pressure of carbon dioxide in the reservoir of 12.5 MPa and more or 750 kg/m$^3$ at the design pressure of carbon dioxide in the reservoir of 15 MPa and more. Specific volume of unpressurized CO$\text{2}$ is 0.56 m$^3$/kg.

When filling the reservoirs, the amount of carbon dioxide may deviate for not more than 0.5 kg per one reservoir from the design value.

In case specified in 3.2.3, the extent of filling shall be decreased for 75 kg/m$^3$ compared with the limits stated above.

3.8.11 CO$\text{2}$ vessels shall be arranged outside the protected spaces, in gastight enclosures or locker, hermetically separated from the other spaces. Doors of these enclosures or lockers shall be intended to open outwards, be lockable and have hazard warnings on the outside, as well as CO$\text{2}$ marking.

3.8.12 The reservoirs shall be fitted in vertical position by rows on supports which may be made of wood. The reservoirs shall be accessible for examination and determination of their gas quantity. Each vessel shall be marked with the following data: charge type, charge weight (kg), vessel No.

The starting reservoirs shall be kept on the fire extinguishing station and have a color different from that of carbon dioxide storage reservoirs.

3.8.13 If the enclosures of CO$\text{2}$ vessels are located in the below-deck section, they shall have a direct access outside. These enclosures shall be equipped with artificial ventilation, independent from other ventilation systems.

Inergen fire extinguishing system

3.8.14 To protect several spaces, each space shall be equipped with individual fire-extinguishing system.

3.8.15 Vessels with inergen fitted in the protected space shall be fitted with safety valves preventing the rise of pressure above the rated value. The valve shall ensure the relief of the vessel content to the protected space.

3.8.16 Vessel filling pressure shall not exceed 20 MPa at +15 °C;

3.8.17 The inergen volume necessary for protection of spaces shall be min. 44 % and max. 50 % of the total volume of these spaces.

Piping and valves

3.8.18 Pipeline connecting a reservoir with the supply manifold shall be seamless and made of tough-pitch copper.

Special flexible hoses made of low-flame-spread materials may be used.

The pipeline shall be fitted with check valve.

3.8.19 Gas fire extinguishing station main shall be fitted with pressure gauge which has a scale with the upper-range value exceeding hydraulic test pressure of the reservoirs on at least 1 MPa. Scaling factor shall not exceed 0.5 MPa.

3.8.20 Reservoir valves of the carbon dioxide fire extinguishing system shall comply with the following requirements:

1. To be fitted with safety devices.

Safety diaphragms shall break down when the pressure in a reservoir reaches the value $(1.3 \pm 0.1)p$ (MPa), where $p$ is the design pressure in the reservoir. For valves with slot
diaphragms fitted additionally with safety dia-
phragms the breakdown pressure of slot dia-
phragm shall exceed the upper limit breakdown
pressure of safety diaphragm by at least 1 MPa.

A checking device shall be also arranged
to monitor the actuation of a safety device;

2 A valve opening device shall be of lever
type and provide for the complete opening
of the valve by turning the lever on the angle not
exceeding 90°. The device shall permit the
valves to be opened both individually and in
group;

3 To have pipes with bevel cut not ex-
tended to the bottom of reservoirs on the dis-
tance 5 to 15 mm. Clear inner diameter of the
pipes as well as pipes connecting the reservoir
valves with the supply main, shall be at least
10 mm;

4 Where valves of starting reservoirs differ
from valves of other reservoirs in the design,
they shall be marked by distinct color and its
casing shall have the “starting” marking.

3.8.21 Gas from the safety devices of valves
of the carbon dioxide fire extinguishing system
shall be withdrawn outside the station
boundaries to the atmosphere either by a
separate pipe which outlet branch shall be
fitted with audible alarm or to the supply
main fitted with:

two pipes, one of which is fitted with check
valve and open end and the second – with
safety diaphragm;

an alarm device on the presence of pres-
sure in the supply main which is led to per-
manently attended spaces.

In this case no checking device monitoring
the actuation of a safety device for valves is
required.

3.8.22 Pipelines which deliver gas from
starting reservoirs to servomotors shall be fit-
ted with check valves interlocked with open-
ing device of starting reservoirs.

Starting devices

3.8.23 Spaces listed in 3.8.4.1 should be
provided with remote start-up from the cen-
tral fire control station or from the place lo-
cated near the entrance to those spaces.

Start-up devices of the system at the fire
control station shall provide for simultaneous
opening of valves of the reservoirs intended
for the above-mentioned spaces.

3.8.24 System remote start-up station shall
be fitted with a device which provides signal-
ing when the gas is delivered to the protected
space.

3.8.25 When fitting the gas extinguishing
system in cargo pump spaces of oil tankers, a
notice shall be exhibited at the controls stat-
ing that due to the electrostatic ignition haz-
ard, the system is to be used only for fire ex-
tinguishing and not for inerting purposes.

3.9 AEROSOL FIRE EXTINGUISHING
SYSTEM

General requirements

3.9.1 Aerosol fire extinguishing system shall
comprise of:

extinguishing aerosol generators;
control and alarm board;
warning detectors about start-up of aerosol
fire extinguishing system;
cable runs.

3.9.2 The design weight of aerosol-forming
composition, in kg, shall be determined by
formula (kg):

\[
G = V + \sum_{i=1}^{n} \left( V_{in_i} P_{in_i} / P_a \right) k \varphi ,
\]  (3.9.2)

where

- \( V \) - design free volume of protected
  space (m³)
- \( V_{in_i} \) - volume of \( i \)th air receiver, (m³)
- \( n \) - number of air receivers in protected
  space
- \( i \) - consecutive number of air receiver
- \( P_{in_i} \) - working pressure in \( i \)th air receiver
  (MPa)
- \( P_a \) - atmospheric pressure (MPa)
- \( \varphi \) - rated fire extinguishing concentration
  of aerosol (kg/m³)
- \( k \) - safety factor equal to 1.5

3.9.3 During the system start-up the fol-
lowing shall be provided:
automatic actuation of warning detector in the protected space and in adjacent spaces, if a single exit leads to the protected space, as per 5 of this Part of the Rules;
automatic ventilation cut-off in the protected space;
automatic cut-off of burning units of boilers and incinerators, if they are located in the protected space.

3.9.4 Design mass of aerosol shall be delivered within max. 2 min for the machinery spaces, emergency diesel generator rooms and other spaces where liquid fuel or other highly inflammable or inflammable liquids are applied.

3.9.5 Generators shall be so located as to provide even distribution of fire extinguishing aerosol in the protected space. If there are dead spaces in the protected space formed by the equipment and boundaries, additional generators shall be provided to deliver fire extinguishing aerosol directly to dead spaces.

Extinguishing aerosol generators

3.9.6 Each generator type shall have data on the distance (along the axis of aerosol jet) from the place of its emanation from the generator until the boundary of the heat zone with temperature of $+75^\circ C$.

3.9.7 After starting, the generator shall be switched over to the operating mode in max. 10 s.

3.9.8 The generator shall operate for min. 20 s (see 3.9.4).

3.9.9 The design number $N$ of generators shall be determined by the following formula:

$$N = \frac{G}{m}$$  (3.9.9)

where $G$ – design mass of aerosol-forming composition (kg)
$m$ – mass of aerosol-forming composition in one generator (kg)

The received broken number $N$ shall be expressed in round bigger integer.

If $N$ is equal to 1, the number of generators is 2, if $N$ is equal to 2, then it is 3.

3.9.10 Generators shall be fitted directly in the protected space on non-combustible foundation.

3.9.11 Generators shall be self-actuated when the ambient temperature is min. $250^\circ C$.

3.9.12 Generators shall be arranged so that the distance from the generators to the escape routes and other places with people, was not less than the distance of the safe area with temperature of $75^\circ C$, and to the combustible materials – not less than the distance of the safe area with temperature of $200^\circ C$.

3.9.13 In storerooms for highly inflammable and combustible materials, explosion-proof generators shall be arranged. For cargo pump rooms of tankers carrying oil products with a flash point of $60^\circ C$ and over, explosion-proof generators of ordinary type may be used.

Control and alarm board

3.9.14 Control and alarm board shall meet the requirements of 2.3, 2.6, 2.8 Part IV of the Rules.

3.9.15 Control and alarm board shall provide for simultaneous remote start-up of all generators in the protected space. If there are more than 4 generators in the protected space they may be actuated in group provided that the requirements of 3.9.4 are complied with.

3.9.16 Where several spaces are protected by aerosol fire extinguishing system, generators in each space shall be actuated separately from the control and alarm board.

3.9.17 In the event of voltage break the aerosol fire extinguishing system power supply shall be switched over automatically to the emergency source of power.

3.9.18 Control and alarm board shall not emit electrical impulses that may result in false start-up of the generators including power supply emergency switch-off and switch-on, short circuit or wire breaking.

Cable runs

3.9.19 Starting circuits shall be provided with the use of shielded cables. The cable
network shall comply with Section 12 Part IV of the Rules.

3.9.20 Aerosol fire extinguishing systems shall have functions to check working order of starting electrical circuits with the fault circuit address, providing functional testing of the detection systems and stopping of ventilation.

3.10 INERT GAS FIRE EXTINGUISHING SYSTEM

3.10.1 As inert gas either smoke gases of autonomous boilers may be used after performing treatment in order to reduce the content of oxygen, carbon oxide, corrosion-active substances and solid combustible particles, or combustion products of specially fitted generators. Each source shall be equipped with automatic air supply regulator for supplying inert gas with oxygen content of max. 5%.

3.10.2 The gas quantity shall be sufficient to obtain the minimum volume of free gas equal to at least 25% of the gross volume of the largest protected space every hour for a period of 72 hours.

3.10.3 The distribution pipeline and discharge nozzles shall be arranged to provide uniform delivery of the inert gas.

3.11 ADDITIONAL REQUIREMENTS TO PASSENGER VESSELS

3.11.1 On passenger multi-deck vessels and vessels equipped with accommodation cabins excepting ships with engine capacity of 220 kW or less, the fire main shall be arranged according to a ring circuit. To disconnect single sections of the fire main the latter shall be fitted with valves in accessible places.

3.11.2 Closed spaces (holds) intended for transportation of motor vehicles and other machinery with filled fuel tanks shall be fitted with one of fire smothering systems and automatic fire detection system.

3.11.3 On ships equipped with remotely driven doors the wheelhouse shall be fitted with executive alarm of the door closing.

3.12 ADDITIONAL REQUIREMENTS FOR FIRE EXTINGUISHING SYSTEMS AND FIRE PROTECTION OF OIL TANKERS AND THEIR TENDERS

3.12.1 On tankers fire extinguishing stations shall be located outside the deck of bulk cargo tanks.

3.12.2 Machinery spaces shall be fitted with forced ventilation producing excessive air pressure.

3.12.3 Pump rooms and cargo pumps fitted therein shall be equipped with facilities for the collection and withdrawal of leaked cargo.

3.12.4 Classification of explosion-hazardous zones and spaces onboard the oil tankers is given in 1.4 of the present part of the Rules.

3.12.5 No belt drives may be used as pump drives in explosive areas and fire-hazardous rooms (see 1.4 of the present part of the Rules).

3.12.6 Tankers carrying oil products with a flash point over 60°C, may be fitted with fixed foam extinguishing system.

3.12.7 Boiler rooms at oil cleaning stations working with inflammable liquids with flash point of max. 60°C shall be fitted with two fire extinguishing systems.

3.12.8 Stems of sluice valves of cargo tanks shall be led on the deck via sealing glands. The glands shall be so designed that they can be replaced or tightened from the deck. The stems shall not be hollow.

3.12.9 The liquid level in cargo tanks shall be measured basically by closed method of measurement without opening the tank neck. The open method of measuring the liquid level may be used only as a reserve method.

3.12.10 To drain the static electricity hoses intended for loading and unloading of inflammable liquids shall be fitted with earthing conductor made of flexible wire or a plate with edges soldered to the flanges.

3.12.11 Gas outlet pipes of boilers and internal combustion engines of oil tankers shall be fitted with spark-extinguishers.
Smoke flues of other technical equipment on board these ships shall be fitted with spark arresters.

3.12.12 All sections of the gas-collecting system shall provide for free flow and drainage of condensate and cleaning the main.

3.12.13 Flame-breaking fittings fitted on gas outlet pipes shall be made of corrosion-resistant material.

Flame-breaking fittings shall be so designed that they can be replaced or disassembled without dismantling gas outlet pipes.

Openings in voids (above cargo) shall not be used for pressure equalization. They shall be provided with self-closing and tightly sealing covers. Flame arresters and screens are not permitted in these openings.

3.12.14 High-pressure monitors shall be fitted on ships with carrying capacity of 2000 t and over; other ships may be fitted only with portable foam generators or manual air-foam hoses. In this case the rate of foam-forming medium solution delivery by each foam generator or air-foam hose shall be at least 25% of the designed value.

3.12.15 The main arranged within fire extinguishing station shall be fitted with a check valve.

Two branches shall be arranged before the check valve led on the deck to monitors, and on each branch – doubled fire nozzles of diameter about 70 mm for connection of fire hoses and air-foam hoses. Monitors which shall be fitted at port and starboard sides near the fore bulkhead of the aft superstructure or accommodation spaces faced to the cargo deck.

If medium expansion foam is used, valve boxes shall be fitted instead of doubled fire nozzles and have the number of fire nozzles equal to 50% of the design number of foam generators.

3.12.16 In oil tankers extending pipes shall be made of steel or light alloys in a number equal to 50% of the design number of the foam generators; both ends of the pipes shall be fitted with connecting fittings for fire hoses and portable foam generators. Extending pipes shall be from 4 to 5 m long; a light tripod shall be arranged in the middle of each pipe. Extending pipes shall be located in the after part of the ship.

3.12.17 Each air-foam hose fitted on the cargo deck shall deliver the foam in a quantity of at least 4 m³/min to the distance of at least 15 m.

3.12.18 Tankers shall be equipped with a system for continuous monitoring the concentration of hydrocarbon gases (oil vapours). Sampling points or detector heads shall be located in places where potentially hazardous leakages may occur. When the hydrocarbon gas concentration reaches a pre-set value which corresponds to 10% of the lower flammable limit, a continuous audible and visual alarm signal shall be automatically effected as per 5 of this Part of the Rules.

3.12.19 Tankers shall be supplied with portable gas analyzer with set of spares and calibration means intended for measuring the concentration of inflammable vapours of carried goods. For monitoring oil vapour contents on ships intended for carriage of oil products with a flash point lower than 60 °C, two manual portable gas analyzers shall be provided.

3.12.20 The cargo system structure shall provide for loading/unloading of goods carried by closed method that is necessary for cargo operations with oil products and inflammable liquids.

The ends of filling pipes of the cargo tanks shall be placed at the tank bottom, the distance between these ends and the tank bottom shall be not less than 0.25 of the pipe internal diameter.

Cargo connections of the cargo system manifold shall be equipped with tight blank flanges made of materials preventing spark formation caused by strikes.

3.12.21 Where pumping oil stations operate with inflammable liquids with flash point of max. 60 °C, they shall be supplied with steam or electricity either from the shore or from another vessel.
3.12.22 Gas outlet pipes of the engines and smoke flues of the boilers of oil tankers carrying oil products with flash point of max. 60 °C and the ships which service oil tankers (service and crew boats, auxiliary ships, floating stores) shall be fitted with spark arresters (spark extinguishers).

3.12.23 Smoking spaces in oil tankers shall be fitted with exhaust ventilation, which provides 20-fold air exchange per hour.

3.12.24 In oil tankers intended for carriage, storage or pumping of liquids with flash point below 60 °C provision shall be made for filling dry compartments adjacent to cargo tanks with inert gases and their ventilation.

For non-self-propelled barges of push-trains ventilation of peak compartments shall be provided if after cofferdams are filled with water up to scuttle covers or these compartments are filled with inert gases.

Ventilation shall provide at least six-fold air exchange per hour in peak compartments and at least three-fold air exchange per hour in the compartments adjacent to cargo tanks.

3.12.25 Structural parts of equipment arranged in or intended for application in explosion-hazardous areas and spaces shall be made of materials providing electrostatic and galvanic sparking safety.

3.12.26 Places where pump / fan drive shafts penetrate bulkheads and watertight decks in explosive areas and fire-hazardous rooms shall be fitted with gastight stuffing boxes. The design temperature of the exterior elements of stuffing boxes shall not exceed the permissible temperature specified according to the vapor flash point of the cargo. The components of stuffing boxes shall be made of materials precluding the spark formation.

3.12.27 If metal bellows are used in glands, such bellows shall be designed to operate at pressure not less than the maximal test one specified for testing the compartments (Table P.10.4.1 Annex 10).

3.12.28 Cargo pumps, ballast pumps and stripping pumps fitted in cargo pump rooms and driven by shafts passing through pump room bulkheads shall be equipped with temperature sensing devices for shafts, bearings and pump casings. Alarm signals shall be automatically effected in the cargo control room or the pump control station.

3.12.29 Shafts of mechanical steering gears of oil tankers intended for transportation of oil products with flash point of max. 60 °C, shall be led above the deck in chutes or boxes. Parts of those gears exposed to friction shall be so designed that to prevent sparking caused by friction or impacts.

3.12.30 All tools (sledge hammers, mallets, wrenches, etc.) used to carry out works in explosive spaces and areas of oil tankers shall be made of materials preventing sparking caused by impacts.

3.13 FIRE EXTINGUISHING SYSTEMS AND STATIONS OF SHIPS LESS THAN 25 M IN LENGTH

3.13.1 The requirements stated in 3.1 – 3.12 apply to ships less than 25 m in length, unless specified otherwise in the present Chapter.

3.13.2 On open undecked vessels the engines shall be covered with removable casings made of non-combustible material.

3.13.3 Removable casings of the engines shall be fitted with air ducts of diameter not less than 80 mm, one of ducts shall end at the height of 70 mm above the bottom and the other – at the casing cover.

3.13.4 On undecked vessels without separate main engines room fuel tanks shall be located at least 800 mm apart from the engine and gas outlet pipelines. In this case fuel tanks shall be enclosed by removable shields.

Ventilation of the fuel tanks area, piping outfit and trays mounting shall be made in the same way as for tanks located in separate rooms.

3.13.5 For fuel tank filling pipes shall be led on the deck preventing from fuel ingress
into the hull. Nipple plugs shall be made of non-sparking material.

3.13.6 The places of penetration of smoke flues through the wooden decks and bulkheads shall be fitted with fireproof bead with a size of at least 150 mm per side. Structures adjacent to the bead from combustible materials shall be insulated with roofing steel above the asbestos layer not less than 10 mm thick.

3.13.7 Cooking oven shall be located at least 150 mm apart from structures of combustible materials protected by non-combustible heat insulation (see 2.3.3) with the thickness of insulation of at least 25 mm and insulated area spreading over the oven borders for at least 250 mm.

3.13.8 Gas appliance and vessel with the capacity up to 20 L may be located in the same room; they may be connected by means of rubberized fabric hose.

3.13.9 On ships of less than 25 m long, excepting tugboats, pushboats, passenger ships, oil tankers and ships carrying hazardous goods, fixed water extinguishing system may be dispensed with. Here the machinery space shall be fitted with gas or aerosol extinguishing system and for other spaces – independent portable or movable gas and foam extinguishers.

3.13.10 In the room where internal combustion engines are located, it is sufficient to have one fire nozzle located directly near the fire pump.

3.13.11 On ships excepting tugboats, pushboats, passenger ships, special purpose ships, oil tankers and ships carrying dangerous goods, water may be fed by one jet.

3.13.12 On ships fitted with foam extinguishing system foam-forming liquid may be fed to the suction chamber of fire pump.

3.13.13 Fire pump may be fed with water from one outboard valve.

3.13.14 Pipelines of water fire extinguishing system, except for such pipelines on M-СІ, М-П and О-П classes ships may be made without corrosion-protective coating.

3.13.15 Fire hoses shall be at least 10 m long.

3.13.16 Hand fire hoses may be used with nozzle of diameter less than 12 mm.

3.13.17 On ships mentioned in 3.3.31 the water manifold for delivery of water for other vessels may be dispensed with.

3.14 FIXED LOCAL FIRE-EXTINGUISHING SYSTEMS FOR MACHINE SPACES

3.14.1 Fixed local application fire-extinguishing systems shall be fitted on М-СІ, М-П and О-П classes passenger ships with minimum gross tonnage of 500 and cargo ships of these classes with minimum gross tonnage of 2000.

3.14.2 Machinery spaces of А category above 500 m³ in volume, in addition to the fixed fire-extinguishing system required in Table 3.1.6, shall be equipped with fixed local fire-extinguishing system. In the case of unattended machinery spaces, this system shall have both automatic and manual start capabilities. Continuously manned machinery spaces shall provide a manual start from the propulsion machinery control station or from another place permanently attended. The automatic system start shall be realized by the fire detection system. In this case, design measures shall be taken to prevent spontaneous start of the system.

3.14.3 Fixed local fire-extinguishing systems are to protect high fire risk areas of the following machinery and equipment (without the necessity of engine shutdown, personnel evacuation, or sealing of the spaces):

1. main internal combustion and diesel generators;
2. incinerators;
3. purifiers for heated fuel oil;
4. boiler fronts (in places where nozzles are arranged);
5. inert gas generators stated in 3.10;
6. fuel heaters.

For units with more than one engine, at least two system sections shall be provided.
3.14.4 Activation of local system shall initiate audible and visual alarms distinct in both respects from other alarms transmitted to the protected space, to the central control station (if any) or to the wheelhouse. Signal shall inform on the particular system in operation.

3.14.5 Electric equipment of the system and its starting alarm shall comply with the requirements of 5 of this Part and 11.4 of Part VI of the Rules.

3.15 ADDITIONAL REQUIREMENTS FOR FLOATING OBJECTS

3.15.1 Landing stages, examination vessels and other floating objects intended for accommodation of more than 12 persons, as well as other floating objects with crew of min. 3 persons, shall be equipped with fixed water extinguishing systems, using fixed fire pumps as per the requirements of 3.3.3, 3.3.5, 3.3.6, 3.3.10, 3.3.13, 3.3.16.

3.15.2 Portable diesel-pump set connected to the ship water extinguishing system may be used as a fire pump as per the following requirements:

1. It shall provide for simultaneous operation of two hand fire hoses with a jet diameter of not less than 12 mm at a suction height of not less than 5 m and a discharge pressure of 0.4 to 0.6 MPa and shall be fitted with self-suction structure;

2. The pump motor shall be capable of start-up both at positive and negative ambient temperature (down to –5 °C). Capacity of the pump fuel tank shall be sufficient for the pump operation within 1.5 hours; fuel capacity on a ship shall be sufficient for filling the fuel tank;

3. Size and type of connecting fittings of flow-line hoses and nozzles shall be the same as those adopted on a ship for fixed water extinguishing station;

4. The diesel-pump set shall be fitted with arrangements and tools according to the manufacturer specification and shall be stored on the deck in special locker or box.

3.15.3 Fire protection of floating objects used as floating hotels, hostels, resthouses, floating bases for processing bioresources of water medium shall depend on the number of people living on the board:

1. up to 50 persons – for passenger ships with a length of 65 m;

2. up to 200 persons – for passenger ships with a length of 65 to 100 m;

3. up to 200 persons – for passenger ships with a length of 100 m.

If the floating objects stated in 3.15.3 provide the presence of special personnel of 50 persons and more, then the fire protection shall comply with the requirements of 3.15.3.2 or 3.15.3.3.

3.15.4 If ships stated in 3.15.3 are not equipped with their own electric power sources, emergency fire pumps, like for passenger ships as per 3.3.1 shall not be fitted there.

3.15.5 Fire protection of floating docks, electric stations, workshops and depot ships is the same as for cargo ships.
4 ADDITIONAL FIRE SAFETY REQUIREMENTS FOR DOMESTIC / GENERAL SERVICE EQUIPMENT AND SYSTEMS

4.1 LOCATION AND EQUIPMENT OF GALLEYS

4.1.1 Galleys shall be separated from cargo zone by accommodation spaces and located in spaces adjacent to store rooms for inflammable and combustible materials, spaces for fuel and lubricating oil excepting distribution stations containing liquefied gas cylinders for domestic purposes.

4.1.2 At least two exits shall be provided for each galley serving more than 50 persons. For galleys working on electricity or steam, only one exit is allowed.

4.1.3 Cookers working on electricity, gas as well as fuel oil or solid fuel may be used. Flash point of fuel oil for galleys shall exceed 60 °C.

Cooking ranges that operate using fuel oil or solid fuel shall be fitted with a metal casing with fire-brick lining and black removal device.

4.1.4 Drip trays for collecting fuel leakage shall be placed below the range fuel nozzles; they shall have a size exceeding the overall dimensions of the nozzle for at least 100 mm with shoulders at least 75 mm high.

4.1.5 Equipment of daily service fuel tanks and supply piping shall comply with the requirements of 10.10.25, 10.10.26 and 10.13.25 – 10.13.30 Part IV of the Rules.

4.1.6 Daily service tanks shall not be located in the galley room.

No fuel tanks may be located above the cooking range. A capacity of daily fuel service tank fitted in the galley room shall be sufficient for daily fuel consumption but not over 0.05 m³.

4.1.7 Check valve of the supply piping shall be remotely controlled from an accessible place outside the galley.

4.1.8 Smoke funnels of the cooking ranges laid inside the ship’s spaces shall be covered with heat insulation made of non-combustible material of a thickness sufficient to prevent heating of the insulation outer surface over 60 °C.

4.1.9 The structure of exhaust ventilation ducts shall comply with the requirements specified in 10.12.32, 10.12.33 of Part IV of the Rules.

4.1.10 The galleys shall have gutterways draining to the water holding tank.

4.1.11 Cooking ranges of М-СП, М-ПР, О-ПР, М and О class ships shall be fitted with storm protective guards. The cooking range side faced towards the personnel shall be fitted with guard rails 0.8 to 1.2 m high.

4.1.12 Structure of electric equipment included in cooking ranges shall comply with applicable requirements specified in 9 Part VI of the Rules.

4.2 STRUCTURE OF HEATING SYSTEMS

4.2.1 For heating ship’s spaces, they use equipment working on oil fuel, solid fuel or gaseous fuel burning units or from power supply network.

4.2.2 On ships carrying hazardous goods in bulk, it is not allowed to use heating appliances working on oil fuel, liquid gas or solid fuel.

The equipment for central heating of ship’s spaces working on solid fuel may be used for ships carrying highly inflammable liquids¹.

¹ Class 3 as per GOST 19433 (closed-cup flash point of max. 61 °C).
4.2.3 Stove heating may be used on non-self-propelled and coast vessels other than passenger ships and oil tankers.

4.2.4 For stoves and heaters, fuel oil may be used with a flash point over 60 °C. Fuel oil stoves shall be equipped with fuel metering units which provide reliable operation of the stove under all operating conditions of a ship, and leaking fuel collectors.

4.2.5 Brick stoves shall be protected with casings of steel roofing as per the following requirements:
   .1 Thickness of outer walls of fire chambers and flues shall be at least 130 mm;
   .2 Thickness of brickwork of the upper ceiling shall be at least 200 mm;
   .3 Fire chamber shall be separated from the deck plating made of combustible materials by a brickwork at least 250 mm thick.

4.2.6 All heaters shall be so designed and arranged as to minimize the fire risk.

4.2.7 Outer surfaces of stoves, heating system heaters with working temperature over 60 °C, shall be closed by protecting housings or screens. The temperature on the casing/screen surface shall not exceed 60 °C.

4.2.8 Electric heating elements shall comply with requirements of 9.2 Part VI of Rules.

4.2.9 In the places where steam heating tubes penetrate wooden bulkheads or bulkheads faced with combustible material, anti-fire beads shall be provided of at least 50 mm on each side, faced with steel sheets over the layer of mineral heat-insulating material 2 mm thick.

        For water heating tubes, the beads shall be of at least 25 mm for each side. In this case, isolation of mineral heat-insulating material is not required.

4.2.10 For the unit and arrangement of heating appliances and stoves the following requirements shall be met:
   .1 Additional solid fuel equipment may not be fitted in spaces with fuel cans or fuel oil equipment;
4.2.11 For stove funnels, the requirements of 4.3.20.6 shall be met: Funnels shall be made of steel and fitted with casings forming a vent cavity or insulated with heat-insulating material. Funnels shall be fastened and fitted with spark-arresters.

4.3 SHIP'S DOMESTIC PLANTS WORKING ON COMPRESSED / LIQUEFIED NATURAL GAS

General requirements

4.3.1 The requirements of this Chapter are applied to all the ship's domestic plants, working on compressed or liquefied natural gas containing mixture of different hydrocarbon gases with methane content in it of over 85%. These units may be used in accommodation spaces and in the wheelhouse for cooking purposes or water heating, they shall include one or several vessels for compressed or liquefied natural gas, one or several pressure regulators, distribution networks and gas appliances, for example, gas ovens or water heaters, which consume max. 1.5 kg/h of compressed liquefied natural gas.

4.3.2 Onboard domestic units working on compressed or liquefied gas may not be located in machinery spaces.

4.3.3 Each ship may be fitted with several compressed / liquefied gas units. Gas appliances in spaces separated by a cargo zone or built-in tank shall not be supplied from the same gas unit.

4.3.4 Deck openings located up to 3 m clear of the doors or other types of enclosures of the spaces or areas which contain elements of domestic compressed / liquefied gas units shall be provided with coamings at least 150 mm high.

4.3.5 All equipment of onboard domestic units, including gas pipelines, shall be secured.

Compressed / liquefied gas vessels

4.3.7 In addition to onboard units, working on compressed or liquefied natural gas, vessels with a maximum capacity of 35 kg, may be used.

4.3.8 Vessels for compressed or liquefied natural gas shall meet the requirements 8 Part IV of the Rules and have marking with at least the following data:

1. manufacturer's brand mark / name;
2. cylinder symbol;
3. cylinder No. as per the manufacturer's system;
4. weight of gas cylinder (kg);
5. weight of light cylinder (kg);
6. cylinder capacity (L);
7. date (month and year) of manufacture;
8. service pressure and test pressure (MPa);
9. stamp of the manufacturer.

The cylindrical part of the cylinder shall bear inscriptions “NATURAL GAS”, “Next survey date” and “DO NOT USE AFTER XX / XXXX”, where XX/XXXX is expiry date month/year.

4.3.9 Vessels shall not be filled with compressed or liquefied gas on board a ship.

Distribution station

4.3.10 Distribution station shall be located on an open deck in a special locker or enclosure of a deck superstructure or a deckhouse, provided that it is gastight and has openings only outside.

The deck station location shall provide the minimum length of the distribution network gas pipelines up to the consumers and free movement of people on the ship's deck.

4.3.11 The distribution station shall not be located in one superstructure or deckhouse with accommodation spaces, and its structure shall comply with requirements 2.5.3.1, as well as the following requirements:

1. Effective natural ventilation through openings or slots in the upper and lower parts of the locker or enclosure shall be provided. In addition to the natural ventilation artificial ventilation may be provided; the ventilators shall be of explosion-proof type and shall preclude the spark formation;
Measures shall be taken to prevent the increase of temperature inside the room by 50 °C, and the temperature increase of the station vessels by 40 °C.

The station shall provide the natural lighting by day and electric lighting with explosion-proof lighting fixtures used only at night. Electric lighting switch shall be fitted outside the room of the distribution station. Elements of the ship's lighting located near the station entrance door and outer ventilation devices of the station shall be as well explosion-proof;

Measures shall be provided for full gas elimination outside the station in case of its leakage, it shall not enter the inner ship spaces;

The doors shall bear an inscription or a symbol warning on the explosion danger and prohibiting the use of open flame and smoking;

The distribution station room shall provide a direct exit to the open deck;

At the distribution station entrance, dry powder fire extinguisher or carbon dioxide fire extinguisher shall be fitted;

Compressed / liquefied gas vessels shall be located in the vertical position, with valves up, in special holders made of spark-proof materials and shall be secured to the station walls by quick-release fastenings;

No unauthorised equipment may be arranged at the distribution station.

Vessel storage locker shall comply with the requirements of 4.3.10 and 4.3.11, and with the following:

The cabinet shall not be located near the plating of the fore / after bulwark;

The cabinet shall be made of fire resistant materials and shall provide for sufficient ventilation through the upper / lower part holes.

The following may be fitted at one distribution station:

A vessel connected to the network; connection to the compressed or liquefied gas line shall be executed by means of a rubber-textile hose not longer than 1 m with metal clamps providing gas-tightness and reliable fastening which is connected to a pressure reducing valve on the vessel top. The hose shall be resistant to working medium and shall be designed for a working pressure of min. 0.6 MPa;

A group of vessels with one of them being connected to the distribution system and other used as spare vessels; two vessels may be connected to the distribution network manifold; a check valve or a cock shall be fitted between each vessel and the manifold and the station shall bear an inscription prohibiting simultaneous use of both vessels.

Each domestic unit, working on compressed or liquefied gas, may be simultaneously connected with up to 4 vessels connected by automatic or non-automatic switch. In this case, the ship shall contain max. six vessels per unit, including reserve ones.

On passenger ships with kitchens or canteens for passengers, each unit may be connected with up to six working vessels connected with automatic or non-automatic switch. Onboard these ships, the number of vessels per unit, including reserve ones, shall not exceed nine.

Storage of spare and empty vessels

Spare and empty vessels outside the distribution station, which are not connected to the distribution network of compressed or liquefied gas, shall be stored outside the accommodation area only in dedicated steel lockers or in closed enclosures meeting the requirements of 4.3.10 – 4.3.14. Stop fittings of the above vessels shall be closed irrespectively of their extent of filling with compressed gas.

Distribution network

Compressed or liquefied gas line and their fittings shall comply with the requirements of 10.2 and 10.3 Part IV of Rules.

Gas-consuming appliances and spaces for their fitting

Domestic gas appliances for cooking and water heaters shall comply with require-
ments of GOST R 50696, GOST R 54821, GOST R 51847, GOST 31856, confirmed by declarations or certificates of products conformity to the requirements of Technical Regulations of the Customs Union “On safety of appliances working on gaseous fuel” (TR CU 016/2011) or to the requirements of stated national standards drawn by authorities accredited as per the legislation of the Russian Federation on accreditation in the national accreditation system, as well as to the requirements of this Chapter.

4.3.18 Domestic units for cooking purposes or water heating shall be:

.1 secured to avoid their shifting for all loading conditions during the ship operation;
.2 connected to the connecting gas pipelines to avoid the risk of their inadvertent disconnection.

Not fixed gas-consuming appliances may be connected to the gas pipeline with the corresponding steel flexible pipes or flexible hoses for high pressure suitable for the used gas of 1 m long.

The structure of domestic units for cooking shall provide the stormy fencing of burners.

4.3.19 Gas-consuming appliances shall be fitted with automatic devices that stop the gas supply in case of the burner extinction. Such device when used in water heaters shall have the pilot flame.

This device may be absent in appliances fitted in spaces above the bulkhead deck and used only in the presence of the attending personnel.

4.3.20 All gas-consuming appliances intended so as to provide the evacuation of the combustion products outside the spaces, shall be provided with separate flues complying with the following requirements:

.1 Horizontal section of the smoke flue shall have an inclination towards the gas-consuming appliance of at least 0.01;
.2 The total length of horizontal sections of the flue shall not exceed 3 m;
.3 Flues shall have not more than 3 bends with a bending radius not less than the pipe diameter;
.4 Flue outlets shall provide sufficient draught in the funnel;
.5 Connections of the pipe sections shall be tight, without any clearance;
.6 Smoke funnel ends in the horizontal plane shall be higher than superstructure, where they are located, but not less than 0.5 m. In oil tankers smoke funnel outlets shall be at least 2 m from the cargo zone. A distance from a funnel or a flue to a combustible structure shall be at least 350 mm;
.7 Flue outlets shall be selected with regard to the requirement on maximum possible exclusion of combustion products entering the ship's space;
.8 Heat insulation of flues laid inside the ship's spaces, including in passages through the hull structures (bulkheads, decks, etc.) shall comply with the applied requirements of 1.9.2 Part IV of the Rules.

4.3.21 The gas consuming equipment may be placed in the wheelhouse only in case of no channels for penetrating the gas into the ship's inner spaces.

On board the tankers and ships carrying hazardous goods, the above placement is not allowed.

4.3.22 Spaces with gas consumers shall be equipped as per the requirements of 4.1 and comply with the following requirements:

.1 They shall not be arranged below the bulkhead deck and shall be fitted with effective ventilation for evacuating the combustion products and air change;
.2 They shall have an exit giving to the open deck and opening scuttle (window). The galley need not be fitted with the scuttle or window, when an exit from the galley is provided to non-accommodation space (a corridor) with opening scuttles or a door leading to the open deck;
.3 Where the space is below the bulkhead deck, it shall be equipped with artificial ventilation, and above the gas oven, the ventilating cowl shall be fitted;
.4 In the lower part of the water heaters' space an air grating shall be provided with a cross-sectional area not less than 0.02 m² per each water heater;
5 Bulkheads and decks shall be watertight, door coamings shall be at least 150 mm high. No ladders or elevators may be arranged from the spaces of gas-consuming appliances to the spaces located below;

6 The space height shall be at least 2.2 m. When using exhaust device of dimensions exceeding the overall dimensions of a gas stove, the space height may be reduced to 1.9 m;

7 The space volume shall be determined on the condition of 4 m$^3$ per each burner of the gas stove and 7.5 m$^3$ per a water heater.

When easily detachable exhaust ventilation box is fitted above the gas stove, the volume of the space with two-burner gas stove may be reduced to 6 m$^3$, that with three-burner gas stove – to 10 m$^3$ and that with four-burner gas stove – to 12 m$^3$;

8 at the entrance to gas consumer space, dry powder fire extinguisher or carbon dioxide fire extinguisher shall be fitted.

4.3.23 The distance between the gas-consuming appliances and the bulkheads shall be at least 75 mm.

4.4 LIGHTING

4.4.1 Ships shall be provided with electric lighting as per the requirements of 10 Part VI of the Rules.

4.4.2 Kerosene lighting may be used only on ships without electric power sources of the lighting network.

Kerosene lamps for lighting shall be fitted in suspended metal peak lanterns, permanently attached on-site and protected from impacts. Upper parts of lighting fixtures shall be situated no closer than 350 mm from the ceiling. The ceiling above the lamp shall be protected with suspended metal plate of diameter 150 mm or shall be fitted onto the non-combustible heat-insulating material.
5 FIRE ALARM

5.1 GENERAL REQUIREMENTS

5.1.1 Ships shall be equipped with manual fire alarm and automatic fire detection alarm systems, as well as fire smothering system release warning system complying with the requirements of 11.4 Part VI of the Rules.

5.1.2 In cargo spaces instead of automatic fire alarm system, automatic sample extraction smoke detection system may be used. The following requirements are imposed to this system:

1. The system shall be designed to operate continuously;
2. Detection of smoke or other combustion products shall initiate visual and audible signals in the wheelhouse or in the permanently attended place (if any);
3. After checking the system response, it shall be returned to the normal working mode without replacement of any elements;
4. The system power interruption shall initiate audible and visual signals different from the system response signals;
5. The system structure shall exclude the leakage of toxic, highly inflammable and extinguishants to accommodation, service and machinery spaces and control stations;
6. Each cargo space shall be fitted with smoke intake, located so that the distance from it to any area of the deck located above it, measured horizontally could not exceed 12 m;
7. Smoke inlets shall not be placed in locations where they can be damaged in case of impact;
8. Each sampling point shall be connected to max. 4 smoke intakes;
9. The same point for air sampling can be connected to smoke intakes of only one cargo space;
10. The structure of air sampling device shall be self-draining and shall be protected from possible damage when loading/unloading;
11. The sensing unit of the system shall be actuated when the smoke density inside the measuring chamber reaches the value to weaken the light by 6.65 % per meter;
12. Smoke monitoring shall be provided in separate pipes for air sampling;
13. At least two ventilators for air sampling shall be provided, with capacity sufficient for system operation in normal working mode of the ventilation system in the cargo space;
14. Devices shall be provided to enable sampling the same air volumes from each connected smoke intake;
15. Minimum internal diameter of air sampling tubes shall be 12 mm. When combining the air sampling with fixed gas extinguishing system, the pipe diameter shall be determined by the requirements to the pipe;
16. Devices for periodic blowing air sampling pipes with compressed air shall be provided.

5.1.3 Ship’s general alarm system shall be used as fire warning alarm for crew, passengers and special personnel in accordance with the requirements of 11.3 Part VI of the Rules.
6 FIRE PROTECTION OUTFIT SPARE PARTS AND TOOLS

6.1 FIRE PROTECTION OUTFIT

General provisions

6.1.1 Requirements of this Section apply to ships under design and construction as well as passenger ships in service with regard to availability of fireman kits and fire extinguishers.

6.1.2 On non-self-propelled ships operated without a crew, fire protection outfit and fire extinguishing systems are not required.

6.1.3 Fire protection outfit shall be provided and its reliability and readiness for immediate use under all operating conditions shall be ensured.

6.1.4 On passenger ships, places of fire protection outfit arrangement shall be marked with indicators made of photoluminiscent material or by means of lighting. Requirements for indicators of photoluminiscent materials shall be similar to those for light evacuation indication panels (see 16.1.11 Part VI of the Rules).

6.1.5 Inland navigation ships shall be fitted with fire protection outfit according to the norms specified in Table 6.1.5, with regard to the following:

.1 Each space where oil fuel is used shall be fitted with one additional blanket;

.2 Tankers shall be supplied with portable gas analyzer for measuring the concentration of inflammable vapours of goods carried. To control the percentage of oil vapour on ships intended for the transportation of oil products with flash point below 60 °C, two hand portable gas-analyzers shall be provided;

.3 Fireman’s outfit shall be required on ships, including those being in operation, with a crew or attending personnel more than 4 persons in number.

6.1.6 All fire protection outfit items shall be kept in permanent ready-for-use condition and be located in accessible places.

</table>

1 See 6.1.8.4.  
2 A greater number of fire extinguishers of minimum capacity with a charge of 12 kg may be used.
.1 In spaces with a floor area not exceeding 4 m² (galleys, distribution stations, stores, stations, broadcasting centers), carbon dioxide and dry powder fire extinguishers with a charge of 1.5 kg may be fitted;

.2 In spaces containing electrical equipment with rated voltage of 24 V gas fire extinguishers may be replaced by foam fire extinguishers;

.3 No portable carbon dioxide fire extinguishers or other gas fire extinguishers may be fitted in accommodation spaces;

.4 The quantity of fire extinguishant in fire extinguishers located in ship's cargo spaces intended for carrying hazardous goods in bulk shall be determined depending on scope of their employment for extinguishing fires of particular hazardous goods;

.5 Gasoline engined ships shall be fitted with at least two air-foam or dry powder fire extinguishers in the machinery space and the spaces where fuel tanks or fuel system units are located.

6.1.9 Manual portable fire extinguishers shall comply with the following requirements:

.1 They shall be located in places protected from direct sunlight and precipitation, with handles located not over 1.5 m above the deck or space flooring; they shall be located at least 1.5 m away from heating appliances or other heat sources;

.2 Fire extinguishers shall be located in special holders ensuring fastening and release of fire extinguishers;

.3 In accommodation spaces they shall be located at the distance not exceeding 15 m of the protected area. Access to fire extinguishers shall be provided through one door only;

.4 Where several fire extinguishers are located in a space according to 6.1.8, part of them shall be located in the vicinity of entrance and the rest – in the places with the greatest risk of fire inside the space;

.5 Where one fire extinguisher is located in a space or on a ship, it shall be located in the vicinity of the entrance to this space or near the place with the greatest risk of fire;

.6 In machinery spaces, the location of fire extinguishers shall provide minimum distance of 10 m between any point of the room and the nearest extinguisher.

6.1.10 Metal boxes with sand shall be fitted in boiler rooms, in rooms containing boilers-incinerators (at the furnace front side) in the area of the paint room as well as at the places of reception and distribution of fuel or at distance not more than 10 meters from the filling station (counting from the filling sleeve).

6.1.11 Metal boxes with sand shall not be fitted in machinery spaces and pump rooms. In those spaces, boxes containing sawdust impregnated with fat soda solution shall be fitted instead. One box with sand or sawdust may be replaced with one portable foam or dry powder fire extinguisher.

Requirements for fire protection outfit

6.1.12 Fire smothering blankets shall be fitted in spaces where fuel oil is used. These blankets shall:

.1 be stout and durable;

.2 be made of non-combustible material; clean unraised felt of minimum 10 mm thickness may be used;

.3 have an area of \((1.5 \times 2)\) m and be stored in special cases made of thin steel plate or in special containers. These cases or containers shall be painted red and bear an inscription “Fire blankets”.

6.1.13 Fire tools shall satisfy the following requirements:

.1 One set of fire tools shall include: fire axe, fire crowbar, fire boat-hook;

.2 Each set shall be stowed and secured on stationary boards in accessible places. The boards and the tools shall be painted red. The tool holder shall prevent the spontaneous tool coming out under conditions of roll and make it easy to release the tool;

.3 On ships for the carriage of motor vehicles with fuel (except for diesel fuel) in tanks, one set shall be placed near the entrances of accommodation and machinery spaces to cargo spaces.
6.1.14 Fire buckets shall be provided with a hemp rope. They shall be stowed on the open decks in supports. The buckets shall be painted red and bear an inscription “Fire”.

6.1.15 The fireman’s outfit shall include:

1. fire helmet ensuring effective protection against impacts;
2. protective clothing made of a material capable of protecting the skin against the heat radiated by fire, against burns and scalding by steam. The outer surface of the clothing shall be waterproof; tarpaulin and polyvinyl chloride fabrics may not be used as outer material of the clothing;
3. boots and mittens of a dielectric material;
4. portable accumulator lantern of a safe type with a minimum lighting period of at least 3 h. Ships carrying hazardous goods, oil tankers and other ships with cargo spaces and areas which may contain explosive mixture with air of combustible gases, vapours or dust, shall provide for IExd or IExp explosion-proof lanterns (see 2.10.7 and Appendix 1 Part VI of the Rules). The group and temperature class shall correspond to the category of the goods carried;
5. a fire axe with a helve made of hard wood. Helves made of other material shall be covered with dielectric insulation;
6. self-contained breathing apparatus operated by compressed air, with air cylinders containing at least 1.2 m³ of air or other self-contained breathing apparatus capable of operation for at least 30 min.

Each breathing apparatus shall be provided with a flexible fireproof lifeline about 30 m in length. The lifeline shall be tested by static load of 3.5 kN. It should be fastened directly to the apparatus or to a separate belt by means of a snaphook to avoid spontaneous separation of the line from the apparatus.

Two spare cylinders or two spare apparatuses shall be provided for each self-contained breathing apparatus. All air cylinders for apparatuses shall be interchangeable.

The passenger ships carrying not more than 36 passengers and the cargo ships fitted with means for complete recharging air cylinders with purified air may have only one spare cylinder or one spare breathing apparatus for each self-contained breathing apparatus.

The passenger ships carrying more than 36 passengers shall have two spare cylinders or two spare apparatuses for each self-contained breathing apparatus.

6.1.16 Manual portable fire extinguishers shall comply with the following requirements:

1. Fire extinguishers shall be charged with an extinguishing medium not releasing toxic gases;
2. Fire extinguishers intended for location on the open decks shall be supplied with charges capable of being used at negative temperatures of ambient air;
3. Capacity of foam extinguishers shall be at least 0.009 m³;
4. Dry powder extinguishers shall contain at least 4 kg of the powder and carbon dioxide extinguishers shall contain at least 3 kg of carbon dioxide;
5. When using fire extinguishers with non-foam extinguishing medium, their fire rating (see 6.1.17.2) shall be not lower than that of foam extinguishers with a capacity of 0.009 m³;
6. Fire extinguishers shall be fitted with safety devices actuated in the event of pressure rise above the permissible value;
7. Weight of the fire extinguisher shall not exceed 23 kg;
8. Dry powder fire extinguishers shall be selected with regard to the purpose of fire-extinguishing powder medium;
9. Portable fire extinguishers shall be provided with devices which indicate whether they have been used.

6.1.17 Portable fire extinguishers shall comply with the following requirements:

1. Fire extinguishers shall be charged with an extinguishing medium which does not release toxic gases;
2. Fire extinguishers intended for location on the open decks shall be supplied with charges capable of being used at negative temperatures of ambient air;
.3 Fire extinguisher shall maintain the steady position, excluding its falling-out or shifting any condition possible during the ship operation;

.4 Fire extinguishers shall be fitted with safety devices preventing from breaking of the casing in the event of pressure rise above the permissible value;

.5 The fire extinguisher shall be fitted with assembled flexible hose with device shutting off the fire extinguishant jet. Flexible hose shall provide for free passage of fire extinguishant through the nozzle, fixed to the fire extinguisher casing without breaks or hoggings. It shall not touch the floor, ground or wheels when transporting the fire extinguisher and shall be flexible in the whole working temperature range.

6.1.18 Metal boxes with sand and soda impregnated sawdust shall comply with the following requirements:

.1 Boxes capacity shall be at least 0.1 m³;

.2 Each box shall have an opening cover and a device for holding the cover open. A scoop shall be provided in each box.

6.1.19 Explosive zones, spaces and areas, as well as open decks of oil tankers and oil recovery ships shall be provided with outfit items, whose material and structure shall exclude sparking when using these items.

¹ It may be replaced with a fire extinguisher.

² On crew boats ships with engines of a capacity up to 165 kW it may be dispensed with.

.2 a box containing sand or dry soda impregnated sawdust with a capacity of at least 0.05 m³;

.3 blankets with a size of 1.0 × 1.5 m.

International shore connection

6.1.23 On М-СІ, М-ПР and О-ПР class ships, international shore connection for receiving water from shore shall be stored in special box painted red with inscription “Connection of international type” in the accessible place together with emergency party equipment.

6.2 SPARE PARTS AND TOOLS

6.2.1 М-СІ, М-ПР and О-ПР class ships shall have spare parts and tools according to the norms specified in Table 6.2.1. The provided standards shall fully apply to fixed firefighting systems of oil tankers, chemical tankers and ships carrying hazardous goods.

Other ships shall have spare parts and tools stated in 1.1, 1.2, 1.5, 1.6, 1.7, 8.2 and 8.3 Table 6.2.1.

6.2.2 Spare parts and tools for fire extinguishing systems shall be stored at fire extinguishing stations.

6.2.3 Spare parts shall be marked.

End of Table 6.2.1
7 EMERGENCY ESCAPE BREATHING DEVICES

7.1 GENERAL REQUIREMENTS

7.1.1 Requirements of this Section of the Rules are applied to emergency escape breathing devices used on M-CTI and M-TPP class ships with gross tonnage of 500 and over for individual protection of respiratory and visual organs of the personnel engaged in evacuation of people in case of fire.

7.1.2 Emergency escape breathing devices shall operate by means of compressed air or oxygen generated as a result of the chemical reaction in the closed cycle device. They shall not be used by the crew for fire-fighting purposes, for entering voids or tanks with insufficient oxygen content, fire-fighting emergency party. In the above cases, they shall use self-contained breathing apparatuses working on compressed air, whose cylinders shall contain min. 1200 L of air or self-contained breathing apparatuses capable of operation for at least 30 min.

7.1.3 The number of emergency escape breathing devices and their location (including the reserve ones) shall be indicated in the fire control plans. There shall be at least two reserve escape breathing devices in a passenger ship and one escape breathing device in a cargo ship.

7.1.4 Operating period of emergency escape breathing devices shall be min. 10 min.

7.1.5 Emergency breathing device shall include a helmet or similar item covering the entire face and having a transparent visor. The helmet and its front part shall be made of flame-resistant material.

7.1.6 Emergency escape breathing device shall be designed in a manner to prevent carrying inactive device in hands.

7.1.7 The structure of emergency escape breathing devices shall provide their easy and fast putting on.

7.1.8 (shall be considered to have lost force.)

7.2 LOCATION OF THE EMERGENCY ESCAPE BREATHING DEVICES

Arrangement in superstructure spaces

7.2.1 All the ships in the accommodation spaces area shall provide for at least two emergency escape breathing devices.

7.2.2 In passenger ships, at least two emergency escape breathing devices shall be located in each vertical fire zone.

7.2.3 In passenger ships carrying more than 36 passengers, in addition to the required in 7.2.2, two more emergency escape breathing devices shall be located in each vertical fire zone.

7.2.4 Requirements of 7.2.2 and 7.2.3 are not applied to the ladder enclosures making separate vertical fire zones, and to vertical fire zones in aft parts of the ship, where they are located:

- cabins, offices, dispensaries and public spaces (having a deck area of less than 50 m²) with furniture and furnishings different from
those of restricted fire risk\(^1\), with the following fire risk characteristics\(^2\):

- flammability group – low-flammable and medium-flammable;
- inflammability group – flame-resistant and medium-inflammable;
- group of flame spreading over the surface – low-spreading and medium-spreading;
- smoke generation group – with small and medium smoke-generating capacity;
- group of toxic effluents – low-hazard and moderate-hazard;

\(^1\) Fire risk – a combination of medium’s (material’s) properties specifying its combustion and flame propagation, generation of fire risk factors.

\(^2\) GOST 12.1.044, GOST R 50810, GOST 30402, GOST 30244.

cleaning gear lockers, drying rooms having a deck area of 4 m\(^2\) or less;

\(^{.3}\) public spaces having a deck area of 50 m\(^2\) and over, with furniture and furnishings different from those of restricted fire risk, barber shops and beauty parlours, saunas;

\(^{.4}\) machinery spaces and main galleys, their auxiliary spaces, trunks and passageways to the spaces listed above.

### Arrangement in machinery spaces

7.2.5 On all ships, within the machinery spaces, emergency escape breathing devices shall be situated in illuminated and accessible places on the escape routes and be ready for use in case of fire. The location of emergency escape breathing devices shall take into account the layout of the machinery space and the number of persons keeping the watch and working in the space. Such places can be control stations and workshops.

This requirement may be omitted, if the personnel in the machinery space is equipped with personal portable breathing devices.
Part IV

POWER INSTALLATION AND SYSTEMS
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 The present Part of the Rules applies to ship power installation components (engines, shafting, gears, disengaging and elastic couplings, propellers, compressors, pumps, fans, separators, boilers, heat exchangers, pressure vessels, refrigerating plants, automation equipment) and systems (pipelines, valves and fittings, tanks, filters and other equipment), unless otherwise specified in the present Part of the Rules, and contains the requirements to the aforesaid ship power installation components and systems, including their arrangement and installation.

1.1.2 The requirements of the present Part of the Rules to power installations and their components, except for 1.11 and 2.14, are established considering that the flash point of fuel oil (in the closed cup) used for engines and boilers shall exceed 60 °C and the flash point of fuel oil used for emergency diesel generators shall be not less than 43 °C.

1.2 TERMS AND DEFINITIONS

1.2.1 The following terms are used in this Part of the Rules.

1. Automatic oil burner unit means a device for combustion of fuel oil, the operation of which is controlled without any direct attendance of the operating personnel.

2. Auxiliary engines mean drive engines of generators providing electrical power for the ship and engines of cargo and fire pumps.

3. High-temperature organic heat transfer fluid means synthetic and mineral oils comprising dialkylbenzenes resistant to high temperatures (up to 450°C).

4. Main engines mean engines intended for driving propellers and/or equipment that ensures the main purpose of the ship.

5. Engines mean internal combustion engines.

6. Dual fuel system means the system which enables the engines to operate both on heavy and diesel fuel due to change-over from one kind of fuel to another; this system includes heavy and diesel fuel preparation systems.

7. Remote control means remote start and stop of ship machinery and remote change of frequency and direction of rotation of main engines.

8. Ship’s length means the design length of a ship (length corresponding to the design waterline).

9. Inflammable liquids — see the definition in 2.2.14 Part 0 of the Rules.

10. Closed method of loading and unloading oil products mean the method of performing cargo handling operations by both shore-based and onboard facilities by means of sealed piping system ensuring communication of the oil compartments with the atmosphere only through the gas outlet system.

Closed method includes also cargo handling operations of oil products by portable ejectors; here, sealing is ensured by sealing devices preventing from leakage of oil products’ vapour.

11. Engine room — see the definition in 2.2.24 Part 0 of the Rules.

12. Machinery spaces — see the definition in 2.2.25 Part 0 of the Rules.

13. Local control station means a control station equipped with controls, in-
instrumentation and communication equipment designed to control power installation components, and located in proximity to a controlled unit or directly on it.

.14 **Normal operating conditions** mean designed operating conditions of the ship, ship machinery, systems and their components in all envisaged operation modes.

.15 **Equipment** means filters, heat exchangers, vessels, tanks and other arrangements ensuring the operation of the power installation.

.16 **Pump rooms** mean cargo pump compartments in tankers.

.17 **Control stations** mean spaces where the main navigational instruments, ship control equipment, radio sets, broadcasting centres, central and fire-fighting stations are located, accumulator rooms and power equipment rooms for radio sets or for emergency lighting as well as spaces for emergency power sources.

.18 **Working pressure** (for boilers, heat-exchangers and pressure vessels) means a maximum pressure determined by the designer for continuous operation mode without limitation in time.

.19 **Rated power** means a maximum unlimited in time power used for calculations required by the Rules.

.20 **Design steaming capacity of the boiler** means maximum output of steam of the design parameters within a time unit in the continuous operation mode without limitation in time and with all possible steam consumers connected.

.21 **Rated rotational frequency** means rotational frequency corresponding to the rated output.

.22 **Design pressure** means over-pressure for which the strength of the components of systems and ship machinery is calculated according to the requirements of the Rules or national standards.

---

1 GOST R 52857, GOST 14249, GOST R 52630, GOST 25215, GOST 25859.
1.3 OPERATION IN CONDITIONS OF HEEL AND TRIM

1.3.1 Power installation components shall be designed for operation under conditions of long-term (static) heel of the ship of up to 15°, short-term (dynamic) heel of up to 22.5° (roll period of 7 to 9 s) with simultaneous static trim by the bow or stern of up to 5° and dynamic trim (pitch) of up to 7.5°.

Power installation components to be used for operation in emergency situations shall be designed for operation under long-term heel of up to 22.5°, dynamic heel of up to 22.5° with simultaneous static or dynamic trim of up to 10°.

Long-term heel and trim shall be taken into account simultaneously, the same as roll and pitch.

In oil tankers of MCTI4,5 class the prime movers of emergency power sources shall be designed for operation under long-term and dynamic heel of the ship of up to 30°.

If the length of the ship of M-CTI4,5 class exceeds 100 m, long-term trim by the bow or stern can be taken as (500/L)°, where L is the ship’s length, in m.

1.4 CONTROL DEVICES

1.4.1 The starting and reversing arrangements shall be so designed and placed that each engine, reverse reduction gear, coupling, and other machinery can be started or reversed by one operator.

1.4.2 The duration of reversing (a period of time from the reversing of a steering control to the beginning of propeller operation with a thrust opposite in direction) depending on the ship’s speed shall not exceed:
- 25 s at full speed;
- 15 s at slow speed.

1.4.3 Proper working direction of control handles and handwheels shall be clearly indicated by arrows and relevant inscriptions.

1.4.4 The setting of the control handle in the direction from or to the right of the operator or turning the handwheels clockwise when controlling main engines, gears and couplings locally or remotely shall correspond to the ahead running of the aforementioned equipment.

If the main engine is controlled by the handle, the latter shall move round the circumference in the vertical plane in parallel to the longitudinal axis of the ship. When this handle is moved in the direction of the bow, the ship shall run forward; when the handle is moved towards the stern, the astern running shall be enabled. The engine shall be started and reversed, when this handle is in the STOP position (neutral position). The amplitude of handle movement from the STOP position to the FULL AHEAD position or from the STOP position to the FULL ASTERN position shall not exceed 90°.

1.4.5 Control arrangements shall be so designed as to eliminate the possibility of spontaneously changing the positions prescribed.

1.4.6 The control devices of main engines shall have an interlocking system so as to prevent non-authorised starting of main engines as well as starting with a shaft-turning gear engaged.

1.4.7 If the design of ship machinery in addition to the power-driven start envisages manually driven start, the manual drive shall be disabled automatically when the drive is started from the power source. The drives of the starting device shall have an interlock excluding the possibility of their unauthorized start while ship machinery is running.

1.4.8 Main engines and propellers shall be controlled from the control station in the wheelhouse or from the control station in the engine room. Transfer of control between the aforesaid stations shall be possible only from

---

1 The heel appearing due to loading of the ship in service when the total center of gravity of variable loads (transported cargo, fuel and oil stores, oily waters and sewage waters) is beyond the centre line of the ship. Long-term heel remains until measures are taken to right the ship.

2 Trim appearing in case of particular loading of the ship and remaining throughout the entire voyage.

The duration of reversing of the thruster at maximum thrust shall not exceed 25 s.
the engine room or from the central control station (see 1.2.1.29).

1.5 CONTROL STATIONS
1.5.1 Remotely controlled equipment and machinery shall be fitted with local control stations.
Local control stations need not be fitted in ships less than 25 m in length.

1.6 MEANS OF COMMUNICATION
1.6.1 Each main engine control station shall be equipped with two independent means of two-way communication with the wheelhouse. One of these means of communication shall be an engine-room telegraph.

In ships with main engines remotely controlled from the wheelhouse one means of communication between the wheelhouse and the engine room may be used. In this case the engine-order telegraph or a similar appliance shall be used.

1.6.2 Engine-order telegraphs shall be equipped with alarm devices.

1.6.3 When two-way communication equipment is used, measures shall be taken to ensure good audibility during the operation of engines and other equipment.

1.7 INSTRUMENTS AND ALARMS
1.7.1 Instruments shall be verified or calibrated and arranged in accessible and illuminated places.

1.7.2 The limiting values shall be marked on scales of pressure and revolution frequency metering devices as brightly painted signs. Forbidden areas of revolution frequency shall be marked on tachometer scales with well visible paint. The marks may be made on protective glasses of the devices.

1.7.3 Sound signals shall be audible in any part of the machinery space while the machinery is running. The sound of engine-room telegraph signals shall differ from other signals in the machinery space.

1.8 MACHINERY SPACES

Passageways

1.8.1 Main and auxiliary engines, assemblies and equipment shall be located in machinery spaces so as to provide free movement of the personnel from their control stations and places of maintenance to the exits. The width of the passageway throughout its length shall be not less than 600 mm and the height — not less than 1900 mm. The width of the passageway may be reduced locally to 500 mm.

In hydrofoil craft, hovercraft and displacement ships of a length less than 25 m, the width of passageways shall be min. 400 mm.

1.8.2 The width of passageways shall be at least 1000 mm from the main engine control station side and between the main engines.
The width of the passageway shall be min. 800 mm if the main engines are remotely controlled.

Means of escape

1.8.3 Each machinery space (other than indicated in 1.8.4), shafting tunnels and each space where main switchboards are installed shall be provided with at least two means of escape, one of which may give through a watertight door to a space which has an independent escape route. The second means of escape shall lead directly to the open deck; for this purpose a vertical steel ladder may be used. The means of escape shall be as widely separated as possible. Ladder trunks shall have clear dimensions not less than 600 × 600 mm.

1.8.4 The second means of escape may be omitted:
.1 from machinery spaces with an area not exceeding 25 m², where the existing escape route does not lead to the adjacent machinery or accommodation space. The area of machinery spaces is determined as per 2.2.5 Part III of the Rules.
.2 in ships not over 25 m in length;
.3 from auxiliary spaces without risk of fire and being enclosed inside the machinery space which has two means of escape;
.4 from enclosed central control stations where main switchboards are not located;
.5 from spaces containing no fuel oil fired engines;
.6 from incinerator rooms.

**1.8.5** If two adjacent machinery spaces communicate through a door and each of them has only one means of escape to the open deck, these means of escape shall be located at the opposite sides.

**1.8.6** Cargo pump rooms in oil tankers shall have at least one means of escape leading directly to the open deck.

**1.8.7** Steps of companion ladders shall have a depth of at least 150 mm and a width of at least 560 mm. Ladders shall be made of sliding-safe plates or grills. Ladder inclination shall not exceed 60° to horizon.

In hydrofoil craft, hovercraft and displacement ships of a length less than 25 m, the width of companion ladders shall be at least 500 mm; vertical companion ladders may be used as well.

**1.8.8** Vertical ladders shall have a width of at least 500 mm. A distance between separate steps shall be not more than 300 mm.

**1.8.9** Plates of bottom plating in the machinery space shall be made of corrugated sheet material. They shall be removable and have fasteners to prevent shifting. Plate thickness shall be such as to avoid sagging in operation. The plate weight and dimensions shall be such as to provide its hoisting by one person (the maximum weight of a single plate is 25 kg).

Engine units, assemblies and valves shall not have prominent parts above the bottom plating in the passageways. Access to such units shall be provided through covers in plating. Covers and hoisting arrangements shall not have prominent parts.

**1.8.10** Platforms intended for maintenance and repair of engines, units, equipment, devices and other components of power installations shall have a width of at least 450 mm and handrails with a height of at least 900 mm.

Hard iron grills shall be provided instead of platforms, where the latter impose the regular air circulation in the machinery space.

Outer edges of the platforms and grills shall have coamings with a height of at least 40 mm.

**1.8.11** All moving parts of engines, assemblies, equipment and drives that are dangerous for attending personnel shall be guarded by handrails or housings.

**1.9 ARRANGEMENT OF POWER INSTALLATION COMPONENTS**

**1.9.1** Power installation components, equipment, pipelines, valves and fittings shall be so located as to be freely accessible for maintenance and repair. Access for repair need not be provided, where a component may be replaced without dismantling other components of the power installation.
1.9.2 All parts of the power installation and pipelines which external surfaces are heated to a temperature above 60 °C and which are dangerous for attending personnel shall be equipped with arrangements to prevent or restrict heat radiation (thermal insulation, screening etc.).

Surfaces of power installation components including pipelines which are heated to a temperature above 220 °C shall have insulation made of non-combustible materials. If insulation is oil-absorbing, in the machinery spaces where fuel or oil is stored or used, insulation shall be coated with metal sheets or equivalent oil-tight material. Measures shall be taken to prevent insulation damage due to vibration and mechanical damages.

1.9.3 The distance from the outer surface of insulation of power installation components to the walls of fuel oil tanks shall be at least 600 mm.

For ships with a length less than 25 m, this distance shall be minimum 400 mm provided that temperature of the outer surface of insulation does not exceed 60 °C.

1.9.4 Boilers which are installed in the same space with internal combustion engines shall be separated by metal enclosures in the furnace area or other design measures shall be foreseen to prevent the equipment of this space from flame action in the event of its ejection from the furnace.

1.9.5 Fuel oil fired boilers situated on platforms or intermediate decks and not enclosed by water-tight bulkheads shall be fenced by tight coamings with a height of not less than 200 mm.

The deck (or platform) under the boilers enclosed by coamings shall be also water-tight.

1.9.6 In oil tankers boilers shall be installed abaft cofferdams beyond the cargo tank area.

In oil tankers intended for transportation of oil products with a flash point up to 45 °C inclusive, tender vessels of oil tankers and cargo ships intended for transportation of easily inflammable cargo solid fuel boilers shall not be installed.

1.9.7 Fuel and oil tanks and oily water collecting tanks shall not be located above the stairways, engines, boilers, exhaust gas pipes, funnel uptakes, electrical equipment and control stations of main components of power installations.

1.9.8 Motors for driving cargo pumps, stripping pumps and pump room fans in oil tankers, combination bulk carriers, oil skimming ships other than steam ones, and driving hydraulic and electric motors of the relevant protection class (see 16.2 Part IV of the Rules) shall not be installed in cargo pump rooms. The motors specified in this paragraph shall be arranged:

- in artificially ventilated rooms adjacent to cargo pump spaces, but having no exits to these rooms and no communication with them;
- in ventilated air-tight enclosures inside the pump room.

Stuffing boxes shall be installed in places where pump/fan drive shafts pass through bulkheads and decks. The structure of stuffing boxes shall comply with the requirements specified in 3.12.16, 3.12.27 and 3.12.28 of Part III of the Rules.

To drive the cargo pumps, stripping pumps and pump room fans in cargo pump rooms of the above mentioned ships, it is allowed to install steam engines with working temperature of max. 150 °C and hydraulic motors.

1.9.9 Equipment used for preparation and delivery of fuel oil to the engine, boiler, inert gas generator, incinerator (fuel pumps, separators, filters and heaters with fuel pressure over 0.18 MPa), as well as hydraulic units containing combustible liquids with working pressure over 1.5 MPa and making no part of main and auxiliary engines, boilers and equipment, shall be arranged in separate rooms with self-closing steel doors.

If it is not possible to arrange such equipment and units in separate rooms, for example, on high-speed ships (hovercraft, hydrofoil craft, WIG craft, captured air bubble craft) and in ships with a length less than 25 m, the arrangements ensuring collection and removal of fuel and working fluid leakages shall be installed in places of possible fuel or working fluid leakages from hydraulic units.
1.9.10 For the requirements to arrangement of emergency diesel generators, see 4.3 Part VI of the Rules.

1.9.11 For the requirements to arrangement of fuel tanks, see 10.13.25 to 10.13.29.

1.10 INSTALLATION OF ENGINES, BOILERS AND EQUIPMENT

1.10.1 Engines, boilers and equipment shall be installed and fixed on foundations. Strength and rigidity of foundations shall be proved by calculations considering static and dynamic loads which can appear during operation of engines, boilers and equipment.

1.10.2 Equipment may be installed on the outer shell plating, watertight bulkheads, shafting tunnel walls and on fuel oil or oil tank walls provided that it is fixed to the stiffeners or on the brackets welded to the plating in the stiffeners area.

1.10.3 Spacers fitted between foundations and bedplates shall consist of not more than two parts.

1.10.4 Main and auxiliary engines, gears, thrust bearings of shaft lines and self-contained boilers shall be fixed to the ship foundations by all fitted coupling bolts or by special stops to prevent its displacement due to any type of load possible while the ship is in operation.

1.10.5 Bolts fastening main and auxiliary engines, boilers, bearings of shafting to ship foundations, bolts connecting the shafting parts, end nuts of propeller, intermediate and thrust shafts, as well as bolts with hindered access during operation, shall be reliably locked to prevent spontaneous unscrewing.

1.10.6 Shock absorbers and shock-absorbing mounts shall:
   .1 maintain their vibration-isolating properties after exposure to limit environmental temperatures specified in 1.3.1 Part V of the Rules;
   .2 be resistant to aggressive mediums and different types of radiations which are possible on board the ship.

1.10.7 Boilers shall be mounted on foundations so that welded joints in boiler structures do not rest on supports.

1.11 USE OF GASOLINE ENGINES

1.11.1 Gasoline engines may be used:
   . to drive portable fire and bilge pumps in all ships other than oil tankers and ships carrying easily inflammable cargoes.

1.11.2 Engines in open ships shall be covered by protective housings. Protective housings made of inflammable materials shall have lining from the inside made of steel roofing on the layer of mineral insulating material.
   In enclosed ships all wooden parts in the machinery space shall have sheeting made of steel roofing on the layer of mineral insulating material.

1.11.3 Watertight floors shall be installed in front of engine and beyond it. Hand pump or motor-driven pump drainage shall be provided in the places of engine installation in enclosed machinery spaces separated by floors as well as in spaces where oil tanks are situated.

1.11.4 Carburettor and engine fuel pumps shall be installed so as to avoid flame ingress from carburettor on fuel pump.

1.11.5 Suction pipes of carburettor shall be led outside the removable housings and be raised over it for at least 500 mm. Suction pipes on the ends shall be fitted with heads with flame arresters.

1.11.6 Carburettor suction pipe inlet shall be located not less than 300 mm above the cylinder heads and provided with flame screens, where engines are installed in enclosed spaces. If there are no suction pipes, flame arresters shall be mounted at carburettor air inlet.

1.11.7 In wooden ships drip trays shall be fitted under the engines, pumps, fuel tanks, valves and all other units of the fuel system where fuel oil leakage is possible. Edges of the trays shall have collars.
1.11.8 A gasoline tank shall be installed in a compartment (enclosure) isolated from the internal combustion engine compartment in ships with continuous deck. These compartments (enclosures) shall be equipped with natural ventilation for gasoline vapour removal.

1.11.9 Protective housings of the engines, machinery spaces, compartments with fuel tanks shall have plenum-exhaust ventilation.

Ventilation tubes of these compartments shall not be connected with each other.

Ventilation tubes from the engine housings and tubes removing gas from the fuel tanks shall be equipped with flame arresters.

1.11.10 Air tubes from the gasoline tank and from the compartment shall be separate, their outlet holes shall be apart from each other as far as possible and shall be fitted with ejecting heads with flame arresters.

1.11.11 Closed motor spaces shall have ventilation which provides removal of accumulated gasoline vapours before the engine start.

1.11.12 Fuel tanks and oil pipelines shall be made of metal resistant to corrosion caused by influence of fuel environment.

1.11.13 For the purpose of fuel tank filling fill-in branch pipes shall be led out to the deck, which shall prevent the fuel ingress inside the hull.

In wooden ships wood around the fill-in branch pipes shall have appropriate lining.

1.11.14 No tubular glass fuel level indicators shall be installed on fuel tanks.

1.11.15 Electric indicator of gasoline level in the tank shall be of explosion-proof type.

1.11.16 It is not allowed to provide devices for sediment discharge in the fuel tanks. When such device is used, self-locking valves shall be additionally provided with thread plug on the outlet end and a drip tray shall be placed under the tank.

1.11.17 A locking device shall be installed on the fuel pipeline directly before the engine which shall allow locking the pipeline from the ship control station.

Fuel pipelines shall be protected against mechanical damage and be located so as they can be inspected throughout the length. The pipes shall be connected by hard-brazed nipples with coupling nuts.

1.11.18 Gasoline pipeline joints shall be free of gaskets. The gasoline pipeline shall be mounted in easily accessible places and protected against damage.

For installation of engines on shock absorbers it is allowed to use gasoline pipeline flexible joints made of gasoline-proof and fireproof materials.

1.11.19 All units of the fuel system shall be placed on the opposite side relatively to the exhaust manifold.

1.11.20 In the motor spaces, accumulators shall be installed only in a closed box on the side opposite to the carburettor or fuel injecting equipment. Exhaust ventilation shall be provided.

Accumulators shall not be located under the fuel tanks.

1.12 SHIP’S SPEED

1.12.1 The output of main engines in self-propelled ships (for tugboats and pushers – in lightship condition) of M-CTI, MIP and O-IIP classes shall be such as to provide the ship’s speed of at least 10 knots in calm deep water in conditions of maximum operating draught.

1.12.2 The power installation shall ensure the ship’s astern operation under normal operating conditions. Rotational speed of shaft lines at steady-state free astern running of the ship shall be at least 70 %, and for ships with direct propeller transmission — at least 85 % of design rotational speed of shafts for ahead running.

1.12.3 The power installation of the ship with a single main engine, when the main engine turbosupercharger (turbosuperchargers) fails, shall provide such a motion speed that the ship can remain steerable.
2 INTERNAL COMBUSTION ENGINES

2.1 SCOPE OF APPLICATION
AND MATERIALS

2.1.1 Requirements of the present Section apply to engines with an output of 55 kW and above.

2.1.2 Engines with output less than 55 kW shall comply with the requirements of 2.3 and applicable requirements of 2.1.3 to 2.1.6 and 2.2.

2.1.3 Engine parts are to be of materials stated in Table 2.1.3.

End of Table 2.1.3

2.1.4 It is allowed to use alloy steels, including heat resistant, high temperature oxidation resistant and high strength steels or alloy cast iron for the engine parts if the chemical composition of these alloy materials does not deteriorate their mechanical properties and strength characteristics as compared to the ones specified in 2 Part X of the Rules and in Table 2.1.3. The compliance of the properties and characteristics of the alloy materials with the requirements of the Rules shall be confirmed by the manufacturer’s documents containing data on chemical composition, mechanical properties and strength characteristics of such materials, as well as documents of test laboratories (centres) on checks and tests of these materials for their compliance with the chemical composition, properties and strength characteristics specified by the manufacturer in the technical documentation agreed with the River Register.

2.1.5 Nodular cast iron is allowed for use at temperatures up to 300 °C, and grey cast iron — up to 250 °C.
2.1.6 In the manufacture process of parts using welding technology the requirements of 7 to 9 Part X of the Rules shall be complied with.

2.2 TESTING OF PARTS

2.2.1 Steel parts of engines are subject to ultrasonic testing during the manufacture process according to Table 2.2.1.

Ultrasonic testing shall be carried out in accordance with the requirements of 2.21 Appendix 10 Part X of the Rules shall be complied with.

2.2.3 Non-destructive testing of engine parts, the numbers of which are not listed in Table 2.2.2 and their welded joints is carried out at the manufacturer’s discretion.

2.3 GENERAL TECHNICAL REQUIREMENTS

2.3.1 Engines shall be capable of operation under overload conditions exceeding the rated output by 10 % for not less than 1 h at operating cycles of not less than 6 h.

2.3.2 Reversible engines intended to be used as main engines in direct propeller transmission units shall ensure at least 85 per cent of the design ahead output in the reverse mode.

2.3.3 Minimum steady rotation frequency of main engines with direct propeller transmission shall not be more than 30 per cent of the nominal rotation frequency.

2.3.4 The possibility of safe cranking of main engines shall be ensured.

2.3.5 Fasteners of engine moving parts as well as fasteners located in hardly accessible places shall have fittings or be so designed as to prevent from spontaneous unscrewing.

Engine moving parts shall be covered by protective housings.

2.3.6 Lubrication devices for engine parts and units shall be easily accessible and safe for maintenance during the operation of the engines.

2.3.7 Safety and protective devices shall be so designed and installed so that in case of their actuation they are not hazardous both as regards fire and for the attending personnel.

2.3.8 Remote and automatic control systems shall meet the applicable requirements of 11 of this Part.

2.3.9 Engine systems and pipelines shall meet the applicable requirements of 10 of this Part.

2.3.10 Turbocharger rotors shall be designed so that equivalent stresses in any section do not exceed 0.95 of the yield point of part’s material at the rotation frequency equal to 1.2 times the rated one.

2.3.11 Engine parts, pipelines and units operating under excessive pressure shall undergo hydraulic tests according to 6.2.2 of RTSC.

2.4 FRAME

2.4.1 Mating surfaces of the frame parts forming the engine crankcase shall be oil- and gas-tight and fixed together by means of calibrated pieces.

2.4.2 The crankcase and detachable covers of the crankcase inspection ports shall withstand maximum possible operating load with the covers being securely fastened in such a
way as to prevent their displacement in the event of explosion.

2.4.3 The engine frame and conjugated parts shall be fitted with draining arrangements (drain grooves, pipes) and other facilities preventing the ingress of fuel and oil into circulating oil.

The cooling spaces of the cylinder blocks shall be fitted with drain arrangements providing complete drainage.

2.4.4 No ventilation of crankcases or use of any arrangements causing flow of external air into the crankcase is allowed. If a forced extraction of the gases from the crankcase is provided (e.g., for smoke detection purpose), vacuum in the crankcase shall not exceed 250 Pa.

For engines with an output up to 750 kW suction of gas/air from the crankcase by turbo-blowers or blowers may be admitted provided that oil separators are fitted to prevent the ingress of oil with the suction gas/air inside the engine.

Vent pipes or drain oil pipes of crankcases of two or more engines shall not be combined.

A diameter of the vent pipes from the crankcase shall be as small as practicable; the ends of the vent pipes shall be fitted with flame arresters and arranged so as to prevent water ingress inside the engine.

Vent pipes shall be led to the weather deck or to the places where exhaust ventilation is provided.

2.4.5 Engine crankcases shall be fitted with safety valves as follows:

1. engines having a bore of 200 mm and over, but not exceeding 250 mm, shall have at least one valve at each end of the crankcase, if the number of cylinders is less than eight; additional valve shall be fitted near the middle of the crankcase, if the number of cylinders is eight and above;

2. engines having a bore exceeding 250 mm, but not exceeding 300 mm, shall have at least one valve in way of each alternate crankthrow, but at least two valves for the crankcase;

3. engines having a bore exceeding 300 mm shall have at least one valve in way of each main crankthrow;

4. Additional safety valves shall be fitted on separate crankcase spaces, such as camshaft drive, when the gross volume of such spaces exceeds 0.6 m³;

5. no crankcase safety valve is required for engines having a bore not exceeding 200 mm or having a crankcase gross volume not exceeding 0.6 m³.

2.4.6 The safety valves shall comply with the following requirements:

1. The design of valves shall ensure immediate opening of valves at an overpressure of not more than 0.02 MPa in the crankcase and their closing to exclude inrush of air into the crankcase;

2. crankcase safety valve discharges shall be shielded in order to reduce the possible danger from emission flame.

2.4.7 The total open flow area of the safety valves fitted on the engine crankcase shall be not less than 0.0115 m² per a cubic meter of the crankcase gross volume. In calculations of the gross volume of the crankcase the moving engine parts located inside the crankcase need not be included.

Each safety valve to be fitted in the crankcase as required in 2.5.5 may be replaced by two combined safety valves of respectively reduced area, provided that passage area of each valve is not less than 0.0045 m².

2.4.8 Crankcase drain holes shall be fitted with gratings or screens to prevent foreign objects from getting into the drain piping.

The aforementioned requirement also applies to dry crankcase engines.

2.4.9 When a cylinder bore exceeds 230 mm, each working cylinder may be fitted with a relief valve set to pressure exceeding the maximum combustion pressure by not more than 40 per cent when running at the rated power.

2.5 CRANKSHAFT

2.5.1 Requirements of the present Chapter apply to forged or cast steel crankshafts of
engines having the cylinders either in line or in V-arrangement with one crankthrow between main bearings; meanwhile intervals between explosions in engine cylinders are equal one to another.

2.5.2 The results of crankshaft strength calculations made according to the Guidelines of the River Register P.008-2004 "Strength calculations for internal combustion engine crankshafts" or according to the method taking into consideration the requirements of the Rules and the above mentioned manual agreed with the River Register shall be submitted for agreement to the River Register together with technical documentation.

2.5.3 A diameter of lightening holes in crankshaft journals shall not exceed 0.4d_j, where d_j is a diameter of the crankshaft journal.

2.5.4 A journal-to-web transition radius for solid-forged and semi-built crankshafts shall be not less than 0.05d_j.

Where flanges are provided, a journal-to-web transition radius shall be not less than 0.08d_j.

2.5.5 The outlets of oil channels to the journal surface shall be arranged in the journal bearing surface areas subject to minimum load.

Edges of oil channel exits to the journal surface shall be rounded by radius not less than 0.25 times the channel (hole) diameter and grinded.

2.5.6 Thermal surface hardening of crankshaft journals shall not extend on fillets except the cases when crankshafts in whole are subject to hardening.

2.5.7 Built-up crankshaft shall be so designed as to provide minimum stress concentration in the journal-to-web transition.

2.5.8 Hot interference of web on journal shall be within (0.0014÷0.0018) d_j.

Control marks shall be drawn on the outside surface of journals in places of connection with journals and crankpins.

2.5.9 If an engine frame has built-in thrust bearing, the thrust shaft diameter in the bearing area shall be not less than the journal diameter and also not less than that determined by the formulae of Section 3 if this Part.

2.6 SUPERCHARGING AND AIR SUPPLY

2.6.1 In the event of failure of the turbocharger the main engine shall be capable of operation at reduced power which shall not be less than 20 per cent of the rated power.

2.6.2 Where supercharging air is cooled, the air discharge branch pipes shall be fitted with thermometers and condensate drain cocks after each air cooler.

It shall be possible to remove the accumulating precipitations from the air receivers if no supercharged air coolers are available.

2.6.3 Air suction branch pipes of engines, turbo-compressors and scavenging units shall be fitted with safety screens to prevent foreign objects from getting inside the branch.

2.6.4 Turbocharger rotors shall be balanced in assembly according to 4.3.2.

2.6.5 Standard specimens (see 1.2.2.19 of RTSC) of turbocharger rotors shall withstand the tests at a rotation speed equal to 1.2 of the design one for at least 3 min without damages and residual deformations.

2.7 FUEL APPLIANCES

2.7.1 High-pressure injection pumps of main engines shall be fitted with a device for quick shutting-off the fuel supply to any cylinder of the engine. Exemption from this requirement is allowed for engines with a cylinder bore not over 180 mm having grouped fuel pumps.

2.7.2 High-pressure fuel oil injection pipes shall be made from thick-walled seamless steel pipes as per GOST 8734 free of welded or soldered intermediate joints.,

2.7.3 Engine fuel system shall allow hand pumping of high-pressure pipelines.
2.7.4 High-pressure pipelines shall be located in places easily accessible for inspection and replacement and shall be fastened.

2.7.5 External high-pressure fuel pipelines from the high-pressure fuel pumps (from the high-pressure fuel manifolds) to the burners shall be protected against the ingress of fuel on engine and surrounding equipment in the event of pipeline failure. The engines shall have the appliances for collection and discharge of fuel leakages and the high-pressure fuel pipeline damage alarm complying with the applicable requirements of 11.4.

If the design of the engine ensures safe operation of the engine when its fuel system components operating under high pressure are faulty (it shall be specified by the manufacturer), instead of the above mentioned measures it is allowed to provide only alarm on fuel system faults affecting safety of engine operation.

2.7.6 There shall be provided pipelines for draining the leaked fuel into special tanks. Measures shall be taken to prevent the ingress of leaked fuel into the lubrication system.

2.8 LUBRICATION

2.8.1 Turbocharger bearings lubrication system shall prevent the ingress of oil into supercharging air.

2.8.2 It shall be possible to lubricate turbocharger bearings in the run-out term after execution of the engine stop command.

2.8.3 If there are separate oil collectors in the lubrication system, oil drain pipelines from two or more engines shall not be combined.

2.8.4 (shall be considered to have lost force.)

2.8.5 The design of pipelines delivering oil to friction assemblies shall exclude water hammers in lubricating system.

2.9 COOLING

2.9.1 Engines shall be provided with cooling systems ensuring their safe operation. Technical justifications for cooling systems (liquid cooling of various types, air cooling, combined liquid-air cooling) shall be submitted to the River Register.

2.9.2 Where telescopic devices are used for cooling of the piston inside spaces, protection against hydraulic hammer shall be provided.

2.10 STARTING ARRANGEMENTS

2.10.1 The manifold supplying air from the master starting air valve to the cylinder starting valves shall be fitted with safety valve and with a device relieving pressure in this manifold after the start or with any other facility protecting the starting manifold from destruction in case of explosion in the pipeline.

The relief valve shall be loaded to a pressure not exceeding 1.2 times of that in the starting air manifold. The relieving device and the relief valve may be fitted directly on the master starting air valve.

2.10.2 Flame arrestors or rupture discs shall be fitted on each branch pipe supplying air to starting valves of cylinder covers on reversible engines.

In case of non-reversible engines a flame arrestor or rupture disk shall be fitted on the manifold supplying starting air from the main starting air valve to the receiver (collector) which supplies air to starting valves in the engine cylinder covers.

It is not required to install flame arrestors or rupture discs on engines with cylinder diameter of 230 mm or less.

2.10.3 Electrically-started engines shall be fitted with hinged generators for automatic charging of starting accumulator batteries.

2.11 GAS EXHAUST

2.11.1 Exhaust collectors shall be so designed as to allow thermal expansion and provide gas-tightness in case of vibration.

2.11.2 Exhaust collectors shall be fitted with drain cocks at the ends of the collector and hatches for cleaning the collector. If the exhaust collectors have liquid cooling the
hatches for cleaning their cooling spaces shall be provided.

2.11.3 When designing exhaust manifolds it is required to provide measuring the gas temperature before turbo-superchargers and after them.

2.12 CONTROL AND ADJUSTMENT

2.12.1 Starting and reversing arrangements shall prevent the engine from:

.1 changing the direction of the crankshaft as compared with the required one;
.2 reversing when the fuel supply is actuated;
.3 starting before reversing is completed.
.4 starting the engine when the turning gear is engaged.

2.12.2 Each main engine shall have a governor so adjusted that the engine speed can not exceed the rated (nominal) value by more than 15 per cent.

Additionally each main engine with an output of 220 kW and over which may be disengaged from the shafting by means of disengaging coupling, shall be fitted with a separate overspeed protective device so adjusted that the engine speed can not exceed the maximum speed by more than 20 per cent.

2.12.3 Each diesel generator shall be fitted with a speed governor which shall meet the following requirements:

.1 when 100 per cent of the diesel generator rated power is suddenly thrown off, the instantaneous rotation speed variation shall not exceed 10 per cent of the rated value, and steady rotation speed after 5 s shall not differ from the rotation speed of previous mode by more than 5 per cent of the rated value;

.2 in case of sudden loading of up to 70 % and further (after reaching the steady rotation speed) instantaneous loading of the remaining 30 %, the instantaneous variation of the rotation speed actuating motor of generator / diesel generator shall not exceed 10% of the rated value, and the steady rotation speed after 5 s after accepting of each part of the specified loads shall not differ from the rated rotation speed by more than 5 %. The value of surged load of the first stage can be reduced to 50 %, or the surge load may be allowed in the form of more than two stages in case when the diesel generator's actuating motor may be loaded by more than two stages, which is specified by the manufacturer of the motor and confirmed by the technical documentation approved by the River Register. The load stages of such actuating motors of the generators and the values of permitted load for each stage shall be specified in "Technical characteristics" section of the documents issued by the River Register for engines / diesel generators in order to take them into account by the design bureaus together with the requirements of Sect. 3 of Part VI of the Rules when designing the ships;

.3 steady rotation frequency recovery time can be increased on agreement with the River Register if in the electrical installation there are no consumers which require increased stability of frequency;

.4 speed governor for emergency diesel generator shall have characteristics meeting the aforementioned requirements with respect to change of the rotation speed when 100 % load is taken off and put on.

In addition to the speed governor each diesel generator with an output of 220 kW and above shall be fitted with a separate overspeed protective device so adjusted that the engine speed can not exceed maximum rotation speed by more than 20 per cent.

The separate protective device stated in 2.12.2 and in the present paragraph shall be a device having no connection with the governor, and shall be actuated in the event of failure of the governor or its driving gear.

.5 the steady rotation frequency when the diesel generator load specified in 2.12.3.1 and 2.12.3.2 is taken off and put on shall be attained within max. 5 s;

.6 steady rotation frequency variations (swing) of AC diesel generator in any of the steady modes under load of 25 to 100 % of the rated power shall be within ±1 % of the nominal rotation frequency.
.7 under idle load of up to 25% of the rated power the steady rotation frequency of the diesel alternator crankshaft shall not differ from the nominal value by more than ±5%.

Each mechanical governor of diesel generator shall have a device for local and remote regulation of rotation frequency within 10% of the rated rotation frequency. Electronic governors of diesel generators do not require a device for local and remote regulation of engine crankshaft rotation frequency.

2.12.4 The requirements to provide the engines with overspeed protective devices according to 2.12.2 and 2.12.3.4 do not apply to the engines equipped with electronic control systems, the design and operation principle of which make it impossible for these engines to exceed the maximum rotation speed by more than 20%.

2.13 INSTRUMENTS

2.13.1 Local control stations of main and auxiliary engines shall be equipped with instruments for measuring the following:

.1 rotational speed of the crankshaft, rotational speed the propeller shaft if disengaging couplings are installed;
.2 lubricating oil pressure at the engine inlet;
.3 water pressure in the inner cooling system;
.4 outboard water pressure in the cooling system;
.5 starting air pressure at the main starting valve inlet;
.6 fuel pressure at the fuel injection pump inlets (where an oil-fuel priming pump is installed);
.7 pressure in the cooling systems of injectors and pistons;
.8 pressure in the reversing arrangement system;
.9 supercharging air pressure at the engine inlet;
.10 exhaust gas temperature at each cylinder (if the engine design makes it possible to measure such temperature) and (or) exhaust gas temperature at the turbine inlet;
.11 temperature of cooling water and oil at the engine inlet and each cylinder and piston outlet (for engines with an output of 220 kW and above), cooling water and oil temperature at the engine outlet (for engines with an output less than 220 kW);
.12 lubricating oil temperature at the engine inlet;
.13 supercharging air temperature after air coolers;
.14 current and voltage in the charging circuit and voltage in the discharging circuit of starting accumulator batteries (for engines with electric starting);
.15 fuel temperature at high-pressure pump inlets (for fuel which requires heating).

Notes. 1. Where pressure (2.13.1.6, 2.13.1.7, 2.13.1.9) and temperature (2.13.1.10 to 2.13.1.13) are measured by means of devices installed directly on the engine, it is not required to install these devices in the local control station.

2. The requirement to the device specified in 2.13.1.4 does not apply to the local control stations for the engines with air cooling systems, combined liquid-air cooling and liquid-cooling systems using coolers, in which water of the internal loop circulates in the channels adjoining to the ship's shell plating from the inside (box coolers). For engines with output less than 220 kW it is allowed not to install the devices for checking the parameters specified in 2.13.1.3 and 2.13.1.4 in the engine local control stations. 2.13.1.3 In this case the efficiency of liquid and liquid-air cooling systems of engines is checked as per the temperatures specified in 2.13.1.11 and air-cooling systems, as per the temperatures specified in 2.13.1.10 and 2.13.1.12.

3. The requirement to the devices specified in 2.13.1.11 does not apply to the local control stations for engines with air-cooling systems. It is allowed not to install the devices to check the temperature specified in 2.13.1.13 in the local control stations.

4. Devices for changing the parameters specified in 2.13.1.14 can be replaced with starting accumulator batteries charge/discharge electronic indicators.

2.13.2 (shall be considered to have lost force.)
2.14 GASOLINE ENGINES

2.14.1 Requirements stated in the present Section are applicable also for gasoline engines. The requirements of 1.11 shall be also executed.

2.14.2 Exhaust manifold and connecting branch pipes shall have water cooling.

2.15 ADDITIONAL REQUIREMENTS TO ENGINES OPERATING ON VARIOUS GRADES OF FUEL

2.15.1 The engines can operate on fuel oil meeting the requirements of 1.1.2 which substitutes for the corresponding types of the specification fuel listed in the technical documentation of the manufacturer or is produced (extracted) by means of non-conventional sources and types of primary energy (alternative fuel), or is a mixture of alternative and specification fuel with properties differing from the specification fuel, provided the engine characteristics during operation on this fuel in all operating conditions, including variable conditions, do not differ from the certificate ones and the engines comply with the requirements of 2.1 to 2.13, 2.15.3 and 2.15.4.

2.15.2 A possibility to switch promptly to the specification fuel oil for fuel fired engines as specified in 2.15.1. In the process of such transfer the engine output shall drop by more than 20%.

2.15.3 When the fuel specified in 2.15.1 is used in the engine, the safety valves shall be fitted in the crankcases and the under-piston cavities of the engine near each crankthrow. The design and actuation pressure of safety valves depend on the properties of fuel-air mixture produced in the crankcase and on the engine output at the moment of transfer from one grade of fuel to another one.

2.15.4 When the fuel specified in 2.15.1 with saturated vapour pressure exceeding 25 kPa at 40 °C is used, the devices (sensors or other similar devices) measuring the concentration of vapours of the specified fuel flowing through the sealings shall be fitted in the crankcases and under-piston cavities.
3 SHAFTING

3.1 GENERAL REQUIREMENTS, MATERIALS, TESTING

3.1.1 Materials intended for shafting parts shall meet the requirements specified in the right column of Table 3.1.1.

3.1.2 It is allowed to use alloy steels, including corrosion resistant and high strength steels, for the shafting parts if the chemical composition of the alloy steel does not deteriorate its mechanical properties and strength characteristics as compared to the ones specified in 2.6 and 2.7 Part X of the Rules and in Table 3.1.1. The compliance of the properties and characteristics of the alloy steel with the requirements of the Rules shall be confirmed by the manufacturer’s documents containing data on chemical composition, mechanical properties and strength characteristics of such steel, as well as documents of test laboratories (centres) on checks and tests of alloyed steels for their compliance with the chemical composition, properties and strength characteristics specified by the manufacturer in the technical documentation agreed with the River Register.

3.1.3 Intermediate, thrust and propeller shafts shall be made of steel with tensile strength from 430 to 690 MPa.

The aforementioned shafts shall undergo non-destructive testing during manufacture according to 2.20 to 2.23 Appendix 10 Part X of the Rules shall be complied with.

3.1.4 (shall be considered to have lost force.)

3.1.5 Propeller shaft liners, sterntube and strut bushes may be made of plastics or other non-metallic materials.

3.1.6 After machining the propeller shaft liners and the stern tubes shall be hydraulically tested according to 6.2.15 of RTSC.

3.1.7 In case of post-assembly oil lubrication of bearings the stern tube sealings shall be hydraulically tested for leakages (tightness) by pressure of not less than 0.1 MPa according to 6.3.11 of RTSC.

3.1.8 Formulae for calculation of the shaft diameter given in the present Section determine the minimum shaft diameter ignoring allowance for subsequent grooving of journals during the service life.

3.1.9 In all ships measures shall be taken to prevent the propeller shaft from slipping out of the stern gland and flooding of the engine.
3.2 SHAFT DIAMETER CALCULATION

3.2.1 Calculations of shaft diameters using the formulae stated in the present Chapter are preliminary, as the dimensions of all shafting elements shall be specified after the torsional circuit has been formed with due regard to the calculation results of torsional vibration stresses including modes corresponding to rotation speed values forbidden for continuous work (see 6.4).

In case when shaft diameter calculation by the formula (3.2.2) is impossible due to special geometry of shafting elements, special strength calculation confirming compliance with the Rules shall be submitted to the River Register.

3.2.2 Intermediate, thrust or propeller shaft diameter, except for hydrofoil craft shafting, shall be not less than that determined by the formula, in mm:

\[
d \geq \frac{560}{R_m+160} k C_{EW} \sqrt{\frac{P}{\left[ n \left[ 1 - \left( \frac{d_i}{d_r} \right)^6 \right] \right]}}.
\]

(3.2.2)

where \( R_m \) — tensile strength of the shaft material, in MPa. The formula (3.2.2) is reliable at \( R_m = 400\div600 \) MPa; when \( R_m > 600 \) MPa, \( R_m = 600 \) MPa shall be taken;

\( k \) — coefficient equal to:

- for intermediate shafts with forged flanges or flanged keyless clutches 130
- for intermediate shafts with key clutches 140
- for thrust shafts in rolling bearings 142
- for propeller shafts at a distance of not more than 4 diameters of the propeller shaft from the bow face of the propeller boss and in the plain bearing journals 160
- for propeller shafts at a distance exceeding 4 diameters of the propeller shaft from the bow face of the propeller boss and the shaft sections between the bearing journals 150

\( C_{EW} \) — strengthening coefficient equal to:

- for ships without ice strengthening 1.0
- for ships designed for navigation in broken ice 1.05
- for icebreakers and icebreaker-type ships 1.07

\( P \) — rated power transmitted by the shaft, in kW;

\( n \) — rated rotational speed, in min\(^{-1}\);

\( d_i \) — diameter of the shaft axial hole, in mm; if this diameter is less than or equal to 0.4\( d_r \), then \( d_i = 0 \);

\( d_r \) — actual shaft diameter, in mm.

The diameter of the bow face of the propeller shaft on the section from the stern tube gland to the flange or the clutch may be gradually reduced to the value equal to 1.05 times of the intermediate shaft diameter. Parts of the propeller shaft contacting with water shall have external diameter as greater as 5 per cent as compared with the diameter determined by the formula (3.2.2), when the shaft has no continuous lining or other effective anti-corrosion protection.

A diameter of hydrofoil craft propeller shafts located outside the hull at an upwash angle of 12° and more considering the running pitch shall be not less than the diameter determined by the formula, in mm:

\[
d_{sh} = 696.19 K_1 K_2 \sqrt{\frac{P}{(R_{EH} n)}}.
\]

where \( K_1 \) — coefficient for power installations taken equal to:

- single-shaft 1.0
- two-shaft 1.15

\( K_2 \) — coefficient taken, depending on propeller shaft surface hardening, equal to:

- no hardening is provided 1.0
- hardening by rolling the shaft surface is provided 0.92

\( R_{EH} \) — yield point of the rudder stock material, in MPa.

3.3 CORROSION PROTECTION

3.3.1 Propeller shafts, including their journals and shaft sections between the journals, shall be protected from corrosion.

3.3.2 Liner material shall comply with the requirements of Table 3.1.1.

3.3.3 A bronze shaft liner thickness \( s \) shall be not less than that determined by the formula, in mm:
\[ s = 0.03d'_t + 7.5, \] (3.3.3)

where \( d'_t \) — actual diameter of the propeller shaft, in mm.

The liner thickness between the bearings may be reduced down to \( 0.75s \).

### 3.3.4 Continuous liners shall be used. Liners consisting of separate sections shall be connected by welding or by another alternative method. The butt welded joints of the liner shall be arranged outside the region of bearings.

### 3.3.5 A sealing shall be installed on the propeller shaft cone to avoid ingress of water on it.

This requirement does not apply to the ships of less than 25 m in length, except for the ships of М-СП, М-ПП and О-ПП classes.

### 3.4 HOLES AND CUT-OUTS IN SHAFTS

#### 3.4.1 If a radial hole is arranged in a shaft, the shaft diameter shall be as greater as 10 per cent along a length of minimum seven diameters of the hole. The hole shall be located in the middle of the thickened part of the shaft and its diameter shall not exceed 0.2 times the increased shaft diameter.

Hole edges shall be rounded with a radius of not less than 0.35 of the hole diameter. The hole surface shall be finished to surface average roughness of 0.63 \( \mu \)m and less according to GOST 2789.

#### 3.4.2 Diameter \( d \) of a shaft having a longitudinal cut-out shall be not less than that determined by the formula, in mm:

\[ d = 1.2d_0 + 0.114(1.5l + b), \] (3.4.2)

where \( d_0 \) — shaft diameter determined by the formula (3.2.2), in mm;

\( l \) — overall length of the cut-out, in mm;

\( b \) — width of the cut-out, in mm.

A thickened part of the shaft shall be of such length that it will protrude from each side out of the cut-out limits for a length not less than 0.25 times the design shaft diameter \( d_0 \). The transition from the increased diameter to the design diameter shall be smooth.

The cut-out width shall be not less than 0.1 times but not greater than 0.25 times the design shaft diameter \( d_0 \). The cut-out ends shall be rounded with a radius equal to the cut-out half width.

The edges shall be rounded with a radius not less than 0.35 times the cut-out width. Cut-out surface shall be finished to surface average roughness of 1.25 \( \mu \)m and less.

#### 3.4.3 Where a key slot is provided on a cylindrical section of a shaft, the shaft diameter shall be increased by 5 per cent as compared with that determined by the formula (3.2.2) on the part exceeding the length of the key slot.

It is not necessary to increase the shaft diameter if the key slot is located on the shaft cone.

### 3.5 SHAFTING DESIGN

#### 3.5.1 Propeller shaft cone for the propeller shall be made with a conicity not greater than 1:12.

#### 3.5.2 For propeller shafts with a diameter of 100 mm and over the end of key slot on the propeller shaft cone shall have a spoon-type shape and shall be at a distance not less than 0.2 times the propeller shaft diameter from the greater cone base.

End of key slot may be of ski-type shape for a propeller shaft diameter less than 100 mm.

Dimensions of key slots, the shape and ratio of dimensions of spoon-type preparation of the bow propeller shaft cone end shall correspond to requirements of national standards1.

#### 3.5.3 The shaft cone for the propeller and coupling in keyless connections shall be made with the following conicity for the following connections:

- with end nut \( \leq 1:15 \)
- without end nut \( \leq 1:50 \)

1 GOST 8838, GOST 24071, GOST 23360
Thread journals

3.5.4 External diameter of a thread journal for propeller fixing nut shall be not less than 60 per cent of the greater cone diameter.

Connecting couplings

3.5.5 Connecting bolts, couplings and half-couplings shall be made of steel with tensile strength not less than that of shafting steel.

3.5.6 Diameter \( d_b \) of coupling flange bolts shall be not less than that determined by the formula, in mm:

\[
d_b = 0.535 \sqrt[3]{d_{int}/(ir)} ,
\]

(3.5.6)

where \( d_{int} \) — diameter of the intermediate shaft determined by the formula (3.2.2) with due regard to reinforcements; if the shaft diameter is increased due to dangerous stresses from torsional vibration, then \( d_{int} \) shall be equal to the actual diameter of the intermediate shaft;

\( i \) — number of bolts in the connection;

\( r \) — bolt pitch circle radius, in mm.

3.5.7 Fifty per cent (50\%) of the total number of cylindrical bolts of shafting flange connections, but not less than three, shall ensure transition fit H/js (finish 5-7) according to GOST 25347.

3.5.8 Intermediate shaft connecting flange thickness measured on the centre circle of connecting bolts shall be not less than the diameter of connecting bolt determined by the formula (3.5.6).

Propeller shaft flange thickness shall be not less than 0.25 times the intermediate shaft diameter determined by the formula (3.2.2).

3.5.9 Rounding radius of transition from a flange to the shaft shall be not less than 0.08 times the shaft diameter.

3.5.10 Safety of use of cardan shafts in ship shaftings shall be confirmed by the technical justifications submitted to the River Register.

Bearings

3.5.11 Length of bearings in the arm shall be not less than 2.5 times the shaft diameter.

3.5.12 A shut-off valve controlling water supply for the stern tube bearing lubrication shall be installed directly on the stern tube or on the after peak bulkhead.

A flow direction indicator shall be fitted on the pipeline feeding water for the stern tube bearing lubrication.

3.5.13 A device for measuring oil temperature in the stern tube is to be provided.

3.5.14 Where hydrostatic lubrication is used for stern tube bearings, the lubricating oil tank shall be located above the maximum ship’s draught waterline and fitted with oil level indicators.

If the tank is located in hardly accessible place or outside the space where main engines or propeller electric motors are installed, low oil level alarm shall be provided which can be seen or heard from the main engine or the propulsion plant control station.

3.5.15 If propeller shaft rotation speed \( n \) 350 min\(^{-1}\), indicative values of maximum permissible distances \( l_{max} \) between the adjacent bearings of the displacement ships shafting shall be calculated by the following formula, in mm:

\[
l_{max} = k_1 \sqrt{d_r} ,
\]

(3.5.15-1)

where \( d_r \) — actual shaft diameter, in mm (see 3.2.2);

\( k_1 \) — coefficient for bearings taken equal to:

- oil-lubricated plain bearings 450
- grease-lubricated stern tube rolling bearings made of grey cast iron 405
- water-lubricated stern tube bearings 440

At 700 n > 350 min\(^{-1}\):

\[
l_{max} = k_2 \sqrt{d_r/n} ,
\]

(3.5.15-2)

where \( k_2 \) — coefficient:

- for oil-lubricated plain bearings, 
  \( k_2 = 11455 - 106373.5/n \);
- for grease-lubricated stern tube rolling bearings made of grey cast iron and rubber or plastic water-lubricated stern tube bearings
  \( k_2 = 133.378 n - 1690.881 - 0.224 n^2 + 0.000126 n^3 \).
At 2000 > n ≥ 700

\[ l_{\text{max}} = 1857.5 \sqrt{d_t/n^{0.5}}. \]

Indicative values of maximum permissible distances \( l_{\text{max}} \) between the adjacent bearings of hydrofoil craft shafting can be determined considering the design by the following formula, in mm:

\[ l_{\text{max}} \leq 57d_t. \]

Values \( l_{\text{max}} \) and \( d_{\text{prop}} \) for hydrofoil craft shall be corrected by results of shaft check for longitudinal stability and determining the critical speed. The static strength of hydrofoil craft shafting shall also be estimated and its fatigue strength shall be calculated.

3.5.16 Minimum distance \( l_{\text{min}} \) between adjacent main bearings of the shaft line shall be not less than \( l_{\text{min}} = 174 \sqrt{d_t}. \)

3.5.17 The propeller shaft shall lean on two bearings in the stern tube. It is allowed to install one stern bearing in a stern tube with a length less than 4.5 times the shaft diameter when using water-lubricated rubber or plastic plain bearings and 3 times the shaft diameter when using oil-lubricated plain bearings.

3.5.18 Length of stern unit bearings and circumferential velocity of propeller shafts shall correspond to the requirements of Table 3.5.18.

**Table 3.5.18**

3.5.19 Propeller shafts supported on rolling bearings and propeller shafts in stern tubes with plain bearings lubricated with oil or closed-loop pressurized water shall be fitted with sealings.

3.5.20 Lubrication shall be supplied to the stern tube in a such manner as to provide its supply to both stern and bow stern tube bearings. If grease is used, it shall be supplied through bow and stern bearings.

3.5.21 Stern tube with oil-lubricated bearings shall be fitted with connections for filling the tube with oil, testing and drainage; a ventilation pipe shall be attached also. These connections and the stern tube shall be so designed that oil, water and air entered the tube could be completely removed.

### 3.6 KEYLESS CONNECTIONS OF PROPELLERS AND SHAFTING COUPLINGS

3.6.1 A keyless assembly of the propeller and the propeller shaft shall be designed without intermediate sleeve between the propeller boss and the shaft.

3.6.2 When assembling keyless connection, the axial shift \( \Delta h \) of the boss in relation to the shaft or intermediate sleeve, as soon as the contact area between mating surfaces is obtained after elimination of the clearance, shall be not less than determined by the formula, in m:

\[
\Delta h = k \left[ 8 \cdot 10^{-3} B \left[ 19.1 P \left( nD_t \right)^2 + T^2 \right] / ( h z ) \right] \]

where \( B \) — coefficient of the connection material and configuration, in MPa:\n
\[
B = \left[ \left( 1 + w^2 \right) / \left( 1 - w^2 \right) - v_y \right] / E_y + \left[ \left( 1 + w^2 \right) / \left( 1 - w^2 \right) - v_w \right] / E_w ;
\]

\( y \) — mean coefficient of the boss outer diameter:

\[
y = \left( D_{z1} + D_{z2} + D_{z3} \right) / \left( D_{y1} + D_{y2} + D_{y3} \right) ;
\]

\( w \) — mean coefficient of the shaft bore:

\[
w = \left( D_{w1} + D_{w2} + D_{w3} \right) / \left( D_{w1} + D_{w2} + D_{w3} \right) ;
\]

\( v_y \) — Poisson’s ratio for boss material;

\( v_w \) — Poisson’s ratio for shaft material, for steel \( v_w = 0.3; \)
$E_r$ — modulus of elasticity of boss material, in MPa;

$E_w$ — modulus of elasticity of shaft material, in MPa;

$P$ — power transmitted by the connection, in kW;

$T$ — propeller thrust at ahead speed, in kN;

$D_w$ — mean outer shaft diameter in the place of contact with the boss or intermediate sleeve (Fig. 3.6.2), in m:

$$ D_w = \left( D_{w1} + D_{w2} + D_{w3} \right) / 3; $$

without intermediate sleeve:

$$ D_{w1} = D_{y1}; \quad D_{w2} = D_{y2} ; \quad D_{w3} = D_{y3} ; \quad D_w = D_y ; $$

with intermediate sleeve:

$$ D_{w1} \neq D_{y1} ; \quad D_{w2} \neq D_{y2} ; \quad D_{w3} \neq D_{y3} ; \quad D_w \neq D_y ; $$

$\alpha_r$ — linear expansion coefficient of boss material, in $1/\degree\text{C}$;

$\alpha_w$ — linear expansion coefficient of shaft material, in $1/\degree\text{C}$;

$t_c$ — temperature of the connection in service conditions, in $\degree\text{C}$;

$t_m$ — temperature of the connection during assembling, in $\degree\text{C}$;

$k$ — coefficient for the connection taken equal to:

without intermediate sleeve 1

with intermediate sleeve 1.1

$h$ — effective length of the shaft cone or intermediate sleeve with the boss, in m;

$z$ — taper of the boss:

$$ z = \left( d_{\text{con.max}} - d_{\text{con.min}} \right) / L_{\text{con}} , $$

$d_{\text{con.max}}$ — maximum cone diameter, in mm;

$d_{\text{con.min}}$ — minimum cone diameter, in mm;

$L_{\text{con}}$ — propeller shaft cone length;

$n$ — rotational speed of the connection, in min$^{-1}$.

For connection with steel shaft without axial drilling the coefficient $B$ can be taken according to Table 3.6.2 by means of linear interpolation.

**Table 3.6.2**

| Coefficient $B \times 10^5$, in MPa$^{-1}$, for the steel shaft with $w = 0$, $E_r = 2.059 \times 10^5$ MPa, $v_r = 0.3$ and for copper alloy boss with $v_r = 0.34$ at $E_r$ in MPa | Coefficient $B \times 10^5$, in MPa$^{-1}$, for steel boss with $v_r = 0.3$ at $E_r = 2.059 \times 10^5$ MPa |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0.98-10^5 | 1.078-10^5 | 1.176-10^5 | 1.274-10^5 | 1.373-10^5 | 1.471-10^5 | 1.569-10^5 |

| 1.7 | 2.79 | 2.56 | 2.38 | 2.22 | 2.09 | 1.97 | 1.87 | 1.50 |
| 1.8 | 2.62 | 2.41 | 2.24 | 2.09 | 1.97 | 1.86 | 1.76 | 1.41 |
| 1.9 | 2.49 | 2.29 | 2.13 | 1.99 | 1.87 | 1.77 | 1.68 | 1.36 |
| 2.0 | 2.39 | 2.20 | 2.05 | 1.91 | 1.80 | 1.70 | 1.62 | 1.31 |
| 2.1 | 2.31 | 2.13 | 1.98 | 1.85 | 1.74 | 1.65 | 1.57 | 1.27 |
| 2.2 | 2.24 | 2.07 | 1.92 | 1.80 | 1.69 | 1.60 | 1.53 | 1.24 |
| 2.3 | 2.18 | 2.01 | 1.88 | 1.76 | 1.65 | 1.57 | 1.49 | 1.22 |
| 2.4 | 2.14 | 1.97 | 1.84 | 1.72 | 1.62 | 1.54 | 1.46 | 1.19 |
3.6.3 When assembling steel couplings and shafts with cylindrical mating surfaces, the interference fit $\Delta D$ shall be determined by the following formula, in m,

$$
\Delta D = 8 \cdot 10^{-3} B \sqrt{19.1 P / (n D_w)} + T^2 / h.
$$

(3.6.3)

Designations are stated in 3.6.2.

3.6.4 For propeller bosses and half-couplings in keyless assemblies with the shafts, the following condition shall be met

$$
A \left[ \frac{C}{D_y} + (\alpha_y - \alpha_w) t_m \right] / B \leq 0.75 R_{eH},
$$

where $A$ — shape factor of the boss:

$$
A = \sqrt{1 + 3 y^4 / (y^2 - 1)}.
$$

The coefficient $A$ can be calculated by the formula $A^4 = 0.5756 - 0.5937 y^2$, which is valid in the range $y = 1.2 - 2.4$;

$C = \Delta h_x z$ — for connections with conical mating surfaces, in m;

$C = \Delta D_e$ — for connections with cylindrical mating surfaces, in m;

$\Delta h_x$ — actual shift when the boss is assembled at a temperature $t_m$, in m $\Delta h_x \geq \Delta h$;

$\Delta D_e$ — actual interference fit of connection with cylindrical mating surfaces, in m $\Delta D_e \geq \Delta D$;

$D_y$ — see 3.6.2;

$R_{eH}$ — yield point of the boss material, in MPa.

Other designations are stated in 3.6.2.

3.7 BRAKING DEVICES

3.7.1 Each shaft line shall comprise appropriate breaking or stopping devices to prevent rotation of shaft in the event of the main engine failure or repair or when towing the ship with non-running main engines.
4 GEARS, DISENGAGING AND ELASTIC COUPLINGS

4.1 GENERAL

4.1.1 The requirements of the present Section apply to reverse reduction gearing with cylindrical gears with external and internal teeth, planetary and bevel gears, disengaging and elastic couplings which are installed in power installation components. The requirements of this section apply to disengaging electromagnetic and hydraulic couplings as far as applicable.

4.2 MATERIALS AND WELDING

4.2.1 Materials intended for manufacture of gearing and coupling parts shall meet the requirements referenced in the right column of Table 4.2.1. Materials of parts specified in points 4, 5 and 6 of Table 4.2.1 may also be selected in accordance with national standards1.

4.2.2 Gearing and coupling shafts shall be made of steel forgings or steel castings. Non-flanged gearing and coupling shafts may be made of round rolled steel.

Separately forged gearwheel shafts and pinion shafts shall be made of steel with tensile strength of not less than 430 MPa. Tensile strength of gearing shafts shall be not less than tensile strength of material of intermediate shafts of the shaft line.

4.2.3 Main gearing pinions shall be made of alloy steel with tensile strength of 620 to 980 MPa.

4.2.4 Gearing and coupling cases are to be made of nodular cast iron or as steel welded structures made of flat steel with sleeves made of forged steel or cast steel. When circumferential velocity of pinions does not exceed 60 m/s and that of the coupling housing — 40 m/s, the gear housings and coupling castings can be made of grey cast iron, nodular cast iron or as steel welded structures made of flat steel with sleeves made of forged steel or cast steel.

4.2.5 Essential parts of couplings intended for transmitting torque to the propeller shall be made of forged steel, cast steel or nodular cast iron having mainly ferrite structure. For medium loaded external parts of couplings aluminium alloys with appropriate mechanical properties may be used. Pinions of hydraulic slip couplings can be made of grey cast iron and the housings — of aluminium alloy if the mechanical properties specified in 2.6, 2.7 and 2.11 Part X of the Rules are provided.

4.2.6 Cases of elastic couplings transmitting torque to the generators shall be made of

---

1 GOST 977, GOST 7505, GOST 8479.
nodular cast iron with ferrite structure, forged steel or cast iron.

4.2.7 It is allowed to use alloy steel or alloy cast iron for gearing and coupling parts if the chemical composition of these alloy materials does not deteriorate their mechanical properties and strength characteristics as compared to the ones specified in 2 Part X of the Rules and in Table 4.2.1. The compliance of the properties and characteristics of the alloy materials with the requirements of the Rules shall be confirmed by the manufacturer’s documents containing data on chemical composition, mechanical properties and strength characteristics of such materials, as well as documents of test laboratories (centres) on checks and tests of these materials for their compliance with the chemical composition, properties and strength characteristics specified by the manufacturer in the technical documentation agreed with the River Register.

4.2.8 Shafts, pinions and gearwheels of main gearings shall undergo non-destructive testing according to the requirements of 2.20 to 2.23 Appendix 10 Part X of the Rules shall be complied with.

4.2.9 Manufacture of gearing and coupling parts with application of welding shall meet the requirements of Part X of the Rules.

4.3 GENERAL REQUIREMENTS

4.3.1 The reverse reduction gears at ahead running in steady mode shall provide not less than 70 per cent of the ahead rated power.

4.3.2 Parts rotating at circumferential speed from 5 to 20 m/s shall be statically balanced, while those rotating at speed over 20 m/s shall be dynamically balanced. The accuracy of dynamic balancing shall be determined by the formula:

$$v \leq (65.786 - 0.139 V) \cdot 10^3 / n,$$

(4.3.2)

where $v$ — distance between the centre of gravity and the geometrical axis of rotation of the part concerned, in mm;

$n$ — rotational speed, in min$^{-1}$;

$V$ — peripheral velocity, in m/s.

The formula (4.3.2) is applicable in the range $V = 20 \div 300$ m/s.

If $V$ is below the stated range, the circumferential velocity shall be taken equal to 20 m/s, above the stated range — 300 m/s.

Rigid elements of the couplings shall be balanced together with the parts they are rigidly adjoined.

4.3.3 The main gearing shall be so designed as to provide access to all bearings.

The gear cases shall have a sufficient number of access manholes with detachable covers.

The manholes shall be so arranged as to allow inspection of the teeth throughout the length and all bearings inside the gearing.

4.3.4 The gear cases shall be provided with venting arrangements.

The vent pipes of gearing cases with volume of 0.5 m$^3$ and above shall be led to the open deck or other places where exhaust ventilation is provided. The ends of the vent pipes shall be fitted with flame arresters and arranged so as to prevent the ingress of water into the gearing.

4.3.5 When the main thrust bearing is housed in the gearing case, the lower part of the case shall be strengthened.

4.3.6 Plain bearings of main gearing shall have devices for measuring axial and radial shaft positions without case disassembling. Each plain bearing and each thrust bearing shall be provided with devices for measuring temperature.

4.3.7 In structures of hovercraft gearing safety devices shall be provided operating when torque reaches values 1.35 times the rated torque.

4.3.8 Planetary gearing shall have equalising devices. The rim of epicyclical wheel with more than three planetary pinions shall be flexible in the radial direction.

4.4 GEARING

4.4.1 While gearwheels manufacture the following shall be checked: pitch and general
Tooth side surface roughness shall not exceed 10 μm before spinning in case of tooth forming by milling or shaping. Roughness shall not exceed 4 μm if the required tooth shape is reached by grinding or lapping. Tooth fillet radius on standard instrument profile shall be not less than 0.25 times the normal pitch.

Tooth side surface roughness shall not exceed 10 μm before spinning in case of tooth forming by milling or shaping. Roughness shall not exceed 4 μm if the required tooth shape is reached by grinding or lapping. Tooth fillet radius on standard instrument profile shall be not less than 0.25 times the normal pitch.

Teeth of pinions and gear wheels with the ratio \( B/d_1 \geq 0.3 \) (Fig. 4.4.3) shall be bevelled on the end faces to an angle of \( 45^\circ \leq \varphi \leq 60^\circ \) to a depth not less than 1.5 of the teeth module, where \( B \) is the gear wheel (pinion) width, \( d_1 \) is the pitch diameter.

**Fig. 4.4.3 Gear wheel section**

**4.4.4** Hardness of the pinion teeth shall be at least 15 per cent greater than that of the wheel teeth. This requirement does not apply to surface hardened gears (carburized, nitrided, face-hardened etc.).

**4.4.5** The strength of teeth and other pinion and wheel elements shall be confirmed by calculations according to 4.4.6. There shall be taken into account additional loads due to torsional vibrations, storm weather, ship manoeuvres, tugging, different loading conditions, relationship between the propeller resistance irregularity and the number of blades.

**4.4.6** The results of strength calculations for the gearings of reduction gears and reverse reduction gears of main engines accomplished according to the Guidelines P.007-2004 "Strength calculations" or according to the method agreed with the River Register shall be submitted for agreement to the River Register together with technical documentation.

**4.4.7** Where oil is fed to tooth gearing and plain bearing under pressure, it shall be possible to filter oil and adjust its pressure adjustment, manometer, thermometer and excessive oil pressure safety device shall be installed.

It shall be possible to control the oil level in the oil bath in case of lubrication by submersion.

**4.4.8** Lubrication of tooth engagements and bearings shall be arranged in such a way as to prevent oil foaming and emulsification.

**4.4.9** Where rolling bearings are used in gears, it is recommended to fit additional thermometer on the oil outlet line from the gear.

**4.5 TOOTH COUPLINGS**

**4.5.1** The spur coupling side surface carrying capacity \( p \) is checked using the following relationship, in MPa:

\[
p \leq p_{zul},
\]

where \( p = 9.9 \times 10^8 \frac{k}{B h d z n} \).  

\[
P = \frac{1}{15} \left( \frac{n^3 d_1^2 M}{M_{zul}} \right) \leq 4.5.
\]

Values are possible if the manufacture accuracy class is less than 6 and residual specific unbalance is less than 100 g mm/kg according to GOST ISO 1940-1.

\[
П = \frac{1}{15} \left( \frac{n^3 d_1^2 M}{M_{zul}} \right) \leq 4.5.
\]

In equations (4.5.1-1) and (4.5.1-2):

\( P \) — power of the drive, in kW;

\( k \) — factor coefficient into account the type of the drive and coupling for engines:

\( \lambda \) turbine, electrical and diesel engines 1.0

with hydraulic coupling or electromagnetic slip coupling between the engine and the gearing;
4.5.2 Teeth of couplings at \( \frac{dn}{2} \leq 6 \times 10^9 \text{ mm/min}^2 \) shall be lubricated by immersion with controlled permanent oil level in the coupling. When \( \frac{dn}{2} > 6 \times 10^9 \text{ mm/min}^2 \), circulation lubricating system shall be provided.

4.5.3 The requirements of 3.5.5 to 3.5.9 shall be taken into account when determining dimensions of sleeves, flanges and bolts of tooth couplings.

### 4.6 ELASTIC COUPLINGS

4.6.1 Dimensions and characteristics of elastic couplings between the main engines and the gearing shall be determined with due regard to the requirement that they shall be capable of withstanding the load due to additional torsional vibration stresses (torques) appearing in the event of failure of any of the cylinders.

4.6.2 Stresses in loaded coupling elements working at shear loads and made of non-strengthened rubber or polyurethane shall not exceed 0.25 to 0.45 MPa depending on rubber quality or design of spring (elastic) elements at average torque of the drive engine. The quality of rubber is considered sufficient if besides the tensile strength, elongation at failure, residual elongation and apparent stresses at preset elongation complying with the appropriate requirements of the coupling manufacturer's design documentation and determined in accordance with GOST 270, elastic-hysteresis characteristics in accordance with GOST 23326, hardness in accordance with GOST 263 and ability to change the form and dimensions under the action of external loads and restore initial configuration when the load is taken off, the elastic compression is within 35 to 65 % and elastic elongation is within 250 to 550 %.

To reduce the negative influence of a nick, the built-in end pieces of couplings made of non-strengthened rubber or organic (organosilicone) material shall be strengthened.

Note. Strengthened rubber is a laminated rubber, the layers of which can be fitted with or separated by cord.

4.6.3 When determining dimensions of cases, flanges and bolts of elastic couplings the requirements of 3.5.5 to 3.5.9 shall be taken into account. 3.5.5 – 3.5.9.

4.6.4 If elastic coupling is so designed that while working under load it produces axial forces on parts of the connected drive engine, measures shall be taken to neutralise these forces.

4.6.5 The elastic couplings of diesel generator sets shall absorb impact loads due to short-circuit. Where no such data is available, the maximum torque shall be at least 4.5 times the nominal torque being taken by the coupling.

### 4.7 DISENGAGING COUPLINGS

4.7.1 Disengaging couplings of main engines shall be fitted with devices to prevent slipping for long (over 10 s) periods of time.

4.7.2 It shall be possible to control disengaging couplings from the station where the
main engines are controlled. Local reserve control arrangements shall be provided directly at the disengaging couplings.

4.7.3 Where two or more engines devoted to a common propeller shaft are driving it through disengaging couplings, their control arrangement shall prevent a simultaneous engagement of the engines when running in opposite directions.

4.7.4 A power-driven turning gear shall be provided with an interlocking to prevent the disengaging coupling from engagement when the turning gear is engaged.
5 PROPELLERS

5.1 GENERAL REQUIREMENTS

5.1.1 The requirements of this section apply to metallic solid and detachable-blade propellers, water-jet and vertical axis propellers and steerable thrusters.

5.1.2 The design and the dimensions of ice-breaker propellers, as well as propulsion units of special design (paddle wheels, hovercraft air propellers, etc.) shall comply with the requirements of national standards.

5.2 MATERIALS, TESTING AND WELDING

5.2.1 Materials intended for manufacture of propellers shall meet the requirements referenced in the right column of Table 5.2.1.

5.2.2 For the parts specified in 1, 2.1, 2.2, 3, 4.1 and 5.2 of Table 5.2.1, it is allowed to use plastic and other nonmetallic materials the requirements to which are outlined in 6 Part X of the Rules shall be complied with.

5.2.3 Propellers for ships without ice strengthening may be made of cast iron with lamellar graphite corresponding with the requirements of 2.12 Part X of the Rules.

5.2.4 Blades of propellers and vertical axis propellers and pumps impellers of water-jet propeller shall undergo non-destructive testing during manufacture. The methods, scope and standards of non-destructive testing are specified in 8 and in 2.20 to 2.23 Appendix 10 Part X of the Rules shall be complied with.

5.2.5 Welding and testing of welded joints shall be carried out according to the requirements of 7 and 8 Part X of the Rules shall be complied with.
5.3 PROPELLER DESIGNING

5.3.1 In solid propellers and detachable-blade propellers the maximum thickness $S$, in mm, of expanded cylindrical section (Fig. 5.3.1-1) shall be not less than:

$$S = A \left[ 13.2 k P \left( \frac{z_b b \sigma_m n}{60} \right) + 9.81 cm \left( \frac{D n}{300} \right)^2 \right] / \sigma_m ,$$

(5.3.1-1)

where $A$ — coefficient determined by the formula

$$A = k_1 + k_2 \cdot \exp \left( - \frac{H}{D} / k_3 \right)$$

(5.3.1-2)

$k_1$, $k_2$, $k_3$ — coefficients adopted from Table 5.3.1-1 depending on the radius $r$ of design cross-section arrangement;

$H/D$ — pitch ratio on radius $r$;

$$m$$

$m$ — blade rake, in mm;

$D$, $R$ — propeller diameter and radius, respectively, in m;

$n$ — propeller rotational frequency, in min$^{-1}$;

$z_b$ — number of blades;

$b$ — width of the expanded cylindrical section of the blade, in m;

$\sigma$ — maximum permissible stress taken equal to $\sigma_m = 0.6 R_m + 155 \text{ MPa}$, in MPa:

- for steels $550$
- for non-ferrous alloys $610$
- for cast iron $290$

$R_m$ — tensile strength of blade material in tension, in MPa;

$H$ — propeller pitch, in m.

Propeller blade thickness is checked in two cross-sections: the design root section and the blade section at the radius (see Figure 5.3.1). $r = 0.6 R$

The location of the design root section is adopted as follows:

- for solid propellers — at the radius of $0.2 R$, if the propeller boss radius is less than $0.2 R$, and at the radius of $0.25 R$, if the propeller boss radius is greater or equal to $0.2 R$;

$k$ — coefficient adopted from Table 5.3.1-2 considering the following:

- if a ship is equipped with the engines having less than 4 cylinders, the coefficient $k$ shall be increased by 5 %;

- for shaft lines fitted with hydraulic or electromagnetic clutches $k$ values may be reduced by 5 %.

For double-propeller ships without ice strengthening $k$ values may be reduced by 5 %.

Fig. 5.3.1 Expanded cylindrical section
for detachable-blade propellers — at the radius of $0.3R$ with coefficients $A$ and $c$ taken for $r = 0.25R$.

Note: In the design section, the blade thickness is determined regardless of the blade-boss fillet. The holes of the fastening elements of the blades of detachable-blade propellers shall not bring to reduction of the design root section.

5.3.2 Minimum thicknesses $S_k$ of the blade end edges for ships:

- without ice strengthening 0.0035$D$
- with ice strengthening 0.0050$D$

5.3.3 If the propeller blades of special shape are used, the thicknesses of blades shall be selected by results of detailed strength calculations fulfilled according to the requirements of this Part of the Rules.

5.3.4 Fillet radii of the transition from the blade root to the boss shall be:

- suction side 0.04$D$
- pressure side 0.03$D$
- both sides if the blade has no slope 0.03$D$

5.3.5 The propeller boss shall be provided with holes through which the empty spaces between the boss and the shaft cone and the hollow inside the propeller cap are filled with grease.

5.3.6 Internal diameter of the thread of studs $d_k$ securing detachable blades to the boss shall be not less than that determined by the following formula, in mm:

$$d_k \geq 1.78\sqrt{\frac{\alpha A F_m}{R_{ch}}}, \quad (5.3.6-1)$$

where $F_m$ — force acting on a stud, in N:

$$F_m = 280 \times 10^6 R_{p0.2} P C^2 R_{m} C_G \left(\frac{1}{n z_b Z C_m d_e}\right); \quad (5.3.8-2)$$

$\alpha_A$ — tightening factor for fastening bolts: $\alpha_A = 1.2 \div 1.6$;

$R_{sh}$ — yield point of material, in MPa;

$R_{p0.2}$ — yield point when plastic deformation reaches 0.2 per cent of the initial design length, in MPa

$P$ — see 5.3.1;

$n$ — propeller rotational frequency, in min$^{-1}$;

$C_m$ — strengthening coefficient equal to:

- for ships without strengthening 1.0
- for ships designed for navigation in broken ice 1.05
- for icebreakers and icebreaker-type ships 1.07

$C_G$ — coefficient taking into account the propeller dimension ($C_G = 0.85 \div 1.1$):

$$C_G = \sqrt{C_F G + D}/12.2, \quad (5.3.8-3)$$

$C_F G$ — coefficient equal to:

- for fixed-pitch propellers 5.2
- for detachable-blade propellers 6.2

If $C_G$ is beyond the range of 0.85 to 1.1, this coefficient is taken equal to the corresponding limit value;

$D$ — propeller diameter, in m;

$z_b$ — number of blades;

$Z$ — number of fastening bolts of blades;

$R_m$ — tensile strength of blade material in tension, in MPa;

$d_c$ — bolt pitch circle diameter, in mm.
5.3.9 Blade fastening bolts shall be screwed using drawing-up controlling device so that preliminary tightening of bolts is 60 to 70 per cent of the yield point.

Measures shall be taken to prevent spontaneous untwisting.

5.4 PROPELLER BALANCING

5.4.1 The completely finished propellers shall be statically balanced. The extent of balancing shall be checked by a test load, which being suspended from the tip of every blade in horizontal position, shall cause the propeller to rotate.

The weight \( m \) of the test load shall be determined by the formula, in kg:

\[
m \leq k \frac{m_p}{R},
\]

where \( k \) — coefficient adopted from Table 5.4.1 depending on the rated rotational speed of the propeller \( n \);

<table>

</tbody>
</table>

\( m_p \) — propeller weight, in t;

\( R \) — radius of the propeller, in m.

5.5 HYDRAULIC DRIVE OF VERTICAL AXIS PROPELLER PITCH CHANGING MECHANISM

5.5.1 In the hydraulic drive system of vertical axis propeller pitch changing mechanism at least two pumps of equal capacity (main and standby) shall be provided. One of these pumps can be driven by the main engine. Each pump shall ensure moving of blades in all operation modes of propellers.

If more than two pumps are installed, their capacity is selected in a way that in case of failure of any of these pumps the total capacity of the remaining operating pumps shall be sufficient to move the blades within a time period specified in 5.6.7.

Ships with two vertical axis propellers shall be fitted with independent standby pump for both propellers.

In ships with main engines of total power of less than 220 kW it is allowed to use a hand pump as a standby pump. The capacity of this hand pump shall be sufficient to move the blades within a time period specified in 5.6.7. Instead of this pump it is also possible to use a hand drive to turn the propellers blades. When served by one person the force on the handle of this drive shall not exceed 160 N.

5.5.2 Pitch changing mechanism shall enable setting of blades to the ahead running position in case of failure of pitch changing mechanism hydraulic drive system.

5.6 REQUIREMENTS TO WATER-JET PROPELLERS, VERTICAL AXIS PROPELLERS AND STEerable THRUSTERS

5.6.1 Pumps of water-jet propellers shall comply with the applicable requirements of 7.7.

5.6.2 Parts of vertical axis propellers, steerable thrusters, water intake and nozzle of water-jet propellers, including their welded joints, shall be tested for absence of surface and hidden effects, including by means of non-destructive testing, the methods, scope and standards of which are specified in 8 and in 2.20 to 2.23 Appendix 10 Part X of the Rules shall be complied with.

5.6.3 Shafts and impellers of water-jet propeller pumps and parts of vertical axis propeller rotors during manufacture shall undergo ultrasonic inspection according to 2.21 Appendix 10 Part X of the Rules shall be complied with.

5.6.4 Strength calculations of vertical axis propeller blades shall be carried out and shall comply with the requirements to propellers described in 5.3.2 and 5.3.3.

5.6.5 Hydraulic control system for moving control centre and blades of vertical axis pro-
peller shall comply with the requirements of 5.5.

5.6.6 In ships with vertical axis propellers, where the overload of main engines under operating conditions is possible, the devices automatically protecting the main engines from overload shall be used.

5.6.7 The travelling time of control centre and blades of vertical axis propeller from full ahead position to full astern position with disabled main engines shall not exceed 20 s.

5.6.8 If propulsion plants with steerable thrusters are used, at least two steerable thrusters shall be installed on the ship.

The control stations equipped with necessary devices and communication facilities according to requirements of 1.5 and 1.6 shall be provided.

5.6.9 Propeller shafts of steerable thrusters shall comply with the applicable requirements of 3 of this Part and their vertical shafts shall comply with the applicable requirements of 2.3 Part V of the Rules.

5.6.10 Steerable thrusters shall be equipped with devices securing their position when the thruster is turned to any permissible angle.

5.6.11 If the ship’s course is changed by turning the steerable thrusters, the time of turning of each thruster by 180° shall not exceed the following values (s) for installations with propeller diameter:

<table>
<thead>
<tr>
<th>Propeller Diameter</th>
<th>Time (s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>up to two (m)</td>
<td>20</td>
</tr>
<tr>
<td>over two (m)</td>
<td>30</td>
</tr>
</tbody>
</table>

5.6.12 The design of steerable thruster shall exclude ingress of overboard water in its internal spaces. When installed the sealings used for this purpose shall be leak tested by pressure corresponding to the maximum height of liquid column in the pressure tanks.

5.6.13 After assembly the inner part of steerable thruster shall be tested by test hydraulic pressure corresponding to the maximum operating immersion depth considering the pressure head of sealing arrangements.
6 TORSIONAL VIBRATION

6.1 GENERAL REQUIREMENTS

6.1.1 Torsional vibration calculations (performed by organization certified by the River Register on computer application for torsional vibration calculations) for onboard propulsion plants, diesel engines tested on the manufacturer’s benches, diesel-generator units, geared diesel units, air-injection units and dieselpump units (hereinafter referred to as the units) with engine output of 110 kW and more shall be submitted to the River Register in the course of approval of:

.1 of engineering design of a new ship;
.2 engineering design of a new engine or unit;
.3 technical documentation modernized, re-equipped or re-classed ship.

6.1.2 In the process of technical documentation development the vibration oscillation calculations are made in the following cases:

.1 when installing a main engine, the model and the parameters of which differ from that of the specification for the ship engine;
.2 when installing onboard an engine of the same model but with increased supercharging or of modified design, or with crankshaft or pistons made of material other than stated in the specification;
.3 when a new flywheel is installed or the existing one is grooved and the moment of inertia of the new flywheel differs from the former one by 10 % and over;
.4 when an additional flywheel is installed;
.5 when a torsional oscillation damper (dynamic vibration absorber) is installed, withdrawn or replaced with a damper (vibration absorber) with other technical parameters; the damper (vibration absorber) has been repaired with changing the damping or elastic characteristics (changing the grade of silicone fluid, clearances in the silicone damper, material or dimensions of the flywheel, spring packs, diameter of the damper pins etc.);
.6 when elastic coupling is installed, withdrawn or replaced by a coupling with different technical parameters;
.7 when a new propeller (propulsion device) is installed which dimensions or material differ from those stated in the specification, or the blades’ edges of the existing propeller were cut off, and the moment of inertia of the new propeller (propulsion device) or propeller (vertical axis propeller) with cut-off blades together with entrained water differs from the former one by 10 % and over;
.8 when additional power consumer (shaft generator, pump etc.) is installed, withdrawn or replaced by a power consumer of other type and the moment of inertia of the receiver is commensurable with the moment of inertia of the crank gear of the working cylinder;
.9 if the shafts’ diameters are changed by 2 % and over or their compliance is changed by more than 5 %. Torsional vibration calculation may not be submitted if the change of dimensions of separate shaft sections does cause the change of shaft flexibility by more than 5 % or, if the shaft flexibility is changed, to dangerous torsional vibrations;
.10 when the unit is modernized with replacement of the engine (generator, reduction gear, compressor, pump) with an engine (generator, reduction gear, compressor, pump) differing from the earlier installed one.

Note. Torsional vibration calculations need not to be submitted if it is proved by the documents that the torsional diagram of torsional vibrating system is fully analogous (by appearance and parameters of torsional diagram links) to the torsional diagram used for the torsional vibration calculations of the propulsion plant of the studied ship or unit and considered by the River Register.
earlier or the differences of mass moment of inertia or flexibility of connections do not exceed 10% and 5%, respectively.

6.1.3 Torsional vibration calculations shall be submitted (see 6.1.1) for the basic variant and other variants of operation of onboard propulsion plants, engines bench tested by the manufacturer and units:

1. maximum power take-off and idling speed (with the propeller blades at zero position) for installations comprising vertical axis propellers;
2. connection of additional power consumers if their moments of inertia are commensurable with the inertia moments of the crank gear of the working cylinder;
3. reverse mode in installations with reverse reduction gear and different reduction at ahead and astern speed;
4. with spare (changeable) propeller if it differs from the primary one;
5. with one disabled cylinder for installations with elastic couplings and reduction gears. A disabled cylinder is the cylinder the non-operation of which has maximum effect on increase of stresses and variable torques.

6.1.4 Torsional vibration calculations shall include:

1. reduced torsional diagram of the system and summary table of data characterising this diagram including rated power, rated and nominal engine crankshaft rotation speed, its cylinder arrangement (in-line, V-type), the number and working order of the cylinders, the cylinder bore, the piston stroke, names of weights and joints, diameters, length of all shafts of the system, compliance of the joints, weight inertia moments, as well as data on the gear-box, couplings, damper (vibration absorber), propeller or power consumer used in calculations;
2. tables of calculations of free vibration frequency of any form having essential resonances in the range from 0.2 to 1.2 times the nominal speed;
3. tables of calculations of disturbing moment values in relation to the shaft rotation frequency and disturbing moment harmonic orders;
4. values of vector sums of vector diagrams for all disturbing moment harmonic orders being under consideration;
5. calculation results of resonance torsional vibration parameters including data on design stresses in the weakest sections appearing due to all essential resonances. If principal order resonance is located near the range of 0.85 to 1.05 of nominal rotation speed, stresses appearing due to non-resonance forced vibrations due to the principal order shall be calculated for this range. When elastic coupling is provided, amplitudes of elastic moments or stresses in its elements shall be determined and compared with the permissible values; if reduction gear is provided, amplitudes of elastic moments shall be determined and compared with mean torque;
6. conclusions based on the calculation results.

For other requirements to the scope and presentation of torsional vibration calculations, see 2 of the Guidelines Ð.009-2004 “Torsional vibration calculations and measurements for shaftings and units”.

6.2 PERMISSIBLE STRESSES AND MOMENTS

6.2.1 Permissible stresses due to resonance, by-resonance and non-resonance forced vibrations in the course of continuous operation (engine operation in a mode with crankshaft constant rotation speed for over 30 min) shall not exceed the values determined by the formulas:

for main engine crankshafts and propeller shafts
\[ \tau_{\text{perm}} = \pm (45 - 0.4\sqrt{d} - 13n/n_{\text{rated}}); \quad (6.2.1-1) \]
for intermediate and thrust shafts
\[ \tau_{\text{perm}} = \pm (69 - 0.6\sqrt{d} - 20n/n_{\text{rated}}); \quad (6.2.1-2) \]
for crankshafts of engines driving generators and other onboard machinery of essential purpose, as well as for generator shafts in rotation speed range of (0.85–1.05)n_{\text{rated}}
\[ \tau_{\text{perm}} = \pm (22.5 - 0.2\sqrt{d}); \quad (6.2.1-3) \]
where \( \tau_{\text{perm}} \) — permissible stresses, in MPa;
— shaft diameter in the weakest section, in mm;

— rotational speed under consideration, in min\(^{-1}\);

— rated rotational speed, in min\(^{-1}\).

For ships, the main engines of which operate in the conditions with crankshaft rotation speed below the rated value for more than 5 h (for example, tugs, trawlers, etc.), in all cases \( n = n_{\text{rated}} \).

It is necessary to avoid resonance in the rotation speed ranges where main engines operate for more than 1 h.

In case when resonances occur in the rotation speed range \((0.85 \div 1.05)n_{\text{nom}}\), stresses due to them shall not exceed 70 % of permissible stresses being determined by the formulae (6.2.1-1) and (6.2.1-2).

### 6.2.2 Permissible stresses due to torsional vibration (see 6.2.1) are given relating to shafts made of steel with tensile strength from 430 to 510 MPa.

For shafts made of steel with tensile strength above 510 MPa, permissible stresses may be determined by the formula

\[
\tau = \tau_{\text{perm}} \left(2R_m - 510\right)/R_m,
\]

where \( \tau_{\text{perm}} \) — permissible stresses, in MPa, determined by the formulae (6.2.1-1), (6.2.1-2) or (6.2.1-3);

\( R_m \) — tensile strength of the shaft material in tension, in MPa.

When using materials with tensile strength above 780 MPa, \( R_m = 780 \) MPa shall be adopted for calculation purpose.

### 6.2.3 To prevent damage of engine crankshaft or propeller shaft caused by impermissible stresses due to torsional vibrations appearing in the rotation speed zones conditionally called prohibited for long-term operation, the stresses from torsional vibrations in these zones free for fast (max. 1 min) passing (see 6.3) shall not exceed the values determined by the formulae:

for intermediate shafts and thrust shafts

\[
\tau'_{\text{perm}} = 1.7\tau_{\text{perm}};
\]

for crankshafts of engines driving auxiliary engines and generator shafts

\[
\tau'_{\text{perm}} = 5\tau_{\text{perm}};
\]

where \( \tau'_{\text{perm}} \) — permissible stresses for rotational speed ranges prohibited for continuous running, in MPa;

\( \tau_{\text{perm}} \) — permissible stresses, in MPa, determined by the formulae (6.2.1-1) to (6.2.1-3) accordingly. Formulae (6.2.3-1) to (6.2.3-3) are not applied in the ranges of \( 0.3 \div 0.4 \) and \( 0.85 \div 1.05 \) of the nominal rotation speed in which forbidden zones are not allowed.

### 6.2.4 Variable torques in shafting in the rotation speed range of 0.85 to 1.05 of rated one shall not exceed 80 % of maximum mid-range torque transferred by shafting.

### 6.2.5 Variable elastic torque in any stage of the reduction gear in the course of long-term operation (see 6.2.1) and fast passing (see 6.2.3) through the resonance shall not exceed the permissible values determined by the manufacturer for these conditions. If there are no such permissible values, the elastic torque shall not exceed 30 % of maximum mid-range torque of the given stage. Alternatively the limit value of elastic torque of gear stage is set to ensure reliable teeth behaviour in bending. In this case the corresponding calculation shall be submitted.

Displacement of clearances in engagement when the direction of rotation is changed shall be considered possible only for short-term transient conditions (max. 5 min) at rotation speed of 0.35 of rated one and lower.

### 6.2.6 Variable torque in coupling with elastic (rubber) components, stresses corresponding to it or temperature in material of elastic component caused by torsional vibrations in the course of long-term operation (see 6.2.1) and fast passing (see 6.2.3) shall not exceed the permissible values determined by the manufacturer for these conditions.
Permissible compression stresses $\sigma_{perm}$ and shear stress permissible in elastic couplings with rubber components shall be determined with the help of the following formulas.

In case of static load — transfer of constant torques at minor dynamic loads due to misalignment, weak torsional vibrations, etc., in MPa:

$$\sigma_{perm} = (70 + 0.5H^2) \cdot (10\beta + H/10.5);$$  \hspace{1cm} (6.2.6-1)

$$\tau_{perm} = H - 20,$$  \hspace{1cm} (6.2.6-2)

where $H$ — Shore hardness of rubber ($H = 30 \div 75$);

$\beta$ — shape variation coefficient at compression equal to the ratio of the loaded surface area of the rubber component to its free surface area.

In case of static load with occasional short-term (max. 5 min) dynamic loads — transient conditions, engine starts and stops, passing through torsional vibration resonances, in MPa:

$$\sigma_{perm} = (50 + H^2/80) \cdot (10\beta + H/10.5);$$  \hspace{1cm} (6.2.6-3)

$$\tau_{perm} = 0.5H - 5.$$  \hspace{1cm} (6.2.6-4)

In case of dynamic load — transfer of considerable variable torque due to torsional vibrations (over 75% of mid-range torque of engine), operation under conditions of increased misalignment, etc., in MPa:

$$\sigma_{perm} = (47 + H^2/130) \cdot (10\beta + H/10.5);$$  \hspace{1cm} (6.2.6-5)

$$\tau_{perm} = 0.4H - 6.$$  \hspace{1cm} (6.2.6-6)

6.2.7 If the prime movers are rigidly connected with generator units with no permissible values determined by the manufacturer, the variable torque in the course of long-term operation (see 6.2.1) shall not exceed the nominal torque of generator over 2.5 times, in case of fast passing through the resonance over six times.

6.2.8 Fitness of dampers for torsional vibration reduction shall be estimated according to the manufacturer’s recommendations, for example, by permissible elastic torque or permissible heat density. The due dates of maintenance of torsional vibration dampers specified by the manufacturer shall be observed.

6.3 MEASUREMENT OF TORSIONAL VIBRATION PARAMETERS

6.3.1 Data obtained from torsional vibration calculations for onboard propulsion plants, engines bench tested at the manufacturer and units shall be confirmed by the results of measurements of torsional vibration amplitudes and/or stresses in torsional vibrating system elements and elastic couplings thermometry carried out by organization certified by the River Register to conduct this type of activity.

Measurement of torsional vibration parameters is made:

1. on propulsion plant of the first ship in a series, prototype engine of a series bench tested at the manufacturer and prototype unit of a series;

2. on series-built propulsion plants, engines, units or propulsion plants, engines, units being repaired, if the modernization or repair has brought to changes in torsional vibrating system in cases specified in 6.1.2.

If after introducing changes to the design or technical parameters of separate components of torsional vibrating system (engine, couplings, gearings, shafts, propeller) the torsional vibration calculations reveal no essential deviations of stress caused by torsional vibration to the dangerous side as compared to the measurements and calculations made prior to introducing such changes, it is allowed not to measure torsional vibration parameters;

3. on propulsion plants, engines and units in service in the course of periodical control tests envisaged by the technical documentation or the manufacturer’s recommendations and conducted by the ship owner to check the operational efficiency of torsional vibration.

---

1 Deviations at which the stress due to torsional vibrations reaches 80% of the values specified in installed 6.2.1.
dampers or special devices to reduce torsional vibration amplitudes after a specific operation period;

4. At control tests after repair of torsional vibration dampers or special arrangements for damping torsional vibration amplitudes, if changes have been introduced in the course of repair which brought to changing their damping or elastic characteristics.

Tests for measuring torsional vibration parameters shall be performed in operation modes of the installation, for which the calculations are made according to 6.1.1 to 6.1.3.

6.3.2 Measured natural vibration frequency shall not differ from the design one by more than 5%. Otherwise, the torsional diagram and (or) the parameters of its members shall be corrected and free vibration parameters shall be recalculated.

6.3.3 The stresses shall be determined on the basis of torsiography (measuring of vibration amplitudes) for maximal vibration amplitudes of the respective section of the torsiogram; when assessing non-resonance forced vibrations harmonic analysis of the torsiogram shall be made.

6.3.4 Torsional vibration parameters shall be measured as per the program developed by the organization conducting the tests according to the requirements of this Section and agreed with the River Register while the ship follows a direct course in the water areas, the depth of which is at least four times the ship draught, with the wind force up to three.

6.3.5 Tests shall include measurement of torsional vibration parameters in operation modes for which the calculations according to 6.1.2 and 6.1.3 shall be made:

1. in the entire rotation speed range from minimum steady to maximum one and in the maximum output mode with different variants of start of engines and power consumers. Special attention shall be given to measurement of parameters at the rotation speeds corresponding to full, moderate and low speed of the ship and to check of resonance and by-resonance stresses detected by calculations and expected by results of rotation speed prohibited zone calculations;

2. for the modes listed in 6.3.5.1 while the engine operates with one disabled cylinder.

Tests shall be carried out with the engine control by means of remote automated control system and manual control.

6.3.6 If the stress measurement (strain measurement) is not carried out during the tests, the calculations by results of torsional vibration amplitude measurement (torsiogram) shall be made. In this case when processing the test results by maximum vibration amplitudes within a cycle the graphs of vibration amplitude progress in the place of their measurement are plotted. Besides the aforementioned graphs the test report shall contain the progress graphs of harmonic component amplitudes obtained by Fourier analysis of the processed test results and the stress scales for various shafting sections determined when calculating free vibration parameters of the shaft system under examination.

Effective stresses on the shafting sections under examination shall be determined by summing the stresses calculated by amplitudes of basic harmonic components and the corresponding stress scales.

If the tests reveal development of forced non-resonance vibrations, the organization performing the tests shall make the Fourier analysis of the torsiogram and determine the stresses in dangerous cross-sections of shafting caused by these vibrations.

6.3.7 In diesel plants with reduction gears and reverse reduction gears the torsional vibration amplitude shall be measured on the crankshaft fore end. If it is impossible to measure torsional vibration amplitude on the crankshaft fore end, the amplitude shall be measured on the shafting after the engine.

Measurements on shafting are also taken in the following cases:

1. when design stresses in any section of shaft system are equal or exceed 80% of the value $\tau_{perm}$ determined by the formulae (6.2.1-1) and (6.2.1-2);
.2 if the torsional vibrating system has elastic coupling;
.3 if dangerous vibration shapes according to results of calculation are predicted which cannot be exactly detected by the torsiographic method on the bow end of the engine crankshaft.

6.3.8 For other requirements to measurement of torsional vibration parameters and processing their results, see Section 3 Guidelines P.009-2004.

6.4 RESTRICTED ROTATION SPEED RANGES

6.4.1 When the effective stresses and temperatures exceed the values permitted for long-term operation (see 6.2.1), the organization conducting the tests shall set prohibited rotation speed zones (see 6.2.3). Forbidden rotation speed zone covers the range between the rotation speed being characterised by the equality of acting and permissible stresses with extension to either side by value of 0.03 of the nominal rotation speed.

6.4.2 Accuracy of tachometer measurement shall be within ±2.5 %, if there are forbidden rotation speed ranges.

6.4.3 Prohibited rotation speed zone shall be clearly marked on the tachometers by well-visible preferably red paint or designated by other method at all control stations of the power installation.

6.4.4 Limit values within the prohibited rotation speed zones:
.1 for direct drives — permissible stresses (see 6.2.1 to 6.2.3) more than 2.5 times;
.2 for reverse reduction gears — nominal torques more than 2 times;
.3 for systems with elastic couplings — maximum pulse torque specified in the technical documentation of the coupling manufacturer.

6.4.5 In the rotation speed zone of \((0.85\div1.05)n_{\text{rated}}\) the prohibited zones are not allowed.

Prohibited rotation speed zone shall be passed at a maximum possible speed determined based on the conditions with no engine overload.
7 COMPRESSIONS, PUMPS, FANS AND SEPARATORS

7.1 SCOPE OF APPLICATION

7.1.1 The requirements of this Section of the Rules apply to:

.1 power-driven air compressors;
.2 pumps being a part of systems regulated by 10 of this Part and 3 of Part III of the Rules, except for hand-driven pumps;
.3 fans being a part of systems regulated by 10 of this Part;
.4 centrifugal separators making part of fuel and oil systems.

7.2 EXAMINATIONS AND TESTS OF PARTS

7.2.1 Shafts and impellers (rims) of compressors, pumps, fans and separators during manufacture are subject to ultrasonic control according to the requirements of 2.21 Appendix 10 Part X of the Rules shall be complied with.

7.2.2 Forged and cast steel parts including their welded joints during the manufacture shall undergo surface soundness control according to 6.1.5 of RTSC. Non-destructive control of parts and their welded joints shall be carried out in case of any doubts about the presence of defects.

7.2.3 Parts of compressors, pumps and fans operating under excessive pressure shall undergo hydraulic test according to 6.2.29 of RTSC.

7.3 MATERIALS AND WELDING

7.3.1 Materials intended for manufacture of compressor, pump, fan and separator parts shall meet the requirements referenced in the right column of Table 7.3.1.

7.3.2 The requirements of 2.1.4 to 2.1.6 shall be taken into account when using alloy steels and cast iron, nodular and lamellar graphite cast iron as well as application of welding.

7.4 GENERAL REQUIREMENTS

7.4.1 Construction and design of compressors, pumps, fans and separators shall meet the requirements of 1.3 and 1.5.

7.4.2 Fasteners of compressors, pumps, fans and separators as well as fasteners located in hardly accessible places shall have fittings or be of such design as to prevent spontaneous slackening and unscrewing.

Drive moving parts shall be covered by protective housings.

7.4.3 Devices for units and parts lubrication shall be easily accessible and safe for serving personnel during the operation of the units.

7.4.4 Safety and protection devices shall be so designed and installed as to avoid the fire risk and danger for servicing personnel due to its operation.

7.4.5 Parts contacting with the environment causing corrosion shall be manufactured of anti-corrosion material or have corrosion-resistant coatings.

Units and parts of mechanisms which are made of materials with different electric potentials and which may contact with aggressive media, shall be protected against electrolytic corrosion.

7.4.6 Heating surfaces of compressors, pumps, fans and separators presenting fire hazard shall have heat- and fire-resistant insulation, or design measures shall be taken to prevent the ingress of fuel and oil to the indicated surfaces of the aforementioned equipment.

Heat insulation shall be covered by metallic housing or fuel- and oil-proof composition.

7.4.7 Systems and pipelines of compressors, pumps, fans and separators shall comply with the requirements of 10 of this Part.

7.5 POWER-DRIVEN AIR COMPRESSORS.

7.5.1 Compressors and their drives shall be so designed as to provide continuous operation (more than 1 h) at full load.

7.5.2 Inlet branch pipes of compressors shall be fitted with meshes.

7.5.3 Air purification and cooling shall be provided according to the requirements of 10.16.15, 10.16.16.

7.5.4 Compressor cooling chambers shall be fitted with discharge devices.

7.5.5 A safety valve shall be installed on each compressor stage or directly after it to prevent the pressure rise in the stage above 1.1 of the rated one at closed valve on the pressure piping.

7.5.6 A fuse or alarm device shall be fitted on the pressure branch pipe directly after the compressor which is actuated when air temperature reaches 125 °C.

7.5.7 Air cooler cases shall be fitted with safety devices ensuring free air discharge in case of piping breakage.

7.5.8 A manometer shall be fitted after each compressor stage.

7.5.9 It shall be possible to measure air temperature on the pressure branch pipe directly after the compressor.

7.5.10 Built-on compressors shall be equipped with instrumentation permitting to estimate the operating parameters of these compressors.

7.5.11 Compressors shall be installed in the places where sucked air has minimum pollution with combustible liquid vapours.

7.6 CRANKSHAFTS OF POWER-DRIVEN AIR COMPRESSORS

7.6.1 Checking calculation method mentioned in 7.6.3 and 7.6.4 is applicable to steel and cast iron crankshafts of onboard compressors with in-line, V-shaped and W-shaped cylinder arrangement, with one- and multi-stage compression.

7.6.2 Crankshafts shall be made of steel with tensile strength from 410 to 780 MPa.

Cast iron crankshafts shall be made of nodular cast iron according to 2.11 Part X of the Rules.
7.6.3 The diameter \( d_k \) of compressor crankshaft journals shall be not less than the one determined by the formula, in mm:

\[
d_k = 0.25k \sqrt{D_p^2 p_k \sqrt{0.3L_p^2 f + (s \varphi_1)^2}} ,
\]

(7.6.3)

where \( k \), \( f \), \( \varphi_1 \) — coefficients adopted from Tables 7.6.3-1, 7.6.3-2 and 7.6.3-3;

\( D_p \) — design diameter of the cylinder, in mm, at compression:
- single-stage \( D_p = D_c \)
- two- and multi-stage in separate cylinders \( D_p = D_h \)
- two-stage in one step piston \( D_p = 1.4D_h \)
- two-stage in one differential piston \( D_p = \sqrt{D_l^2 + D_h^2} \)

\( D_c \) — cylinder diameter, in mm;
\( D_h \) — high pressure cylinder diameter, in mm;
\( D_l \) — low pressure cylinder diameter, in mm;
\( p_h \) — high-pressure cylinder pumping pressure;

\( L_p \) — design distance between main bearings, in mm:
- \( L_p = L' \) if there are two displaced crankthrows between two main bearings;
- \( L' \) — actual distance between main bearing centres, in mm;
- \( s \) — piston stroke, in mm.

7.6.4 Thickness of crank web \( h_k \) (Fig. 7.6.4) shall be not less than that determined by the formula, in mm:

\[
h_k = 0.105k_1 D_p \sqrt{\psi_1 \psi_2 + 0.4} p_c \varphi_1 \varphi_2 / b ,
\]

(7.6.4-1)

where \( k_1 \) — coefficient:

\[
k_1 = a \sqrt{R_m/(2R_m - 430)},
\]

(7.6.4-2)

Fig. 7.6.4. Shaft web thickness.

\( r \) — fillet radius

\( \varepsilon \) — absolute value of the shaft journal overlap, in mm

\( a \) — coefficient for shafts equal to:
- with entire surface nitrided or strengthened 0.9
- forged in dies or in the direction of fibers 0.95
- not exposed to strengthening 1

\( R_m \) — tensile strength of the material at tension, in MPa; if the material with tensile strength over 780 MPa is used, \( R_m = 780 \) MPa shall be taken for calculations;

\( D_d \) — design diameter of the cylinder (see 7.6.3), in mm;

\( \psi_1, \psi_2 \) — coefficients adopted from Tables 7.6.4-1, 7.6.4-2; for determination of
coefficient \( \psi_2 \), minimum fillet radius shall be taken;

45^\circ & 1.7 & 90^\circ & 1.1 \\
\hline
\end{array}
\]

\textbf{Table 7.6.4-3}

\textbf{7.7.3} Pumps shall be so designed as to provide control of their parameters, draining of inner spaces and connection of pressure gauge and for self-priming pumps — vacuum pressure gauge.

\textbf{7.7.4} If the pump design allows the pressure rise above the rated value, there shall be provided a safety valve on the pump case or on the pipeline before the first shut-off valve.

\textbf{7.7.5} In pumps intended for inflammable liquid pumping liquid cross-over from safety valves shall be directed into the suction chamber of the pump.

\textbf{7.7.6} Measures shall be taken to avoid water hammers; application of relief valves for these purposes is not recommended.

\textbf{7.7.7} Strength of the pump parts shall be checked by the manufacturer for loads corresponding to the design parameters of the pump. Stresses in the parts shall not exceed 40 per cent of tensile strength of the part material.

\textbf{7.7.8} Critical rotation speed of the pump rotor shall be not less than 1.3 times the design rotation speed.

\textbf{7.7.9} Pumps equipped with self-sucking devices shall provide operation in conditions of “dry suction”\(^1\) and shall have devices (strainer, fine filter) to prevent the operation of the self-sucking device with contaminated water.

\textbf{7.7.10} Shaft sealings of pumps for inflammable liquids shall be such that the possible leakages do not cause formation of inflammable mixture of liquid and air vapours.

\textbf{7.7.11} Glands of rotating parts of pumps for inflammable liquid pumping shall be so designed as to prevent their heating above 50 °C.

\textbf{7.7.12} When using material with low electric conductivity (plastic, rubber etc.) in conditions of

\(^1\) Pump operation mode in which the suction pipeline and the wet end of pump are not filled with pumped liquid.
structure of pumps for inflammable liquids measures shall be taken for removal of electrical charges from them by means of additions to its composition or using discharging and earthing devices.

7.7.13 Cases of cargo pumps (except for submersible pumps) shall be fitted with temperature sensors.

7.8 FANS

7.8.1 Fans intended for the systems indicated in 10 of this Part shall comply with the following requirements:

.1 fan and air blower rotors shall be dynamically balanced jointly with connecting couplings according to 4.3.2;

.2 inlet branch pipes of fans and air blowers shall be fitted with safety screens to prevent foreign objects from getting inside.

7.8.2 Impeller shall be so designed that equivalent stresses in any section shall not exceed 0.65 of the yield stress of the impeller material at rotation speed equal to 1.3 times the rated value.

7.8.3 The impeller shall undergo strength test at the manufacturer on acceleration unit at a rotation speed equal to 1.3 of the rated value for 5 min. Strength shall be considered sufficient if no signs of deformation are revealed after the test.

7.9 REQUIREMENTS TO FANS OF CARGO PUMP SPACES ONBOARD OIL TANKERS

7.9.1 Air clearance between the impeller and the body of a fan shall be not less than 0.1 of the diameter of the impeller shaft journal in the bearing area, but not less than 2 mm in all cases. Clearance exceeding 13 mm is not allowed.

7.9.2 Protective meshes with square cells having a side dimension not greater than 13 mm shall be fitted at the inlet and outlet of ventilation ducts to prevent foreign objects from getting inside the fan.

7.9.3 To prevent accumulation of electric charges on rotating parts and the body the latter shall be made of antistatic materials. Installation of fans onboard the ship shall ensure their safe grounding to the ship’s hull according to requirements of 2.6 Part VI of the Rules.

7.9.4 The impeller and the body in the area of possible contact with the impeller shall be made of non-sparking materials.

The following combinations of the impeller and the body materials are considered non-sparking:

.1 non-metallic materials having antistatic properties;

.2 non-ferrous base alloys;

.3 stainless austenitic steel;

.4 the impeller is made of aluminium or magnesium alloy and the body is made of cast iron or steel (including stainless austenitic steel), when a ring made of non-ferrous base alloys is installed inside the body in the impeller area;

.5 any combination of cast iron and steel impellers and bodies (including the variant when the impeller and the body are made of austenitic stainless steel) provided that the clearance between them is not less than 13 mm.

7.9.5 The following combinations of materials are not admitted:

.1 the impellers are made of aluminium and magnesium alloys, and the bodies are made of ferrous base alloys;

.2 the impellers are made of ferrous-base alloys and the bodies are made of aluminium or magnesium alloys;

.3 the impellers and the bodies are made of ferrous-base alloys and the clearance between them is less than 13 mm.

7.10 CENTRIFUGAL SEPARATORS

7.10.1 The design of separators shall exclude leakages of oil products and their vapours in any separation mode.

7.10.2 Separator drums shall be dynamically balanced. Position of detachable parts shall be marked. The design of disk holder and drum shall exclude the possibility of their incorrect assembly.
7.10.3 The “rotor – stator” systems shall be designed in a way that the critical rotation speed zones exceed the operating rotation speed in empty and filled states.

7.10.4 The design of shift sleeves shall exclude the possibility of sparking and overheat of couplings in all operation modes of separator.

7.10.5 The design of separator electric heaters shall comply with the requirements of 16.2.32 to 16.2.34 Part VI of the Rules. The design of steam heaters shall comply with the applicable requirements of 8.18.

7.10.6 Rotating parts of separator shall meet the strength requirements at the rotation speed exceeding the rated one (see 1.2.1.21) by less than 30 %. The equivalent stresses in these parts shall not exceed 0.65 of the yield point of the material of parts.

7.10.7 Strength of rotating parts of separator shall be tested while testing a specimen on the manufacturer's bench at a rotation speed exceeding the rated one by not less than 30 %.

7.10.8 The separation process monitoring system, including check of drum rotation speed, shall be provided.

7.10.9 The separators shall be equipped with protection system automatically disabling the separator in case of impermissible vibration of the unit according to 13.2.17.
8 BOILERS, HEAT EXCHANGERS AND PRESSURE VESSELS

8.1 GENERAL REQUIREMENTS

8.1.1 The requirements of this Section of the Rules apply to:
steam boilers (including waste-heat boilers) with steam working pressure of at least 0.07 MPa;
hot-water boilers with water temperature above 115 °C;
heat exchangers and pressure vessels (except for fluid pressure vessels), which being in service are fully or partially filled with gas or steam with a working pressure of at least 0.07 MPa and have a capacity of at least 0.025 m³ or with a production of working pressure for a capacity of at least 0.03 MPa m³ (boiler vaporizers, condensers, steam heaters, pneumatic tanks of ship systems, carbon dioxide cylinders and fire extinguishing medium reservoirs making a part of fire-fighting systems etc.);
boilers with high-temperature organic heat transfer fluid, including waste-heat boilers;
burning units of fuel oil fired boilers as pertaining to materials and dimensions conditioned by strength of structural members.

8.1.2 Hot-water boilers water temperature of max. 115 °C, filters and coolers of main and auxiliary machinery as pertaining to materials and dimensions of components shall comply with the requirements to heat exchangers and pressure vessels according to this Section of the Rules.

8.1.3 Vessels intended for storage of compressed gases and used in various systems and units while the ship is in service can be manufactured according to the national standards1. The requirements of 8.18.17 to 8.18.20 shall be met.

8.1.4 Prior to manufacture of boilers, heat exchangers and pressure vessels the documentation which is specified in RTSC shall be submitted to the River Register for approval.

8.1.5 Requirements for feed water systems are stated in 10.17.

8.1.6 Scope of technical supervision for boilers, heat exchangers and pressure vessels during the manufacturing process is specified in RTSC.

8.1.7 Provisions of the present Section of the Rules do not apply to:
.1 manned submersibles and deep water diving systems as pertaining to their design and strength of pressure hull;
.2 liquefied gas cylinders manufactured according to national standards2;
.3 units and parts of ship machinery which are not independent pressure vessels;
.4 arrangements comprising a system of pipes under pressure and arranged outside the boilers, heat-exchangers and vessels;
.5 air coolers with working pressure in air cavity less than 0.1 MPa;
.6 heat exchangers and fluid pressure vessels, except for the ones specified in 8.1.2.

8.1.8 Requirements to hydraulic tests are specified in 6.1.7 to 6.1.9 and 6.2.41 to 6.2.42 of RTSC.

8.2 CLASSIFICATION

8.2.1 Boilers, heat exchangers and pressure vessels are classified in accordance with Table 8.2.1 depending on their parameters and design features.

1 GOST 9731, GOST 12247, GOST R 50539.
2 GOST 15860, GOST R 55559.

Note. $p$ — working pressure, in MPa; $t$ — operating temperature, in °C; $s$ — wall thickness, in mm.

8.3 MATERIALS, WELDING AND HEAT TREATMENT

8.3.1 Materials intended for manufacture of parts of boilers, heat exchangers and pressure vessels shall meet the requirements referenced in the right column of Table 8.3.1.

Materials for parts of boilers, heat exchangers and pressure vessels of class III, as well as parts specified in 1.5 and 2.5 of Table 8.3.1, can be selected in accordance with the national standards.

8.3.2 For manufacture of components of boilers, heat exchangers and pressure vessels it is allowed to use carbon and carbon-manganese steels at design temperatures of up to 400°C and low-alloy steel of up to 500°C. Application of these steels for media with temperatures above the specified values is allowed provided their mechanical properties and long-term strength within 100 000 hours are guaranteed by the manufacturer of steel. The same shall be specified in the accompanying documents. Components and valves of boilers and heat exchangers for media with temperatures above 500 °C shall be made of alloy steel.

8.3.3 For heat exchangers and pressure vessels with design temperatures below 250 °C the shipbuilding steel can be used according to 2.2 Part X of the Rules shall be complied with.

</tbody>
</table>

1 GOST 5520, GOST 5654, GOST 1060, GOST 977, GOST 7505, GOST 8479.
For noncritical parts of heat exchangers (partitions, displacers, branch pipes, bends, supports) and vessels with working pressure below 0.7 MPa and design temperatures below 120°C it is allowed to use semi-killed steel.\(^1\)

8.3.4 If the yield point at elevated temperature is taken as the design characteristic of the material, the tensile tests of the material shall be carried out at the design temperature according to Appendix 10 Part X of the Rules; if the long-term strength limit is taken as the design characteristic, the data on limit long-term strength at the design temperature shall be submitted to the River Register and shall comply with Table 2.3.7-2 Part X of the Rules shall be complied with.

8.3.5 The manufacturer is to submit to the River Register data on mechanical properties and long-term strength of steel and welded joints at the design temperature, technological characteristics, welding technique and heat treatment.

8.3.6 Boiler valves up to 200 mm in diameter designed for working pressure up to 1 MPa and temperature up to 200 °C with the exception of safety and feed valves may be manufactured of nodular cast iron which meets the requirements given in 2.11 Part X of the Rules shall be complied with.

8.3.7 Components and valves of heat exchangers and pressure vessels with a working pressure up to 1 MPa and a diameter up to 1000 mm may be manufactured of nodular cast iron with entirely ferritic structure according to 2.11 Part X of the Rules shall be complied with.

8.3.8 Application of copper alloys for components of boilers, heat exchangers and pressure vessels as well as for their valves is allowed at design temperatures up to 250 °C and working pressures up to 16 MPa.

It is not allowed to use copper and copper alloys for parts of boilers with high-temperature organic heat transfer fluid and parts of their systems.

8.3.9 For parts specified in 1.2 and 2.3 of Table 8.3.1 electric-welded tubes with longitudinal seam can be used provided their density and strength correspond to that of seamless tubes (see also 8.5.35).

8.3.10 Welding and testing of welded joints shall be carried out according to the requirements of 7 and 8 Part X of the Rules shall be complied with.

8.3.11 Butt joints shall be used.

8.3.12 Arrangement of longitudinal welds in line with longitudinal seams of structures composed of several sections is not allowed.

8.3.13 Components in which the material structure may be changed after welding of plastic processing shall undergo the relevant heat treatment.

When performing heat treatment of a welded structure, the requirements of Part V of RINS shall be met. X of the Rules shall be complied with.

8.3.14 Heat treatment is required for:

1. plate-steel elements of boilers, vessels and heat exchangers subjected to cold stamping, bending and flanging with plastic deformation of surface fibres exceeding 5 per cent;
2. tube plates welded of several components; in this case heat treatment may be performed before drilling tube holes;
3. welded end plates manufactured by cold stamping;
4. elements subjected to hot forming with the temperature at the end of this process being lower than that of forging;
5. welded structures manufactured of steels with carbon content over 0.25 per cent.

8.4 TESTS

8.4.1 Boilers, heat exchangers and pressure vessels as well as their valves and fittings, assembly units and parts shall undergo hydraulic strength and leak tests in accordance with the requirements of RTSC.

---

1 GOST 380, GOST 1050.

2 GOST 8731, GOST 8733, GOST 1060.
8.5 BOILER DESIGN

8.5.1 Requirements of the present Chapter apply to structure of onboard steam and hot-water boilers.

8.5.2 Boilers shall be designed and manufactured so as to keep their workability in conditions of list and trim in accordance with 1.3.

8.5.3 Boiler walls heated by smoke gases shall be isolated from thermal flow influence. It is allowed to use non-isolated smoke-heated boiler walls over 20 mm thick only for gas temperatures up to 800 °C.

8.5.4 Long and short stays in the boiler structure as well as connecting tubes shall be located so as to avoid bending or shearing loads. Members, strength walls, reinforcements etc. shall have no changes in length of cross-sections exceeding 20 %.

Control drilled holes shall be provided at short-stay ends with a depth of 25 mm plus wall thickness, plus weld height.

8.5.5 For walls reinforced by short stays and exposed to flame and high-temperature gases the distance between the stays’ centres shall be not greater than 200 mm.

8.5.6 Corner stays of gas-tube boilers shall be arranged at least 200 mm clear of the flame tubes. Where flat walls are reinforced with welded-on girders, this should be done so that the load involved is transferred as far as possible to the boiler shell or the most rigid parts.

8.5.7 The distance between flame tubes and the boiler shell shall be not less than 100 mm. The distance between any two flame tubes shall be not less than 120 mm.

8.5.8 Branches and nozzles shall be of rigid construction and have a minimum length sufficient for fixing and dismantling the boiler valves without removing the insulation. Branch pipes shall not be exposed to bending forces exceeding the limits determined by the designer.

8.5.9 Pads intended for installation of valves and pipes, as well as branches, sleeves and nozzles passing through the entire thickness of the boiler wall shall be welded from both sides. Branches and nozzles may also be welded by a fillet joint with single-edge preparation using removable backing strip, or by some other method that ensures the penetration throughout the thickness of the part being attached.

8.5.10 Walls are considered protected against the influence of heat flow if they are protected by refractory insulation or by compact tube row (with maximum clearance between tubes in row up to 3 mm) or by two tube rows situated in staggered order, with longitudinal interval equal to not more than two external tube diameter, or by 3 or more tube rows situated in staggered order with longitudinal interval not exceeding two and a half of external tube diameters.

8.5.11 Boiler drums and headers having a wall thickness greater than 20 mm shall be protected against direct heat flow in accordance with the requirements of 8.5.10. It is recommended that in vertical gas-tube boilers the gas uptake pipe passing through the steam space of the boiler shall be protected against direct affection of hot gases.

8.5.12 Boilers shall be equipped by manholes for inspection and cleaning of all inner surfaces. If it is impossible to equip manholes, sight holes shall be foreseen.

8.5.13 Where non-metallic sealing gaskets are used, manhole and sight hole closures shall be so designed as to prevent the gasket from being forced out.

8.5.14 Manholes shall have clear dimensions of not less than: 300×400 mm — for oval-shaped manholes, 400 mm — for round-shaped manholes.

Oval-shaped manholes on cylindrical shells shall be located so that the minor axis of the manhole is arranged longitudinally.

8.5.15 Gas-tube vertical boilers shall have at least two sight holes on the casing in the working water level area located one opposite the other.
8.5.16 All boiler components that impose free access to inner surfaces or their inspection shall be of a removable type.

8.5.17 Openings for manholes and sight holes in flat walls, end plates and covers having a diameter over 4-time wall thickness, where \( s \) is the wall thickness, shall be reinforced by means of welded nozzles, branch pieces and pads, or by increasing the design wall thickness. Openings shall be arranged at a distance not less than 1/8 of the size of the opening from the design diameter contour.

8.5.18 Openings in cylindrical, spherical and conical walls and in dished ends shall be reinforced by increasing the wall thickness by means of welded disc-shaped reinforcing plates (pads), welded tubular elements, nozzles, sleeves, branches or by compensation of wall weakening in the opening area by excessive wall thickness as compared to the design one.

Opening reinforcements shall be made on removable spacers or using other methods providing the proper welding quality at weld root.

Disc-shaped pads and tubular elements may be used jointly for reinforcement of the same openings in non-flat walls and end plates.

8.5.19 Materials used for the wall to be reinforced and for reinforcing elements shall have identical strength characteristics. When using reinforcing materials with lower strength characteristics as compared to those of the wall to be reinforced, the area of the reinforcing sections shall be increased as compared to the area of reinforcing section of the material having the same strength characteristics as the wall to be reinforced according to the results of strength and stability calculation of the wall to be reinforced with use of reinforcing material with lower strength characteristics.

The reinforcing elements shall be reliably attached to the reinforced wall.

8.5.20 Openings in non-flat walls shall be located at the distance at least 3-time wall thickness, but not less than 50 mm apart from the welded joints.

8.5.21 The greatest dimension of openings being reinforced in non-flat walls shall not exceed 500 mm.

8.5.22 Minimum thickness of tubular elements (branches, sleeves, unions) attached to the walls of boilers, heat exchangers or pressure vessels by welding shall be not less than 5 mm;

8.5.23 Thickness of smooth flame tube shall be not less than 7 and not greater than 20 mm. Thickness of corrugated flame tube shall be not less than 10 and not greater than 20 mm.

8.5.24 Smooth flame tubes with a length up to 1400 mm may be made without stiffening rings. If there are two and more flame tubes in the boiler, stiffening rings of adjacent tubes shall not lay in one plane.

8.5.25 In the flanged area of solid ends non-reinforced openings are allowed with a diameter less than the wall thickness but not more than 25 mm. Solid ends are heads which have no openings or those with openings located at a distance of not less than 0.2 times of the external diameter from the outside contour of the cylindrical section and with a diameter of not more than 4-time wall thickness but not over 100 mm.

8.5.26 The minimum wall thickness of dished steel ends shall not be less than 5 mm. The requirement does not apply to the end plates made of non-ferrous alloys and stainless steels.

8.5.27 The use of welded dished end plates is allowed provided the positive results of strength calculations of such bottoms are submitted to the River Register. Strength calculations shall comply with the requirements of Section 9 of Guidelines P.010-2004 “Strength calculation of boilers, heat exchangers and pressure vessels” and apply strength coefficient \( \varphi \) (strength coefficient of welded joints or coefficient of bottom weakening by holes depending on the value of which coefficient is less).
8.5.28 Flanged end plates (Fig. 8.5.28) are allowed within the range of diameter up to 500 mm and for working pressures not over than 1.5 MPa. The radius of curvature of the end plates $R_b$ shall not exceed $1.2D$ and distance $l$ shall not exceed $2s$.

![Flanged end plates](image)

8.5.29 Radius of curvature of rectangular header sides shall be not less than 1.3 of the wall thickness and in any case not less than 7 mm. The minimum thickness of header walls designed to accommodate expanded tubes shall be not less than 14 mm; the width of ligaments between the holes shall be not less than 0.25 times the pitch between the centres of the holes.

8.5.30 Fillet welded joints (Figure 8.5.30) are allowed at $\alpha_2 \leq 30^\circ$ and $s \leq 20$ mm. The joint shall be welded by two-side welding. For conical shells with $\alpha_1 \geq 70^\circ$, fillet joints may be welded without edge preparation provided that the strength requirements for walls of conical elements subject to external pressure are met.

![Fillet welded joints](image)

8.5.31 Working pressure depending on minimum thickness of smoke tube walls shall correspond to the value stated in Table 8.5.31. A minimum wall thickness of stay tubes more than 70 mm in diameter, in mm, for tubes:

- peripheral, 6
- arranged inside a tube bundle, 5

8.5.32 Thickness of spherical and cylindrical walls and tubes shall be not less than:
- .1 5 mm for drawn and welded elements;
- .2 12 mm for tube plates with expanded tubes and radially situated holes;
- .3 6 mm for tube plates with welded tubes;
- .4 stated in Table 8.5.32 (for tubes). Reduction of wall thickness caused by bending or expansion shall be compensated by allowances.

**Note.** $D_s$ — internal tube diameter; $s$ — tube wall thickness.

8.5.33 It is allowed to use tubes with alternating knurled smoothly outlined stamped turbulators of circular, spiral or hemispheric form on their inner surface. The tube wall thickness after knurling or bending shall be not less than the design value.

8.5.34 Length of expanding end in the tube plate in expanded connection shall be not less than 12 mm and not greater than 40 mm.
Expanded connections for working pressure above 1.6 MPa shall be made with packing grooves.

8.5.35 The tubes securely seated in the headers and tube plates by expansion of their ends shall be seamless.

8.5.36 Design measures shall be taken to prevent steam generation in economizers of boilers.

8.5.37 Finned-tube boilers shall be provided with an effective soot-blowing system and be accessible for inspection of heating surfaces.

8.5.38 Fastening elements of the boiler excepting those which are not loaded, shall be not welded directly to the boiler walls (shell, ends, headers, drums etc.) but shall be attached by means of welded-on plates.

8.5.39 A nameplate indicating all main technical characteristics of boiler (nominal heat load, efficiency, fuel type, maximum power consumption, maximum water or steam temperature, permissible and maximum working pressure, water flow rate or steam output) shall be provided in a visible place.

8.5.40 Boiler rooms shall satisfy the requirements of 1.8 to 1.10.

8.6 GENERAL REQUIREMENTS TO VALVES

8.6.1 All boiler valves shall be fitted on special welded-on branches, nozzles and pads, and shall be secured thereto on flanges by studs and bolts. The studs shall have a full thread holding in the pad for a length of at least one external diameter of the stud; stud holes in pads shall be blind.

The bore of threaded nozzle fitted valves shall be not greater than 15 mm, special pads being used for attaching them to the boiler. Construction of pads, branches and nozzles shall satisfy the requirements of 8.5.18, 8.5.19, and 8.5.22.

8.6.2 The valve covers shall be secured to the valve cases by studs or bolts. Valves with bore diameter of 32 mm and less may have screwed covers provided that they are fitted with stops.

8.6.3 The valves and cocks shall be fitted with open and shut position indicators. Position indicators are not required where the design allows to see whether the valves are opened or shut.

All valves shall be arranged to be shut with a clockwise motion of the wheels.

8.6.4 Each self-contained boiler of class I (see 8.2) shall be equipped with at least two feed valves. Boilers of class II and waste-heat boilers shall have one feed valve.

8.6.5 The feed valves shall be of a non-return type (check valves). A shut-off valve shall be installed between the check valve and the boiler. The check and shut-off valves may be housed in one casing. The shut-off valve shall be fitted directly on the boiler.

8.7 WATER LEVEL INDICATORS

8.7.1 Each boiler with free water evaporating surface shall be provided with at least two independent water level indicators, one of which shall be a sight glass with a scale (see 8.7.3). A lowered or remote water level indicator with independent measuring points can be used as a second water level indicator. The second level indicator need not be installed when the boiler is fitted with the low water level protection devices, as well as low and high water level alarms. The sensors of protection devices and alarm shall be independent and shall have different measuring points.

Boilers with a steaming capacity of 750 kg/h and less as well as waste-heat boilers with free water evaporating surface and steam accumulators of waste-heat boilers may be fitted with one water level indicator having a transparent face provided that the boiler water sampling valve is fitted according to 8.13 on lower water level mark.

8.7.2 Forced circulation boilers shall be provided with two independent alarm devices to signal a shortage of water supply to the boiler instead of water level indicators.
The second alarm device is not required if it is fitted in the burning unit according to the requirements of Section 11 of this Part.

These requirements are not applicable to waste-heat boilers.

8.7.3 Flat rippled sight glasses shall be used in water level indicators for boilers with a working pressure up to 3.2 MPa. For boilers with a working pressure of 3.2 MPa and above sets of mica sheets shall be used instead of glass or plain glass with a mica layer to protect the glass from water and steam effects, or other materials resistant to action of the boiler water.

8.7.4 The water level indicators shall be fitted on the front of the boiler, at the same height and at equal distance from the vertical centre line of the drum/boiler shell.

8.7.5 All water level indicators shall be provided with shut-off devices both on the water and steam sides.

Shut-off devices shall have safe drives for disconnection of the devices in the event of glass breakage.

8.7.6 It shall be possible to blow off the water and steam spaces of water level indicators separately. Blow-down ducts shall have an inner diameter of not less than 7 mm. The design of water level indicators shall prevent the gasket material from being forced into the ducts, and allow cleaning the blow-down ducts as well as replacing the glasses while the boiler is in operation.

8.7.7 Water level indicators shall be so installed that the middle of the glass is above the lowest working level of water in the boiler, and the lower edge of the gauge slot is above the highest point of the heating surface by not less than 50 mm.

8.7.8 Water level indicators shall be connected to the boiler by means of independent branch pieces. No tubes leading to these branches are allowed inside the boiler. The branches shall be protected from affection of hot gases, radiant heat flow and intensive cooling. If the gauge glasses are fitted on hollow bodies, the inside space of such water level indicators shall be divided by partitions.

No nozzles or branch pieces for other purposes may be fitted on the water level indicators and connecting pipes.

8.7.9 The branch pieces for attachment of water level indicators to the boiler shall have an inside diameter, in mm, of not less than:

<table>
<thead>
<tr>
<th>Branch Type</th>
<th>Diameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bent branch pipes for steam boilers of class I</td>
<td>32</td>
</tr>
<tr>
<td>Straight branch pipes for boilers of class I</td>
<td>20</td>
</tr>
<tr>
<td>Bent branch pipes for other boilers</td>
<td>15</td>
</tr>
</tbody>
</table>

8.7.10 Design, dimensions, number, location and lighting of water level indicators shall ensure control of water level in the boiler.

Where water level visibility is inadequate, irrespectively of the height of water level indicator location, or where the boilers are remotely controlled, provision shall be made for remote (lowered) water level indicators or other types of water gauges installed at the boiler control stations.

This requirement is not applicable to waste-heat boilers and their steam accumulators (steam separators).

8.7.11 Remote water level indicators for boilers may have an error not exceeding ±20 mm as compared to water level indicators of gauge glasses fitted on the boiler while the relevant delays of the level indications at the highest possible rate of change shall not exceed 10 per cent of the difference between the upper and lower levels.

8.8 LOWEST WATER LEVEL AND HIGHEST HEATING SURFACE POINT

8.8.1 On each boiler with free water surface (surface of evaporation) the lowest water level shall be marked on the boiler water level indicator by means of a reference line drawn on the indicator frame or body. Moreover, the lowest water level shall be marked on a plate with a reference line and inscription “Lowest level”. The plate shall be attached to the boiler shell close to the water level indicators.

The reference line and the plate shall not be covered with boiler insulation.
8.8.2 The lowest water level in the boiler shall be not less than 150 mm above the highest heating surface point, including the heel conditions up to 5° to either side and all possible operation trim conditions.

For boilers with design steaming capacity less than 750 kg/h the distance between the lowest water level and the highest heating-surface point may be reduced down to 125 mm.

8.8.3 The upper ends of the uppermost downcomers are assumed to be the highest point of the heating surface of water-tube boilers.

For vertical fire-tube boilers with smoke tubes and gas uptake pipes passing through the steam space, the position of the highest heating surface point shall be specified.

8.9 PRESSURE GAUGES AND THERMETERS

8.9.1 Each boiler shall have at least two pressure gauges connected with the steam space by separate pipes fitted with check valves or stop cocks.

Three-way valves or cocks shall be provided between the pressure gauge and the pipe to shut off the pressure gauge from the boiler, connect it to the atmosphere, blow off the connecting pipe and install the control pressure gauge.

8.9.2 One of the pressure gauges shall be installed on the front of the boiler on clearly visible and lightened place, the other — on the panel at the central control station or at the local boiler control station.

8.9.3 Boilers with design steaming capacity below 750 kg/h and waste-heat boilers are allowed to have one pressure gauge.

8.9.4 A pressure gauge shall be provided at the water outlet from the economizer.

8.9.5 Pressure gauges shall have a scale sufficient for hydraulic testing of the boiler.

The working pressure shall be marked with a red line on the pressure gauge scale.

8.9.6 Pressure gauges fitted on boilers shall be protected against affection of heat from the boiler hot surfaces.

8.9.7 Steam superheaters and economizers shall be equipped with thermometers. Remote temperature control does not preclude the need for providing local thermometers.

8.9.8 Thermometers shall also be installed on the following pipelines:

.1 lines feeding water to the boiler;
.2 suction lines of waste-heat boiler circulation pump;
.3 lines feeding hot water or steam-water mixture from waste-heat boilers to the steam separator (steam accumulator) or to autonomous boiler drum;
.4 outlet hot water or steam lines.

8.10 SAFETY VALVES

8.10.1 Each boiler shall be fitted with at least two spring-loaded safety valves of the same design and size, which shall be installed on a common branch piece of the drum and one valve fitted on the superheater outlet header. The superheater safety valve shall be so adjusted as not to open before the safety valve being installed on the drum.

Safety valves of the impulsive action type are recommended for steam boilers with a working pressure of 4 MPa and above.

One safety valve is sufficient for steam boilers with design steaming capacity below 750 kg/h as well as steam accumulators and steam separators.

Safety valve shall be adjusted and sealed by the ship crew. If there are two safety valves, one of them shall be sealed.

8.10.2 Total passage area of safety valves $f$ shall be not less than the one calculated by the formulae, in mm$^2$:

for saturated steam

$$f = k \frac{G}{(10.2 p + 1)}; \quad (8.10.2-1)$$

for superheated steam

$$f = k \sqrt{\frac{v_h}{v_s}} \frac{1}{(10.2 p + 1)}, \quad (8.10.2-2)$$
where \( k \) — coefficient adopted from Table 8.10.2;

<table>
<thead>
<tr>

<tr>
<td>( d/4 \leq h &lt; d/3 )</td>
<td>5.25</td>
</tr>
<tr>
<td>( d/4 \leq h )</td>
<td>3.3</td>
</tr>
</tbody>
</table>

*Note.* \( d \) — minimum diameter of the valve, in mm.

\( G \) — design steaming capacity, in kg/h;

\( p \) — working pressure, in MPa;

\( \nu_s \) — specific volume of superheated steam at the corresponding working pressure and temperature, in \( \text{m}^3/\text{kg} \);

\( \nu_t \) — specific volume of saturated steam at the corresponding pressure, in \( \text{m}^3/\text{kg} \).

Safety valves shall be not less than 32 mm and not greater than 100 mm in diameter.

8.10.3 The passage area of the safety valve installed on non-disconnected superheater is included in the total cross-sectional area of the valves to be determined by the formulae (8.10.2-1) and (8.10.2-2). This area shall not exceed 25 per cent of the total area of the valves.

8.10.4 The safety valves shall be so adjusted that the maximum pressure during their operation shall not exceed the working pressure by more than 10 per cent.

Safety valves of boilers of class I after each actuation shall be totally closed at a pressure drop in the boiler not below 85 % of the working pressure.

8.10.5 Economizers shall be fitted with a spring safety valve with a diameter not less than 15 mm.

8.10.6 Where safety valves are fitted on the common branch, the cross-sectional area of the branch shall be not less than 1.1 times the total cross-sectional area of the valves.

8.10.7 Passage area of waste-steam branch of the safety valve and of the pipe connected thereto shall be not less than twice the total free passage area of the valve. If safety valve is double, total cross-sectional area of both valves shall be taken for calculation.

8.10.8 A drain pipe free of stopping devices shall be provided on the valve body or on the waste-steam pipe, if the latter is located below the valve, for condensate removal.

8.10.9 The safety valves shall be connected directly to the boiler steam space without any stopping devices. No feeding pipes leading to the safety valves may be installed inside the boiler. No steam extraction devices for other purposes may be fitted on the safety valve bodies or their connections.

8.10.10 Safety valves shall be so arranged that they can be lifted manually by a special drive. The gear of one of the valves shall be controlled from the boiler room, and that of the other valve — from the upper deck or other accessible place outside the boiler room.

Remote drive for safety valves of steam superheaters, waste-heat boilers and their steam accumulators (separators) may be controlled only from the boiler room.

8.10.11 Safety valves shall be so designed as to prevent their adjustment when the seal is not removed.

Safety valve springs shall be protected against direct affection of steam and shall be manufactured of heat- and corrosion-resistant material, as well as sealing surfaces of seats and valves.

8.11 SHUT-OFF VALVES

8.11.1 Each boiler shall be separated from all connected pipelines by means of shut-off valves fitted directly on the boiler.

8.11.2 In addition to local control, the shut-off valves of steam pipelines shall be provided with remote control gears for the operation from the upper deck or from other accessible position outside the boiler room.

8.11.3 Where on a ship there is one boiler of class I with a superheater or economizer, the superheater and economizer shall be so arranged as to be disconnectable from the boiler.
8.11.4 Requirements for steam pipes and boiler blow-down pipes are set forth in 10.18.

8.12 BLOW-DOWN VALVES

8.12.1 Boilers, steam superheaters, economizers and steam accumulators shall be fitted with blow-down arrangements and, if required, with drain valves.

Blow-down and drain valves shall be fitted directly on the boiler shell. At a working pressure below 1.6 MPa these valves may be installed on welded-on profiled branch pieces.

8.12.2 The inner diameter of blow-down valves and pipes shall be not less than 20 mm and not more than 40 mm. For boilers with design steaming capacity below 750 kg/h the inner diameter of the valves and pipes may be reduced to 15 mm.

8.12.3 In boilers with free water surface of evaporation, the scum arrangements shall be so provided as to ensure scum and sludge removal from the entire evaporation surface.

8.13 SAMPLING VALVES

8.13.1 Each boiler shall be provided with at least one water sampling valve or cock. Such valves or cocks shall not be fitted on pipes and branches intended for other purposes.

8.14 DEAERATION VALVES

8.14.1 Boilers, steam superheaters and economizers shall be equipped with sufficient number of valves and cocks for deaeration.

8.15 CONTROL, ADJUSTMENT, ALARM AND PROTECTION OF BOILERS

General requirements

8.15.1 Requirements of this Chapter apply to the boilers designed for attended operation according to the technical documentation.

Requirements to control, adjustment, alarm and protection of boilers designed for unattended operation are stated in Section 11 of this Part.

8.15.2 Automation systems and their elements shall meet the requirements of Section 11 of this Part.

Adjustment and protection

8.15.3 Water-tube boilers of class I shall be equipped with feed water governors and combustion controls.

8.15.4 Governors and controls shall be capable of maintaining the water level and other controlled parameters within the predetermined limits over the entire load range and shall ensure change-over from one operation mode to another one within not more than 5 min.

8.15.5 Boilers shall be equipped with non-disconnectable protective devices for the lowest water level limit in the boiler.

8.15.6 Boilers with automatic combustion controls shall be fitted with protection devices according to the requirements of 8.16.9 to 8.16.11.

Alarm

8.15.7 Boilers with automatic feed water governors and combustion controls shall be equipped with visual and audible alarm at the boiler control station.

8.15.8 Visual and audible alarm shall be actuated when:

1. water level reaches the lowest limit;
2. water level reaches the highest limit;
3. failures occur in the boiler oil burning system (see 8.16.10);
4. failures occur in the automatic control systems and protection devices.

8.15.9 The lowest level limit alarm shall be actuated prior to actuation of the protection devices.

8.15.10 When heavy fuel is used, audible and visual alarm shall be provided, which shall be actuated when:

1. heavy fuel before the injector reaches the minimum or maximum temperature;
. heavy fuel in the boiler fuel service tank reaches the minimum or maximum temperature (only for ships of Group I as regards the automation scope).

8.15.11 Provision shall be made for manual disconnection of the audible alarm after it has been actuated.

8.16 OIL BURNING UNITS OF FUEL OIL FIRED BOILERS

General requirements

8.16.1 Control, protection, interlock and alarm devices shall meet the requirements of Section 11 of this Part.

8.16.2 Electrical equipment for burning units shall meet the requirements of Part VI of the Rules.

8.16.3 Fuel oil used for boilers shall have a flash point in accordance with the requirements given in 1.1.2.

Burners

8.16.4 The burners shall be so designed as to ensure the possibility of controlling the size and shape of the flame jet.

8.16.5 In case of variable-delivery burners provision shall be made for controlling the combustion air supply.

8.16.6 Inlets of the boiler fans shall be protected against the ingress of moisture or foreign items.

8.16.7 Rotating parts of burners and boiler fans shall be fenced by protective housings for the attending personnel safety.

Burning units

8.16.8 The present requirements apply to burning units equipped with automated mechanical combustion controls of boilers.

8.16.9 Burning units shall be interlocked for fuel supply to the boiler furnace to be possible only under the following conditions:

.1 the burner is in the operating position;

.2 electrical supply is fed to all the electrical equipment;

.3 air is fed into the boiler furnace;

.4 the pilot burner is alight or electrical ignition is switched on;

.5 water level in the boiler is normal;

.6 program of furnace and gas ducts ventilation is completed before lighting up.

8.16.10 Burning units shall be equipped with non-disconnectable protection devices being actuated within not over than 1 s (for pilot burner – not more than 10 s) and shutting off automatically the fuel supply to the burner in the cases of:

.1 loss or low head of air flow to the furnace;

.2 flame-jet cut-off at the burner;

.3 water level in the boiler reaching its lowest limit.

Fuel supply shall be cut-off by two self-closing series-connected valves. This requirement is not mandatory when the fuel service tank of the boiler is arranged below the burning unit.

8.16.11 Burning units shall be equipped with a burner flame jet monitor. Such monitor shall respond only to the flame jet of the burner under control.

8.16.12 Burning units of boilers of class I shall be capable of being manually controlled. Manual control shall be provided directly at the boiler; in this case all automatic devices required in 8.16.9 and 8.16.10 shall function as well.

8.16.13 Provision shall be made for the burning unit to be shut off from two stations, one of which shall be situated outside the boiler room.

8.16.14 Before each boiler ignition the furnace and gas ducts shall be well-ventilated to provide three air changes in the entire furnace and gas ducts prior to smoke tube inlet. The furnace and gas ducts shall be ventilated for at least 15 s.

8.16.15 Abrupt turns and stagnant zones in exhaust gas pipelines are not allowed.
8 Boilers, Heat Exchangers and Pressure Vessels

Piping and valves

8.16.16 Pipelines and valves of burning units shall meet the requirements of Section 10 of this Part.

8.16.17 On the fuel pipeline near the burners it is allowed to use flexible pipelines made of fuel resistant materials.

8.16.18 Design measures shall be provided to prevent the burners from being turned and removed from their working positions until fuel supply to them is not shut off.

8.16.19 When steam or air atomizing burners are used, design measures shall be provided to prevent the ingress of air or steam into the fuel oil and vice versa.

8.16.20 If boiler fuel is heated, design measures shall be taken to prevent inadmissible oil overheating in the heaters in case when the steam-generating capacity of the boiler is reduced or the burners are shut-off.

8.16.21 Drip trays shall be provided in places of possible oil leakage.

8.16.22 Inspection devices shall be provided in the boiler furnace for observing the combustion process. There shall be installed arrangements to prevent flame and hot air ejection from the furnace space when removing the burners.

8.16.23 Appropriate devices shall be provided for the suppression of hand lighting primers of the boiler.

8.17 HEAT EXCHANGERS AND PRESSURE VESSELS

8.17.1 The elements of heat exchangers and pressure vessels contacting with salt outboard water or other aggressive media shall be manufactured of corrosion-resistant materials protected from corrosion by means of corrosion-resistant coatings.

8.17.2 Heat exchangers and pressure vessels shall meet the requirements of 1.3.

8.17.3 The requirements of 8.5.4, 8.5.8, 8.5.9, 8.5.12, 8.5.13, 8.5.17 to 8.5.22, 8.5.25, 8.5.32 to 8.5.35 apply to heat exchangers and pressure vessels.

8.17.4 Heat exchangers and pressure vessels shall be so designed as to provide thermal elongation of their shells and separate parts.

8.17.5 Heat exchangers and pressure vessels shall be so designed as to provide their attachment to the foundations. If fastening to foundations of heat exchangers and pressure vessels is impractical, overhead attachments shall be provided.

8.17.6 Manholes shall be provided to enable inspection of the internal surfaces of heat exchangers and pressure vessels. If it is impossible to equip manholes, sight holes shall be foreseen. If the length of a heat exchanger or pressure vessel is over 2.5 m, sight holes shall be provided at both ends.

Manholes or sight holes are not required for dismountable structures or when the design and materials of heat exchangers and pressure vessels completely exclude corrosion and contamination of internal surfaces.

Manholes or sight holes may be omitted for heat exchangers and pressure vessels for which inspection through such holes is impossible due to their construction.

Dimensions of manhole openings are indicated in 8.5.14.

8.17.7 Requirements to installation of the heat exchangers and pressure vessels are stated in 1.10.

8.17.8 Each heat exchanger, pressure vessel or their groups shall be fitted with non-disconnectable safety valves. Where there are several non-communicating spaces, safety valves shall be provided for each space. Hydrophores shall be fitted with a safety valve to be installed on the water side.

8.17.9 Safety valves shall be of spring-loaded type. In fuel and oil heaters it is allowed to use safety diaphragms installed on the fuel or oil side.

8.17.10 The discharge capacity of the safety valves shall be such that under no condition
the working pressure is exceeded by more than 15 per cent.

8.17.11 The safety valves shall be so designed as to allow their stamping or be fitted with equivalent protection means to prevent the valve adjustment without authorization by the attending personnel.

The materials used for springs and sealing surfaces of the valves shall be capable to withstand corrosion effect of the medium.

8.17.12 Level indicators and sight glasses may only be installed on heat exchangers and pressure vessels where the conditions of control and inspection stated in technical documentation of the manufacturer require so. Level indicators and sight glasses shall be protected from impacts. Flat glass plates shall be used for level indicators containing steam, fuel, oil or refrigerants.

In deaerators cylindrical glasses may be used.

8.17.13 Heat exchangers and pressure vessels shall be fitted with welded-on pads or short rigid connecting pieces to mount valves. At hydrophores threaded connections may be used.

8.17.14 Pressure vessels and heat exchangers shall be equipped with blow-down and drainage devices.

8.17.15 Each heat exchanger and pressure vessel or their groups being disconnectable from each other shall be equipped with pressure gauges and compound gauges.

If heat exchangers have several spaces, pressure gauges shall be provided for each space.

The pressure gauges shall meet the requirements set forth in 8.9.1 and 8.9.5.

8.17.16 On fuel heaters where temperature of fuel on heating elements may exceed 220 °C, a warning alarm sensor giving indication of temperature rise or failure of fuel flow through the heater shall be installed in addition to the temperature control device.

8.18 SPECIAL REQUIREMENTS FOR HEAT EXCHANGERS AND PRESSURE VESSELS

Air receivers

8.18.1 Safety valves on air receivers after actuation shall fully stop the air bleeding in case of pressure drop in the air receiver to 0.85 of the working pressure.

8.18.2 Where compressors, reduction valves or pipelines intended for air supply to air receivers are fitted with safety valves which are so installed that air supply to air receivers under pressure exceeding the working pressure is excluded, the safety valves on the air receiver may be omitted. In this case each air receiver shall be equipped with a fuse instead of the safety valve.

8.18.3 The air receiver fuse shall have a fusion temperature from 100 to 130 °C. The fusion temperature shall be punched out on the fuse.

Air receivers having a capacity over 700 l shall be fitted with fuses of not less than 10 mm in diameter.

8.18.4 Each air receiver shall be equipped with a drain device for moisture removal. In case when air receivers are arranged horizontally, moisture drain devices shall be fitted at both ends of the receiver.

Condensers

8.18.5 The condenser design and its location onboard a ship shall be such as to enable the tube replacement. The condenser shall have welded steel shell. Baffles shall be provided inside the condenser at the steam inlets to protect the tubes against direct steam impact.

Pipe attachments shall exclude sagging and vibration with an amplitude exceeding 1 mm in the midspan of pipe.

8.18.6 Covers of condenser water chambers shall be fitted with manholes in a such number and so located as to ensure access to the tubes in any part of the tube nest for the pur-
pose of expansion, replacement, packing or plugging.

Cathodic protection shall be provided for the water chambers, tube plates and tubes for prevention of electrolytic corrosion.

8.18.7 The condenser of the turbo generator shall ensure the operation under emergency conditions with any casing of the turbine set being disconnected.

8.18.8 The condenser shall be so designed as to enable connecting of monitoring and control instrumentation.

Heat exchangers and vessels of fire-fighting installations

8.18.9 The design of heat exchangers and pressure vessels of refrigerating plants and fire-fighting installations shall meet the requirements of Sections 9 of this Part and 13 Part III of the Rules.

Pressure vessels being a part of process equipment

8.18.10 Covers of the pressure vessels being a part of the process equipment which are periodically opened shall be fitted with devices preventing their incomplete closing or spontaneous opening. It is also necessary to prevent the cover opening in case of excessive pressure or vacuum in the pressure vessel as well as against pressurization of the vessel in case of incomplete closing of the cover.

8.18.11 The inside arrangements of the pressure vessels being a part of the process equipment (mixers, coils, trays, diaphragms etc.), which interfere the internal inspection, shall be of removable type.

8.18.12 Sight glasses not more than 150 mm in diameter intended for observation of the mixer working space may be fitted on pressure vessels with a pressure not exceeding 0.25 MPa.

8.18.13 For the pressure vessels being a part of the process equipment with a pressure over 0.25 MPa closing appliances of the loading holes shall be so designed that in case of cover sealing loss the hot medium shall be removed in the direction safe for the operating personnel.

8.18.14 The pressure vessels being a part of the process equipment that operate under vacuum and are heated by steam or hot water with a temperature over 115 °C shall be fitted with safety valves to prevent an excessive pressure in the space operating under vacuum above 0.85 times the test pressure in case of leakage in the heating system.

The vessels mentioned herein shall be designed for strength at the design pressure equal to safety valve opening pressure. In this case the design stresses in the pressure vessel walls shall not exceed 0.8 times the yield stress of the material at the design temperature.

8.18.15 Strength of flanges, bolts and studs of periodically opened covers of pressure vessels being a part of the process equipment shall be confirmed by calculations carried out by designer according to the requirements of the Rules. The design stresses shall not exceed 0.4 times the yield stress of the material at the design temperature.

Diameter of bolts and studs shall be not less than 16 mm in all cases.

8.18.16 For steam-heated and water-heated agitators and also for walls of pressure vessel mixing chambers which are in contact with the processed products an allowance c to the design wall thickness shall be taken for at least 2 mm.

Compressed and liquefied gas vessels

8.18.17 Strength calculations for compressed/liquefied gas vessels carried out in accordance with the Guidelines P.010-2004 shall be submitted. Compressed/liquefied gas vessels are portable pressure vessels specially made for storage of compressed gases, refrigerant or CO₂ which are used during the ship operation and can not be filled using onboard facilities.

For manufacture of these vessels it is allowed to use steels with upper yield point over 750 MPa, but less than 850 MPa.
8.18.18 Non-disconnectable safety devices shall be provided in case of temperature rise inside the vessels to avoid impermissible internal pressure. It is possible to use safety valves and diaphragms with an opening pressure exceeding the working pressure by 10%, but less than 90% of the test pressure.

8.18.19 Durable marking indicating the date of the next test of the vessel shall be applied on compressed/liquefied gas vessels.

8.18.20 It is not required to install safety devices for the compressed gas vessels with capacity less than 100 litres, provided the following requirements are met:

.1 vessels shall not be arranged in the ship’s hull below the main deck;
.2 temperature in the rooms where the vessels are placed shall not exceed the temperature specified in 1.3.1 Part V of the Rules.
.3 rooms where compressed gas vessels are placed shall not be in the immediate proximity from accommodation spaces, control stations and rooms in which inflammable substances and fuel are stored.

8.18.21 Gas from the safety devices shall be withdrawn to the atmosphere through closed takeoff.
Gas from safety devices of cylinders carbon dioxide fire extinguishing system shall be withdrawn according to requirements of 3.8.21 Part III of the Rules.

8.19 STRENGTH CALCULATION

8.19.1 Strength calculations for boilers, heat exchangers and pressure vessels shall be carried out according to the Guidelines P.010-2004 and (or) Guidelines P.037-2010 “Procedure of strength calculations for ship heat exchangers”. It is allowed to use other procedures and programs agreed with the River Register.

8.20 BOILERS WITH HIGH-TEMPERATURE ORGANIC HEAT TRANSFER FLUID

8.20.1 Boilers with high-temperature organic heat transfer fluid shall be arranged in separate rooms with exhaust ventilation ensuring at least six air changes per hour.

If the location is different, the boilers specified in this Section shall be enclosed with welded coaming of at least 150 mm in height equipped with a drain pipe into closed discharge tank.

8.20.2 The design of boiler shall exclude the possibility of rise of heat transfer fluid temperature above the permissible value when the heat transfer fluid circulation stops.

Maximum operating temperature of heat transfer fluid shall be lower than its heat-resistance by at least 50°C.

8.20.3 The design of furnace and burning unit shall ensure uniform distribution of heat flows or such distribution of heat flows at which in any point of heated surfaces the temperature of fluid boundary layer does not exceed the value determined for the used heat transfer fluid by the designer.

Arrangement of burning unit and design of furnace shall make it impossible for the flame to contact the heated surfaces.
The burning unit shall guarantee that the heat flow of the boiler does not exceed its nominal value.

8.20.4 Each boiler shall be equipped with:

.1 stop valves on pipelines feeding the heat transfer fluid to the boiler and discharging the heat transfer fluid from it. Valves shall be arranged in a place accessible and safe for maintenance and have a remote control, or a device for discharge of high-temperature organic heat transfer fluid from system shall be provided. It is allowed to install three-way valves with remote control and non-return-stop valves without remote control at the outlet of heat transfer fluid from the boiler;
.2 spring safety valve of fully covered design. Total capacity of the installed safety valves shall be not less than the volume gain of heat transfer fluid in the boiler at maximum heating intensity. Nominal inside diameter of valves shall be not less than 25 mm and not more than 130 mm. It is allowed not to install the safety valve if the boiler is directly connected to the expansion tank and cannot be disconnected from it. Safety valve actuation pressure shall not exceed the maxi-
mum working pressure by more than 10% (for the requirements to safety valves, see 8.10.4, 8.10.10 and 8.10.11);

.3 pressure gauge installed on the pipeline delivering high-temperature organic heat transfer fluid to the boiler;

.4 device for emergency enclosed discharge of heat transfer fluid to separate discharge tank and remote stop of circulating pumps;

.5 hatches specified in 8.5.12, 8.5.14 and 8.5.15.

8.20.5 Each boiler shall be equipped with soot-blowing system.

8.20.6 Boiler pipes shall be connected to manifolds by means of welded joints.

8.20.7 Boilers shall be equipped with valves having bellow seals, the valves being attached by welding.

8.20.8 Boilers shall be equipped with alarm and protection against limit values of gas and heat transfer fluid temperatures at the outlet of the boiler.

8.20.9 If waste-heat boilers have bypass channels, the boiler shall be equipped with a stop arrangement to stop gas delivery to the boiler when the protection operates.

8.20.10 Boilers with high-temperature organic heat transfer fluid shall be equipped with automatic controls of combustion, audible and light alarm according to the applicable requirements of 8.15, interlock according to 8.16.9 and protection according to 8.16.10.
9 REFRIGERATING PLANTS

9.1 SCOPE OF APPLICATION

9.1.1 The requirements of this Section of the Rules apply to onboard refrigerating plants of transport, refrigeration and catching vessels and their equipment.

9.1.2 Refrigerating plants for cooling cargo holds and cargo chambers of portable refrigerating containers carried by a ship, shall comply with all requirements of the present Section of the Rules.

9.2 GENERAL TECHNICAL REQUIREMENTS

9.2.1 Elements of the refrigerating plant shall maintain workability under conditions of rolling and trim according to 1.3.

9.2.2 The equipment being a part of the refrigerating plant shall be installed and fastened onboard in accordance with 1.10.2, 1.10.3, 1.10.5, 7.4.2.

9.2.3 For the requirements to hydraulic tests, see 6.2.54 to 6.2.57 of RTSC.

9.3 REFRIGERANTS AND DESIGN PRESSURE

9.3.1 In this Rules the refrigerants are divided into the following three groups:

I — non-flammable refrigerants (halon);

II — toxic and inflammable refrigerants with lower inflammability point at the bulk concentration of the refrigerant vapour in the air of 3.5 per cent and over (ammonia);

III — explosive or inflammable refrigerants with lower inflammability point at the bulk concentration of the refrigerant vapour in the air of less than 3.5 per cent (propane, propylene).

Refrigerants of Group III are allowed only for refrigerating systems of ships intended for carriage of liquefied gases in bulk when the cargo is used as a refrigerant.

9.3.2 In strength calculations of the elements operating under the pressure of the refrigerant a design pressure shall be taken not lower than the excessive pressure of the refrigerant saturated vapour at 50 °C according to Table 9.3.2.

<table>

* To be used instead of R12 which is not permitted for newly built refrigerating plants.

** To be used at medium (from minus 30 to plus 30 °C) condensation points instead of R22 which is not permitted for new refrigerating plants since 01 January 2020.

Design pressure for the components of refrigerating plants operating under pressure of refrigerants with low (below 50 °C) critical temperatures shall be selected according to thermodynamic properties of the refrigerant.

Refrigerating plant components operating under pressure shall be checked by strength calculation at a pressure equal to the hydraulic test pressure. Here, the stresses occurred shall not exceed 0.9 times the yield stress of the material.

9.4 REFRIGERATING CAPACITY AND COMPOSITION OF REFRIGERATING EQUIPMENT

9.4.1 Refrigerating plant shall provide permanent maintaining the temperature within
cooled spaces that is required according to the type of the cargo carried and the navigation area at a ship’s normal operating conditions.

9.4.2 Refrigerating plant shall maintain the required temperature when the main equipment operates for all refrigeration consumers at ambient air temperature not lower than +40 °C and outboard water temperature not lower than +30 °C.

9.4.3 The drive capacity, the refrigerating capacity, the heat-exchange surface area of evaporators and air cooler condensers as well as the heat-exchange surface area of cooling batteries with coolant circulating therein shall be sufficient for maintaining the required temperatures within cooled spaces at continuous 24-hour operation of the main equipment and supplying refrigeration to other consumers.

The main equipment shall include at least two similar condensers and, when intermediate coolant systems or cascade and stage cycles are used, two similar evaporators, interstage heat exchangers and intermediate vessels.

9.4.4 The drive capacity, the refrigerating capacity, the surface areas stated in 9.4.3, of the refrigerating plant intended also for refrigerating non-precooled cargo onboard, shall be sufficient for its cooling down to the required temperature within period of time for which its undamaged state is guaranteed, at continuous operation of all the equipment including standby units.

9.4.5 Standby equipment of a compressor refrigerating plant shall consist of a compressor together with a drive motor, condenser, control system and valves which are necessary to provide independent operation of all units of the equipment.

Refrigerating capacity of standby equipment shall be such as to supply refrigeration to all consumers when any one of the main compressors or condensers is out of order.

9.4.6 In ships with a capacity of cooled holds not exceeding 300 m³ the refrigerating plant without standby equipment may be used. The plant capacity and the cooling surface area shall be sufficient for maintaining the required temperatures at continuous operation for 18 hours a day.

9.4.7 Piping joints between the elements of the refrigerating plant shall be such that the equipment is able to operate at any combination of the equipment. Heat exchangers and other apparatus shall be fitted with connection joints for suction and discharge lines for the refrigerant pumping and exhaustion.

9.4.8 Cooling batteries shall be so located as to provide the uniform cooling of the space.

The batteries shall consist of at least two independent sections, with each section capable of being shut-off separately. No cooling batteries with direct evaporation of refrigerant of Group II may be used.

9.4.9 Where the refrigerant pump circulation systems are used, at least two refrigerant circulation pumps shall be fitted with one of them being a standby pump.

If the pump circulation system capable of operating when the pumps are switched off, standby pump may be dispensed with. In this case the refrigerating plant capacity shall comply with the requirements of 9.4.1 and the refrigerating capacity of freezing chambers or refrigerants shall not be reduced by more than 20 per cent.

9.4.10 Liquid coolant system of a group of refrigeration consumers shall have at least two liquid coolant pumps with one of them being standby.

If onboard the ship there are two or more groups of refrigeration consumers with independent liquid coolant systems, including those with different temperatures, each group of consumers shall be fitted with at least one liquid coolant pump; For this consumers one common pump ensuring required delivery and head of working medium can be used as a standby pump.

9.4.11 Refrigerating plant shall be fitted with at least two cooling water circulation pumps, one of them shall be standby. Any
outboard water pump of adequate supply capacity and liquid head may be used as a standby one.

9.4.12 Cooling water shall be supplied by at least two outboard valves. Where general-purpose outboard valves are used, each of them shall provide the sufficient water supply to ensure operation of the refrigerating plant in normal operating conditions of the ship.

9.5 MATERIALS

9.5.1 Quality and main characteristics of materials used for manufacture of component parts, units and fastening of the refrigerating equipment subject to dynamic loads, excessive pressure, variable and low temperatures at operation, shall comply with the relevant requirements of Part X of the Rules shall be complied with.

Materials shall be chosen depending on the working temperature and physical and chemical properties of the refrigerant with due regard to the following:

.1 materials of the elements being in contact with refrigerants and their solutions, lubricating oils, cooling media and media to be cooled, shall be inert and resistant to their action;

.2 materials of the equipment parts operating at temperatures below minus 70 °C shall not have irreversible structural changes and shall maintain sufficient strength at these temperatures;

.3 steel structures operating at temperatures down to minus 50 °C shall comply with the requirements of 2.3.7 Part X of the Rules;

.4 materials used for manufacture of refrigerating plant components operating at temperatures below minus 50 °C shall be selected according to the requirements of Section 5 Part X of the Rules shall be complied with.

9.5.2 The elements contacting with corrosive media shall be made of materials with adequate corrosion-resistant properties to those media or shall be protected with corrosion-resistant coatings.

Joints and structures of machinery and equipment made of materials with different electrolytic potentials, that can contact with sea water, shall be protected against galvanic corrosion.

9.5.3 Steel pipes of the refrigerant, liquid coolant and their connecting parts made of steel other than stainless steel, shall be zinc-plated from the outside or have equivalent protection against corrosion from the outside. Surfaces being in contact with the refrigerant or liquid coolant shall not to be zinc-plated.

9.6 ELECTRICAL EQUIPMENT

9.6.1 Electrical equipment of refrigerating plants, automatic devices as well as illumination of refrigerating machinery rooms, refrigerant storerooms and cooled spaces shall comply with relevant requirements of Part VI of the Rules.

9.7 REFRIGERATING MACHINERY ROOM

9.7.1 The refrigerating machinery room shall comply with the requirements of 1.8.1, 1.8.7 and the present Chapter.

Refrigerator machines using refrigerants of Group II and III shall be located in separate gas-tight spaces.

Drainage of the refrigerating machinery room shall be made in accordance with the requirements of 10.7.34.

9.7.2 Pumps, compressors, apparatus and pipelines shall be located in the refrigerating machinery room in a such manner as to be readily accessible for maintenance and replacement of their parts without dismantling the pumps, compressors, apparatus from their foundations. They shall be located apart from the bulkheads of other spaces and surfaces of the adjacent equipment for at least 100 mm.

9.7.3 The refrigerating machinery room shall have two exits located as far apart as possible from each other with doors opening outwards. Where the refrigerating machinery room is located above or below the open deck, the exits shall be fitted with steel stair-
ways leading to the doors of spaces giving to the open deck.

In unattended automated refrigerating machinery rooms, where refrigerants of Group I are used, the second exit may be dispensed with.

9.7.4 Exits from the refrigerating machinery room where refrigerants of Groups II and III are used shall not lead to accommodation and service spaces or spaces communicating with them and shall be arranged considering the refrigerant density. One of the exits shall lead to the open deck.

Exits with corridors or trunks shall be fitted with supply and exhaust ventilation; The supply ventilation shall be of forced type. The switching-on device of this ventilation shall be located both inside and outside the refrigerating machinery room in the immediate proximity to the exit door.

9.7.5 Exits from the refrigerating machinery room where refrigerants of Groups II and III are used, shall be fitted with a water-screen arrangement. The water screen actuation device shall be located outside the room in the immediate proximity to the exit door.

A fire hydrant with a hose connected to the fire main system shall be installed in the refrigerating machinery room.

9.7.6 The refrigerating machinery room shall be equipped with an independent ventilation system providing 10 air changes per hour.

9.7.7 In addition to the main ventilation satisfying the requirements of 9.7.6 each refrigerating machinery room shall be equipped with emergency ventilation ensuring air change per hour for refrigerating machinery room using refrigerants:

<table>
<thead>
<tr>
<th>Groups</th>
<th>Air Changes per Hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>II and III</td>
<td>30</td>
</tr>
<tr>
<td>I</td>
<td>20</td>
</tr>
</tbody>
</table>

The ventilation system shall ensure air exhaust from either the uppermost or lowermost parts of the room depending on the refrigerant density.

When calculating the emergency ventilation system the supply of the main ventilation fans may be taken into account provided that the main ventilation is able to operate together with the emergency ventilation in the event of de-energization of the refrigerator machinery distribution switchboard.

9.8 REFRIGERANT STOREROOMS

9.8.1 Refrigerant storerooms shall be separated from other spaces; their location onboard and the construction of the boundaries shall comply with the requirements of Part III of the Rules.

Refrigerant storerooms shall be gas-tight.

9.8.2 The refrigerant reservoirs shall be fastened in such a way as to prevent their shifting at rolling motions of a ship.

Non-metal spacings shall be placed between the bottles and the storeroom plating as well as between particular bottles.

9.8.3 Refrigerant storerooms shall be fitted with an independent ventilation system and shall be insulated in such a manner that the inside temperature can not exceed 45 °C.

9.8.4 In the room where the refrigerant store is kept reservoirs with other compressed gases shall not be kept. No combustible materials may be used for the room fitting.

9.8.5 The refrigerant may be stored in fixed receivers if the receivers and the rooms where they are located, comply with the requirements of 9.7.5, 9.7.7, 9.13.1, 9.13.2, 9.13.4, 9.16.5, and 9.16.6.

It shall be possible to discharge the refrigerant of Group II from the discharge pipe of each receiver after the system has been filled or replenished.

Discharge pipes from the refrigerant storage receivers shall not be laid through accommodation and service spaces.

9.9 COOLED CARGO SPACES

9.9.1 Refrigerating equipment, batteries, devices as well as pipelines and air pipes located in cooled spaces shall be secured and protected against damage by the cargo.

9.9.2 Air coolers of air cooling systems may be located both in separate spaces and in
cooled cargo spaces. When installed in cooled cargo spaces, the air coolers shall be fitted with a condensate collector. For cooled spaces with temperatures below 0 °C it is recommended to provide condensate collectors with a heating system.

No air coolers with direct evaporation of refrigerants of Group II may be used.

9.9.3 If air coolers of air cooling systems are installed in a separate room, they shall be accessible when the cargo space is completely loaded. Where this is impracticable, air coolers shall be accessible from the adjacent non-cooled neighbouring spaces. Dimensions of the opening for passage to the air cooler room shall be sufficient to permit the fan impeller and the electric motor to be carried through.

9.9.4 Where air cooling channels pierce tight bulkheads, the latter shall be equipped by sluice valves rated for the same pressure as the bulkheads. The sluice valve controls shall be located in accessible places above the freeboard deck.

9.9.5 For transportation of cargoes that require air change in cooled cargo spaces to ensure its safety, a ventilation system shall be provided that ensures supply of clean atmospheric air, cooled or heated, into the cargo spaces.

9.9.6 Each inlet and outlet in the bulkheads or enclosures of the cooled cargo spaces shall be supplied with air-tight closers.

9.9.7 Air channels laid through the cooled spaces to other spaces shall be sealed and insulated.

9.9.8 Where refrigerating plants are fitted with air cooling system of cargo holds with direct evaporation of refrigerant of Group II in the air coolers, an independent ventilation system shall be provided for each hold or a group of such holds.

9.9.9 Cooled spaces shall be equipped with telethermometric arrangements. Otherwise these spaces shall be equipped with at least two thermometric tubes with a diameter not less than 50 mm.

Thermometric tube sections laid through non-cooled spaces shall be insulated.

9.9.10 Drainage of the cooled spaces shall be accomplished according to the requirements of 10.7.40 to 10.7.43.

9.10 FREEZING AND COOLING CHAMBERS

9.10.1 Air coolers and fans shall be located within freezing chambers according to the requirements of 9.9.1 and 9.9.3.

9.10.2 The refrigerating machinery room shall be equipped with devices for controlling the operation of freezing and cooling apparatus using the direct evaporation system.

9.10.3 Where the direct evaporation system of refrigerant of Group II is used in the freezing chamber, an emergency exhaust ventilation is required and the chamber shall be gastight.

9.10.4 Valves of pipelines running into the freezing chamber shall be located outside the chamber.

9.10.5 It shall be possible to open freezing and refrigerating chambers from inside even if the doors are closed from outside.

9.11 SPACES CONTAINING PROCESS EQUIPMENT

9.11.1 Compressors, pumps, apparatuses and vessels operating under refrigerant pressure shall be located in the refrigerating machinery room.

9.11.2 Spaces containing the process equipment using the direct evaporation system of refrigerant of Group II, shall be fitted with a fire hydrant with a hose connected to the water fire-extinguishing system.

9.11.3 Spaces containing the process equipment shall be fitted with an independent ventilation. In addition to the main ventilation, spaces which contain the process equipment using the direct evaporation system shall be fitted with emergency ventilation.
The number of air changes per hour of the main and emergency ventilation systems shall comply with the requirements of 9.7.6 and 9.7.7.

9.11.4 Spaces containing the process equipment using the direct evaporation system of refrigerant of Groups II and III, shall be fitted with two exits in accordance with 9.7.3 and 9.7.4. Where refrigerant of Group II is used, these exits shall be equipped by the water-screen arrangements. The water screen starting device shall be located outside the room in the immediate proximity to the exit door.

9.12 COMPRESSORS, PUMPS, FANS

9.12.1 Compressors shall comply with the requirements of 7.6.8, 7.7 and the present Section.

9.12.2 Strength of the compressor parts subject to dynamic loads and excessive pressure during operation shall be rated on the assumption of the design pressure values in accordance with 9.3.2.

9.12.3 Compressors arranged on the refrigerant suction and discharge sides shall be fitted with shut-off valves regardless of automatically controlled valves’ availability.

9.12.4 Refrigerant, oil and cooling water cavities shall be equipped with drain arrangements.

9.12.5 A safety valve or any other self-operating safety device bypassing the refrigerant to the compressor suction side at excessive pressure rise above the permissible value according to the requirements of the operating documentation shall be fitted on the discharge line of the intermediate and final compression stages of the compressor between the discharge chamber and the shut-off valve. The discharge capacity of the safety device shall be not less than the maximal volume or bulk flow of the protected compressor stage.

The pressure rise after opening the safety valve shall not exceed the opening pressure by 10 per cent.

No shut-off devices are permitted on the bypass line.

9.12.6 Pumps shall comply with the requirements of 7.8.

9.12.7 Fans shall comply with applicable requirements of 7.9.

9.13 HEAT EXCHANGERS AND PRESSURE VESSELS

9.13.1 Heat exchangers and pressure vessels included in the refrigerating plants as pertaining to materials and valves shall comply with the requirements of 8.17 (except for 8.17.8 and 8.17.10), 8.18 (except for 8.18.1 to 8.18.4, 8.18.7, 8.18.8) and this Chapter. Strength calculations for them shall be fulfilled considering 8.19.1.

9.13.2 Shell-and-tube heat exchangers and vessels with the refrigerant chamber capacity of 50 dm³ and over shall be fitted with safety valves of such design discharge capacity as to prevent the pressure rise by more than 10 per cent of the opening pressure at full opening of the safety valve.

The discharge capacity $G$ shall be not less than that determined by the formula, in kg/s,

$$G = \frac{qS}{r},$$

where $q$ — heat flow intensity in the event of fire, in kW/m² (taken equal to 10 kW/m² in all cases);

$S$ — area of the vessel (apparatus) outer surface, in m²;

$r$ — specific heat of refrigerant evaporation at the opening pressure of the safety valve, in kJ/kg.

Safety devices shall consist of two safety valves and a changeover device providing connection of at least one safety valve to the vessel or apparatus in all cases. Each valve shall be rated for the full discharge capacity.

No shut-off valves may be installed between the apparatus or vessels and the safety device.

9.13.3 Pressure apparatus and vessels shall be fitted by discharge devices for the discharge of air, water, lubricating oil and liquid coolant.
9.13.4 Apparatus and vessels containing liquid refrigerant of Groups II and III shall be fitted with emergency discharge devices for the refrigerant.

The design drainage period of the refrigerant shall not exceed 2 minutes at constant excessive pressure of the refrigerant in the vessel (apparatus) being equal to the design pressure taken in accordance with 9.3.2.

9.14 AIR COOLERS

9.14.1 The evaporators of air coolers with direct evaporation of the refrigerant shall have welded or soldered structure. Flanged joints between sections and pipelines are normally not used, but if it is impossible to make welded or soldered joints the flanged joints shall be located in places accessible for leak tests.

9.14.2 Where a single air cooler is used for cooling of the cargo spaces, its evaporator shall consist of at least two independent sections with each section capable of being shut-off separately.

9.15 VALVES AND FITTINGS. SAFETY VALVES

9.15.1 Refrigerating plant systems shall be fitted with shut-off, control and safety valves rated for pressure of at least 1.25p, where p is the design pressure taken in accordance with 9.3.2.

Valves shall be made of steel. Application of built-in shut-off valves made of lamellar graphite cast iron for inlet and outlet cavities of the refrigerator compressors as well as valves made of nodular cast iron is allowed for refrigerants of Groups I and II at the medium temperatures not lower than –40 °C.Π

9.15.2 The safety valve spring attachments shall provide opening of the safety valves at a pressure not exceeding the design pressure according to 9.3.2 by more than 10 per cent.

9.16 PIPING

9.16.1 Piping of the refrigerant, liquid coolant and cooling water systems shall comply with applicable requirements of Section 10 and the present Chapter.

Piping for refrigerants of Groups II and III as well as the piping sections containing liquid refrigerant of Group I belong to Class I piping according to Table 10.1.2.

9.16.2 The refrigerant and liquid coolant pipelines shall be made of seamless pipes. The liquid coolant pipelines shall be made of steel pipes.

9.16.3 The refrigerant discharge lines of compressors and pumps shall be fitted with retaining (non-return) valves. The latter are not required for compressors using refrigerants of Group I and not fitted with discharge facilities.

9.16.4 Liquid piping of refrigerants with low water solubility shall be fitted with desiccating facilities for moisture absorption. The latter shall be installed either together with filters or structurally combined with them.

9.16.5 The refrigerant drainage pipes from the safety valves other than those specified in 9.12.5 shall be led overboard below the waterline corresponding to the minimal draught of a ship. These pipes shall be fitted with the refrigerant leakage detectors and retaining valves installed in the immediate proximity of the ship’s side. Refrigerants of Group I may be discharged into the atmosphere in the places non-hazardous for people.

9.16.6 Refrigerant emergency drainage pipes from the apparatus and vessels shall be led to the emergency drainage manifold located outside the refrigerating machinery room but near the entrance thereto. Each drainage pipe shall be fitted with shut-off valves and refrigerant leakage detectors behind the each valve. The valves shall be protected from access of unauthorized personnel and be adapted for sealing in the closed position.

The common line from the overboard drainage manifold shall be fitted with retaining valve and be led overboard below the waterline corresponding to the minimal draught of a ship. Compressed air or steam feeding line shall be provided for purging the common line.
The inner diameter of the refrigerant emergency drainage pipe from single apparatuses or vessels shall be not less than the safety valve diameter determined by valve capacity according to 9.13.2. Cross-sectional area of the overboard drainage manifold shall be not less than the sum of the cross-sectional areas of three largest emergency drainage pipes from single apparatus and vessels connected with the manifold.

9.16.7 The minimal wall thickness of the sections led overboard below the waterline according to 9.16.5 and 9.16.6 shall be taken not less than specified in column 3 of Table 10.2.13.

9.17 INSTRUMENTS

9.17.1 Compressors, units and piping of the refrigerating plant shall be fitted with control and monitoring devices for checking the parameters of working media and the performance characteristics. In addition, a provision shall be made for installation of control and monitoring devices for testing.

9.17.2 Instrumentation shall be installed in accessible and illuminated places. Maximal and minimal permissible values of the controlled parameters checked shall be indicated on the instrumentation scales.

9.18 AUTOMATION MEANS

9.18.1 Automation systems including their elements and joints shall comply with applicable requirements of Section 11.

9.18.2 When the refrigerating plant is controlled automatically, manual control shall be available also.

Where the two automatic devices operating in parallel are provided, manual control may be dispensed with.

9.18.3 The refrigerant compressors shall be necessarily fitted with automatic devices disconnecting its drive in the event of:

1. impermissible (hereinafter as compared to the value specified in the technical documentation of refrigerating plant) suction pressure drop;
2. inadmissible rise of the discharge pressure;
3. inadmissible drop of the lubricating oil pressure;
4. inadmissible rise of the discharge temperature (for refrigerating plants using the refrigerants of Groups II and III as well as automated plants with unattended operation);
5. inadmissible axial displacement of the centrifugal compressor rotor;
6. inadmissible rise of temperature of the centrifugal compressor friction bearings.

9.18.4 Liquid separators, intermediate vessels and circulation receivers (where pump circulation system of the refrigerant is used), as well as free-level type evaporators shall be fitted with automatic devices that ensures the following:

1. maintaining either constant level of the refrigerant required for normal operation of the evaporator or constant vapour overheating temperature;
2. stopping the feeding of the liquid refrigerant to the evaporators and intermediate vessels of all types at the compressor switching off;
3. switching off the compressor in the event of inadmissible rise of the refrigerant level.

9.18.5 Installations with shell-and-tube type evaporators shall be fitted with automatic devices switching off the compressor in the following cases:

1. flow of the liquid coolant through the evaporator is interrupted, or this evaporator is disconnected from the refrigerant system;
2. in case of inadmissible drop of the liquid coolant temperature.

9.18.6 Refrigerating plants shall be fitted with alarm devices sending warning to the refrigerating plant control station in case of actuation of the automatic protection devices specified in 9.18.3 to 9.18.5.

It shall be possible to decode the above signals at the local control station of the refrigerating plant.

9.18.7 Where entirely automated refrigerating plant is used, the wheelhouse shall be fit-
ted with an alarm device which is actuated when the temperature inside the cooled spaces deviates from the admissible value required for the given type of cargo.

9.18.8 Each room where pressurized refrigerant equipment is located shall be fitted with gas analysers and refrigerant leakage alarm devices. The alarm signals shall be sent to the refrigerating plant control station.

9.18.9 Automated refrigerating plants shall comply with the requirements of Section 11 of this Part.

9.19 INSULATION OF THE COOLED SPACES

9.19.1 All metal parts of the hull located inside the cooled cargo spaces shall be insulated.

9.19.2 Insulation of the cooled cargo spaces shall be made of biostable odourless materials.

9.19.3 Surfaces of bulkheads and inner bottom plating in the fuel tanks area shall be coated by oil-resistant odourless material. The coating shall be applied prior to insulating those surfaces.

9.19.4 Insulation of the cooled cargo spaces shall be either protected against penetration of moisture or fitted with effective drainage means during operation; it shall also be protected against damage by rodents.

9.19.5 Insulation of the cooled cargo spaces shall be covered by lining or any other suitable coating. Insulation coating shall be protected in the places which can be damaged by the cargo.

9.20 INSULATION OF PIPELINES

9.20.1 Pipelines in the places where they penetrate the bulkheads and decks shall not have direct contact with the latter to avoid heat exchange.

9.20.2 Insulation of the pipelines shall be protected against moisture penetration.

9.20.3 Insulation of pipelines shall be made of non-combustible heat-insulating materials according to the requirements of Part III of the Rules. This requirement is not applied to insulation of the pipes located within cooled cargo spaces and storerooms.

9.20.4 Anti-condensate materials and adhesives used with insulation and insulation of pipeline valves shall comply with the requirements of Part III of the Rules.
10 SYSTEMS

10.1 GENERAL PROVISIONS

10.1.1 Requirements of the present Section of the Rules apply to the following systems used in ships:
- .1 bilge and drain systems;
- .2 ballast systems;
- .3 cargo systems of oil tankers;
- .4 air, gas-freeing, overflow and sounding pipes;
- .5 exhaust gas systems;
- .6 fuel systems;
- .7 lubricating oil systems;
- .8 cooling water systems;
- .9 compressed air systems;
- .10 ventilation systems;
- .11 steam and boiler blow-down systems;
- .12 liquefied gas systems;
- .13 toxic media systems;
- .14 feeding and condensate systems;
- .15 open-ended steam pipes from safety valves;
- .16 tank cleaning and washing systems;
- .17 hydraulic drive systems.
- .18 with high-temperature organic heat transfer fluid;
- .19 cargo heating.

Requirements to systems and pipelines are set out in the relevant Sections of this Part and other Parts of the Rules. For the requirements to cargo heating system, see 4.19 Part IX of the Rules.

The requirements described in 10.1.2, 10.2, 10.3, 10.4, 10.5 and 10.6 also apply to ship systems ensuring ship’s habitability for the crew and passengers (systems of steam and water heating, fresh water, etc.), if applicable to the specified systems.

10.1.2 Depending on purpose and parameters of pumped media the pipelines in the present Rules are divided into 3 classes as indicated in Table 10.1.2. For each class of pipelines the joint types, heat treatment, welding procedures and methods and scope of testing are assigned.

### Medium parameters for pipeline classes

<table>
<thead>
<tr>

</tbody>
</table>

*see 10.2.12.

Note. 1. Piping with one of the above-stated parameters are Class I pipelines; piping with both parameters are Class II and Class III pipelines.
2. Cargo oil pipes of oil tankers and ships carrying dangerous cargos in bulk, as well as open-ended pipelines (draining, overflow, gas exhaust, air and steam discharge from valves), are class III pipelines.
10.2 PIPELINES
Material, manufacturing and application

10.2.1 Materials used in the manufacturing of pipes and valves shall comply with the requirements of Part X of the Rules shall be complied with.

10.2.2 Steel pipes intended for manufacturing of Class I and Class II pipelines as well as for the following Class III pipelines:
1. bilge and drain pipelines;
2. feed water pipelines;
3. ballast pipelines (if they are used as fuel pipes or laid through the fuel tanks);
4. fuel oil, lubricating oil pipelines;
5. fuel and lubricating oil heating coils;
6. boiler steam and circulation pipelines;
7. compressed air systems;
8. hydraulic pipelines,
shall be seamless or welded if they are equivalent to weldless pipes by density and strength.

Pipes and valves made of carbon steel and carbon-manganese steel shall be used for media with a temperature not exceeding 400 °C; those made of low-alloy steel — with a temperature not exceeding 500 °C.

It is allowed to use carbon and carbon-manganese steels for media with temperature exceeding the permissible one, provided their mechanical properties and long-term strength within 100 000 h are guaranteed by the steel manufacturer at such high temperature; the same shall be specified in the accompanying documentation.

Pipes and valves for media with a temperature above 500 °C shall be made of alloy steel. This requirement does not apply to exhaust gas pipes.

10.2.3 Copper pipes for pipelines of Classes I and II shall be seamless.

Pipes and valves made of copper and copper alloys shall be used for media having a temperature not exceeding 200 °C and those made of copper-nickel alloys — for temperatures not exceeding 300 °C. Bronze valves can be used for media having a temperature of up to 260 °C.

10.2.4 Nodular cast iron may be admitted for pipes and valves of bilge, ballast and liquid cargo piping laid inside the double bottom space or cargo tanks.

Nodular cast iron valves may be admitted for media with a temperature not over 350°C.

Side valves and side branch pipes, as well as valves fitted on the collision bulkhead and in fuel and lubricating oil tanks, can be made of nodular cast iron of entirely ferritic structure according to requirements of 2.11 Part X of the Rules shall be complied with.

10.2.5 Piping made of lamellar graphite cast iron may be used for cargo and ballast tanks of tankers except clean ballast pipelines laid through the cargo tanks.

Pipes and valves made of lamellar graphite cast iron may also be used for cargo lines on the open deck, excepting the end sections and valves of cargo piping for connection to the cargo hoses.

However, lamellar graphite cast iron shall not be used for:
1. valves for media with a temperature above 220 °C;
2. pipes subject to water hammer;
3. pipes directly connected to the outer shell plating;
4. valves fitted on the hull plating and the collision bulkhead;
5. valves arranged on fuel and lubricating oil tanks under static head, unless they are protected against mechanical damage.

10.2.6 Pipes made of aluminium alloys may be used for handling media with temperature nor exceeding 150 °C if the measures for protection of pipelines against contact corrosion are taken.

10.2.7 Application of plastic pipelines shall comply with Table 10.2.34.

10.2.8 The plugs and threaded portion of deck bushes of sounding pipes on the open decks shall be of bronze or brass.

10.2.9 Self-closing valves of sounding pipes in fuel oil tanks shall prevent formation of sparks. Sight glasses on fuel and lubricating oil pipelines shall be heat-proof.
Piping bend radii

10.2.10 The inner bending radius of steel, copper and aluminium pipes handling media under a pressure above 0.5 MPa or having a temperature over 60 °C, as well as bending radius of pipes intended for homing action shall be at least 2.5\(d_1\) (\(d_1\) is the outer diameter of the pipe).

Bending of a lesser radius may be permitted provided that no thinning of the pipe wall occurs during the bending.

The inner bend radius of the boiler blow-off pipes shall be at least 3.5\(d\) (\(d\) is inside diameter of the pipe).

Bend radius of pipes used in other conditions than those mentioned herein can be lessen to 1.5\(d\) in case of machine bending.

Heat treatment of pipes

10.2.11 For the requirements to heat treatment of pipes after bending, see 2.4.9 Part X of the Rules shall be complied with.

Pipe wall thickness

10.2.12 The wall thickness \(s\), in mm, of metal pipes operating under the internal pressure shall be not less than determined by the formula:

\[
s = s_0 + b + c, \quad (10.2.12-1)
\]

where \(s_0\) — basic thickness of a wall, in mm:

\[
s_0 = d_p/(2\sigma_{\text{lim}} \varphi + p);
\]

\(d\) — outside diameter of a pipe, in mm;

\(p\) — design pressure (maximum working pressure that shall be assumed equal to the maximum opening pressure of safety valves or hydraulic test pressure in cases where safety valves are not provided), in MPa.

For pipelines of carbon dioxide fire extinguishing systems (from the bottles to the starting valves) \(p\) shall be assumed equal to the design pressure of bottles.

For pipelines with fuel heated to temperature over 55°C the design pressure shall be taken not less than 1.4 MPa;

\(\sigma_{\text{lim}}\) — permissible stress, in MPa;

\(\varphi\) — strength factor taken as 1 for seamless pipes and welded pipes which are considered to be equivalent to seamless pipes;

\(b\) — allowance for actual reduction of pipe wall thickness due to bending, in mm; it shall be chosen in such a way that the stresses in the bent part of the pipe due to internal pressure do not exceed the permissible stresses.

Where precise values of thickness reduction after bending are not known, the allowance is determined by the formula:

\[
b = 0.4d s_0/R, \quad (10.2.12-2)
\]

\(R\) — mean radius of the pipe bend, in mm;

\(c\) — corrosion allowance, in mm, adopted from Table 10.2.12-1 for steel pipes and Table 10.2.12-2 for non-ferrous metal pipes. For pipes manufactured of corrosion-resistant alloys in accordance with GOST 5632 the corrosion allowance can be reduced to zero.

</tr>
</tbody>
</table>

**Notes:**
1. If the pipes have corrosion protection, the corrosion allowance can be reduced by not more than 50 %.
2. Where pipes of special steel alloys with sufficient corrosion resistance are used, the corrosion allowance may be reduced to zero.

<tr>
<td>Copper-nickel alloy 70/30</td>
<td>360</td>
<td>81</td>
</tr>
</tbody>
</table>

Note. The permissible stresses for intermediate values of $\sigma_{lim}$ should be determined by linear interpolation.

For the pipes laid inside the tanks the corrosion allowance stated in Table 10.2.12-1 shall be increased by the corrosion allowance for the external medium influence which is assumed for the appropriate medium in accordance with the present Table.

For carbon or alloy steel pipes the permissible design stresses are chosen equal to the lowest of the following values: $R_m/2,7$; $R_{y,\alpha}/1,8$; $R_{\sigma,\alpha}^{100000}/1,8$; $R_{\sigma,\alpha}^{100000}/1,0$, where $R_m$ — tensile strength of the pipe material, in MPa; $R_{y,\alpha}$ — minimum yield strength or proof stress at the design temperature, in MPa; $R_{\sigma,\alpha}^{100000}$ — ultimate long-term stress to produce rupture in 90 000 h at design temperature, in MPa; $R_{\sigma,\alpha}^{100000}$ — ultimate stress to produce 1% creep in 90 000 h at design temperature, in MPa.

The design temperature $t$ for determining permissible stresses is taken equal to the maximum temperature of the media inside the pipes.

The determining of permissible stresses on the long-term strength and on the creep limit is not required.

For copper and copper alloy pipes which have undergone heat treatment the permissible stress is taken according to Table 10.2.12-3.

In case of using pipes having negative manufacturing allowance for the wall thickness, the pipe wall thickness shall be determined by the formula, mm:

$$s_i = s/(1 - 0.01a),$$ (10.2.12-3)

where $s$ — pipe wall thickness calculated by the formula (10.2.12-1); $a$ — negative manufacturing tolerance for pipe wall thickness, in %.

10.2.13 Wall thickness of steel, copper and copper-alloy pipes shall be not less than the values stated in Table 10.2.13. If corrosion-resistant steel and titanium pipes are used, their wall thickness is determined by results of pipe strength calculations agreed with the River Register.

10.2.14 Wall thickness of plastic pipes are determined according to national standards.

10.2.15 Heat exchangers and pressure vessels used in the systems shall meet the requirements of Section 8 of this Part.

Protection of pipelines against excessive pressure

10.2.16 The pipelines where pressure may exceed the design value shall be fitted with safety devices preventing the pressure rise in the pipelines over the design pressure.

Fuel and lubricating oil shall not be bled off from the safety valves in an open way.

10.2.17 If a pipeline is fitted with a reducing valve, a pressure gauge and safety valve shall be provided after it.

Bypass of the reducing valve is permissible.

1 GOST 29325, GOST ISO 4065, GOST 18599, GOST R ISO 3126.

protected rooms and in carbon dioxide cylinder room;

.5 screwed nipple joints — for pipelines of all classes with inner diameter of 32 mm and less. The number of screwed nipple joints shall be kept to a minimum.

10.2.19 Flange connections of pipelines shall correspond to the following types shown on Fig. 10.2.19.

Fig. 10.2.19 Types of flanged joints and pipelines

Dimensions of flanges shall comply with the national standards1.

Note. In tapered threaded connection of pipes of type D, if necessary, the pipe shall be flared after the flange is fitted.

10.2.20 Type of flange connection shall be chosen depending on the pipe class in compliance with the requirements of Table 10.2.20.

The following galvanic intrinsic safety means shall be provided on pipelines of any purpose intended for connection of pipelines from the shore or other ship and located in explosive zones and spaces:

.1 electrically insulating joints (flanged or of other type), electrically insulating supports or non-conductive pipe sections with total insulation resistance from the hull of at least 10 kOhm;

.2 electrically insulating mats, plates and guards to prevent contact between metal parts of the piping from the shore or other ship and the hull. This requirement applies also to ships in service.

10.2.21 Material for gaskets shall be resistant to the media conveyed.

Gaskets in the joints of the fuel pipelines shall provide tightness at temperatures of the media conveyed of not lower than 120 °C.

10.2.22 Flexible joints shall be fitted with flanges or nipples at the ends. Flexible joints shall be located in easily accessible places. It shall be possible to shut down these joints by valves from the fuel oil, lubricating oil, compressed air and cooling water systems to replace the flexible joint in the event of breakage.

Flexible joints shall be of fire-resistant type when being used in pipelines of the following types:

pipelines for conveying fuel oil and lubricating oil;
used for delivery of other flammable fluids if a damage of the joints can cause danger to the ship or people;
driving watertight doors;
connected to holes in the outer shell plating (including the bilge system).

Note. A fire-resistant joint is a joint that, being attached to the pipeline filled with water and having an open end, withstands the temperature of 800 °C during 30 minutes and is watertight in the following testing by the design pressure.

Material of flexible joints shall be chosen with due regard to the media used, pressure, temperature and environment conditions. The bursting pressure of flexible joints shall at least 4 times exceed the design pressure.

Flexible joints being used in hazardous spaces shall be electrically conductive.

Testing of welds

10.2.23 The control of welded joints using non-destructive methods shall be accom-

Notes. 1. For the type of flange connection see Fig. 10.2.19.
2. The type B* joint shall be applied only for pipes with outside diameter not exceeding 150 mm.
3. The type F connections are used only for water pipelines.

Testing of electrical resistance

10.2.24 Electrical resistance of each flexible joint intended for use in explosive rooms and spaces shall be tested prior to installation of the joint. Electrical resistance between any two points of such flexible joint shall not exceed $1 \times 10^6$ Ohm.

Corrosion protection

10.2.25 Steel pipes of outboard water, as well as air, measuring and overflow pipes of water, ballast and fuel tanks, gas outlet pipes of cargo tanks, air pipes of cofferdams of oil tankers after bending and welding, shall be protected against corrosion.

10.2.26 In the process of design and installation of ship pipelines of overboard water the design measures shall be taken to reduce the corrosive and erosive wear of pipelines.

10.2.27 Pipelines for corrosion-active medium shall be made with minimum number of bends. Bending radii shall be not less than 2.5 of their outer diameters.

If it is not possible to keep to these bending radii, for example, in confined places, special fittings shall be used.

Do not apply welded bends made of pipe sectors with nominal diameter less than 200 mm. Bend of 90° shall have at least three sectors.

Do not apply bent or welded fittings for manufacture of side or sea chest branch pipes.

10.2.28 Use of tee-joints, legs and nipples for connection of branches, welded pieces and other elements shall not cause reduction of flow area of the main in places of their installation.

10.2.29 The flow rate determined by the formula (10.2.29) for pipeline sections with welded fittings (tee-joints, welded branches, etc.), orifice plates, as well as side and sea chest branch pipes, shall not exceed the values stated in Table 10.2.29.

Compliance of the design flow rate in pipeline sections specified in this paragraph and sea chest connecting passages with the present requirements shall be proved by calculation by the formula, in m/s:

<table>
<thead>
<tr>
<th>Pipeline material</th>
<th>Permissible flow rate, m/s</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steel, including zinc-coated steel</td>
<td>2.5</td>
</tr>
<tr>
<td>Copper</td>
<td>0.9</td>
</tr>
<tr>
<td>Copper-nickel alloys: ( \text{M} \text{J} \text{K}5-1 )</td>
<td>2.0</td>
</tr>
<tr>
<td>( \text{M} \text{J} \text{K} \text{M} \text{t}10-1-1 )</td>
<td>2.5</td>
</tr>
<tr>
<td>( \text{M} \text{J} \text{K} \text{M} \text{t}30-1-1 )</td>
<td>3.5</td>
</tr>
<tr>
<td>Aluminium brass</td>
<td>2.0</td>
</tr>
</tbody>
</table>
Notes. 1. In pipelines with fittings having radii of rounding in places of connection to the main of 0.15 diameters of the latter and more, bent branches with bending radius exceeding 2.5 of outer diameter without welded bends and orifice plates the flow rate can exceed the values stated in Table by 30%.

2. In drenching, water-screen, sprinkling and ballast systems the permissible flow rates irrespective of design version of used components of pipelines can exceed the values specified in the Table by 30%.

\[ V_m = 0.354 \times 10^{-3} \frac{Q}{d^2} \]  \hspace{1cm} (10.2.29)

where \( Q \) — maximum flow rate on the gage section, in m³/h;
\( d \) — pipeline inner diameter, in mm.

10.2.30 If non-ferrous alloy bottom and side valves are used, the hull plating and all components of the system contacting these valves shall be protected from contact corrosion. Sacrificial anode system against contact corrosion of receiving and discharge welded branch pipes with valves shall be made with use of standard bracelet type end sacrificial anodes or bracelet type interflanged sacrificial anodes installed on branch pipe flanges. Mated elements shall have electrical insulation. Bottom and side valves shall have insulation from both sides.

10.2.31 When connecting sea water steel pipelines with valves and cases of pumps, units and heat exchangers made of non-ferrous alloys, the measures shall be taken to protect from contact corrosion as specified in 10.2.30.

Plastic pipelines

10.2.32 The requirements of 10.2.33 to 10.2.54 apply to pipelines and pipeline components made of the following types of plastic:

1. thermoplastic and thermosetting plastic materials with or without reinforcement;

2. polyvinyl chloride (PVC);

3. fibre reinforced plastic (FRP).

10.2.33 Plastic pipes and pipelines components of ship systems responsible for damage control and floodability shall be fire-proof (see 1.2.1.9, 1.2.1.13 Part III of the Rules).

10.2.34 Depending on pipeline ability to maintain integrity during fire resistance tests, the following three levels of fire resistance are specified:

L1 — for pipelines which withstand the fire resistance tests in dry condition during 1 h;

L2 — for pipelines which withstand the fire resistance tests in dry condition during 30 min;

L3 — for pipelines which withstand the fire resistance tests in filled condition during 30 min.

For the scope of application of plastic pipelines depending on fire resistance level, location and supplied media, see Table 10.2.34.

Ship systems footnoted in Table 10.2.34 shall meet the supplementary requirements corresponding to the footnote number:

1. valves with remote control outside the room shall be provided on the ship’s side;

2. remotely closing valves shall be provided for cargo tanks;

3. if the cargo tanks contain inflammable liquids with flash point over 60°C, the "O" symbol may be used instead of "--" or "++";

4. for bilge pipeline servicing only the given space, the "O" symbol may be used instead of "L1";

5. when control functions are not provided, the "O" symbol may be used instead of "L1";

6. for the pipeline between machinery space and deck hydraulic gate the "O" symbol may be used instead of "L1";

7. for passenger ships the "++" symbol shall be used instead of "L1".
