D — cargo spaces of ro-ro ships;  
E — cargo spaces of dry cargoes and trunks;  
F — cargo tanks and trunks;  
G — fuel tanks and trunks;  
H — ballast tanks and trunks;  
I — cofferdams, dry compartments, etc;  
J — accommodation, service spaces and control stations;  
K — open decks.  

**Note.** The following symbols indicate:  
“+” — fire resistance tests not required;  
“*+” — only metallic materials with melting point over 925 °C are to be used.
10.2.35 Material of all pipes, except for pipes located on open decks, in tanks, cofferdams, pipeline tunnels, etc., shall have low flame spread properties (see 1.2.1.16 Part III of the Rules).

10.2.36 Where fire protective coatings are used to provide the fire endurance level required, they shall meet the requirements of 2.1.2.1 Part III of the Rules.

10.2.37 In cases described in 10.2.36 in the places of connections of the system the fire protective coatings shall be applied according to the requirements of 2.1.2.1 Part III of the Rules. These coatings are to be applied only after hydraulic tests of the system. The coatings shall be applied according to the recommendations of the pipe manufacturers.

10.2.38 Fireproof coatings are to be used according to the manufacturer’s instructions.

10.2.39 To select the supports and the distance between them, the permissible stresses and maximum permissible flexure of pipes specified by the pipe manufacturer shall be taken into consideration.

The distance between the supports shall not exceed the values determined by the manufacturer.

To select the supports and the distance between them, it is also needed to consider mechanical and physical properties of pipe material, weight of pipes and liquid in them, external pressure, operating temperature, effect of thermal expansion, external force loads, thrust forces, water hammers and vibration which can appear in the system.

10.2.40 Pipe weight load shall be uniformly spread over the entire bearing surface of the support. Measures shall be taken to minimize the wear of pipes in places of their contact with the supports, such as, for example, use of insulating rubber or fluoroplastic gaskets (sleeves).

10.2.41 Valves, expansion joints and other system components, the weight of which exceeds 2 kg, shall have separate supports.

10.2.42 During installation of pipelines the possible displacement of plastic pipes relative to steel hull structures due to difference of linear expansion coefficients of plastic and steel shall be taken into consideration.

10.2.43 For thermal expansion calculations the operating temperature of the system and installation temperature shall be taken into consideration.

10.2.44 During pipeline installation the temporary point loads shall be taken into consideration (where needed). Such allowance is to include at least the force exerted by a load (person) of 90 kg at mid-span on any pipe of more than 90 mm nominal outside diameter.

10.2.45 To ensure robustness for plastic piping, including open-ended piping, the minimum wall thickness complying is to be increased by 1 to 2 mm as compared to the thickness values calculated taking into account the conditions encountered during service on board vessels.

10.2.46 The pipes shall be protected from mechanical damages, if needed.

10.2.47 Piping systems conveying fluids with a conductivity less than 900 picosiemens per metre (pS/m), such as refined products and distillates, are to be made of conductive pipes.

10.2.48 Regardless of the fluid to be conveyed, plastic pipes passing through hazardous areas are to be electrically conductive.

The resistance of the pipes and fittings to the ground in any point of the piping system shall not exceed 10⁷ Ω. Electrically conductive layers of pipes and mated pipeline components shall have equal conductivity. Otherwise, the pipelines shall be protected from damage by electrical discharges caused by different conductance of electrically conductive layers of pipes and mated pipeline components.

10.2.49 Upon completion of installation the quality of pipeline grounding shall be tested. Attachment points of grounding wires shall be accessible for inspection.
Connections of plastic pipes

10.2.50 The strength of connections shall correspond to the strength of pipeline in which they are installed.

10.2.51 The pipelines can be assembled with use of adhesive, welded, socket welded, flanged and slip-on joints.

10.2.52 Adhesives used for assembly of pipelines shall ensure tightness of joints in the entire range of possible operating temperature and pressure values.

10.2.53 The joints shall be tightened according to the manufacturer’s instructions.

Laying of plastic pipes

10.2.54 When laying plastic pipelines through watertight and fireproof decks and bulkheads of types A or B the requirements of 10.5 shall be met.

Ship hoses

10.2.55 The requirements of this section apply to ship hoses for reception and transfer of chemical cargo, crude oil, oil products, fuel, oil, oily waters and contaminated ballast waters and transfer of cargo vapours.

10.2.56 Only ready-made hoses consisting of hose pieces and end pieces (flanged branch pipes, nipples or other connections) shall be used onboard the ship.

10.2.57 The hose shall be made of rubber reinforced with textile band and (or) steel wire braiding. The hose can be additionally reinforced with one or several layers of wire spiral, rings or in a different way.

Hose material shall be resistant to conducted medium in the entire range of operating temperatures or its inner surface shall be covered with a special coating resistant to such medium.

10.2.58 The outer surface of hose shall be resistant to wear, attrition, sun rays and atmospheric phenomena and shall be impermeable for overboard water and transferred liquids. The outer surface can be covered with polyurethane or other material ensuring buoyancy. Such coating shall have similar properties with regard to external actions.

Design and material of hoses to be used for transfer of liquefied gases shall comply with the requirements of national standards.

10.2.59 End pieces shall be connected to the hose by mechanical or chemical method.

10.2.60 When welding is applied for the end pieces, it shall be carried out by welders having admission certificate of the River Register, and 90% of welded joints shall be exposed to non-destructive testing (see 8.2 Part X of the Rules).

10.2.61 The material of end pieces and flanges shall exclude the possibility of spark formation when contacting with the ship’s hull. The surfaces of end pieces shall be protected from corrosive action of overboard water and transferred medium.

10.2.62 The hose is considered buoyant if its buoyancy reserve when the hose is fully immersed in overboard water and fully filled with it is not less than 20%. The hose buoyancy reserve is calculated by the formula, in %:

\[
K = 100 \left( 1 - \frac{W_h - W_w}{W_h + W_w} \right),
\]

where \( B \) — weight of outboard water displayed by the filly immersed hose, including the weight of the overboard water displaced by the materials ensuring buoyancy and the weight of overboard water in the hose, in kg;

\( W_w \) — weight of outboard water in the hose, in kg;

\( W_h \) — weight of an empty hose in the air, including the weight of materials ensuring its buoyancy, in kg.

Any materials used to provide buoyancy shall be secured on the hose.

10.2.63 Floating hoses shall be of orange colour, or a strip of orange colour in the form of a spiral shall be applied on them. Strip width — 90 mm, spiral pitch — 450 mm. The strip is to be connected to external coating during vulcanization.

1 GOST 6286, GOST 18698.
10.2.64 To transfer the cargo from one ship to another one under way and in the course of cargo handling with use of single point mooring, the floating hoses shall be used. The hose lines shall have a device for emergency detachment.

When using hose lines with a device for emergency detachment, the water hammers which can appear upon device operation shall be taken into consideration; to prevent the water hammers, the flow rate of liquid shall be limited.

10.2.65 The following marking shall be clearly applied on both ends of each hose: manufacturer’s name or trademark; hose serial number by manufacturer’s data; month and year of hose manufacture; pressure ratings; electrical conductivity instructions.

10.2.66 Hoses shall be stored on board in places protected against exposure to direct sunlight and be coiled with due regard to a minimum bending radius and hose manufacturer’s recommendations. Design measures shall be taken to drain and remove cargo remains from the hoses. Store rooms for hoses shall comply with the applicable requirements of 2.5.1 to 2.5.4 Part III of the Rules.

10.2.67 Hoses with permissible nominal pressure not less than 0.034 MPa and vacuum not less than 0.014 MPa shall be used to transfer the evaporations of cargo. Hose bursting pressure shall be not less 5-fold nominal pressure of the hose. Last meter from each end of the hose shall be painted according to Figure 10.2.67 and have a “vapour” inscription made with black characters of at least 50 mm in height. Each flange shall have additional hole on the line of coupling bolts permitting to connect the flange to the connecting branch pipe for vapour delivery. Only electrically conductive hoses shall be used in the systems for vapour delivery to shore.

10.2.68 Electric equipment in systems with use of pipeline heating cables shall comply with the requirements of Part VI of the Rules.

10.2.69 The heating cable shall be installed after hydraulic tests of pipelines and application of corrosion-resistant coating.

10.2.70 Electrically heated pipelines in places of possible mechanical damages of heating cables shall be covered with protecting housings.

10.2.71 Warning notices “Caution! Electric heating!” shall be affixed to electrically heated pipelines and valves.

10.3 PIPELINE VALVES

Construction

10.3.1 The covers of valves with internal diameter over 32 mm shall be secured to valve bodies by bolts or studs. Threaded covers may be used for valves having internal diameter up to 32 mm inclusive, if stops are fitted on these covers.

The nut of plug in a cock shall be well locked to prevent self-unscrewing while handling the cock.

10.3.2 All valves which are provided with remote control are also to be designed for local manual operation.

10.3.3 Compressed air shall not be used in remote control systems of valves located inside the cargo tanks.

10.3.4 Where the valves inside the cargo tanks are remote-controlled by means of a hydraulic system, they shall be also operable with the aid of a hand pump connected to the hydraulic control system of each valve via a separate pipe or directly to the valve actuator.

10.3.5 The service tank of the hydraulic remote control system of the valves inside the cargo tanks shall be located above the top
level of the cargo tanks and all pipelines of the hydraulic system shall be led to the cargo tanks through its upper part.

The service tank shall also be fitted with an air pipe fitted with a flame arresters and led to a safe position on the open deck. This tank shall be fitted with audible and visual alarm being actuated in case the liquid level in the tanks is lowered down to the minimum permissible level.

Marking of valves

10.3.6 The shut-off valves shall be provided with clearly visible fixed nameplates with inscriptions indicating their purpose.

10.3.7 Remotely controlled valves at control stations shall have fixed identification plates indicating their purpose as well as “open” and “closed” position indicators.

Where the remote control is used only to close the valve, the indicators need not be fitted.

Arrangement and installation of valves

10.3.8 The valves fitted on watertight bulkheads shall be secured to welded pads by studs, or the valves may be installed on bulkhead pieces. The stud holes shall be blind.

10.3.9 Valves with a diameter exceeding 10 mm arranged on plastic pipelines shall be secured to the hull structures.

Filters

10.3.10 The design of filters shall enable periodic cleaning of filtering elements.

10.3.11 Filters shall be equipped with devices permitting to see that there is no working medium pressure in filters prior to their opening.

Tubes from such devices shall be brought to trays so as to prevent splashing of working medium.

10.3.12 Filters included in the systems with combustible working medium shall be equipped with interlock excluding the possibility of their opening in case of excessive pressure in the internal spaces of the filter and the possibility of ingress of working medium to the internal spaces of opened filters. If such interlock is not provided, the indelible and non-deformable warning inscription prohibiting opening of filter under pressure shall be applied on filter casing.

10.3.13 Filter casing shall be designed for strength under pressure not less than the test pressure during hydraulic tests of the system.

10.4 SEA CHESTS AND ICE BOXES. BOTTOM AND SIDE VALVES. OPENINGS IN THE OUTER SHELL PLATING

Construction and installation of valves

10.4.1 Bottom and side valves fitted below the freeboard deck level shall not be made of materials easily damaged by fire.

10.4.2 The spindles and closing parts of the bottom and side valves shall be manufactured of corrosion-resistant materials.

10.4.3 Sea chests and ice boxes shall be equipped with detachable gratings or manholes with covers to provide access inside the boxes. See also 5.6.29 Part II of the Rules.

10.4.4 In ships with ice strengthening one of the sea chests shall be ice sea chest. Ice boxes shall be so designed as to provide separation of ice and removal of air from the ice box to ensure operation of the outboard water system.

10.4.5 In ships strengthened for ice navigation, provision shall be made for the heating of the outboard valve boxes and ice boxes, as well as side valves and fittings located above the load waterline.

10.4.6 All discharge openings in the shell plating shall be provided with devices to prevent occasional sea water penetration inside the hull.

Overflow outlets of pipes other than those indicated in 10.4.7, led from spaces located below the freeboard deck as well as along the freeboard deck shall be fitted with check (non-return) valves with forced valve closing
from easily accessible places above the freeboard deck.

10.4.7 Outboard inlet and discharge holes of systems and pipelines of the power installation main and auxiliary machinery located in the machinery spaces shall have locally controlled valves or slide valves accessible for control and maintenance. Drives of the valve controls shall be fitted with an indicator showing whether the valve is open or closed.

The side discharge valves shall be of the non-return shut-off type. Such valve can be replaced with non-return valve or pipeline loop lifted above the highest cargo waterline.

10.4.8 The controls of inlet bottom valves shall be located in readily accessible places and shall be provided with an indicator showing whether the valve is open or closed.

In passenger ships these drives shall be located above the floor level of the machinery space.

10.4.9 Bottom and side valves are to be attached to welded pads.

The valves may be also installed on welded branch pipes provided that they are rigid. Branch pipe wall thickness shall not be less than the minimum thickness of the shell plating in the ship extremities, but not more than 8 mm.

The stud holes shall not penetrate the shell plating and shall be terminated in the welded pads. Gaskets made of lead or other materials which readily deteriorate in the event of fire are not shall not be used.

10.4.10 Side valves of boiler blown-down pipelines shall be attached to welded pads. Welded protective ring shall be fitted on the outer side of the plating.

Valves shall have a collar on the flange that comes through the welded pad, plating and protective ring. The collar on the flange is not needed if there is a collar on the welded pad.

Openings in the outer shell plating

10.4.11 Discharge pipelines of several ship systems can be output through one common opening of the corresponding cross-section in the shell plating of the hull. In these cases discharge pipelines of systems shall have arrangements preventing ingress of working medium from other discharge pipelines brought out through one common opening in the shell plating of the ship.

10.4.12 The location of outboard water inlet and discharge openings in the outer shell plating shall be such as to provide the following:

1. to prevent sucking of the discharged water, sewage, ash and other wastes by outboard water pumps;

2. to prevent the ingress of sewage and discharged water into the ship spaces through the side scuttles as well as discharge of water into the lifeboats and life rafts during launching.

If the requirement of 10.4.12.2 is not met, the discharge openings shall be fitted with appropriate arrangements to prevent ingress of discharged water into the ship spaces, lifeboats and life rafts.

10.4.13 The openings in the outer shell plating of outboard valve boxes and ice boxes shall be fitted with protective gratings. Holes or slots may be provided in the hull instead of gratings. The total area of the holes or slots shall not be less than 2.5 times the area of the outboard valve.

The hole diameter and the slot width in the gratings or outer shell plating shall be not over 20 mm.

The gratings of the sea chests shall be provided with a steam, compressed air or water blowing device. Blowing pipes shall be provided with non-return shut-off valves. The pressure of steam or compressed air in the blowing system shall not exceed 0.3 MPa.

10.5 PIPING ARRANGEMENT

General requirements

10.5.1 Pipes shall be secured in such a way as not to induce excessive stresses in the pipelines due to thermal expansion, the hull deformation and vibrations.
10.5.2 The pipes of the systems and the vent ducts shall be fitted with arrangements for draining or blow-down of the working medium or moisture.

Appropriate design measures shall be taken to protect the hull structures and the equipment from adverse effect of the blown products.

10.5.3 Pipelines conveying hot media and extended along the ship for at least 3 m shall have compensators or sufficient number of bends to provide adequate self-compensation of pipelines.

10.5.4 Piping of the hydraulic systems pipelines shall not be led inside the double-bottom space. Piping of the hydraulic systems shall not have detachable joints in hardly accessible spaces.

Piping penetration through watertight structures

10.5.5 Pipelines through impermeable bulkheads shall be laid considering the room structures and ship systems located in them. Minimum possible number of pipelines shall be laid through the impermeable bulkheads.

10.5.6 Only one pipeline conveying liquid medium to be processed in the fore peak may be routed through the collision bulkhead below the freeboard deck. Furthermore, if the pipeline is led outside the double bottom space, it shall be provided with a shutoff valve or a slide valve mounted on the bulkhead from the fore peak side with a drive located above the freeboard deck.

10.5.7 Penetrations of the piping through the watertight bulkheads, decks and other watertight structures shall be made using sleeves, welded pads or other joints providing tightness of the structures.

The holes for studs shall not penetrate these structures, but shall be kept within the welded pads.

10.5.8 Penetrations of plastic pipes through the watertight bulkheads and decks enclosing watertight compartments shall be fitted with valves with a drive located above the freeboard deck. In places where the plastic pipes pass through the bulkhead of the main vertical fire zone the bulkhead steel sleeves and shut-off valves shall be installed on both sides of the bulkhead.

The valves shall be made of steel or other material equivalent to steel as regards fire resistance properties.

Laying of piping inside the tanks

10.5.9 Laying of drinking water and boiler feed water pipelines through the fuel and lubricating oil storage tanks, and laying of fuel and lubricating oil pipelines through the drinking water and boiler feed water tanks is permitted only when the pipes are led in oil-tight ducts being a structural part of the tank.

Duct-free laying of outboard water and lubricating oil pipelines as well as air, overflow and sounding pipes through the fuel storage tanks is permitted if seamless pipes free of detachable joints inside the tanks are used (see Table 10.2.13).

10.5.10 In case of duct-free laying of the pipelines through the tanks pipe bends shall be arranged inside the tank, if the compensation of thermal expansion is required.

10.5.11 Pipelines laid in tankers shall meet the requirements of 10.9.7 to 10.9.18.

Laying of piping inside the cargo holds and other spaces

10.5.12 Pipes laid through the cargo holds, chain lockers and other spaces in which they are subject to mechanical damages shall be protected.

10.5.13 Fuel, steam and water pipes as well as pressure pipes of hydraulic drives other than drainage pipes shall not be laid inside the cargo holds.

These pipelines can be laid in tunnels only if the use is made of pipes with thick walls (see column 5 of Table 10.2.3) and protective steel casings.

10.5.14 Steam pipes and pipes conveying heated liquids shall not be led inside the paint
stores, lantern rooms or other spaces intended for carriage and storage of readily flammable materials.

10.5.15 Fuel pipelines shall not be laid through accommodation and service spaces. The exception is made for the fuel pipeline of emergency diesel generator and the fuel reception pipelines, which can be laid through sanitary spaces, provided the pipes have a wall thickness of not less than 4 mm and no detachable joints are employed.

Laying of piping in refrigerated spaces

10.5.16 The pipes shall not be laid through the cooled spaces, if they are not intended to serve these spaces. Where laying of such pipes cannot be avoided, they shall be insulated. This requirement is equally applied to air pipes and sounding pipes. In these spaces the pipes shall be free of sections in which water may accumulate and freeze.

Laying of piping in the vicinity of electrical and radio equipment

10.5.17 Pressure pipes shall not be laid neither above the main and emergency switchboards, control panels of the main engines and other essential machinery and equipment nor behind them.

Such pipes may be laid at least 400 mm away from the front and lateral sides of these switchboards and control panels. The pipes laid at a distance of less than 700 mm from the switchboards and control panels shall be free of detachable joints.

If the pipelines with flanged joints are led within the above-mentioned zone, the latter shall be protected by casings.

10.5.18 Laying of pipelines through special electrical spaces (see 2.1.1.15 Part VI of the Rules) and also through accumulator rooms is not allowed, except for carbon dioxide fire extinguishing pipelines and pipelines serving the electrical equipment installed in these spaces.

Laying of piping in unattended machinery spaces

10.5.19 Joints of Class I pipelines conveying fuel oil and lubricating oil shall be of welded type. It is allowed to use detachable joints, but protective casings shall be installed in the places where detachable joints are fitted.

10.6 HYDRAULIC TESTS

10.6.1 Hydraulic tests of valves and pipelines shall be carried out according to 6.2.55 to 6.2.61 and 6.3.45 to 6.3.50 of RTSC. The stresses arising during the hydraulic test shall not exceed 0.9 of the yield point at the test temperature.

10.7 BILGE SYSTEM

Pumps

10.7.1 Each self-propelled ship with the main engines’ total output of 220 kW and above shall be provided with at least two bilge pumps. One of these pumps, a mechanically-driven one, shall be fixed and connected to the bilge system. Self-priming mechanically-driven ballast, sanitary or general service pumps having a sufficient capacity may be used as bilge pumps. A pump driven by the main engine, a water-jet or a steam-jet ejector, if steam boiler is operating continuously, may be used as one of the bilge pumps.

10.7.2 On self-propelled ships with the main engines’ total output less than 220 kW at least two draining means shall be installed. One of them may be a mechanically-driven fixed pump or an ejector and the other — a hand pump with a capacity not less than indicated in Table 10.7.7.

In ships less than 25 m in length not fitted with water fire extinguishing system, one hand bilge pump may be installed. Drainage of compartments may be carried out with flexible hose.

10.7.3 If fire pumps are used as bilge pumps, follow the requirement of 3.3.13 Part III of the Rules.
10.7.4 Passenger ships of more than 100 m in length shall have three bilge pumps connected to the bilge main. These bilge pumps shall be driven from a power source. One of the pumps can be driven from the main engine.

Passenger ships of 100 m in length and less shall have two bilge pumps driven from the power source.

In ships with main engine capacity less than 220 kW one of two bilge pumps driven from the power source can be replaced with a hand pump with a sufficient delivery determined by results of bilge system calculations according to 1.6.2 Appendix 8 of RTSC.

10.7.5 Onboard the ship with water fire extinguishing systems the total capacity of bilge facilities shall be sufficient to remove onboard the water brought inside the ship during operation of these systems.

10.7.6 Non-self-propelled and floating objects fitted with power sources or being supplied from the shore, shall be equipped with drainage means in a same manner as self-propelled ships with the main engines' total output less than 220 kW.

Non-self-propelled and berth-connected ships not fitted with fuel oil fired steam boilers, except bulk oil barges, can have portable pumps as bilge facilities.

A capacity of the hand pump shall be not less than 3.5 m³/h.

10.7.7 In crewed non-self-propelled ships without power sources and not being supplied from the shore, mechanically-driven bilge pump may be omitted, however, the hand pump shall be of portable piston type with a capacity of not less than indicated in Table 10.7.7.

<table>

<tr>
<td>Over 200</td>
<td>8</td>
</tr>
</tbody>
</table>

Note: Definitions of L, B, H (ship’s length, breadth and depth) are given in Part I of the Rules.

If the required capacity of the pump exceeds that of the hand pumps, the ship shall be provided with portable ejector and a set of hoses ensuring the ejector’s operation from the fire mains of escorting ships.

10.7.8 On non-crewed non-self-propelled ships drainage may be carried out using a pusher or a roadstead ship means.

10.7.9 Centrifugal bilge pumps shall be of self-priming type; otherwise, the system shall be equipped with an air drawn-off device.

10.7.10 Each bilge pump other than the pumps intended for draining bilges and hand pumps of non-self-propelled ships, shall have the capacity determined on condition that the design water flow in the of suction branch of a diameter obtained by the formula (10.7.15), shall be not less than 2 m/s under normal service conditions.

10.7.11 The cargo pump rooms of oil tankers shall be drained by separate pumps or ejectors arranged in these rooms. Stripping pumps may be used as bilge pumps, provided that non-return shut-off valves are fitted at the open ends of the bilge suction and a shut-off valve is arranged on a pipe connecting the valve box and the stripping pump. These spaces can also be drained by hand pumps. The pumps shall be so designed as to prevent spark formation.

10.7.12 For draining fore compartments of oil tankers provision shall be made for a separate pump or ejector, which may be also used for filling and draining of the tanks intended only for ballast water.

10.7.13 To drain cargo spaces of bulk carriers of M-ClI 4,5 class, the pump (pumps) and (or) ejector with capacity (m³/h) of not less than 320A shall be installed, where A — free cross-sectional area of the greatest air or ventilation pipe brought to this space from the open part of the deck (m²).

For bulk carriers of M-ClI 4,5 class, the bilge and filling facilities located towards the bow from the collision bulkhead of ballast tanks and bilge wells of dry spaces, any part...
of which stretches towards the bow from the first fore hold, shall be actuated from the wheelhouse or the power installation control station or from a closed space, which can be accessed from the wheelhouse or power installation control station without passing through open decks of freeboard or superstructure.

10.7.14 On high-speed ships the number of bilge pumps and their capacity are selected by results of fire-extinguishing system hydraulic calculations according to 1.6.2 Appendix 8 RTSC.

Piping diameters

10.7.15 Inner diameter of the bilge main and branch bilge suction diameters directly connected to the pump shall be determined by the formula, in mm:

\[ D_i = 1.5 \sqrt{L (B + H)} + 25, \quad (10.7.15) \]

where

- \( L \), \( B \), \( H \) — ship's length, breadth and depth, see Part I of the Rules.

For worksite craft, \( L \) — the total length of drained compartments, in m.

10.7.16 Inner diameter of branch bilge suction diameters \( d_i \) connected to the main and the diameter of reception pipeline of the hand pump shall be determined by the formula, in mm:

\[ d_i = 2.0 \sqrt{l (b + H)} + 25, \quad (10.7.16) \]

where

- \( l \) — length of a drained compartment, as measured at its bottom, in m;
- \( b \) — width of a drained compartment, in m;
- \( H \) — ship's depth, see Part I of the Rules.

The value \( d_i \) shall not exceed \( D_i \) calculated by the formula (10.7.15).

10.7.17 In all cases the internal diameter of bilge pipelines shall be not less than 40 mm, in ships less than 10 m in length this diameter may be lessen to 20 mm.

The internal diameter of pipes connected to the bilge pump shall be equal to the internal diameter of bilge pump suction.

10.7.18 The cross-sectional area of the pipe connecting the distribution chest with the main bilge line shall be not less than the total cross-sectional area of two greatest branch bilge suction connected to that chest, but not greater than the cross-sectional area of the bilge main.

10.7.19 In ships where bilge pumps are intended for draining only the machinery space, the cross-sectional area of the main bilge line shall be not less than twice the cross-sectional area of the branch suction having the diameter determined by the formula (10.7.16).

10.7.20 The diameters of the emergency bilge suction in the machinery space shall be determined according to 10.7.28.

Pipelines and branch bilge suction arrangement

10.7.21 The bilge lines and their branch suction shall be arranged so as to enable any watertight compartment to be drained by one of the pumps required in 10.7.1 and 10.7.2. This requirement does not apply to the spaces and cofferdams of oil tankers drained by individual pumps, as well as to the tanks intended only for storage of liquids.

10.7.22 The system shall be arranged so as to prevent ingress of outboard water inside the ship or from one impermeable compartment to another one.

For this purpose the suction valves of the distribution chests of bilge lines as well as the valves on the branch suction shall be of non-return shut-off type.

Other equivalent arrangements are allowed.

10.7.23 Each separate bilge pump shall have a direct bilge suction from the compartment where it is installed. The internal diameter of the suction shall be determined by the formula (10.7.15)

10.7.24 The arrangement of the bilge pipes shall ensure draining of the machinery spaces through the suction directly connected to the pump, with the other compartments being simultaneously drained by other pumps.
10.7.25 The arrangement of the bilge pipes shall be such as to enable one of the pumps to operate in cases when the rest of the pumps are inoperative or used for other purposes.

10.7.26 If one pipeline coming forward of and abaft the pump located in the machinery space is available, the control of the non-return shut-off valves mounted on the suction pipes passing to the compartments being drained, shall be carried out from the freeboard deck.

10.7.27 Bilge pipes are not to pass through double bottom compartments. Where it is necessary to lead these pipes through the storage tanks for fuel, lubricating oil, boiler feed water and drinking water, the pipes shall meet the requirements of 10.5.9 to 10.5.11.

Where the pipe is led within the double-bottom space, the bilge suction in each watertight compartment shall be fitted with non-return valves.

10.7.28 In all self-propelled ships with the main engines’ total output of 220 kW and above, emergency draining of machinery spaces shall be provided in addition to the suction pipes required in 10.7.23. For this purpose the cooling water pump with the greatest capacity shall be fitted with the direct bilge suction fitted with a non-return shut-off valve installed at the level providing the drainage of the machinery space. The diameter of this bilge suction shall be equal to the diameter of the pump suction branch.

Where the aforementioned pump is not suitable for operation as an emergency bilge pump in the machinery space, a direct emergency bilge suction shall be led to the pump of greatest available capacity which is not a bilge pump. The capacity of such pump shall exceed the value specified in 10.7.7. The diameter of the emergency bilge suction shall be not less than that of the pump suction branch.

10.7.29 In ships where portable bilge pumps or draining from the tug-pusher are allowed, the drainage of the compartments may be carried out through the deck manholes using a flexible hose, provided that no cargo is stowed under the hose, or through the inlet riser pipes ending in a deck socket or a branch pipe to which the hose is connected.

10.7.30 Oily water separating and filtering equipment shall be used for purification of water before discharging overboard, or collecting tanks shall be provided for bilge water contaminated with oil.

The installation and operation of purification equipment shall not interfere with normal operation of the bilge and ballast systems.

10.7.31 The location and the number of branch bilge suctions shall be chosen by a designer in each particular case in accordance with the design and position of the compartments.

At least two branch bilge suctions of the bilge system shall be installed in each compartment being drained.

One branch bilge suction can be used in short (3 to 4 frame spaces) and narrow (less than 2 m) compartments if it provides draining of compartments.

10.7.32 Branch bilge suctions shall be installed in each compartment so as to provide the maximal extent of draining of the compartment at heel up to 5° to port or starboard.

10.7.33 Branch bilge suctions shall be installed in each watertight compartment at both sides. In compartments with the floor inclination exceeding 5° and in the ship extremities the branch bilge suctions shall be installed as close to the centre line as possible.

10.7.34 Branch bilge suctions of the bilge system shall be installed throughout the entire length of the ship in the following way:

.1 in ships without a trim the suctions shall be installed at the aft bulkheads of the forward compartments and at the fore bulkheads of the aft compartments;

.2 in ships with the trim by the stern the suctions shall be installed at the aft bulkheads of the compartments.

Drainage of machinery spaces

10.7.35 The location and the number of strum boxes of the bilge system (the bilge water collection system) in machinery spaces
shall be taken in accordance with 10.7.31 to 10.7.34; here, one of the strum boxes of the bilge system shall be directly connected to a separately driven bilge pump.

In passenger ships each of the power-operated bilge pumps located in the machinery spaces shall have two branch bilge suction s positioned at the both sides of these spaces.

10.7.36 Branch bilge suctions for bilge drainage of the machinery spaces shall be fitted with accessible mud boxes. The pipes between the mud boxes and the bilges shall be straight. The lower ends of these pipes need not be fitted with strum boxes.

Mud boxes shall have opening covers. The total cross-section area of the mud box holes shall be not less than twice the clear area of the given branch suction.

In ships up to 25 m in length strum boxes may be used instead of mud boxes, provided that they are accessible for cleaning (see 10.7.43).

10.7.37 No strum boxes or strainers may be fitted on the emergency bilge drainage suction.

10.7.38 Refrigerating machinery space accommodating refrigerating plants working on refrigerant can be connected to the bilge system of the ship.

The space for ammonia refrigerating machinery shall have an independent bilge system.

Drainage of tunnels

10.7.39 Bilge suctions shall be located in the after part of the shaft tunnels.

The bilge suctions of the shafting tunnel shall comply with the requirements set forth in 10.7.36.

Drainage of watertight compartment and cargo spaces

10.7.40 Where there is a double bottom under a watertight compartment or a cargo hold which is extended over the full breadth of the compartment, a bilge well shall be arranged at each side.

10.7.41 Where the length of the watertight compartment or a cargo hold exceeds 35 m, the bilge suctions shall be installed in the fore and after parts of this compartment or hold.

10.7.42 Water drainage into the bilges of the watertight compartments or cargo holds from the spaces located in other watertight compartments below the freeboard deck is not allowed.

10.7.43 Branch bilge suctions shall be fitted with strum boxes or strainers. The total cross-section area of holes shall be not less than twice the clear area of the given branch suction.

The strum boxes and strainers shall be removable, or it shall be possible to clean them without disassembling the suction.

The strum boxes shall be protected against corrosion.

Drainage of refrigerated spaces

10.7.44 Provision shall be made for drainage of water from all the spaces, trays, chutes and other places which may accumulate water.

10.7.45 Drain pipes from non-refrigerated spaces shall not be led into the bilges (wells) of refrigerated spaces.

10.7.46 Each drain pipe of refrigerated cargo spaces shall be fitted with a liquid sealed trap or with other equivalent arrangement.

The head of liquid in the trap shall be such as to ensure effective operation of the trap under any service conditions. The liquid sealed traps shall be placed in accessible place outside the insulation.

10.7.47 No shut-off valves may be fitted on the water drainage lines from the refrigerated spaces.

Drainage of cofferdams

10.7.48 Cofferdams filled with water shall be fitted with drainage means. The location of branch bilge suctions shall comply with the requirements of 10.7.40 to 10.7.43.
10.7.49 The cofferdams of oil tankers shall be drained by pumps, including water ejectors.

**Drainage of peaks and other spaces**

10.7.50 Where the peaks are not used as ballast or other tanks, they may be drained by their own hand pumps or water ejectors. The pumps shall be installed above the freeboard deck.

10.7.51 Drainage of the after peak may be carried out through the drain pipe into the bilges or drainage wells of the adjacent compartment. The drain pipe shall be fitted with a self-closing valve installed on the afterpeak bulkhead from the adjacent compartment side.

10.7.52 Drainage of the peaks on non-self-propelled ships and ships less than 25 m in length may be carried out by water draining into the adjacent compartments, if self-closing valves installed on the peak bulkheads are controlled from the deck.

10.7.53 Drainage of chain lockers may be carried out by water draining through the drain openings into the fore peak compartment.

10.7.54 Each sidehull of the catamaran shall be fitted with a separate bilge system complying with the requirements of this Chapter.

**Draining of spaces protected by fixed fire extinguishing systems**

10.7.55 Bilge facilities shall remove water with use of any fixed water fire-extinguishing systems, including spraying systems.

10.7.56 To maintain ship stability in case of application of water fire-extinguishing systems, the following design measures shall be taken:

.1 in passenger ships:

   in spaces above the bulkhead deck, scuppers shall be fitted so as to ensure that such water is rapidly discharged directly overboard;

   in spaces located below the bulkhead deck, the drain system shall be sized to remove not less than 125 % of the total quantity of water delivered by water fire-extinguishing system pumps and shall have required number of fire hose nozzles. The drainage system valves shall be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells shall be arranged at the ship's side at a distance of not more than 40 m from each other in each watertight compartment.

.2 on cargo ships, chemical tankers and ships carrying hazardous goods:

   measures excluding formation of free surfaces in the ship spaces in the course of fire extinguishing. In this case the drain system shall ensure removal of not less than 125 % of total amount of water delivered by water fire-extinguishing system pumps. The drainage system valves shall be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells shall be arranged at the ship's side at a distance of not more than 40 m from each other in each watertight compartment. If during transportation of some cargoes the bilge wells are to be covered, the negative effect on ship stability caused by water which can be delivered to the spaces from fire-extinguishing system and free surfaces which appear in the spaces shall be taken into consideration when calculating ship stability.

10.8 **BALLAST SYSTEM**

**Pumps**

10.8.1 Ballast system of the ship shall be serviced by at least one pump ensuring working medium delivery and pressure required for operation of the system. The capacity of each of such pumps shall be such as to ensure the water flow rate of not less than 2 m/s in ballast system receiving pipelines with diameter calculated by the formula 10.8.5 for the greatest ballast tank.

On catamaran type ships each sidehull shall be equipped with independent ballast system.
10.8.2 General service pumps of capacity sufficient for ballasting operations, including bilge, fire or standby cooling pump, may be used as ballast pumps.

10.8.3 The application of bilge pumps of oil tanker fore compartments as ballast pumps is described in 10.7.9.

10.8.4 The pumps used for pumping ballast water from the double-bottom tanks shall be of self-priming type.

10.8.5 Inner diameter \( d \) of ballast pipe suction for ballast tanks shall be not less than the value determined by the formula, in mm:  
\[
d = 16 \sqrt[3]{V},
\]
where \( V \) — ballast tank capacity, in m³.

10.8.6 The arrangement of the suction shall be such as to ensure pumping of the water from any of the ballast tanks, whether the ship is upright or has a list of \( 5^\circ \).

10.9 LIQUID CARGO PIPING SYSTEM OF OIL TANKERS

Pumps and their drives

10.9.1 Cargo piping system of oil tanker shall make it possible to regulate the loading rate of separate tanks. Provision shall be made for limitation of the flow rate at the suction pipe outlet in the tank up to 1 m/s at the initial loading stage and up to 8 m/s at further loading.

Regulation of the flow rate shall be made by one of the following methods or their combination:

1. using the pump drives capable of smooth adjusting the rotation frequency;
2. using the pump drives capable of adjusting the pump flow; 
3. using the control valves in the system;

10.9.2 Cargo pumps and cargo stripping pumps shall be used only according to their purpose, except as provided in 10.7.11. Intake or pressure pipelines brought to non-cargo compartments shall not be connected to these pumps.

The cargo and stripping pumps shall be arranged in the cargo pump rooms, or these pumps shall be submersible. Electric motors of submersible pumps shall have overheat protection when the pump is in idle operation.

Cargo pumps can be installed on the deck in the cargo tanks area.

10.9.3 The arrangement of the cargo pump driving engines shall comply with the requirements of 1.9.8.

10.9.4 The design of pumps, valves and their drives shall exclude spark formation.

10.9.5 Arrangements shall be provided for stopping each cargo pump and cargo stripping pump from an easily accessible place on the deck.

Where a central control station is provided for cargo operations, pump stopping arrangements shall be also fitted therein.

Switching devices of pump electric motors shall comply with the requirements of 16.2.31 Part VI of the Rules.

10.9.6 Pressure gauges of the cargo oil discharge and cargo stripping mains shall be placed near the pumps, as well as at the central control station of cargo operations.

Piping arrangement

10.9.7 Fuel system intended for fuel supply to other ships shall comply with the applicable requirements of Part III of the Rules.

10.9.8 The cargo pipes shall not be laid through the tanks not intended for liquid cargo storage and shall not be connected to other tanks or pipelines, including the fuel piping of the power installation.

The cofferdams shall not have any connections to the cargo tanks. Cargo bypass valves shall not be fitted inside the cofferdams.

10.9.9 Pipelines not intended for servicing of the cargo tanks shall neither be laid through these tanks and shall nor have any joints with them, except air and sounding pipes of the fuel tanks, which may be laid
through the cargo tanks if they are free of detachable joints, reliably secured and protected against mechanical damage. The wall thickness of these pipes shall be not less than that indicated in column 5 of Table 10.2.13.

10.9.10 Remotely controlled valves shall meet the requirements of 10.3.2 to 10.3.4.

The spindles used to operate the valves located inside the tanks shall be carried to the open deck in gas-tight sealing glands.

The drives shall be so designed as to prevent accumulation of liquid cargo residues inside them.

Replacement of the sealing shall be made from the open deck. The drives shall have arrangements showing whether the valve is open or closed.

The pipes of systems in which different cargo kinds may become mixed or contaminated by water shall have duplicate shut-off valves.

10.9.11 Equipment for liquid cargo heating shall meet the requirements of 10.13.9 to 10.13.15; the pressure of steam used for heating shall not exceed 0.7 MPa.

10.9.12 The pipe flanges and fastening pieces intended for hose connection from the shore, as well as earthing devices shall be made of materials precluding the spark formation.

10.9.13 The piping on the deck and in the cargo tanks shall be secured and fitted with expansion joints.

Where the cargo pipeline is led to the aft, it shall be free of any detachable joints in the superstructure area.

The cargo pipeline penetrating superstructures shall be led in the open trunk. Such pipeline shall be connected to the cargo main by means of an adapter blank flange or a detachable branch pipe positioned in front of the fore bulkhead of the superstructure.

A blank flange shall be installed on the outlet end of this pipe regardless of the number and the construction of the shut-off valves fitted.

Where the pipeline is led to the afore part of the ship, these requirements shall also be complied with.

10.9.14 All the sections of the cargo pipeline interconnected by flanges shall have electrical connection between each other and the pipeline shall have a connection to the hull (see 16.2.25, 16.2.26 and 16.2.28 Part VI of the Rules).

10.9.15 Remote-controlled valves fitted between the cargo mains and the pumps shall have a local manual control.

10.9.16 Where the rubbing parts of valve drives are passed inside the cargo tanks and cofferdams, as well as on the cargo deck, precautions shall be such as to preclude the spark formation.

10.9.17 The ends of filling pipes of the cargo tanks shall be located as close as possible to the tank bottom, however, the distance between these ends and the tank bottom shall be not less than 0.25 of the filling pipe internal diameter.

10.9.18 Piping outlet for washing water drainage to the settling tank shall be located at least 0.25 of the pipe internal diameter above the tank bottom. Free falling of liquid into the settling tank containing washing water and oil residue shall be avoided.

10.9.19 On combination carriers provision shall be made for arrangements disconnecting the pipelines which connect the pump room to discharge tanks. The means of isolation shall consist of a valve followed by a spectacle flange or a spool piece with blank flanges. This arrangement shall be located near discharge tanks or in the pump room immediately after the place where the pipeline passes through the bulkhead.

During transportation of bulk goods the content of discharge tanks is pumped out immediately on the open deck for delivery to shore receiving facilities by means of separate stationary pump and pipeline comprising a valve box with shut-off valve and blank flange.
Cargo tank heating

10.9.20 Steam, hot water or high-temperature organic heat transfer fluids shall be used as a heating medium in cargo heating systems in tanks.

10.9.21 Upstream of each stream heating coil, a non-return shut-off valve shall be fitted, and upstream of shut-off valves at the outlet the gauge valve for checking the condensate quality shall be installed.

Fuel heating coils shall be arranged in the lower part of cargo tanks. In deep tanks, where the heating coils are arranged in several sets throughout the tank height, provision should be made to shut off separate sections of the heating coils when the level of liquid cargo is lowered.

10.9.22 Observation tank shall be provided in the line of condensate return from heating system.

Air pipes of observation tanks of heating steam condensate from the cargo tanks with cargo flash point of 60 °C and less shall be equipped with flame arresting arrangements and brought out to the open deck where they present no hazard to people.

10.9.23 For use of systems with high-temperature organic heat transfer fluid for heating the tanks the requirements of 10.19 shall be met.

10.9.24 Maximum temperature of heating medium shall be not less than the flash point of transported cargo vapours by at least 15 °C.

10.9.25 The heating system shall be equipped with cargo temperature control facilities in tanks. Current temperature in tanks, as well as light and sound alarm about exceeding maximum permissible temperature of cargo or flow rate reduction during pumping through cargo heaters, shall be checked.

10.9.26 Steam temperature in cargo pump room heating system shall not exceed 150 °C.
wave slamming without loss of strength under the most unfavourable operating conditions of the ship. Pipe wall thickness shall be not less than 6.3 mm.

Bending stresses and loads for air pipes of ships of M-CTI class shall be determined in the most dangerous zones, including deck sockets, welded or flanged joints and lower angles of support plates.

Bending stresses shall not exceed 0.8\(R_{el}\), where \(R_{el}\) is yield point of steel.

Irrespective of corrosion protection, the corrosion allowance shall be not less than 2 mm.

Pipes of 600 mm in height and more shall be provided with radially arranged knees used as a reinforcement.

10.10.5 The upper end of each air pipe shall be made as a bend, with its opening facing downwards or shall have other construction preventing the ingress of water, precipitation and solids inside the air pipe.

10.10.6 The open ends of air pipes of the fuel and lubricating oil tanks, as well as those of cofferdams in oil tankers separating cargo or discharge tanks shall be led to positions on the open deck where the issuing vapours have no risk of fire.

The total cross-sectional area of the air pipes of each fuel tank filled by the onboard pumps or shore pumps, shall be not less than 1.25 times the total cross-sectional area of all filling pipes of this tank.

10.10.7 The air pipes of non-heated independent lubricating oil storage tanks of the basic store and waste oil tanks may terminate in spaces where the tanks are installed if precautions are taken precluding slippage of oil onto electrical equipment or heated surfaces in case the tank is overflowing.

10.10.8 Each open end of the air pipes of fuel and discharge-and-circulating oil tanks, as well as those of cofferdams in oil tankers separating cargo or discharge tanks shall be protected with flame arresters. The cross-sectional area of flame arresters shall be not less than the cross-sectional area of the air pipe.

10.10.9 Outlets of air pipes of ships of all classes, except for ships of P and J class, arranged on the open decks shall be fitted with fixed automatic devices to prevent the water ingress into the tank.

Automatic closures of air pipes of ships of M-CTI 4,5 class shall be operational at a roll of up to 40°.

When float-type automatic closures are used, guides ensuring their correct operation at any permissible heel and trim of the ship shall be provided.

10.10.10 The total cross-sectional area of the air pipes in tanks filled by gravity method shall be not less than the total cross-sectional area of the filling pipes of these tanks.

10.10.11 The total cross-sectional area of the air pipes of a tank filled by the onboard pumps or shore pumps, shall be not less than 1.25 times the cross-sectional area of the tank filling pipe. When the diameter of the filling pipeline is less than 50 mm, a diameter of the air pipe may not exceed the diameter of the filling pipe.

The cross-sectional area of a common air pipe from several tanks shall be at least 1.25 times the area of the common filling pipeline of these tanks.

10.10.12 Where a tank filled by onboard pumps or shore pumps is fitted with an overflow pipe, the total cross-sectional area of the tank air pipes shall be not less than one-third of the filling pipe area.

Where the air pipes from several tanks fitted with overflow pipes are combined, the cross-sectional area of the common air pipe shall be at least one-third of the area of the common filling pipe of these tanks.

10.10.13 The air pipes shall be so arranged as to prevent formation of hydraulic locks in the pipes at a heel and trim of the ship specified in 1.3.

10.10.14 The air pipes of fuel and lubricating oil tanks in way of accommodation and refrigerated spaces shall be free of detachable connections.
The laying of the air pipes of fuel tanks through the cargo tanks shall meet the requirements of 10.9.9.

10.10.15 Nameplates shall be affixed to the upper ends of the air pipes.

10.10.16 The air pipes from crankcases of internal combustion engines shall meet the requirements of 2.5.4.

Gas outlet pipes of oil tankers and oil-ore carriers

10.10.17 Each cargo tank shall be provided with a gas-outlet pipe connected to the top of the tank.

Gas-outlet pipes shall not be connected to the air pipes servicing other ship spaces.

The construction of the gas-outlet pipes shall provide measurements of pressure in the cargo tanks, as well as pressure difference at fire-retarding divisions.

Gas-outlet pipes shall be self-draining to cargo tanks at heel and trim specified in 1.3, or shall have fixed arrangements for draining gas-outlet pipes to cargo tanks.

10.10.18 Gas-outlet pipes may be combined into one or several mains. Such combination is allowed only for pipes from cargo tanks with homogeneous cargo. Gas-outlet pipes can be combined with inert gas pipeline.

Internal diameter of separate gas-outlet pipes shall be not less than 80 mm, and that of main pipelines — not less than 100 mm.

Cross-sectional area of the separately laid gas-outlet pipe shall be not less than 1.25 of the cross-sectional area of filling pipeline of the tank on which this pipe is installed, and the cross-sectional area of the gas-outlet main from several tanks shall be not less than 1.25 of the cross-sectional area of the common filling pipeline of these tanks. It shall be taken into account that the cross-sectional area of each gas-outlet pipe shall be not less than 1.25 of the cross-sectional area calculated considering the maximum speed of cargo handling operations specified in the technical design assignment for the ship.

If gas-outlet pipes from various cargo tanks are combined in one main, to disconnect any cargo tank, the shut-off valves or other acceptable means shall be provided. The shut-off valves installed shall have locking arrangements.

Visual indication of the actual state of shut-off valves or cargo tank disconnecting arrangements shall be provided. Where these tanks are disconnected from the gas-outlet main, the relevant shut-off valves shall be opened before starting cargo loading, unloading or ballasting of these tanks. Disconnecting of cargo tanks from gas exhaust pipeline shall not stop flow of gases due to temperature variations in the cargo tank.

10.10.19 Outlet ends of gas-outlet pipes communicating with the atmosphere shall be provided with flame arresters. The cross-sectional area of flame arresters shall be not less than the cross-sectional area of the gas-outlet pipe.

When gas-outlet pipes are combined in a common main, the pipes led from each tank shall be provided with fire-retarding divisions. Fire-retarding divisions shall be positioned in the places where the possibility of liquid cargo ingress into them is excluded in any sailing conditions of the ship including rolling.

Fire-retarding divisions shall be made of material resistant to corrosion. Fire-retarding divisions shall be so designed as to provide the possibility of their replacement or dismantling without gas-outlet pipes reassembling.

10.10.20 Gas-outlet pipes laid from the cargo tanks shall be led to the open deck with due regard to the following requirements:

1. in ships carrying oil products with a flash point less than 45 °C the pipe outlet openings may be positioned above the main deck at a height of not less than \( \frac{1}{3} \) of the ship’s breadth; moreover, their height may not exceed 5 m, but shall be not less than 3 m;

2. in ships carrying oil products with a flash point from 45 up to 60 °C, the pipe outlet openings may be positioned above the main deck at a height of not less than 2.4 m;

3. in ships carrying oil products with a flash point over 60 °C the pipe outlets can be
positioned above the deck at a height of not less than 600 mm.

4 Outlets of gas-outlet pipes of oil tankers of M-СП, M-ПИ and O-ПИ classes during loading, unloading or ballasting shall:
- permit the free flow of vapour mixtures;
- or
- permit the throttling of the discharge of the vapour mixtures to achieve a velocity of not less than 30 m/s;
- be so arranged that the vapour mixture is discharged vertically upwards;
- where the free vapour release method\(^1\) is used, be such that the outlet is not less than 6 m above the cargo tank deck or from the gangway if situated within 4 m of this gangway and at a distance of not less than 10 m horizontally from the nearest air intakes and openings to enclosed spaces accommodating a source of ignition and from the windglass and hawse pipe of chain locker and equipment which can constitute an ignition hazard; and
- where the high-velocity vapour release method\(^2\) is used, be equipped with appropriate discharge arrangements and be arranged at a height not less than 2 m above the cargo tank deck and at a distance of not less than 10 m horizontally from the nearest air intakes and openings to enclosed spaces accommodating a source of ignition and from the windglass and hawse pipe of chain locker and equipment which can constitute an ignition hazard.

Outlets of gas-outlet pipes of oil tankers of M, O, P and \(\mathcal{J}\) classes shall be arranged at a distance of at least 3 m from deck houses, superstructures and places of air intake for the cases specified in 10.10.20.1 and 10.10.20.2 and not less than 1 m for the case described in 10.10.20.3.

10.10.21 Breathing valves fitted on the gas-outlet pipes shall be designed and positioned in such a way that the pressure in cargo tanks does not exceed 15 kPa, if the tanks are not specially designed for higher pressure; and

---

\(^1\) SOLAS, Chapter II-2, Part B, Regulation 4, Para 5.3.4.1, Subpara 1.1.

\(^2\) SOLAS, Chapter II-2, Part B, Regulation 4, Para 5.3.4.1, Subpara 1.2.

---

10.10.22 Each cargo tank shall have additional arrangement for free flow of mixtures of vapours, air or inert gas to prevent excessive pressure or vacuum in case of failure of arrangements specified in 10.10.20 or other design measures shall be taken to ensure that in the course of cargo handling the cargo tanks are not exposed to excessive pressure and no vacuum is created in them.

Instead of additional arrangement for free flow of mixtures of vapours, air or inert gas in control stations for cargo operations it is allowed to provide continuous indication of pressure in each tank. Alarm for excessive pressure or vacuum in the tank shall be provided.

A gas-outlet pipe with the breathing valve shall have a bypass pipe provided with shut-off valves, or other design measures shall be taken to avoid exceeding pressure or vacuum formation in the cargo tanks during cargo handling.

Overflow pipes

10.10.23 Overflow pipes shall be installed in service and fuel oil settling tanks and led to the fuel storage tank of the basic store.

10.10.24 The cross-sectional area of the overflow pipe shall be not less than the cross-sectional area of the tank filling pipe when filling it with hand pump.

When the tank is filled with the mechanically-driven pump, cross-sectional area of the overflow pipe shall be not less than 1.25 of the cross-sectional area of the tank filling pipeline.

Sounding arrangements

10.10.25 Each tank intended for storage of liquid, as well as bilges and bilge wells with no free access, shall be provided with sounding pipes extended to the open deck or with other liquid level indicators.

Sounding pipes of independent tanks may not be led to the open deck.
Sounding pipes of the fuel oil and lubricating oil tanks shall not be led to the passenger and crew spaces.

10.10.26 Level indicators of fuel oil and lubricating oil tanks fitted with transparent inserts shall be protected against damage.

The transparent inserts of the fuel oil tanks shall be made of flat glass or shockproof plastics which do not lose transparency under the action of fuel oil.

A self-closing cock shall be fitted at the lower end of the level indicator at the connection of the tank. If the level indicator is connected to the tank below the maximum liquid level, the self-closing cock shall be fitted at the top end of the level indicator.

In lubricating oil tanks with a capacity less than 0.5 m³ the installation of self-closing cocks is not required.

10.10.27 Where the double bottom forms bilges at the sides, or the ship has a flat bottom, the sounding pipes shall be installed at each side. These pipes shall be led to positions above the freeboard deck which are at all times accessible for taking soundings. The sounding pipes shall be straight and shall not interfere with taking soundings with a sounding rod.

In ships where the compartments are drained with portable pumps, raisers with fitted portable drain pumps may be used as sounding pipes.

10.10.28 Sounding pipes of fuel oil and lubricating oil tanks may be led above the machinery space floor plates, or into the shafting tunnel, if such design measures are provided or the sounding pipes terminate at such positions that fuel or lubricating oil at occasional spillage through sounding pipes will not come into contact with hot surfaces of boilers, engines, exhaust gas pipes, etc., and also with electric machines and distribution switchboards. Such pipes shall be fitted with self-closing cocks and their height shall be at least 0.5 m above the floor level. These pipes shall not be used as air pipes.

Laying of the sounding pipes of fuel oil tanks through the cargo tanks shall comply with the requirements of 10.9.8.

10.10.29 Sounding pipes of the double-bottom water storage tanks may be led into the above spaces accessible at all times. Such pipes shall not be used as air pipes and shall be fitted with self-closing cocks.

10.10.30 The ends of the sounding pipes led to the open decks shall be fitted with tight plugs complying with the requirements of 10.2.8.

If the sounding pipes are extended above the open decks, they shall be located at such positions where they cannot be damaged, otherwise they shall have appropriate guards.

10.10.31 Provisions shall be made to preclude damage of the bottom plating under the open ends of the sounding pipes while measuring the fuel level in the cargo tanks.

In case of slotted sounding pipes with closed ends, the measures described herein shall be taken for the sounding pipe plug.

10.10.32 The internal diameter of the sounding pipes shall be not less than 25 mm.

Sounding pipes which are laid through refrigerated spaces in which the temperature may be reduced to 0 °C and below, as well as sounding pipes of the tanks provided with the heating system shall have an internal diameter of at least 50 mm.

10.10.33 Outlet ends of sounding pipes shall have nameplates with indelible inscriptions containing information required for identification of these sounding pipes.

10.10.34 Sounding rods and other devices intended for measuring the cargo level on oil-tankers carrying oil products with a flash point 60 °C or less shall be made of spark-proof material.

10.11 EXHAUST GAS SYSTEM

Exhaust gas piping

10.11.1 The gas exhaust pipelines shall be brought to the open decks, except for the
cases specified in 10.11.2. The gas exhaust pipelines shall be so designed as to exclude the possibility of ingress of foreign objects, overboard water or atmospheric precipitations into engines and boilers.

10.11.2 The gas exhaust pipelines can be brought out through the shell plating in the stern in ships of less than 25 m in length. Gas exhaust pipelines can be brought out through the side shell plating to the atmosphere only for the ships with gas exhaust systems in which the gases are cooled by outside water injection/supply. Places for bringing out gas exhaust pipelines shall be selected so as to exclude the possibility of ingress of released gases to the ship’s spaces.

10.11.3 In ships it is allowed to use gas exhaust systems in which the gases are cooled by outside water injection/supply. Places for bringing out gas exhaust pipelines shall be selected so as to exclude the possibility of ingress of released gases to the ship’s spaces.

10.11.4 Each main engine shall be fitted with an individual exhaust gas pipe. Exhaust gas pipes of auxiliary engines may be connected to a common exhaust line provided that a safety device is fitted to preclude:
- gas flow from the common line to the pipes of the engines not actually at work;
- damage of any of the engines during starting.

10.11.5 When the uptakes of the boilers are arranged to discharge into a common uptake, dampers are permitted, provided they have arrangements to lock them in open position. Manholes and vertical ladders shall be provided for inspection and cleaning of the uptakes and air ducts of boilers.

10.11.6 If the waste heat boilers and the composite boilers are so designed that in drained condition (without water) they can not be heated by the exhaust gases, bypass lines and dampers disconnecting the boilers from the exhaust gas supply shall be fitted. Exhaust gas pipelines of the main and auxiliary engines may be connected to a common waste heat boiler or a composite boiler, provided the reliable devices are fitted to prevent exhaust gas pipelines of the engines not actually at work or disconnected ones from the penetration of gases from the working engines; as well as devices to disconnect a waste heat boiler or a composite boiler from the exhaust gas pipeline of any engine; and devices to lead the gases from this engine to the bypass pipeline. Safety and locking devices shall be provided with position indicators of the shut-off device.

10.11.7 Gas exhaust pipelines of engines and boilers shall be thermally insulated by means of suitable insulating material, double walls or screen. It is allowed not to insulate gas exhaust pipelines of engines, the exhaust gases of which are cooled by outside water injection/supply if the temperature of the gas exhaust pipeline surface does not exceed 60°C.

These pipelines can be manufactured with use of flexible hoses and their connections.

10.11.8 Exhaust gas pipelines of the engines and boilers shall be fitted with thermal expansion compensators. Gas exhaust pipelines shall have handholes for cleaning, as well as drain cocks and devices for condensate collection and removal with allowances made for the design of the pipelines.

10.11.9 Exhaust gas pipes laid through the accommodation spaces or the wheelhouse shall be fitted with a gas-tight protective casing inside these spaces. The space between the exhaust gas pipes and the protective casing shall communicate with the atmosphere.

Silencers and spark arresters

10.11.10 Gas exhaust pipelines of engines and boilers shall have spark arresters. Silencers and spark arresters are to be so arranged as to provide easy access for cleaning. For this purpose the pipelines shall have handholes and drain cocks.

10.11.11 Where waste heat boilers and spark arresters of the wet type are installed, measures shall be taken to prevent the ingress of water into the engines when in case of leakage in the boiler pipes or at other failures.

Spark arresters in which the flow of exhaust gases is water-sprayed or passes through the water.
The drain pipes shall be led into the machinery space bilges and shall have hydraulic seals.

10.12 VENTILATION SYSTEM

Ventilation ducts

10.12.1 The ventilation system shall be so designed as to exclude flame and smoke propagation by the system itself. Fans shall be arranged in a way so that the ducts used for different rooms remain within the vertical fire zone served by the fans.

Ventilation ducts shall not penetrate impermeable bulkheads below the freeboard deck.

Exhaust ventilation ducts shall be provided with hatches for inspection and cleaning. The hatches shall be located near the fire dampers.

Ducts used for ventilation of accommodation and service spaces or control stations passing through the machinery spaces, which accommodate engines and boilers, galleys and vehicles spaces, shall meet the following requirements:

.1 Duct walls shall be made of steel according to 10.12.2.1 and 10.12.2.2;
.2 automatic fire dampers shall be installed near the limiting structures through which the ducts are laid;
.3 in places where the ducts pass through the limiting structures of the above mentioned spaces the fire-resistance of these structures shall be provided; or (instead of 10.12.1.2 and 10.12.1.3)
.4 ducts shall be insulated with fireproof structures of A-60 type within the above mentioned spaces;
.5 if ventilation ducts pass through decks, measures shall be taken to decrease the hazard of smoke and hot gas passing from one tween-deck space to another one through ventilation system. These measures shall not affect fire-resistance of the deck.

10.12.2 Trunks and vertical ventilation ducts passing through impermeable decks within one impermeable compartment below the freeboard deck shall be impermeable and shall withstand loads equal to the loads of limiting structures of the specified compartment which appear during tests of this compartment for tightness.

All ventilation ducts shall be made of non-combustible materials. Duct sections of not more than 2 m in length and clear area not more than 0.02 m² shall be manufactured of material with low flame spread properties (see 2.1.3.1 Part III of the Rules), if:

they are to be used only at the end of the ventilation device;
the ducts are not situated less than 600 mm measured along the duct, from an opening in an A or B class division, including continuous B class ceiling.

The ventilation system of the machinery spaces with engines and boilers, galleys and vehicles spaces shall be separated from each other and from the ventilation systems serving other spaces. Ventilation ducts of the above mentioned ventilation systems shall not pass through accommodation and service spaces or control stations. Ventilation ducts can be laid through accommodation and service spaces or control stations if:

.1 duct walls are made of steel having a thickness of at least 3 mm for ducts with width or diameter of up to 300 mm, inclusive, or thickness of at least 5 mm when the duct width or diameter is 760 mm and more; If the duct width or diameter D exceeds 300 mm, but is less than 760 mm, the duct wall thickness δ, in mm, is calculated by the formula:
\[ \delta = 1.7 + \frac{D}{230} \];
.2 ducts are secured and their walls are reinforced;
.3 the ducts are fitted with automatic fire dampers close to the boundaries penetrated;
.4 ducts are insulated by type A-60 structures from the machinery spaces, galleys, vehicle spaces to a point at least 5 m beyond each fire damper; or (instead of 10.12.2.2 to 10.12.2.4);
.5 ducts are insulated with type A-60 structures in accommodation and service spaces or control stations.

10.12.3 If the ventilation duct with clear cross-sectional area of 0.02 m² or less with walls made of metal sheets of max. 1.5 mm passes through type A bulkheads or decks, it
shall be fitted with a steel sheet sleeve having a thickness of at least 3 mm and a length of at least 200 mm. If the duct passes through type A bulkhead, the sleeve shall protrude from each side of the bulkhead by 100 mm. If the duct passes through the deck, the sleeve shall be fully arranged on the lower side of the deck. In the points of passing through the bulkheads the above specified sleeves and ducts shall be fitted with insulation made of non-combustible materials as specified in 2.7.1 of Part III of the Rules.

If the ventilation ducts with clear cross-sectional area over 0.02 m$^2$ pass through type A bulkheads or decks, they shall also be fitted with steel sheet sleeves. The ducts and the sleeves shall meet the following requirements:

.1 sleeves' walls shall have thickness of at least 3 mm and length of at least 900 mm. If the duct passes through type A bulkhead, the sleeve shall protrude by 450 mm from each side of the bulkhead. The insulation of sleeves and ducts shall have at least the same fire integrity as the bulkhead or deck through which the duct passes;

.2 Ducts with clear cross-sectional area more than 0.075 m$^2$ shall be equipped with fire dampers installed on bulkheads. The fire damper shall close automatically, but it shall also be possible to close the damper manually from both sides of the bulkhead or deck. Locations of the dampers and their control drives shall be readily accessible and be painted with red retro-reflecting colour. If the dampers are placed behind ceilings or linings, these ceilings or linings shall be provided with hatches for inspection of dampers. Identification numbers of fire dampers shall be applied on these hatches. Identification number shall also be applied on any remote control of dampers. The dampers shall be fitted with position indicators showing whether the dampers are open or closed.

When the damper is not installed on the bulkhead, the duct between the bulkhead and the damper shall be made of steel or other equivalent material and shall be provided with insulation corresponding to the degree of fire-resistance of the bulkhead.

Fire dampers are not required, however, where ducts pass through spaces surrounded by A class divisions, without serving those spaces, provided those ducts have the same fire integrity as the divisions which they pierce.

Ventilation ducts with clear cross-sectional area more than 0.02 m$^2$ passing through type B bulkheads shall be provided with sleeves of 900 mm long made of steel of not less than 2 mm thick. The sleeve shall protrude by 450 mm from each side of the bulkhead only if the steel duct does not have the same length.

10.12.4 Ventilation ducts shall be properly insulated in places of possible sweating. Drain plugs shall be provided for the portions of ducts where water is likely to accumulate.

10.12.5 Ventilation ducts for removal of explosion and fire-dangerous vapours and gases shall be gas-tight and shall not communicate with the ducts of other spaces.

Closing arrangements of the ducts shall be so designed as to prevent the spark formation.

Outer openings of the ducts other than those indicated in 10.12.18 shall be provided with flame arresters.

10.12.6 Where the artificial ventilation is used on cabin passenger vessels, fans and ventilation ducts are recommended to be placed within the same vertical fire zone where the ventilated spaces are located.

10.12.7 Ventilation ducts which do not pass through cargo spaces:

.1 ducts with clear cross-sectional area not less than 0.075 m$^2$ and all vertical ducts serving more than one tween-deck space shall be made of steel or other material of equivalent fire-resistance;

.2 ducts with clear cross-sectional area less than 0.075 m$^2$, other than the vertical ducts referred to in 10.12.7.1, shall be made of non-combustible materials. Where such ducts are laid through type A or B divisions, due regard shall be given to ensuring the fire-resistance of the division; and

.3 ducts with clear cross-sectional area not more than 0.02 m$^2$ and length not more
than 2 m shall meet the requirement of 10.12.2 for short ducts.

**Arrangement of ventilator heads and air inlets**

10.12.8 Ventilator heads of plenum ventilation and air inlets of the ventilation system shall be so located that the risk of drawing-in air contaminated by gas, oil vapours, etc., is minimized, and the ingress of outboard water into the ventilation ducts is precluded.

The height of fan coamings shall meet the requirements set out in 5.6.20 Part II of the Rules.

**Ventilation of machinery spaces**

10.12.9 The ventilation of machinery spaces shall provide a sufficient supply of air necessary for maintenance and operation of the power installation components in all service conditions.

The ventilation shall ensure removal of air from the lower zones of the spaces, as well as from below floor plates where gases heavier than air may be accumulated.

The ventilation of refrigerated spaces shall meet the requirements set out in 9.7.6 and 9.7.7.

10.12.10 Shafting tunnels shall have ventilation.

10.12.11 The emergency diesel-generator room shall be fitted with an automatic arrangement ensuring air supply sufficient for the emergency diesel-generator to run under full load in any service conditions when the doors (hatches) are closed. If the emergency diesel-generator room is above the bulkhead deck, steel splash-proof shutters opening automatically upon start of emergency diesel generator are used as an arrangement of automatic air inflow for diesel generator operation. Under normal operating conditions the shutters shall be closed.

**Ventilation of ferries’ closed spaces and holds intended for the carriage of motor vehicles and mobile plants**

10.12.12 Closed spaces and cargo holds intended for the carriage of motor vehicles and other mobile plants with fuel in their tanks shall be provided with independent artificial exhaust ventilation capable of ensuring at least:

10 air changes per hour on ferries and passenger ships transporting more than 36 passengers;

6 air changes per hour on all other ships.

10.12.13 The ventilation system shall be equipped with fan control devices. These devices shall be installed in the wheelhouse.

10.12.14 The pumps shall be so designed as to prevent spark formation.

**Ventilation of refrigerated spaces**

10.12.15 Ventilation of cooled rooms shall comply with the requirements set out in 9.9.5 to 9.9.8.

**Ventilation of accumulator rooms and boxes**

10.12.16 Ventilation of the accumulator rooms and boxes shall be of independent type and ensure removing air from the upper part of the ventilated spaces.

The exhaust ducts shall be gas-tight.

10.12.17 The inlet air shall be supplied into the lower part of the ventilated space.

10.12.18 The outlets of ventilation ducts shall be so designed as to preclude the ingress of water, atmospheric precipitation and solids inside them.

No flame arresters shall be installed at the ventilation duct outlets.

The exhaust ducts shall be led to places where the issuing gases do not present a fire risk.
10.12.19 Accumulator boxes with batteries of a charging capacity not over 0.2 kW may be ventilated through the openings in the lower and upper parts of the box to ensure removal of the gases. Charging capacity of batteries is determined according to 8.5.1 Part VI of the Rules.

10.12.20 The rate of air flow $Q$ for the natural ventilation of an accumulator room or box shall be not less than that determined by the formula, in m$^3$/h:

$$Q = 0.111 I n,$$

(10.12.20)

where $I$ — maximum charging current during gas emission, but not less than 0.25 of the current rating of the charging device, in A;

$n$ — number of battery cells.

10.12.21 The cross-sectional area $F$ of a duct in case of natural ventilation of accumulator rooms and boxes shall be not less than that determined by the formula, m$^2$:

$$F = 2.9 \cdot 10^{-4} Q,$$

(10.12.21)

but not less than 0.008 m$^2$ for acid accumulators and 0.012 m$^2$ for alkaline accumulators.

Here $Q$ — air flow rate determined by the formula (10.12.20), in m$^3$/h.

10.12.22 Natural ventilation of the spaces may be used in the following cases:

.1 required air flow rate determined by the formula (10.12.20), is at least 85 m$^3$/h;

.2 the angle of the duct deflection from the vertical is less than 45$^\circ$;

.3 the number of bends of the duct does not exceed 2;

.4 the length of the duct does not exceed 5 m;

.5 the operation of the ventilation system does not depend on the wind direction;

.6 the cross-sectional area of the duct is taken not less than that determined by the formula (10.12.21).

10.12.23 Where the rate of air flow determined by the formula (10.12.20) is 85 m$^3$/h and over, the accumulator room shall be provided with artificial exhaust ventilation.

10.12.24 The internal surfaces of the exhaust ducts, as well as the fans shall be protected against gases emitted by the electrolyte.

10.12.25 The motors of fans shall not be arranged in way of gas exhaust.

The design of fans shall prevent the spark formation as far as practicable.

Ventilation of foam fire-extinguishing and smothering stations, as well as station for drinking water preparation by ozone treatment

10.12.26 Foam fire-extinguishing and smothering stations shall be equipped with the ventilation ensuring at least six air changes per hour.

The carbon dioxide fire-extinguishing stations shall be provided with an exhaust and supply ventilation independent from other ventilation systems. The inlets of exhaust ducts shall be located in lower parts of the station rooms.

Drinking water stations (ozone treatment) shall be equipped with plenum-exhaust ventilation system with 10 air changes per hour.

Ventilation of cargo pump rooms

10.12.27 The cargo pump rooms shall have artificial exhaust ventilation fitted separately for each space. This ventilation shall ensure at least 20 air changes per hour. Outlets of ventilation systems equipped with sparkproof exhaust fans shall be brought out to safe place on the open deck. Inlet ventilation of these spaces may be natural.

lighting in cargo pump rooms, except emergency lighting, shall be interlocked with ventilation such that the ventilation shall be in operation when switching on the lighting. Failure of the ventilation system shall not cause the lighting to go out.

It is also required to meet the requirements of 16.2.30 Part VI of the Rules.

10.12.28 Steam engines for the fan drives may be located in the pump room.

Electrical motors for driving the fans shall be arranged in accordance with 1.9.8 Part IV of the Rules.
10.12.29 Inlets of exhaust ducts shall be situated in the lower zones of the spaces in the places where liquid cargo vapours accumulate.

Outside the pump room these ducts shall be gas-tight and shall not communicate with the vent ducts of cargo tanks or other spaces.

Where the ventilation system of the pump room is used for ventilating the cargo line and the communicating cargo tanks through the cargo line, duplicate shut-off valves shall be provided at the connections of the ventilation duct to the cargo line.

10.12.30 All the closures of the ventilating ducts shall prevent the spark formation as far as practicable.

The fans shall be so designed as to prevent spark formation.

10.12.31 Outlets of exhaust ducts shall be not less than 2 m clear of any opening leading into the ship spaces which may contain a source capable of igniting oil vapours, and shall be so located relative to the inlets of plenum ducts as to prevent contamination of air entering the inlets of ventilation system.

The air intakes of the plenum ventilation shall be situated at least 2.4 m above the main deck and at least 5 m clear of any openings of the cargo tanks and outlets of the exhaust gas pipes (see also 10.10.20).

The outlets of exhaust ducts shall be fitted with flame arresters.

**Ventilation of galleys**

10.12.32 Ventilation systems of galleys shall be separated from ventilation systems serving other spaces.

Supply or exhaust ventilation ducts from galley are to be made as type A structures where passing through accommodation spaces or spaces containing combustible materials. In the upper part of supply ventilation duct at the inlet to galley the fire damper shall be installed. If necessary, the fire damper shall cut off all ventilation duct sections outside the galley.

10.12.33 Each exhaust ventilation duct from galley ranges passing through accommodation spaces or spaces containing combustible materials shall be equipped with:
- detachable box for fat collection;
- fire sliding valve located in the lower part of the duct and fire damper installed in the upper part of the duct.

Exhaust fan switch shall be installed in the galley.

**Ventilation of ship cargo spaces fit for dangerous cargoes**

10.12.34 Ventilation systems of the ships used for transportation of dangerous cargoes shall comply with 3.2 and 4.5 Part IX of the Rules.

**Closing appliances and stopping devices of ventilation**

10.12.35 Inlets and outlets of ventilation system shall be equipped with closing devices operated both from the inside and outside of the ventilated space. These devices shall be installed in easily accessible places and shall have closing device position indicators (opened or closed). Each of the closing devices shall have a marking about its purpose.

10.12.36 It shall be possible to stop forced ventilation of accommodation, service and cargo spaces, control stations and machinery spaces both from the inside and outside of these spaces.

10.12.37 Machinery spaces shall have control facilities for opening and closing the decklights and closing the fire dampers of ventilation system.

The controls of devices used for forced ventilation of machinery spaces shall be so located as to be operated both from the machinery space and from the outside. The devices for stopping forced ventilation of machinery spaces shall be arranged separately from the devices for stopping ventilation of other spaces.

10.12.38 Artificial ventilation system, except for machinery space and cargo space
ventilation system, shall be fitted with controls so grouped as to enable stop of all fans from either of two separate positions which shall be situated as far apart as possible. It shall be possible to stop the fans of ventilation system of cargo spaces from a safe place outside such spaces.

**Ventilation of stairway enclosures of passenger ships**

10.12.39 Passenger ships with stairway enclosures shall be equipped with autonomous ventilation system of these enclosures independent from ventilation system of other ship spaces

**10.13 FUEL SYSTEM**

**Pumps**

10.13.1 Mechanically-driven fuel transfer pump and a standby hand pump shall be provided for fuel oil transferring from reserve tanks into the service tanks. When the fuel oil separator is available, the separator pump may be used for standby purpose.

In ships with a daily consumption of fuel less than 1 t, one hand pump is admissible.

10.13.2 The fuel transfer pumps and the separator pumps, besides local control, shall be provided with stopping means operable from readily accessible positions outside the spaces where the pumps are installed.

**Design and arrangement of pipelines**

10.13.3 Fuel oil pipelines shall be separated from other piping systems. They shall not be affected by intensive thermal flows and shall be accessible for inspection throughout the entire length.

10.13.4 Pipelines used for delivery of heated fuel oil under pressure shall be arranged in accessible and illuminated places.

10.13.5 The fuel pipes shall not be laid under the internal combustion engines, turbines, boilers, near the heated parts and air intake devices of the engines, compressors and electrical equipment, as well as above gas exhaust pipelines, steam lines (except heating steam coils), steam boilers and their funnel uptakes.

10.13.6 Fuel oil pipes from the tanks of capacity over 50 l located outside the double bottom space as well as the pipes intended to equalize the level of fuel in the tanks shall be fitted with shut-off valves located directly on the tanks. These valves shall be capable of being remotely closed from readily accessible places located outside the space containing the tanks.

Daily service tanks shall be fitted with quick-closing valves.

Inlet fuel pipes from the double bottom tanks shall be fitted with shut-off valves located above the tanks (see also 10.13.24).

10.13.7 Service and settling fuel tanks shall have overflow pipes brought to the main fuel tanks. The cross-sectional area of overflow pipe shall be not less than the cross-sectional area of the tank pipe when filling it by means of hand pump. When the tank is filled with a power-driven pump, cross-sectional area of the overflow pipe shall be not less than 1.25 of the cross-sectional area of the tank filling pipeline.

When the fuel oil tanks are connected with each other, a cross-sectional area of the connecting pipelines (valves) shall be at least 1.25 times the cross-sectional area of the filling pipelines for fuel intake.

10.13.8 Filling pipelines of main fuel tanks shall be brought on the deck and fitted with shut-off valves controlled from the deck.

**Heating arrangements of fuel oil tanks**

10.13.9 Fuel oil shall be heated by means of steam or water heating coils, coils with high-temperature organic heat transfer fluid or electric heaters. Electric heaters shall comply with the requirements of 16.2.32 to 16.2.34 Part VI of the Rules.

10.13.10 Heating coils shall be fitted in the lowest part of the fuel tanks. In tanks, where the heating coils are arranged in several sets (sections) throughout the tank height, provision should be made to shut off separate sec-
tions of the heating coils when the fuel level is lowered.

10.13.11 The suction ends of fuel pipes from the daily service tanks and settling tanks shall be so positioned above the heating coils and electric heating appliances as to prevent baring of the latter. This requirement is not applied to the ends of stripping pipes.

10.13.12 Maximum temperature of heated fuel in tanks shall be lower than fuel vapours flash point by at least 10 °C. Fuel heating in service, settling and other tanks of systems for fuel supply to engines and boilers up to the temperature exceeding the specified one is allowed, provided the requirements of 10.10.6 and 10.10.8 and the following conditions are met:

.1 electrical equipment shall not be arranged in the steam space of fuel tanks, unless it is of group II B (see Table II2.1 Appendix 2 Part VI of the Rules) and unless it is explosion-proof electric equipment with explosion protection of i type with sparkproof electric circuit level ie (see Table II2.3 Appendix 2 Part VI of the Rules);

.2 vapours from the upper part of the tank and air pipeline shall not penetrate the machinery spaces;

.3 closed spaces shall not be located above these fuel tanks, except for ventilated cofferdams.

10.13.13 Where necessary, temperature gauges shall be fitted to control the temperature of the fuel oil being heated.

10.13.14 Heating steam condensate shall pass through a sight glass to control its purity.

10.13.15 The pressure of the steam used for fuel oil heating shall not exceed 0.5 MPa.

Water drainage arrangements of fuel oil tanks

10.13.16 For draining water from daily service and settling tanks, these tanks shall be fitted with self-closing valves and pipes connected to contaminated fuel collecting tanks. Water and sludge drain pipes shall be fitted with sight glasses. Where drip trays are available, open funnels may be used instead of sight glasses.

Arrangements for fuel leakage collection

10.13.17 Independent tanks, pumps, filters and other equipment shall be fitted with drip trays in places where the oil may be leaked.

10.13.18 Drain pipes from the drip trays shall be led into collecting tanks.

10.13.19 The internal diameter of drain pipes shall be not less than 15 mm.

10.13.20 The ends of the drain pipes shall be led to the tank bottom with a minimum clearance.

Where the drain tank is situated in the double bottom space, measures should be taken to prevent the ingress of water into the machinery spaces through the open ends of the drain pipes in the event of the shell plating damage. Provision should be made for an alarm device to give warning if the fuel oil reaches the upper limit level in the collecting tank.

10.13.21 If the drain pipes from drip trays fitted in different watertight compartments are led into a common collecting tank, design measures shall be made to prevent water from one flooded compartment to enter the other compartment via open ends of the drains.

Filling of fuel storage tanks

10.13.22 The bunkering of the ship shall be carried out by a closed method through a special pipeline fitted with the valves ensuring fuel supply to all the basic fuel storage tanks. The end of the filling pipe shall be led to the tank bottom with a minimum clearance.

Main fuel tanks shall be equipped with light and sound alarm for 95 % and 98 % filling.

10.13.23 On passenger ships provision shall be made for bunkering stations which are separated from the other spaces and fitted with drain pipes leading into the fuel collecting tanks.
10.13.24 Filling pipes of the tanks located above the double bottom space, as well as filling pipes of the double bottom tanks, shall be connected to the upper part of the tanks. The filling pipeline shall be brought into the tank above the maximum fuel level. The pipeline inside the tank, but above the maximum fuel level, shall have a hole (hydraulic rupture). If for design reasons it is not possible to provide hydraulic rupture, the filling pipes shall be provided with non-return or non-return shut-off valves installed directly on the tank.

Where the filling pipe is used as a discharge pipe, the non-return valve shall be replaced by a remote-controlled shut-off valve operable from an accessible place outside the space where the tank is located.

Fuel tanks

10.13.25 Fuel tanks shall be made of steel or material equivalent to steel (see 1.2.1.13 Part III of the Rules), and shall be arranged outside the machinery spaces accommodating engines and boilers. This requirement does not apply to service tanks and fuel tanks, the capacity of which does not exceed 12 litres and tanks built in the auxiliary units during manufacture of these units.

Types and design of fuel tanks shall comply with the requirements of 2.4.139 to 2.4.141 Part I of the Rules.

10.13.26 The arrangement of the fuel tanks in the machinery spaces (engine rooms) shall comply with the requirements of 1.9.7.

10.13.27 The fuel tanks located on the weather decks and superstructures, as well as in other exposed places shall be protected against the action of sunrays.

Fuel oil tanks, fuel pipelines and pipeline valves shall be located and arranged in such a way as to prevent ingress of fuel or its vapours in spaces where people may stay.

10.13.28 Daily fuel service tanks intended for direct fuel supply to the main engines in the unattended machinery spaces shall be fitted with devices actuating visual and audible warning signals to the wheelhouse when the minimum and maximum fuel oil level is reached in the tanks, or an automatic filling of daily service tanks shall be provided.

If service fuel tank is used for supply of several internal combustion engines, provisions shall be made for the facilities cutting off fuel supply pipelines to each engine and the leakage collection pipelines. The means of isolation shall not affect the operation of the other engines and shall be operable from a position not rendered inaccessible by a fire on any of the engines.

Valves used for taking fuel samples from service fuel tanks shall be of self-closing type.

10.13.29 The compartments located towards the bow from the collision bulkhead shall not be used as fuel tanks or tanks for transportation of other flammable liquids.

10.13.30 Fuel oil tanks shall be provided with manholes with gas-tight covers for inspection and cleaning of the inner chambers.

Fuel supply to internal combustion engines

10.13.31 The equipment of the fuel system shall be capable of supplying fuel duly prepared and cleaned according to the technical documentation of the manufacturer.

10.13.32 The system for fuel supply to internal combustion engines shall have places for release of air from the system. Control cocks on fuel filter cover can be used for this purpose.

10.13.33 Power installations including heavy oil fired engines shall be fitted with dual fuel supply system.

10.13.34 If the main engines are dual fuel internal combustion engines and auxiliary ones are intended for working on diesel fuel only, precautions should be taken to avoid the penetration of heavy fuel into the fuel supply system of auxiliary engines.

10.13.35 The fuel filters shall be capable of cleaning without interrupting the operation of the engine.

Automatically cleaned filters shall be installed in the heavy fuel preparation systems.
10.13.36 When flowmeters (other than fuel consumption meters) and/or fuel combustion catalysts are installed in delivery fuel pipelines, precautions shall be taken to prevent the stopping of fuel supply to the engines in the event of their adjustment or failure.

10.13.37 The diesel generators designed for use as emergency electrical power sources shall be supplied with fuel from independent service tanks located in the emergency diesel generator room. Consumption of the fuel from this tank for other purposes is not allowed. In the course of ship operation the fuel in independent service tanks shall be sufficient to ensure operation of diesel generators with electric power supply to the consumers set out in 4.5.1 Part VI of the Rules within a time period stated in Table 4.2.1 Part VI of the Rules.

10.13.38 Diesel generators shall be supplied with fuel oil from an independent pipeline fitted with filters and shut-off valves.

Fuel supply to boilers

10.13.39 The pipes conveying fuel oil to the burners of each boiler shall be fitted with a locally controlled quick-closing valve. The quick-closing valve is not required when a separate automatic boiler is used.

10.13.40 Thermometers and pressure gauges shall be installed on heavy fuel pipes supplying fuel to the burners for checking temperature and pressure of heavy fuel.

10.13.41 Where fuel is fed to the boilers under hydrostatic pressure, the pipeline supplying fuel to the burners shall be fitted with filters.

10.14 LUBRICATION SYSTEM

Lubricating oil pumps of engines

10.14.1 For maintenance of one main engine with an output of 220 kW and above provision shall be made for at least two lubricating oil pumps (main and standby), one of which may be driven from the engine.

The capacity of the standby pump shall be not less than the capacity of the main one.

10.14.2 Where two or more main engines are installed, a standby oil pump need not be fitted.

10.14.3 Each auxiliary engine shall have a separate lubricating system.

10.14.4 Where the lubricating oil pump is not fitted with a safety or a transfer valve, such valves shall be fitted on the delivery piping.

Lubricating oil supply to engines

10.14.5 The lubricating oil drain pipes from the engine crankcase to the circulating-discharge tank shall be located in the latter in such manner as to be permanently submerged into the oil during the operation of the engine.

Drain pipes from two or more engines shall not communicate with each other.

10.14.6 The pipes of the lubricating oil system shall not communicate with other piping systems, except where they are connected to separators which may be used for fuel separation provided that reliable arrangements are fitted which preclude mixing of fuel and lubricating oil.

While separating, precautions shall be taken to prevent mixing of different lubricating oil grades intended e.g. for main and auxiliary engines, if they use immiscible lubricating oil grades.

10.14.7 The pipelines of the lubricating oil circulating systems shall be provided with:

0.1 magnetic filter on the suction side of the gear pump;

0.2 one coarse filter (strainer) on the suction side of the pump;

0.3 two parallel filters or one duplex filter, or a self-cleaning filter on the discharge side of the main engine pump.

10.14.8 In case of common lubricating oil system of the engine and turbo-superchargers, fine filters shall be installed in front of the turbo-supercharger bearings. The design of the filters shall provide their cleaning without stopping of the lubricating oil circulation. A pressure gauge shall be installed after the filters.
10.14.9 Capacity of each oil filter shall exceed the maximum capacity of the pump by 10 per cent.

10.14.10 The lubricating oil pipelines shall be fitted with pressure gauges and thermometers.

A device for checking the oil supply to the gear shall be installed on the gear oil supply pipeline.

Lubricating oil tanks

10.14.11 Oil tanks, including oil storage tanks, used in the power transmission systems, control systems and heating systems shall be made of steel or material equivalent to steel (see 1.2.1.13 Part III of the Rules) and shall be build in the ship's hull or secured on it. These requirements do not apply to tanks with capacity of 25 litres and less.

Oil tanks shall comply with the requirements of 2.4.139 to 2.4.141 Part I of the Rules for fuel tanks. Hull structures of oil tanks shall not be combined with hull structures of tanks used for other purposes (drinking water, boiler water, fuel, sewage and oily waters tanks) and hull structures of accommodation spaces. Oil tanks shall not be arranged in front of the collision bulkhead.

Oil tanks, their pipelines and valves shall be located and arranged in such a way as to prevent ingress of oil or its vapours in ship spaces. Filling holes of oil tanks shall have nameplates with indelible inscriptions containing information required for identification of these filling holes.

Oil tanks shall be equipped with air pipes according to 10.10.1 to 10.10.16.

10.14.12 The suction pipes from the tanks located outside the double bottom shall be fitted with shut-off valves installed directly on the tanks.

10.14.13 Where lubricating oil in the tanks requires preheating, the requirements of 10.13.9 to 10.13.15 shall be met.

10.14.14 Lubricating oil tanks shall be provided with manholes with watertight covers for inspection and cleaning of inner chambers.

10.14.15 Lubricating drip trays shall be fitted in the places where fuel oil leakage from hydraulic drive and lubricating oil systems is possible.

10.14.16 Lubricating oil service tanks shall be equipped with level indicators. If transparent inserts are used for this purpose, they shall comply with the requirements of 10.10.26.

Arrangements for fuel leakage collection

10.14.17 Tanks, trays and drainage pipes used for collection of oil leakages shall comply with the requirements of 10.13.17 to 10.13.21.

10.15 COOLING SYSTEM

Pumps

10.15.1 Cooling system of engines shall comply with the requirements of 2.9.1.

In ships with a single-shaft power installation the additional pump driven from the power source shall be provided to ensure standby operation of the outer and inner engine cooling pumps. Standby pump need not be installed, if the power installation output is less than 220 kW.

10.15.2 Inner circuit water cooling system may be common for the main and/or auxiliary engines and include one independently-driven pump. In this case, the capacity of the pump shall be sufficient for simultaneous cooling of all engines when running at maximum load.

In this case, the cooling pipe shall have a water control valve at inlets to each of the engines.

10.15.3 Where each of the auxiliary engines is provided with an independent cooling water pump, the standby pumps for these engines are not required.

Where, however, a group of auxiliaries is supplied with cooling water from a common system, one standby pump for inner and outer circuits is sufficient.

If a common cooling line is fitted for the main and auxiliary engines, standby pumps
for cooling the auxiliary engines are not required.

10.15.4 Ballast or other general service pumps used only for clean water may be used as standby cooling pumps.

Piping arrangement

10.15.5 Water cooling system shall be supplied from at least two receivers which shall be interconnected.

In ships with one main engine with an output less than 220 kW one receiver is permitted which is located in the machinery space; two parallel-connected filters are required in such case.

10.15.6 Heating of sea chests of ships with ice strengthening shall comply with the requirements of 10.4.5.

10.15.7 The arrangement of the outboard water discharge pipeline shall be such that the highest cooled spaces of the engines, water coolers and oil coolers are always filled with water and no dead zones are created.

Cooling water filters

10.15.8 Filters shall be fitted on the suction lines of outboard water cooling system servicing the main and auxiliary engines.

Means shall be provided to enable the filters to be cleaned without stopping the cooling pumps.

Other devices of cooling system

10.15.9 Equipment for heating up the engines before starting shall be fitted in ships with ice strengthening. The heating up shall be carried out by heated cooling water. Steam heating up is not allowed.

10.15.10 The dual-cycle engine cooling system shall have expansion tank where the cooling water level is higher than the maximum cooling water level in the engine. The expansion tank shall be connected to the suction piping of the pumps and may be common for the cooling system of several engines. This tank shall be equipped with liquid level monitoring device and alarm on minimum level of cooling liquid in the tank.

To prevent cavitation damages of parts limiting the cooling spaces, the expansion tank shall be installed at the maximum possible height and fitted with hydraulic gate.

10.15.11 Expansion tanks shall be provided with manholes with gas-tight covers for inspection and cleaning of inner chambers.

Cooling systems with shell plating coolers

10.15.12 In engine cooling systems it is allowed to use shell plating coolers of inner cycle liquid. Such coolers are flat rectangular boxes directly adjoining the shell plating of the ship (inner cycle liquid circulates in flat ducts formed by partitions of these boxes and gives up heat to overboard water through shell plating of the ship), provided the following conditions are met:

.1 ships with one main engine shall have at least two shell plating coolers, one of which is a standby one;

.2 in ships with two and more main engines with one shell plating cooler for each engine it is allowed not to install standby cooler;

.3 each shell plating cooler shall be equipped with a device for air discharge;

.4 pipelines for delivery of inner cycle to coolers and discharge of cooling liquid from them shall be fitted with shut-off valves complying with applicable requirements of 10.4;

.5 devices for removal of inner cycle cooling liquid from the shell plating coolers shall be provided;

.6 calculations confirming serviceability of coolers under operating conditions of the ship set out in the specification shall be submitted.

10.16 COMPRESSED AIR SYSTEM

Number and capacity of starting air receivers

10.16.1 The compressed air system of main engines shall ensure simultaneous starting and reversing of main engines.

10.16.2 The total amount of starting air for the main engines starting and pneumatic con-
trol system shall be stored in at least two air receivers or two groups of air receivers; the capacity of each air receiver, or each group of air receivers shall be at least 50 per cent of that required in 10.16.3 and 10.16.4.

10.16.3 The total capacity of the air receivers for starting and reversing of the main engines shall be sufficient to provide at least 12 successive ahead and astern starts of the main engine in ready-to-start condition.

10.16.4 The total amount of starting air for the main non-reversible engines, as well as for main diesel generators shall be sufficient to provide at least 6 starts of the engine of the greatest available capacity in ready-to-start condition and, where there are more than 2 engines, not less than 4 starts of each engine in ready-to-start condition.

10.16.5 For auxiliary engines starting at least one air receiver shall be provided with the capacity sufficient for 6 starts of each auxiliary engine in ready-to-start condition and, where there are more than two auxiliary engines, not less than 4 starts of each engine in ready-to-start condition.

When one such air receiver is installed, it shall be possible to start the auxiliary engines from one air receiver or one group of air receivers of the main engines.

10.16.6 The total amount of the starting air stored in air receivers of the main engines indicated in 10.16.2 can be used to feed the typhoon whistle, as well as for domestic needs provided that:

.1 one air receiver (one group of air receivers) is separated from the other receivers by non-return valve and is intended only for main engines starting;

.2 the air receiver is fitted with automatic replenishing means and with alarm devices warning if pressure in the air receiver drops below the working pressure by not more than 0.5 MPa.

10.16.7 Air receivers of the auxiliary engines indicated in 10.16.5 may be replenished from the main air receivers indicated in 10.16.6; here, back air flow shall be precluded.

10.16.8 The air receivers shall be installed in such a way as to provide total removal of moisture under all working conditions.

Compressors

10.16.9 There shall be at least two main compressors, one of them may be hinged. In the event of failure of the compressor with the greatest capacity, the capacity of the rest compressors shall be sufficient to fill air receivers of the main engines from the pressure required to carry out the last start and manoeuvre to the pressure required to carry out the number of starts and manoeuvres referred to in 10.16.3 and 10.16.4, within one hour.

One self-contained compressor or compressor driven from auxiliary diesel with electric starter and manual start can be installed on high-speed ships. On high-speed ships with non-reversible main engines it is allowed to install one compressor suspended on main engines, provided the air receivers are filled by means of on-shore facilities.

10.16.10 In ships with non-reversible main engines the air receivers may be filled using an independently driven compressor. Compressed gas from the gas intake device, electric starter or other starting equipment may be used as the second starting device.

The capacity of the compressor or gas intake devices shall comply with the requirements of 10.16.9.

Piping arrangement

10.16.11 Pipelines intended to fill the air receivers shall be entirely separated from the starting pipelines.

10.16.12 Each of the starting air receivers specified in 10.16.2 to 10.16.8 shall be capable of being filled from each main compressor specified in 10.16.9 to 10.16.10.

10.16.13 Non-return shut-off valves shall be installed on the discharge pipe of each compressor.

The manifold supplying starting air to each engine shall have a non-return valve fitted before the starting valve.
The check valve may be omitted, if suitable devices preventing the spreading of explosion are provided in the engine design (see 2.11.1).

10.16.14 The pipes shall be led as straight as practicable with a slope for water drainage. The pipes shall not be sloped towards the master starting valve of the engine.

10.16.15 Temperature of air or compressed gases fed to air receivers shall not exceed 90°C. If the temperature exceeds 90°C, air coolers shall be provided.

The compressed air pipes shall not be laid under the machinery space flooring.

10.16.16 Suitable arrangements for draining oil and water accumulations shall be fitted on the pipes between the compressor and the air receivers, unless drain arrangements are fitted on the compressors.

10.17 BOILER FEED WATER SYSTEM

Pumps

10.17.1 Each self-contained boiler of class I or a group of boilers connected during operation shall be provided with at least two independently driven feeding pumps.

For self-contained boilers of class II one feeding pump and injector shall be sufficient.

For waste-heat exhaust gas boiler or a group of boilers which can be free of water when being heated by exhaust gas one feeding pump is sufficient per boiler or a group of boilers.

For boilers with manual feeding control the capacity of each pump shall be not less than 1.5 times the design steam capacity of the boilers, and for automatically controlled boilers — not less than 1.15 times the design steam capacity.

Where more than two feeding pumps are installed, their design capacity shall be such that if any of the pumps is out of operation, the total capacity of the rest is not less than the aforementioned capacity of one pump.

The capacity of each feeding pump of a direct-flow boiler shall be not less than the design steam capacity of the boiler.

10.17.2 Steam-driven feeding pumps shall have a separate live steam line supplied with steam from all boilers fed by these pumps.

10.17.3 Forced-circulation self-contained boilers of class I shall be serviced by not less than two circulating pumps, one of which is a standby pump.

The standby pump is to be automatically actuated.

Piping arrangement

10.17.4 In case of open circuit feeding system it shall be possible for the feeding pumps and injectors to intake water from the heated box, from the outboard and from the feeding water storage tanks.

10.17.5 The feeding system of each self-contained boiler of class I shall be so designed as to enable to feed the boiler or a group of boilers by each of the feeding pumps through two separate feeding lines, i.e. main and auxiliary lines.

For self-contained boilers of class II boilers one feeding pipeline is sufficient.

10.17.6 Design measures shall be taken to prevent the contamination of the feeding water system with oil and oil products.

10.18 STEAM AND BLOW-OFF LINES

Piping arrangement

10.18.1 Where two or more boilers are interconnected, steam pipe of each boiler shall be fitted with a non-return valve before connection to the common line. These valves may be omitted if the boiler stop valves are of non-return shut-off type.

10.18.2 Blow-down and scum valves of two or more boilers may be connected to a common discharge line, if a non-return valve is fitted on the blow-off pipe of each boiler before the connection to the discharge line. Boiler blow-off system shall be fitted with special devices preventing the circulation failure while blowing-off.

10.18.3 The facilities and equipment connected with the steam lines shall be relieved
10.18.4 The steam lines supplying the equipment and arrangements designed for a lesser pressure than the boiler pressure, shall be fitted with reducing valves, and the requirements of 10.2.17 shall be complied with.

10.18.5 The steam line branches intended for steaming out and steam smothering of the fuel tanks and liquid cargo tanks shall be fitted with check valves; the main line of the branches shall be fitted with a shut-off valve located in easily accessible place outside the tanks.

10.18.6 The steam lines in the engine and boiler rooms shall be laid in the upper parts of these spaces, in places accessible for inspection and maintenance.

Steam lines other than boiler heating and blow-off pipes shall not be laid under the floor plates of the engine and boiler rooms.

Steam pipelines shall be laid at a distance of not less than 1 m from fuel tanks.

10.18.7 Live steam lines shall have condensate drain arrangements to protect the equipment against water hammer.

10.18.8 Open ends of the steam blow-off pipes shall be led below the machinery space flooring (see also 10.5.2).

10.19 SYSTEMS WITH HIGH-TEMPERATURE ORGANIC HEAT TRANSFER FLUID

Pumps

10.19.1 At least two pumps, one of which is standby, shall be used to ensure circulation of heat transfer fluid.

10.19.2 Pressure gauge shall be installed on discharge pipeline of each pump.

10.19.3 Transfer pump shall be provided to fill the expansion tank and to pump the high-temperature organic heat fluid.

10.19.4 To ensure circulation of heat transfer fluid, the electric motors of pumps shall be fitted with shut-off devices meeting the requirements of 7.8.2 Part VI of the Rules to shut-off devices of electric motors of fuel and oil transfer pumps and separators.

Expansion tank

10.19.5 Systems with high-temperature organic heat transfer fluid shall have expansion tank placed in the highest point of the system.

Expansion tank capacity shall exceed the increase of volume of heat transfer fluid after heating to operating temperature at least 1.5 times.

10.19.6 The expansion tank shall be equipped with thermometer and level indicator. If transparent insert is used for this purpose, it shall comply with the requirements of 10.10.26.

Level indicator shall have heat transfer fluid low permissible level mark.

10.19.7 In open-type systems the expansion tank considering the applicable requirements of 10.10 shall be equipped with air pipe and overflow pipe brought out to discharge tank. If the discharge tank is not available, the pipe shall be brought out to high-temperature organic heat transfer fluid storage tank.

10.19.8 The expansion tanks shall be equipped with alarm of minimum and maximum levels of heat transfer fluid in the tank. When the alarm of minimum and maximum levels operates, the heating of high-temperature organic heat transfer fluid shall be automatically stopped with simultaneous shut down circulating pump.

10.19.9 The expansion tanks of close-type systems with inert gas in the upper part of the tank shall be equipped with pressure gauges or other pressure monitoring devices in the tank and safety valves. Branch pipe from safety valve shall be connected to discharge tank or heat transfer fluid storage tank.

It shall be possible to operate close-type system in the open-type system mode.
10.19.10 The expansion tank shall be equipped with a device for catching and discharging vapours and gases produced during operation of the system.

Storage tank

10.19.11 Storage tank capacity shall be sufficient for draining all high-temperature organic heat transfer fluid from the system.

10.19.12 When the storage tank is used for draining the high-temperature organic heat transfer fluid in it, this heat transfer fluid shall be drained from system by natural flow.

Air pipes

10.19.13 Air pipes of tanks with high-temperature organic heat transfer fluid shall comply with the requirements of 10.10.1 to 10.10.15.

Devices for collection of leakages and draining high-temperature organic heat transfer fluid

10.19.14 Devices for collection of leakages of high-temperature organic heat transfer fluid shall comply with the requirements of 10.13.17 to 10.13.20 to devices for collection of fuel leakages.

10.19.15 If the shut-off valves specified in 8.20.4.1 have no remote control, the device for draining high-temperature organic heat transfer fluid from the system to the discharge tank or storage tank according to 10.19.12 shall be provided.

10.19.16 Waste-heat boilers-heaters shall have devices preventing ingress of high-temperature organic heat transfer fluid to engine in case of leakages.

Cooling of heat transfer fluid

10.19.17 Systems with high-temperature organic heat transfer fluid provided with waste-heat boilers-heaters shall have a device for cooling heat transfer fluid if the boiler-heater has no bypass channel.

Boilers-heaters of high-temperature organic heat transfer fluid

10.19.18 Boilers-heaters of high-temperature organic heat transfer fluid shall comply with the requirements of 8.20.

Insulation

10.19.19 Insulation of pipelines and equipment of the system shall comply with the requirements of 1.9.2.

Heating of liquid cargoes

10.19.20 Systems with high-temperature organic heat transfer fluid for heating liquid cargoes with flash point of 60°C and less shall be used only if independent intermediate system located within cargo area is used.

Independent intermediate system is not required in the following cases:

- when circulating pump is stopped, the excessive pressure exceeding the static pressure of cargo by at least 0.03 MPa is maintained in the coils;
- the expansion tank of the system with high-temperature organic heat transfer fluid is provided with facilities for detection of flammable vapours of cargo;
- valves of separate heating coils are fitted with interlocking device that ensures that the coils are constantly under the static pressure.

10.19.21 Heat accumulators shall be used in the system for energy conservation. Their design shall comply with the requirements of 1.9.2, 10.19.6 to 10.19.9, as well as applicable requirements of 8.20.

Tests of pipelines of systems with high-temperature organic heat transfer fluid

10.19.22 Pipelines of systems with high-temperature organic heat transfer fluid shall be tested according to 10.6 similarly to fuel pipelines.

10.20 CARGO VAPOUR DISCHARGE SYSTEM

10.20.1 If the ship is equipped with cargo vapour discharge system, the system of cargo
level measurement shall be closed. Semi-closed systems, where only a part of tank limited by the gauge tube communicates with the atmosphere, can be used as a standby level measurement system.

Cargo vapour discharge system shall be arranged so as not to impede normal operation of gas outlet system.

The cargo vapour discharge system shall be designed based on maximum loading efficiency. Pressure drop in the cargo vapours discharge pipeline obtained by hydraulic calculations shall not exceed 80% of opening pressure of any of gas outlet system valves specified in 10.10.21.

10.20.2 Cargo vapour discharge system shall be so designed as to exclude the possibility of mixing the vapours of incompatible cargoes transported on the ship.

10.20.3 Devices for removal of condensate accumulated in the system pipelines shall be provided.

10.20.4 System pipelines shall be electrically conductive throughout the entire length and shall be reliably grounded.

10.20.5 End sections of cargo vapours discharge pipeline shall be equipped with pressure sensor and alarm. The alarm operates when reaching the pressure not higher than the pressure at which high-speed gas-outlet arrangement operates and in case of vacuum. In this case alarm actuation pressure shall be not less than the pressure at which vacuum valve operates.

This requirement does not apply to ships where excessive pressure/vacuum sensor is installed in each cargo tank according to 10.10.22.

10.20.6 Manually operated shut-off valve shall be installed near the connecting branch pipes of end sections of cargo vapours discharge pipeline in a place accessible for maintenance.

10.20.7 Hoses used in the vapour discharge system shall comply with the requirements of 10.2.67.

10.20.8 To exclude incorrect connection of cargo vapours discharge pipeline to the liquid cargo pipeline of shore terminal, pins of 12.7 mm dia and at least 25.4 mm long shall be installed on connecting flanges of end section of cargo vapours discharge pipeline in the uppermost point on the line of coupling bolts as it is shown in Figure 10.20.8-1. End section of the cargo vapours discharge pipeline shall be marked as shown in Figure 10.20.8-2.

Fig. 10.20.8-1. Pin on connecting flange of the end section of cargo vapour discharge pipeline

Fig. 10.20.8-2. Marking of the end section of cargo vapour discharge pipeline

10.21 INERT GAS SYSTEM OF OIL TANKERS

10.21.1 Inert gas system shall ensure supply of gas in the amount of not less than 125% of the maximum rated capacity of cargo pumps and creation of pressure not exceeding 20 kPa in the filled spaces.

10.21.2 Inert gas plant shall have the following:

.1 inert gas generators or equipment drawing off gases from boiler funnel uptakes;

.2 equipment for gas cooling and purifying from solid particles and sulphur combustion products and inert gas drying (gas purifying installations);
.3 fans (steam ejectors) for gas injection; 
.4 piping and valves for gas delivery and gas discharge control in the protected spaces; 
.5 control devices monitoring the volume fraction of oxygen or carbon dioxide, gas temperature and pressure; 
.6 audible and visual alarm on the limit temperature of inert gas supplied to the protected compartments.

The delivery piping of inert gas system shall be fitted with temperature sensors in front of the first branch to the protected space.

10.21.3 Oxygen volume fraction in inert (smoke) gases shall not exceed 5%.

10.21.4 Temperature of the inert gas delivered to the protected spaces shall not be above 40°C.

10.21.5 Gas purifying installations shall be installed from the suction side of fans or from the injection side of steam ejectors.

10.21.6 The inert gas system shall be so designed as to enable blow-down of compartments by air. Air inlet shall be fitted with shut-off valves with indicators “Open” and “Closed”.

10.21.7 Audible and visual alarm shall be actuated resulting from changes of the installation parameters in the following cases: 
.1 rise of inert gas temperature above 40°C — audible and visual alarm is actuated; 
.2 rise of inert gas temperature above 60°C — the fan is switched off or steam supply to the ejector is stopped.

10.21.8 Inert gas system shall be fitted with cooling system. No special pumps may be provided for that purpose.

Piping and valves

10.21.9 Atmospheric pipeline shall be provided for stable operation of the inert gas installation during its preparation for operation or stopping the gas delivery to the protected spaces. Pipe for gas discharge to the atmosphere shall be fitted on the discharge line of inert gas supply to the protected spaces in front of the first shut-off valve.

10.21.10 Gas supply pipelines shall be fitted with bleeder plugs for condensate drainage the devices providing for the piping steaming and cleaning from corrosion products and dirt.

10.21.11 The inert gas system pipeline in front of a branch to the nearest protected space shall be fitted with non-return shut-off valve or similar device preventing from gas entering from cargo compartments to the gas purifying installation (the heat exchanger — the gas cooler) if fans/steam ejectors stop. Where a waterlock is used as a check device, the latter shall be supplied with water simultaneously.

10.21.12 Measures should be taken to prevent the waterlock from freezing but in a such way that its impermeability is not imposed by heating.

10.21.13 If a fan (steam ejector) can create pressure exceeding the permitted value, the inert gas pipeline shall be fitted with a safety device of liquid type or other equivalent type to prevent creation of excessive pressure of more than 20 kPa in the protected spaces.

10.21.14 Pipeline branches for inert gas delivery to the protected cargo spaces shall be arranged in the upper part of the spaces above the oil level as far apart as possible from gas outlet lines and those for gas delivery to spaces adjacent to cargo spaces — in the lower part of the spaces. Each branch shall be fitted with fire barriers and shut-off valves.

The inlet of such outlet pipes may be located either at deck level or at not more than 1 m above the bottom of the tank. The cross-sectional area of inert gas outlet pipe shall be such at to ensure gas rate of at least 20 m/s at the outlet when inert gas is simultaneously fed to any three tanks.

Outlets shall be above the deck level at a height of at least 2 m and a system for their closing shall be provided.

10.21.15 Provision shall be made for devices to connect the inert gas main to external source of inert gas.
10.21.16 Tankers fitted with a fixed inert gas system shall be provided with closed system of liquid level measurement in tanks. Semi-closed instruments can be used as standby level measurement facilities.
11 AUTOMATION

11.1 SCOPE OF APPLICATION TERMS AND DEFINITIONS

11.1.1 Requirements of this Section apply to automation systems and devices and their components used in ships of all types and purposes irrespective of automation symbol in the class of ship. In addition to requirements of this Section the following requirements shall be met: 9.18, 10.21.2.6, 10.21.7 of this Part, 3.4.11, 3.4.17, 3.8.24, 3.9.3, 3.9.14, 3.9.16, 3.9.17, 5 Part III and 3.4, 3.5, 3.7, 4.2.10, Table 4.5.1, 6.1.16, 6.10.8, 7.1.1, 7.2.6, 11.3 to 11.6, 17.6.2, 17.6.3, 17.7.2, 17.7.5 Part VI of the Rules.

11.1.2 The requirements of the present Section shall be met when ships operate with unattended machinery spaces or with attended central control station.

Requirements of 11.7, 11.8.3, 11.9 to 11.12, 11.14 and 11.15 apply to ships of all types and purposes irrespective of automation symbol in the class of ship, unless otherwise specified.

11.1.3 The following definitions are used in this Section.

.1 Actual status indication system means an independent unit or part of automation system which are intended for informing the personnel about accomplishment of the preset commands by control systems and availability of power supply.

.2 Generalized alarm means a signal emitted by an object or a group of objects which parameters are being checked; however, these signals are not passed directly from control sensors to the control panel and are not decoded. Such a signal is generated by the alarm system when at least one of the controlled parameters deviates from the preset range.

.3 Propulsion plant means an executive part of the ship’s power installation where energy of fuel used by the main engines is converted into thrust transmitting movement to the ship’s hull. Generally the propulsion plant comprises main engines, gearings, shaftings and propellers.

.4 Alarm system means a system intended to give visual and audible signals when the preset limits of monitored parameters are exceeded or in the event of abnormal running condition of the power installation components.

.5 Automation system means a complex of elements, appliances and joints intended for performance of assigned monitoring and control functions.

.6 Remote automated control system means a control system which ensures setting up the desired mode of operation of the machinery from a remote control station by single manipulating the control element (e.g. handle) with all subsequent intermediate steps performed automatically.

.7 Remote control system means a control system for which an operator shall manipulate the control elements fitted at a remote control station for performing intermediate steps.

.8 Protection system means a system intended for a specified automatic influence on the plant under control in order to prevent an emergency or restrain its consequences.

.9 Monitoring system means a system which ensures visual control of the proper functioning of supply, control and checking systems as well as clarifying the situations when a parameter ensuring normal operation of the power installation or systems deviates from the safe operation range.
.10 **Automation element** means any hydraulic, pneumatic, electrical or electronic item being a part of automation devices and/or systems (e.g. amplifier, sensor, relay, microchip, logic element etc).

### 11.2 GENERAL REQUIREMENTS

11.2.1 Automation systems shall be so designed that in case of failure of light or sound alarm units the serviceability of other circuits shall remain intact.

11.2.2 Electrical, pneumatic and hydraulic elements, equipment and automation systems shall be operable in service conditions indicated in 2.2 Part VI of the Rules.

11.2.3 Protection class of electrical and electronic automation elements and devices depending on their location shall comply with the requirements of 2.3.6 Part VI of the Rules.

11.2.4 Hydraulic and pneumatic automation systems shall operate reliably under working medium pressure variation within ±20 % of the nominal value.

11.2.5 Automation systems shall be so designed that the replacement of any elements or devices by similar ones neither affects the system serviceability no requires additional adjustment of the system.

11.2.6 In automation systems measures shall be taken to prevent false alarms caused by momentary changes of parameters (see Table 2.2.1 Part VI of the Rules) due to roll and pitch of the ship, activation and deactivation of the onboard machinery.

11.2.7 Automation systems shall be based on the “fail-safe” principle.

11.2.8 Automation systems and devices shall have protection against interferences created by external magnetic and electric fields with consideration of parameters specified in 2.7 Part VI of the Rules and protection against sudden deviations of voltage and current frequency from their rated values specified in 2.2.1 Part VI of the Rules. Automation systems shall be electromagnetically compatible with other electrical and electronic equipment, including communication and navigation facilities. In the course of operation the automation systems shall not create electromagnetic interferences the levels of which exceed the ones in Table 2.7.3-1 and 2.7.3-3 Part VI of the Rules.

11.2.9 Automation systems shall make it possible to activate onboard machinery and installations, automatically or remotely, after they have been switched off by protection devices, only after the protective devices manual have been manually reset to the initial position from the local control station.

11.2.10 It shall be possible to check the automation devices without changing operation mode of onboard equipment.

11.2.11 Provision shall be made for manual adjustment of each of the automatically adjusted parameters. Any damage, failure of automated control system or remote control system shall not bring to failure of the manual control.

11.2.12 It shall be possible to control each remotely controlled technical facility from local control stations, except for the cases specified in 1.5.1.

11.2.13 When remote control of the technical facilities is provided, it shall be possible to control the accomplishment of the given orders.

11.2.14 Piping of hydraulic and pneumatic control systems shall comply with the requirements of 10.2 including their fitting with protection devices. Protection class of electrical control systems shall comply with the requirements of 2.3.6 Part VI of the Rules.

11.2.15 All automation systems and equipment installed in the machinery spaces shall be adapted for unattended operation at least for a period when the machinery space is not attended by the personnel. Single short-term
(up to 2 h) maintenance operations of automation systems and devices are permitted, if these operations are envisaged by respective instructions and their periodicity complies with technical and operating documentation.

11.2.16 Replaced components and devices requiring adjustments, as well as check measurements points (terminals, sockets), shall be arranged in a way to have free access.

11.2.17 Adjustment components shall have protection against inadvertent change of adjustment and have a possibility of repeated adjustment.

11.2.18 Places for input of cables and wires, including the places of connection to moving components and devices, shall be provided with arrangements for tension relief and prevention of cable or wire bending.

11.2.19 Measures shall be taken to exclude the possibility of incorrect replacement of detachable units with plug and socket connectors, as well as measures on their reliable detention in the operating position. If this is required by functional or design features of components and devices, their arrangement ensuring correct installation shall be marked or their design shall be such as to exclude the possibility of their installation in other position.

11.2.20 Actuating mechanisms and devices shall be so designed as to prevent inadvertent change of their preset position.

11.2.21 Measurement range of analogue sensors shall exceed the variation range of the respective measured parameter by at least 20%.

11.2.22 It shall be possible to clean the filters of pneumatic and hydraulic automation systems during operation without stopping the system.

11.2.23 Hydraulic automation systems shall not be combined with other hydraulic systems of the ship.

11.2.24 Feeding pipelines of pneumatic automation systems shall be equipped with safety valves operating when nominal working pressure is exceeded by more than 10%.

Pressure-reducing valves, if any, shall be backed up.

11.2.25 Hydraulic, pneumatic and electrical or electronic components and devices installed together on consoles, cabinets and units shall be separated from each other so that the leakages in pipelines and hoses and in their connections cause no damage of pneumatic, electronic and electrical components and devices.

Consoles, cabinets and units accommodating equipment with fluid working medium shall be equipped with devices for collection of fluid leakages.

11.2.26 Pneumatic and hydraulic components and devices shall remain serviceable in case of short-term (up to 1 min) increase of working medium up to 1.5 of working pressure of this medium.

11.3 POWER SUPPLY

11.3.1 Automated control system of standby component of the power installation shall be supplied independently of the automated control system of the respective main component of the power installation.

11.3.2 Alarm system and protection circuits shall be energized and de-energized automatically at energization and de-energization of the control system of the particular component of the power installation.

11.3.3 Hydraulic and pneumatic automation systems shall be supplied from two sources. Standby source shall be connected automatically in case of supply pressure loss in the main source.

Automation systems may be supplied from the starting air system, if the automatic replenishing of air reservoirs is provided.

11.3.4 If air for supplying pneumatic automation systems requires drying or cleaning, two devices shall be provided. However, one device may be used, if filtering elements can be replaced without interrupting the operation.
11.3.5 Electrical automation systems shall remain serviceable under supply voltage and frequency deviations specified in 2.2.1 Part VI of the Rules. Triple power supply failure with interval of not more than 30 s shall not affect serviceability of automation systems.

11.3.6 Automation systems and devices shall receive power supply from main and emergency power supply sources if such power supply is provided for automated technical facilities.

11.3.7 Power installation electrical control systems shall receive power supply via two independent lines — main and standby— from different boards. The main line shall be connected to the main switchboard; reserve line, to the board feeding power supply to critical consumers or to the nearest switchboard. In case of power supply failure or it further normalization on the buses of main switchboard, the power supply shall be changed over between the lines automatically with transfer of light signal to the control station in the wheelhouse.

11.3.8 Stop of power supply or deterioration of working medium or power supply parameters in automatic or remote control systems shall not cause failure of technical facilities and change of their operation mode.

11.3.9 Alarm and protection systems shall receive power supply from interrupted power supply source; when supply voltage at its input disappears, the alarm signal shall be fed.

Accumulator battery of such source shall ensure power supply of alarm and protection systems for at least 30 min of their continuous operation.

11.3.10 Power supply of generator driving motors control system shall not depend on availability of voltage on the buses of main switchboard.

11.4 CONTROL, ALARM, PROTECTION AND MONITORING SYSTEMS

11.4.1 Each of the control, alarm, protection and monitoring systems shall be independent and perform not more than one of the respective functions. Malfunction or failure of any of the systems shall not affect the operation of the others. Connection of the control, alarm and protection systems including common sensors for alarm and protection systems is permitted if the operability of the systems is provided.

11.4.2 The alarm system shall give visual and audible signals simultaneously. An existing alarm is not to prevent the indication of any further fault. Reception of one signal shall not impede reception of another one. Failure of one component (device) of the system shall not cause failure of the entire alarm system.

Alarm system shall have self-check functions in case of such damages, as short-circuit, circuit opening and ground fault. In case of power supply failure the alarm signal shall also be fed.

Central information panels of the alarm system are to be placed in the central control station or in the wheelhouse. Alarm system shall be equipped with the general alarm subsystem, the units of which shall be placed in:
- machinery spaces if they are not equipped with uninterrupted light sources operated in case of alarm system signal;
- wheelhouse if the central information panels are not placed in the wheelhouse;
- places where the service personnel stays most of the time if the ship has no central control station and wheelhouse.

Audible signal may be generalized for all alarm systems; there shall be a possibility of switching-off such a signal provided that it is ready for operation immediately after it has been switched off, for forthcoming signals about faults. Disabling of sound signal on general alarm units shall not disable sound signal in the central control station.

Visual signals shall indicate the reason of the alarm system actuation and be actuated by means of indicators which correspond to the current situation or fault. When an indicator is actuated in the event of faulty, it shall generate flashing light signal. After acknowledgement the flashing light signal shall be transformed into a signal of permanent light intensity and be extinguished automatically only after
the fault has been withdrawn or the fault mechanism, device, system or the part of the alarm system has been disconnected. Sound and light signals shall be fed simultaneously.

It is allowed to use common monitors instead of individual light signal indicators.

11.4.3 Light signals shall comply with the requirements of 6.1.16 Part VI of the Rules.

11.4.4 Audible signal of the alarm system should differ from other audible signals.

11.4.5 It shall be possible to check the alarm system without changing the operation mode of onboard equipment.

11.4.6 Protection system shall operate automatically for the preset parameters in case of faults which can cause failure of the protected ship machinery. When protection system operates, light and sound signals shall be generated. Protection system indication shall fix the parameter because of which protection operated.

11.4.7 Protection systems of separate components of power installations shall be independent of each other.

11.4.8 Faults after which the system restores its serviceability without repair or intervention of specialist (transient failures) shall be treated by alarm system in away to save the signal until acknowledgment.

11.4.9 Irrespective of the power installation automation and their operation monitoring the alarm system shall generate the signal in the following cases:

1. monitored parameters reach the limit values;
2. protection system operation;
3. no power supply for separate automation systems or start of emergency power sources;
4. change of other parameters or states, the alarm for which is required in accordance with this Part of the Rules.

Fault alarm for technical facilities shall be provided in remote control stations of these facilities.

11.4.10 Alarm system shall be so designed that the signals other than ship control and navigation situation signals are fed first to the consoles (boards) to machinery spaces and central control station. If the machinery spaces (central control station) are unattended, these signals shall be fed to the wheelhouse.

11.4.11 The "personnel in machinery space" alarm shall inform the wheelhouse on safety of an engineer on duty in the machinery space without other personnel.

11.4.12 Manually locked signals shall be indicated on alarm console.

11.4.13 Interlock of alarm and protective functions in some operation modes of the power installation (for example, during start of engines) shall be automatically disabled when the power installation is switched to other operation mode.

11.4.14 Protection cut-off devices shall exclude their inadvertent start. The control consoles of technical facilities shall have a light signal about activation of protection cut-off device.

11.4.15 If the technical facilities are stopped after emergency protection operation, such facilities shall not be started automatically after eliminating the causes of protection operation.

11.4.16 Indication systems shall be so designed that the information is indicated in the units used in the Russian Federation for measured values without conversion.

11.5 GENERAL REQUIREMENTS TO AUTOMATION

11.5.1 By the scope of requirements to automation in this Rules the ships are divided into the following two groups:

Group I — ships without continuous attendance of machinery spaces and central control station by the servicing personnel;

Group II — ships without continuous attendance of machinery spaces by the servicing
personnel and with continuous attendance of central control station;

**Notes.**
1. "+" — warning signal; ☐ — emergency signal; R — recommended.
2. Requirements of 1.5, 1.12, 1.13, 1.14, 1.15 and 2.5 of this Table do not apply to ships of groups I and II with a length less than 25 m or total capacity of main engines of 400 kW and less or dynamically supported ships (hydrofoil craft, hovercraft).

Each engine designed to drive ship machinery or electrical equipment of ships irrespective of "A" symbol in the ship class formula of ship shall have sound and light alarm installed to generate signals when oil pressure in lubrication system of the engine reduces. Alarm devices for the following parameters shall also be installed on this engine:

1. Reduction of pressure in inner cycle of engine cooling system or increase of temperature of liquid circulating in the inner cooling cycle at the engine output;
2. Reduction of oil level in header tank of turbochargers;
3. Increase of temperature of thrust bearing built in the engine.

**11.5.4** In the case of no central control station the general alarm signals of power installation components listed in Table 11.5.2 shall be indicated in the wheelhouse. These signals shall be decoded in the machinery spaces, either centrally or at local control stations. Alarm signals of the main engines, power propulsion plant, diesel generators, boilers, compressors, separators, pumps, compressed air systems, fire fighting and drainage systems for each of the monitored parameters shall be decoded in machinery spaces at local control stations.

**11.5.5** Visual alarm signals at the ship control station shall be as far as possible generalized. Generalization shall comply with the following requirements:

1. For each main engine together with its gear and shafting as well as for each auxiliary engine warning signals and generalized emergency signals shall be separated;
11 Automation

.2 for each group of auxiliary components of the power installation intended for the same purpose together with their systems one generalized alarm signal may be provided;

.3 signals on the control systems’ supply break-out, fire danger, water presence in the holds, faults of fire protection and spark-extinguishing systems shall not be generalized.

11.5.6 Generalized alarm for Group I ships is to be fitted in spaces attended by responsible personnel (service, public, accommodation spaces etc.); this requirement is recommended for Group II ships.

11.5.7 Changeover of control from the local control of the main components of the power installation to the automatic one and back shall be possible only at local stations; the indication of the station from which the control is being exercised shall be provided in the wheelhouse. Possibility of simultaneous control from a remote station and a local station shall be precluded.

In case of several control stations the central control station shall have a priority with respect to the control station in the wheelhouse. Local control station of main engines shall have a priority with respect to the central control station.

The control can be changed over from one station to another only from the priority station.

When the control is changed over, sound and light signal shall be fed to all control stations. At each control station it is to be indicated which location is in charge.

11.6 PROPULSION PLANT

11.6.1 Main engines and gearings and the entire propulsion plant, including steerable thrusters, shall be controlled from the wheelhouse by means of remote automated control system or remote control system and from the machinery space.

If the ship’s breadth exceeds 10 m, in addition to the main station of the remote automated / remote control system at the ship control station, provision shall be made for side stations of the remote automated / remote control system. The possibility of simultaneous control of propulsion plant components from the specified stations shall be excluded.

For propulsion plants with non-reversible engines with reverse reduction gears the remote automated control systems may be used, which ensure the change of direction and rotation frequency of the reverse reduction gear output shaft by one control device and the engine start-up and shutdown by other control device.

In propulsion plants with engines having output less than 220 kW the engines or the entire propulsion plant can be controlled by the remote control systems.

11.6.2 Remote automated control system of each main engine shall ensure:

.1 remote setting of the required operational modes by a single control device;

.2 execution of the last set command irrespective of the sequence and speed of setting;

.3 start-up of the engine prepared for operation, mode change, shutdown, reversing and automatic execution of intermediate operations according to the set program without the engine and gear overloading;

.4 stepless (smooth) rotation frequency change at all operation modes of the engine;

.5 stable engine operation in the whole working rotation range;

.6 air supply stoppage or electric starter switch-off when the engine reaches the mode ensuring reliable switching over to the fuel consumption as well as in case of start-up failure.

.7 prevention of engine overload under normal standard operating conditions;

.8 generation of alarm signal about unsuccessful engine starting.

11.6.3 Static error of remote automated control system of main engines or propulsion plant with steerable thrusters for rotation speed control circuit shall not exceed +1.5 % of the rated speed of engine shaft or rotation speed corresponding to full power.

11.6.4 No malfunctions or supply failure of the remote automated control system may result in shutdown, rotation frequency in-
crease or change of the propeller’s thrust direction.

11.6.5 All engine control operations shall be carried out from any remote control station in the wheelhouse without any change-over, or the indication indicating which station is used for control shall be provided.

Control handles at remote control stations in the wheelhouse shall move simultaneously independently of the particular station from which control is exercised.

11.6.6 Provision shall be made for switching-off remote control station of the remote automated control system and changeover to the local control regardless of the current position of the remote control handle, with the exception of the remote automated control systems in ships with diesel-electric propulsion plant.

Changeover of control from one station to another one shall not result in changing of the operation mode of the main engines or propellers.

11.6.7 Provision shall be made for devices of immediate remote shutdown of engines independently of the control, alarm and protection systems.

11.6.8 The wheelhouse shall be provided with devices for disabling the automatic protection of the engine, except for rotation speed protection and, in justified cases, protection against minimum pressure of lubricating oil at the engine inlet and “Protection disabled” indication.

11.6.9 Cooling water (liquid) temperature in the inner circuit as well as oil temperature in the cooling system and lubrication system of the main engines shall be regulated automatically.

11.6.10 All control stations of the ships equipped with engine-order telegraphs shall have permanent indication of commands set by an engine-order telegraph.

11.6.11 For the engine using fuel oil the following shall be met: requirements of Table 11.5.2 to minimum scope of control, type of automatic protection and alarm and additionally the requirements of Table 11.6.11. Central station or wheelhouse shall have permanent indication of alarm on engine operation at the parameters stated in Table 11.6.11.

</tbody>
</table>

The valves supplying fuel to engines shall be automatically closed upon alarm operation at the parameters stated in Table 11.6.11. It is recommended to provide alarm on maximum combustion pressure.

11.6.12 Devices for emergency stop of main engines and forced disabling of protection shall be so designed as to exclude their unauthorized start.

11.6.13 Operation modes of main engines set from the wheelhouse shall be indicated in the central control station (if any on the ship) and in the local control stations of main engines.

11.6.14 Remote automated control system of propulsion plant with steerable thrusters shall ensure:

1. possibility of start/stop of main engine by separate control;
2. remote setting of the required operational modes by a single control device;
3. execution of subsequent forthcoming command with cancelling the previous ones in case of quickly alternating commands;
4. change of mode, reversing (for setting with limited angle of thruster turning), turning of thruster to the preset angle and automatic execution of intermediate operations under the given program without engine overload;
5. stepless (smooth) change of rotation speed and turning and direction of propeller thrust;
6 stable engine operation in the whole working rotation range;
7.2 air supply stoppage or electric starter switch-off when the engine reaches the mode ensuring reliable switching over to the fuel consumption as well as in case of start-up failure.
8 impossibility to start propeller drive and thruster turning system if the steerable thruster is not in the operating position;
9 possibility of check of system serviceability.

11.6.15 No malfunctions or supply failure of the remote automated control system shall result in shutdown, rotation speed increase or change of the propeller thrust direction.

11.6.16 Provision shall be made for switching-off remote control station of the remote automated control system of propulsion plant with steerable thrusters and changeover to the local control irrespective of position of the remote control handle.

11.6.17 Remote control system of the propulsion plant with steerable thrusters and remote control system of the thruster shall ensure:
1. possibility of start of propulsion plant main engine and its stop by means of separate control;
2. for the reversible plants equipped with reverse coupling or reverse reduction gear with limited angle of turning of $\pm 35^\circ$ and reversible (fixed) thrusters — change of rotation speed and direction of propeller rotation by means of one control;
3. control of steerable thruster turning by means of separate control;
4. possibility of control of propulsion plant and transverse thruster with disabled (faulty) remote control system from local control station;
5. possibility of stepless smooth change of rotation speed and direction of propeller thrust, change of angle of turning of propulsion plant thruster;
6. impossibility to start propeller drive and steerable thruster turning system if the propulsion plant or transverse thruster is not in the operating position;

11.6.18 Any faults of remote control system shall not stop, increase rotation speed and change direction of rotation of propeller thrust.

11.7 PRIME MOVERS OF GENERATOR SETS

11.7.1 Prime movers of the ship generators shall be equipped with remote control system or remote automated control system from the wheelhouse or the central control station.
Prime movers shall be automatically maintained in the ready-to-work condition.

11.7.2 Interval from the moment of activation of start-up signal to the preparedness for reception of 100 per cent load for the ready-to-work engine shall not exceed 30 s.

11.7.3 It shall be possible to receive load by non-warmed-up prime movers of auxiliary generator in case of emergency start from the remote control station.

11.7.4 Cooling water temperature in the inner cycle of prime movers of generators shall be adjusted automatically.

11.7.5 Control systems of generator units shall provide the following types of control:
1. remote start and shut-down of generator unit;
2. automatic start of standby generator unit, automatic synchronization, reception and distribution of load in the following cases: operating generator / generators reaches / reach maximum permissible load;
3. automatic start of standby generator unit and its start in case of failure of main (at the given moment) operating generator unit;
4. remote start and automatic switching-on of the diesel generators for operating in parallel from the wheelhouse or the central control station (when Group I or Group II ship is equipped with remotely controlled drives of capacity commensurable with that of the generator set);
5.5 remote start, shutdown, synchronization, distribution of load from the central control station or from the main switchboard, when the latter is located in the central control station room (for ships of group II).

11.7.6 Control stations of generator units shall have indicators to indicate readiness of generator units for immediate (automatic) start.

11.7.7 Control system of generator unit primary movers shall ensure preliminary selection of generator units automatic start sequence and their connection to main switchboard busbars.

11.7.8 The start system of high power consumers, the start of which can cause impermissible voltage drop as compared to deviations listed in Table 2.2.1 Part VI of the Rules or de-energizing of main switchboard buses, shall have automatic pre-start of standby generator, synchronization, reception and distribution of load or interlock prohibiting start of such consumers till the moment of connection of standby generator to the main switchboard buses and the appropriate indication.

11.8 FUEL SYSTEMS

11.8.1 Daily service fuel tanks of engines and boilers shall be replenished automatically.

11.8.2 Dual-fuel (diesel oil and heavy fuel) systems of engines’ supply shall provide the following:

.1 remote control of heating-up and pumping of heavy fuel, supply changeover from diesel oil to heavy fuel and vice versa;

.2 automatic maintaining of preset viscosity (temperature) of heavy fuel;

.3 automatic changeover to diesel oil in case of inadmissible increase of viscosity (temperature drop) of heavy fuel as well as at supply break of drives of the dual-fuel system valves and pumps;

.4 automatic maintaining of fuel circulation through the heaters after they have been switched off for a period of time sufficient for the prevention of fuel overheating in the heaters.

.5 installation of alarm sensors for excessive fuel temperature.

11.8.3 Technological operations of start, shutdown, slag and sludge removal processes in heavy fuel purifying installations shall be automated.

11.9 COOLING, LUBRICATION AND COMPRESSED AIR SYSTEMS

11.9.1 In ships of Group I automatic start of stand-by circulating cooling and lubrication pumps of main and auxiliary engines and gears, stand-by pumps of lubrication and pumping of shafting bearings shall be provided in the event of failure of the main pumps.

11.9.2 Preliminary oil circulation pumps of the main engines shall start remotely and switch off automatically after the completion of the engine’s start.

When the turbo-compressor rotor bearings are not provided with separated (independent) lubrication system, preliminary oil circulation pumps shall start automatically at the moment of the engine shutdown signal actuation and stop automatically after the turbo-compressor rotor has been stopped.

11.9.3 Air receivers for starting air, typhoon and domestic needs as well as supply air for automation systems shall be replenished automatically.

It is necessary to provide the possibility of start and shutdown of self-contained compressors from the wheelhouse (for ships of group I) or the central control station (for ships of group II).

Compressor separators shall be blown-off automatically.

11.9.4 Air compressors shall start automatically under pressure drop in the air receivers by not more than 30 per cent of the nominal value and shut-down when reaching 97 to 103 per cent of the nominal pressure.

11.10 BOILERS

11.10.1 The automation system of fuel oil fired steam boilers shall provide:

.1 automatic regulation of the steam pressure, water level in the boiler, pressure of the feed water, fuel pressure at the atomizer inlet;

.2 automatic control of the boiler pumps;
11 Automation

11.10.2 Each boiler shall have at least two independent water level sensors connected to different sampling points, one of which is used solely for emergency protection.

11.10.3 Automation system of exhaust heat boilers in which steam pressure is regulated by changing the flow direction of engine exhaust gases through the boiler, shall provide automatic switching-over of gas bypass device.

When the steam pressure is regulated by steam bypassing to the condenser, automatic regulation of the bypass device shall be provided.

Water level in the steam separator shall be maintained automatically.

11.10.4 The automation system of fuel oil fired hot-water boilers shall provide:

- automatic regulation which guarantees continuous hot water supply of consumers for their operation in all operation modes;
- ventilation of furnace space with sufficient air change before supplying fuel;
- interlock preventing automatic switching-on of boiler in case of faults for which in Table 11.5.2 protection is provided.

11.10.5 Automation system of exhaust-heat hot-water boilers shall provide automatic switch-over of the device regulating flow direction of exhaust gases through the boiler or directly to the atmosphere depending on the temperature in the boiler.

11.10.6 When two and more boilers operating for the common main are installed on the ship, it is necessary to provide automatic control of single operation under load of each boiler, if envisaged by the design, keeping of standby boilers in ready state and their connection to load, parallel operation of boilers and their disconnection from load.

11.10.7 It shall be possible to disconnect the burning units of self-contained boilers remotely and close the dampers of waste-heat boilers from the continuously attended control station.

11.10.8 Actuation of boilers from cold state after protection operation and in case of unsuccessful ignitions of fuel or flame extinction shall be carried out only from the local control station.

11.11 SHIP GENERAL SYSTEMS

11.11.1 Where remote control and indication of actual opening and closing of shut-off and stop valves of ballast piping, remote indication or water level alarm in ballast compartments are available, valve controls, indicators and alarm devices shall be fitted at local stations.

11.11.2 Tankers shall be fitted with remote indication system or a system signalling on the limit (95%) and emergency (98%) of the liquid level in tanks; indicators or alarm devices shall be located in the wheelhouse or the loading control station. General light and
sound signals about limit and emergency levels of liquid in tanks shall be brought to the open deck.

11.11.3 It is allowed to fit ships of group I with automated drainage system of machinery spaces by means of pumping bilge water to a special tank or overboard where discharge is allowed, if the ship is equipped with system purifying bilge water from oil fractions to the values stated in Table П2.1 and Table П2.2 Appendix 2 of RPPS.

11.11.4 Separate sensor independent from sensors installed for control of bilge pumps shall be provided for alarm about maximum permissible level of bilge waters.

11.12 WHEELHOUSE EQUIPMENT

11.12.1 Control devices, indication and alarm appliances in the wheelhouse shall be fitted at the panels constructed for using by one person.

11.12.2 Control of the main engines, fire pumps, aerosol fire suppression system and spark extinguishing system shall be exercised from the wheelhouse irrespective of the presence of the central control station on the ship.

Moreover in ships of group I the following power installation components and ship machinery which are not started automatically shall be controlled from the wheelhouse:

.1 electric power plant;
.2 self-contained boilers;
.3 compressor units;
.4 bilge pumps;
.5 machinery ensuring operation of main engines.

11.12.3 Visual alarm shall be so designed as not to blind the ship’s operator and be distinctly visible during daylight hours.

Provision shall be made for the regulation of luminescence brightness of actual status indication lamps.

11.12.4 Indication of the following parameters shall be provided:

.1 rotation speed and direction of propellers (rotation speed and position of blades of controllable pitch propellers);
.2 lubricating oil pressure at the main engines’ inlet;
.3 cooling water temperature in the inner circuit at the main engines’ outlet;
.4 air pressure in starting air bottles of the main engines and audible signal air bottle;
.5 pressure of working medium in the remote automated control systems of the main engines and couplings;
.6 voltage and load current of generators.

The indication of the parameters mentioned in 11.12.4.2, 11.12.4.3 and 11.12.4.6 may be dispensed with in the permanently attended central control station.

11.12.5 In case of non-reversible main engines and reversible main diesel-reduction gear sets the indication of crankshaft rotation frequency shall be provided. Indication of rotation frequency and direction of propellers may be dispensed with for non-reversible engines with capacity up to 220 kW inclusive, however, indication of actual reversing shall be provided.

11.12.6 In ships with shaft generators the indication of electric current frequency and voltage shall be provided.

11.12.7 Where side stations of the remote automated control system of the main engines are provided on the ship, the frequency and direction of propellers’ rotation, position of rudders and thrust direction shall be indicated on these stations. On side stations control of steering drives and thruster shall be provided also.

11.12.8 Generalized visual alarm signals of “emergency” category shall be formed according to emergency alarm signals (activation of the emergency protection, necessity of immediate shutdown of machinery, activation of the stand-by equipment etc.)

For alarm signals which shall be led to the wheelhouse, see 11.5.5.

11.12.9 The following visual indication signals shall be led to the wheelhouse:

.1 operation of each diesel generator;
.2 the kind of fuel fed and preparedness for changeover to heavy fuel (for ships equipped with double fuel systems);
.3 start-up of stand-by cooling and lubricating pumps in accordance with 9.10.1;
.4 operation of self-contained compressors;
.5 operation of self-contained pumps of spark-extinguishing system.
.6 the following positions of wheelhouse changing its position in height:
   lower limit position of wheelhouse;
   upper limit position of wheelhouse.
Actual status indication specified in 11.12.9.2 to 11.12.9.4 may be dispensed with in the permanently attended central control station.

11.12.10 Provision shall be made to stop the main engines from the wheelhouse irrespective of the availability of the remote automated control or remote control.

11.12.11 The following automation systems or their components (if envisaged by the ship design) shall be arranged in the wheelhouse:
.1 fire alarm and respective indicator panel or central fire control station (see 1.2.1.29 Part III of the Rules);
.2 automatic fire-extinguishing system control facilities;
.3 fire door indicator panels;
.4 facilities for control of fire door closing;
.5 watertight door indicator panels;
.6 facilities for control of fire door opening and closing;

11.12.12 If the ship is equipped with remote-controlled anchor release device, the device indicating the length of hauled-off anchor chain shall be installed in the wheelhouse on the device control console.

11.12.13 The equipment of control stations on the open bridge wings shall include devices having electrical equipment protection class stated in Table 2.3.6 Part VI of the Rules and adjustable illumination.

11.12.14 The wheelhouse of the ship equipped with propulsion plant with steerable thrusters and transverse thrusters shall be provided with the following indication:
.1 lubricating oil pressure at the engine inlet;
.2 cooling water temperature in the inner circuit at the engine outlet;
.3 air pressures in compressed air starting cylinders if such starting system is provided;
.4 engine crankshaft revolution frequency;
.5 if reverse coupling is available — propeller rotation speed;
.6 current and voltage in the charging circuit and voltage in the discharging circuit of starting accumulator batteries (for engines with electric starting);
.7 working medium pressures in remote automated control system.

11.12.15 If electric motor (performs the functions of propulsion engine) is used as a drive for steerable thrusters and transverse thrusters, the following indication shall be provided on the control console in the wheelhouse:
.1 rotation speed and direction of rotation of propeller;
.2 voltage in power supply circuit and control circuits;
.3 overloads of drive motor.

11.12.16 The following parameters shall be indicated for engines of steerable thrusters turning drive:
.1 for electric motor:
   voltage in power supply circuit;
   overload of steerable thrusters turning motor;
.2 for hydraulic drive:
   pressure in working medium system;
   minimum level of working medium in service tank.

11.12.17 Control stations of main and standby turning drives of steerable thrusters shall be equipped with indicators of thruster position and direction of thrust.

11.12.18 Transverse thruster control console shall be equipped with:
.1 for electric motor:
   indication of voltage in power supply circuit and control circuits;
.2 for hydraulic drive:
   indication of pressure in working medium system;
indication of minimum level of working medium in service tank.

.3 thrust direction indicator.

11.12.19 Indication of operation condition of steerable thrusters or transverse thrusters shall be provided.

11.12.20 Propulsion plants with steerable thrusters and transverse thrusters shall be equipped with alarm and protection system or prepared for its installation in the wheelhouse after propulsion plant installation onboard the ship. The alarm and protection system shall be designed for the following parameters:

.1 for engines:
maximum rotation speed protection (interruptible);
alarm and stop at minimum oil pressure at the engine inlet (interruptible protection);
alarm about maximum oil temperature in lubricating system of the engine;
alarm about maximum temperature of cooling liquid in the inner cycle of the engine;
alarm about engine overload for fully steerable thruster;

.2 for electric motors of electrical or electrohydraulic turning gear of steerable thrusters — device for protection against short-circuit currents only. Protection against minimum voltage and overload is not allowed;

.3 for the electric motors used for driving the propellers and turning the steerable thrusters — alarm about breakage (failure) in the control circuit.

Propulsion plant control station shall be provided with devices signalling about availability of voltage in the supply circuit of the steerable thruster turning gear. Overload signal shall be light and sound one.

11.12.21 Hydraulic units of steerable thrusters and transverse thrusters shall have alarm about minimum oil level in the service tank.

11.12.22 Electric drive of thrusters shall have short circuit protection.

11.13 EQUIPMENT OF PERMANENTLY ATTENDED CENTRAL CONTROL STATION

11.13.1 The central control station shall be equipped with control devices, remote indication devices, communication and automation means, alarm and actual status indication for the equipment installed in the machinery spaces.

Control devices of the main engines may be dispensed with in the central control station. Composition of remote indication devices for the power installation components with the exception of the main engines, which shall be provided in the central control station, shall be specified depending on the ship purpose and type of the power installation.

11.13.2 Main switchboard of the ship’s power plant in the central control station or in its close vicinity.

If the main switchboard is situated beyond the range of visibility from the central control station, the latter shall be equipped with alarm devices indicating the position of generator circuit breakers of the main switchboard.

11.13.3 If remote control of the main engines is performed from the central control station pneumatically, hydraulically, electrically or in combination, the remote automated control system of the main engines from the wheelhouse shall be independent of control system from the central control station.

11.13.4 If control of the main engines is transferred to the central control station, the alarm shall actuate at the control station in the wheelhouse from which control has been carried out before.

11.14 INDICATION SYSTEM, ALARM AND PROTECTION OF SHIPS WITH STEERABLE THRUSTERS AND TRANSVERSE THRUSTERS

11.14.1 Local control station of propulsion plant with steerable thrusters shall be provided with:
11 Automation

11.14.1 Indication of the following parameters shall be provided for the engine on the local control station of the propulsion plant:
- oil pressure at the engine inlet;
- temperature of the inner cycle cooling water at the engine outlet;
- engine crankshaft revolution frequency;
- current and voltage in the charging circuit and voltage in the discharging circuit of starting accumulator batteries (for engines with electric starting).

11.14.2 Local control station of the steerable thrusters shall be provided with:
- indication of voltage in power supply circuit and control circuits;
- control station changeover switch;
- ammeter;
- thrust direction indicator.

11.15 REQUIREMENTS TO COMPUTERS AND COMPUTER SYSTEMS

Scope of application

11.15.1 These requirements apply to computers and computer systems designed for control of the ship, monitoring and control of ship machinery and equipment ensuring safety of ship running and operation, as well as computers and computer systems ensuring domestic needs of the crew and passengers or used for providing access to Internet for passengers of the ship.

11.15.2 Onboard the ships the use can be made only of computers and computer systems with protection class complying with the requirements of 2.3.6 Part VI of the Rules and tested for electromagnetic compatibility and safety of operation under conditions of the ship according to requirements of 2.7 Part VI of the Rules and Appendix 15 of RTSC.

11.15.3 Computers and peripheral devices shall be serviceable under operating conditions described in 2.2 Part VI of the Rules, unless other operating conditions are specified in the relevant Sections of this Part of the Rules for the ship objects serviced by them.

11.15.4 Design of computers and computer systems shall ensure easy access to components and units to be replaced for repair and maintenance.

11.15.5 All replaced components shall be designed in a way to exclude their incorrect connection and installation. When this is impossible, the appropriate marking shall be made.

11.15.6 Computers, which are not used as a part of other installation, and peripheral devices shall have protection class not less than the one specified in 2.3.6 Part VI of the Rules.

General technical requirements to design of monitoring and controls computer systems

11.15.7 Computer automation systems shall meet proper functional requirements of the design specification under all operating conditions, including emergency ones, to provide the following:
- safety of people;
- preventing equipment damages or emergencies;
- convenience of servicing;
- serviceability of other devices and systems.

11.15.8 It shall be impossible for the personnel of the ship to modify the programs.

11.15.9 For the installations equipped with computers any change of user programs influencing fulfillment of installation functions is considered to be a design change and it shall be agreed with the River Register.

11.15.10 Any disconnection of peripheral devices from the computer or computer system and restart of computer system shall not
cause uncontrolled execution of commands causing critical or undefined state.

11.15.11 Computer system shall operate quickly to ensure fulfilment of all functions in accordance with the technical documentation within a preset time considering maximum load and maximum number of simultaneously solved tasks, including data rate in the network, under normal and emergency conditions.

11.15.12 Incorrect actions of operator shall not cause damage of computer, deleting or change of information stored in the computer.

11.15.13 Programs and data required for operation of computer system shall be stored in non-volatile memory.

11.15.14 Software in monitoring, control and alarm computer systems shall not be lost or damaged due to fluctuation of voltage and current frequency in the network.

11.15.15 If forced ventilation or air conditioning is required during operation of computers and computer systems, provisions shall be made for indication or alarm on exceeding permissible limit values of climatic parameters.

Configuration, operation check, self check and alarm on faults

11.15.16 Computer systems and software shall have hierarchic structure.

11.15.17 Computer system components shall be so selected as to ensure safe operation of the controlled equipment.

11.15.18 It shall be possible to check all functions of the computer with use of special programs, if required.

11.15.19 Computer systems shall have built-in self check function ensuring appropriate alarm in case of fault.

11.15.20 Faults in computers and computer systems shall not cause faults of serviced equipment and the entire ship.

11.15.21 Failure of peripheral devices shall not affect operation of other peripheral equipment of the computer system. Fault alarm shall be provided.

11.15.22 Software shall have detailed technical description of all possible functions.

11.15.23 Information transfer channel shall have means for continuous self check for detection of data transfer faults and failures in the channel itself. When a failure occurs in one network, an alarm is to be activated.

Additional requirements to computers for controlling ship power installations and their components

11.15.24 Structure of integrated automation systems shall ensure back-up of all controlling functions (by means of computers or standard automation means) in case of faults in separate computers or in communication lines between them.

11.15.25 It is allowed to use functional units of one system with a computer as a back-up one for another computer system.

11.15.26 Computers or computer systems shall be used in protection systems only if automatic operation of protection system in a standard way in case of computer failure is provided. If the computers have a back-up, fulfilment of this requirement is not required.

11.15.27 When systems under control are required to be duplicated and in separate compartments, this is also to apply to control elements within computer based systems.

11.15.28 Computers used for control and (or) setting of ship power installations and systems shall operate without delay and perform monitoring and protection functions in real time.

11.15.29 Faulty peripheral devices required for operation of the system shall be replaced with back-up devices having the same connection conditions.

11.15.30 If monitors are used for display of processes, the fault alarm of power installations and systems shall instantaneously appear on the screen. It is not allowed to separate
acknowledged signals from unacknowledged ones only by change of colour.

11.15.31 If monitors are used for visual indication of emergency states, it is necessary to provide back-up displays or means for indicating the alarm in other form (lamps, light-emitting diodes, etc.).

Installation of computers and computer systems onboard the ships

11.15.32 Layout of data input/output devices shall ensure the possibility of free access to them for maintenance. Connection routes in computer systems with constant redundancy shall be backed up and arranged as far as possible from each other.

11.15.33 During installation of computers and laying of cable routes provisions shall be made to ensure electromagnetic compatibility between assembled computer system and other systems on the site.

11.15.34 Power supply sources shall have proper serviceability check. Alarm signal shall be generated in case of fault, deviation of parameters, or any power supply failure.

11.15.35 Back-up computer systems shall receive power supply via separate lines protected by independent short circuit and over-load protection devices.

User interfaces

11.15.36 Each computer system shall have user manual comprising the following:
- purpose of functional buttons and indicators;
- description of screen menus;
- operator actions for system operation.

11.15.37 Input devices shall be safe at all operation conditions of the ship. When data are input by the operator, the input check shall be provided (for example, with the help of monitor, printer).

11.15.38 Computer system control panels in the wheelhouse shall be equipped with independent adjustable illumination.

11.15.39 The state of computer system and equipment controlled by it shall be clear for operator at any moment of time.

11.15.40 Size, colour, density of text and graphic information on the monitor screens shall make it possible to read the information from the operation station under all light conditions in the room. For proper reading of information under all light conditions the image brightness and image control shall be provided.

11.15.41 When colour monitors are used, the change of colour shall not affect reliability of transmitted information.

Test and checks

11.15.42 Computer systems shall be designed, manufactured and tested for compliance with requirements of this Section and 2.2, 2.3 and 2.7 Part VI of the Rules.

11.15.43 The computer system shall be tested and checked to confirm correctness of operation and quality of equipment.

11.16 REQUIREMENTS TO PROGRAMMED ELECTRONIC SYSTEMS

11.16.1 The requirements of this Section apply to programmed electronic systems used in ship control, alarm, monitoring and protection systems.

Data links

11.16.2 Data links of programmed electronic systems shall ensure automatic recovery of data link if a single failure of any component results in loss of communication.

11.16.3 Failure of any communication link shall not affect the possibility of control of critical consumers with the help of alternative means.

11.16.4 Means ensuring data integrity and recovery of damaged or unreliable data.

11.16.5 The data transmission is to be self-checked, regarding both the network transmission medium and the interfaces / connec-
tions. When failure is detected, alarm signal shall be fed.

**Protection against changes**

11.16.6 Programmed electronic systems shall be protected against program changes by the user.

11.16.7 Changes of systems parameters by the manufacturer shall be agreed with the River Register.

11.16.8 Any changes in design or software of programmed electronic system after its tests under technical supervision of the River Register shall be documented.
12 VIBRATION OF SHIP MACHINERY AND EQUIPMENT

12.1 CONSIDERATION OF SHIP MACHINERY AND EQUIPMENT VIBRATION AT THE SHIP DESIGN STAGE

12.1.1 This Chapter outlines the vibration standards for ship machinery and equipment at the place of their installation onboard the ship. These standards shall be taken into consideration at the design stage to ensure vibration protection of the machinery and equipment producing no continuous vibration. Parameters of vibration of ship structures set out in 2.6 Part I of the Rules shall not exceed these standards. If vibration parameters in the place of installation of ship machinery and equipment exceed the standards set out in this Chapter, such machinery and equipment shall be protected with the help of vibration isolators.

12.1.2 For operating internal combustion engines the standardized parameter of vibration is the amplitude of horizontal-transverse oscillations which shall not exceed 0.5 mm atop of the engine.

12.1.3 For centrifugal pumps, fans and air-conditioners the vibration is limited by amplitude of oscillations depending on their power stated in Table 12.1.3.

<table>

12.1.5 The equipment of galleys and sick-bays is installed without limitations if the equipment specifications have no limitations. This requirement applies also to electrical equipment.

12.1.6 If vibration parameters in the place of installation of instruments having vibration level limitations exceed the permissible standards specified in technical documentation, such instruments shall be installed on vibration isolators. Rigidity of vibration isolators is determined by the following formula:

\[ c = \frac{m_0^2}{\omega^2 \left( 1 - \sqrt{\left( \frac{w}{\gamma} - 1 \right)^2} \right)} \]

where \( m_0 \) — weight of the device, in kg;
\( \omega \) — frequency of forced oscillations in the place of device installation, in s⁻¹;
\( w \) — ratio of permissible acceleration in the place of sensor installation;
\( \gamma \) — coefficient of in-depth energy deposition equal to:
- for rubber: 0.032±0.19
- for springs: 0.002±0.005

12.1.7 Standards of vibration generated by various ship machinery during operation are specified in 12.2.
12.2 STANDARDIZATION OF VIBRATION OF SHIP MACHINERY AND EQUIPMENT DURING SHIP CONSTRUCTION AND OPERATION

Measurement and standardization of ship machinery and equipment vibration

12.2.1 This Chapter outlines limit permissible vibration levels (vibration standards) of ship machinery and equipment.

The standards are used for estimation of permissible actual vibration levels of ship machinery and equipment of ships under construction (after repair) and ships in service by results of measurements of their vibration parameters. The standards distinguish three categories of technical condition of ship machinery and equipment of ships:

A — condition of machinery and equipment after manufacture (ship construction) or repair at the time of commissioning;
B — condition of machinery and equipment at the time of normal operation;
C — condition of machinery and equipment requiring maintenance or repair.

The standards determine upper limits for categories A and B.

12.2.2 Vibration of ship machinery and equipment is measured during construction of the ship as per the program agreed with the River Register.

12.2.3 During ship construction (or after repair) the vibration of ship machinery and equipment shall not exceed the level of upper boundary of category A.

During further service of the ship the vibration of ship machinery and equipment shall not exceed the level of upper boundary of category B, which ensures vibration strength and reliability of operation of ship machinery and equipment.

12.2.4 The results of measurement of vibration parameters shall be compared to the permissible vibration levels (standards) specified in this Section.

If the vibration exceeds the specified standards, measures aimed at reduction of vibration parameters to the specified permissible levels shall be developed and implemented.

12.2.5 Vibration levels of ship machinery and equipment shall not exceed the standards both when the ship is at berth and in operation in ahead running modes recommended by the manufacturer at different engine loads.

In ahead running modes not recommended by the manufacturer and in astern running modes the vibration exceeding the specified standards is considered harmless if the duration of these modes does not exceed 30 minutes.

Standardized vibration parameters

12.2.6 The main parameter characterizing vibration level of ship machinery and equipment is the mean square value of vibration speed measured in third-octave frequency band (preferable) or in octave frequency bands. Root-mean-square value of vibration acceleration is to be measured along with vibration velocity.

12.2.7 Vibration parameters are measured in absolute units or in decibels relative to standard threshold (reference) values of oscillating speed or acceleration equal to 5·10^{-8} m/s or 1·10^{-6} m/s², respectively.

12.2.8 When measuring vibration in octave frequency bands the permissible values of measured parameter can be increased 1.41 times (by 3 dB) as compared to the values specified in 12.2.11 to 12.2.19 for the bands with root mean square frequencies 2, 4, 8, 16, 31.5, 63, 125, 250 and 500 Hz.

12.2.9 Vibration of ship machinery is measured in three mutually perpendicular directions relative to ship’s axes: vertical, horizontal transverse and horizontal longitudinal. Vibration measurement points are shown in Figure 12.2.9. Points and directions of vibration measurement are shown with dots.
Vibration standards for engines

12.2.10 Vibration standards apply to engines of 55 kW and more with rotation speed of 3000 min⁻¹ and less.

12.2.11 Vibration of engines and units including the engines is considered permissible for categories A and B if root mean square values of vibration velocity or vibration acceleration do not exceed the values stated in Table 12.2.11.

12.2.12 Vibration of units and devices hung on engine shall not exceed the levels specified in 12.2.11.

12.2.13 Vibration of turbocompressors measured on bearing body is considered permissible for categories A and B if root mean square values of vibration velocity or vibration acceleration do not exceed the values listed in Table 12.2.13.

Vibration standards for rotor type auxiliary machinery

12.2.14 Vibration of vertical pumps of 15-75 kW and their electric drives is considered permissible for categories A and B if root mean square values of vibration velocity or

</table>

Vibration standards for centrifugal separators is considered permissible for categories A and B if root mean square values of vibration velocity and vibration acceleration do not exceed the values stated in Table 12.2.14.

Vibration standards for radiator coolers is considered permissible for categories A and B if root mean square values of vibration velocity or vibration acceleration do not exceed the values stated in Table 12.2.14.

Vibration standards for pumps of 2–15 kW with vibration standards for categories A and B are taken 3 dB less as compared to the standards for pumps of 15–75 kW, and for the pumps of 75–300 kW these standards are increased by 2 dB. Vibration standards for horizontal pumps of the above mentioned capacities are taken 2 dB less.

Vibration standards for fans and gas blowers of inert gas systems is considered permissible for categories A and B if root mean square values of vibration velocity and vibration acceleration do not exceed the values stated in Table 12.2.14.

Vibration standards for ship machinery and auxiliary equipment not specified in 12.2.11 to 12.2.19 shall be taken according to 12.2.19.

Part V

SHIP ARRANGEMENTS AND OUTFIT
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION
1.1.1 The present Part of the Rules applies to ship arrangements, deck machinery, equipment and outfit of ships of all classes.

1.1.2 Requirements of the present part of the Rules do not apply to arrangements, equipment and outfit intended for special and technological purposes of industrial ships (for example, cross dredging arrangements of suction-tube dredgers, door lifting devices on scows).

1.2 TERMS AND DEFINITIONS
1.2.1 Terms related to the Rules general terminology and their definitions are stated in Section 2, Part 0 of the Rules. The following terms are used in the present Part of the Rules:

.1 **Tug-and-push boat** is a ship fitted with towing and coupling arrangements and intended for towing and convoying other ships and floating structures by pushing;

.2 **Towing equipment** is towing winches, hooks, bollards, towing arches, blocks, towing chock ports, bits, shackles, stoppers, rope retainer and limiters, reels, raised platforms, guide ropes, fenders, fender guards, lifeline guns;

.3 **Upper structure of the floating crane** is a cargo-handling device installed on a specially designed pontoon. Slewing device foundation is the boundary between the upper structure and the pontoon;

.4 **Jib radius** is the horizontal distance between the axis of the derrick rotation and the vertical axis of the gripping device without load determined when pontoon (ship) heeling and trim are precluded;

.5 **Height above the hull** is a height above the uppermost deck in the place of signalling means installation;

.6 **Immersion suit** is a suit made of watertight material intended for protection of the body of a person wearing it against overcooling in cold water;

.7 **Cargo boom** is a cargo-handling appliance intended for holding and transferring the cargo by means of the system of blocks and ropes attached to the derrick structure and outside it (to masts, posts, decks and winches);

.8 **Cargo-gripping devices** are all devices by means of which cargo can be attached to the cargo-handling appliance but which are not integral part of the cargo-handling appliance or cargo, for example grabs, container spreaders, cargo-lifting electromagnets, lifting beams, platforms, frames, cables, buckets, slings, cargo nets and other devices belonging to the ship. Cargo-gripping devices shall be considered as loose gear;

.9 **Cargo-handling appliance** is a ship’s device for cargo lifting and handling (crane, ship’s derrick and lift);

.10 **Lifting capacity** is the greatest permissible cargo mass to be lifted and handled by a cargo-handling device in the determined working conditions including the mass of the loose cargo-gripping gear;

.11 **Range of visibility** is a distance from which navigation lights are visible on a dark night during fair weather;
12 **Range of audibility** is a distance from which an audible signal is heard when the tailwind velocity is up to 3 m/s;

13 **Rescue boat** is a life-saving appliance which is carried on board in a state of continuous readiness for immediate use to rescue persons fallen into water, persons from a ship in distress as well as for marshalling and towing of liferafts;

14 **Actual loads** are static and dynamic loads determined by the gravity force, inertia, wind pressure, heeling and trim, ship’s motions, temperature strains, impact effects, pushes as a result of crane track movement and swinging on a flexible suspension, etc;

15 **Components** are the components of cargo-handling appliances intended to transmit forces and to provide kinematic connection except parts of machinery;

16 **Length and width of a ship** are design length and width of a ship, unless otherwise provided in the present part of the Rules;

17 **Safe working load (SWL)** is the maximum allowable static load applied to each individual component of the cargo-handling appliance;

18 **Standby steering drive** is an equipment intended for wheellover or steerable nozzle reversal with purpose of the ship steering in case of failure of the main steering drive;

19 **Individual life-saving appliances** are a lifebuoy, a lifejacket, an immersion suit;

20 **Individual thermal protective aid** is a bag or suit made of waterproof material with low thermal conductivity intended for restoring the body core temperature of the person having been in cold water;

21 **Collective life-saving appliances** are life and rescue boats, liferafts (rafts intended for accommodation of persons outside the water), life buoyancy aids (light rafts, tables, benches intended for supporting of persons on the water surface);

22 **Limit switch** is an electric device to be used in control system as a sensor which automatically gives a signal or disconnects or switches the power circuit of the appliance, gear at a mechanical contact of pair of any parts of this appliance, gear. The limit switch is used for limiting movement of any gear, assembly, appliance or any of its part (also movement of cargo in the cargo handling appliance) by disconnecting the drive of this gear, assembly, appliance in extreme positions;

23 **Safety factor** is the ratio of the minimum breaking load to the safe working load;

24 **Crane** is a cargo handling appliance intended for lifting and handling the cargo by means of a gripping device without any blocks and ropes attached outside its own structure;

25 **Drum winch** is a winch provided with a drum for winding the ropes;

26 **Metal structures** include derricks, gauge heads, rigid guy ropes, slewing cargo platforms, posts, bridges, portals, foundations, supporting drums and other structures taking up loads on the cargo handling appliance;

27 **Machinery of a cargo handling appliance** includes cargo lifting, jib luffing, boom-out and slewing appliances;

28 **Fixed parts** include items attached permanently to the cargo handling appliance load-bearing structures or to the ship’s hull;

29 **Normal operation** is designed operating limits and conditions of the vessel, ship technical facilities, systems and their components including operation at all operating modes, bunkering, maintenance, repair and other activity as related to the above mentioned;

30 **Cargo turning moment limiter** is a device that automatically switches off the lifting of the cargo and luffing in case when the cargo which mass exceeds the determined one for this boom-out is being lifted (see 6.8.3);
.31 **Lifting capacity limiter** is a device that automatically switches off all the working movements of the cargo-handling appliance except cargo lowering and movements which lessen the tipping moment when the cargo of exceeding mass is lifted (see 6.8.4);  
.32 **Main steering drive** means mechanisms, power plants of the steering drive, if any, auxiliary equipment and means for torque transfer to the rudder pin or the steerable nozzle (for example, tiller or sector) for the purpose of the ship steering at normal operating conditions;  
.33 **Rudder blade width** is a width calculated as a mean of \( b_1 \) and \( b_2 \) as shown in Fig.1.2.33.

![Fig. 1.2.33. Calculation of a rudder blade width](image)

.34 **Deck machinery** means windlasses, capstans, winches, locks, tensioning stations, force and torque transfer means, limiters and other machinery which are the parts of steering, anchoring, mooring, towing, coupling, cargo devices, and also hoisting arrangements of the wheelhouse, masts etc;  
.35 **Floating crane** – see 2.2.43 Part 0 of the Rules;  
.36 **Design loads** are combinations of actual loads determined separately for working and non-working conditions of the cargo-handling appliance;  
.37 **Design load** \( P_p \) is a force due to action of the design torque;  
.38 **Design bending moment** \( M_p \) is a maximum bending moment due to external forces (including inertial ones), acting in a horizontal plane relatively to the vertical axis of the coupling passing on the line of intersection of the coupling joint plane with the centre line plane of the convoy;  
.39 **Luminous intensity** is a ratio of luminous flux to solid angle in which this flux is being spread;  
.40 **Launching (launching and recovery appliances)** are davits and other onboard arrangements intended for launching and recovering of life and rescue boats and liferafts;  
.41 **Ship’s derrick** is a crane installed on board dry cargo ship;  
.42 **Coupling equipment** means locks, tensioning stations, winches etc;  
.43 **Loose gear** includes items attached to a cargo-handling gear by means of loose joints. These are blocks, hooks, chains, shackles, swivels as well as accessories, such as lifting beams, frames and others;  
.44 **Pushed convoy** is a rigid or bendable single-thread convoy or a composite cargo motor vessel. Pushboat is a part of the pushed convoy. The term “bower anchors” is related to barges of the convoy, the term “stern anchors” is related to the pushboat;  
.45 **Rope** is a common term for twisted and twined cordage made of natural and artificial fibre materials as well as steel wire. The rope is a synonym for the term “line”;  
.46 **Angle backlash of the coupling arrangement** is a mutual turn angle of ships within the range of free clearances of connections while changing the direction of the turning moment;  
.47 **Lifting capacity indicator** is a device to indicate automatically and visually (no matter whether the cargo is suspended or not) the maximum allowable design load for a particular crane at different jib radii;  
.48 **Safety devices** are devices intended to provide safety operation of the cargo-handling machinery such as: working movements and lifting capacity limiters, hoisting capacity and boom angle indicators, dangerous voltage warning and wind shielding devices, anti-stealing devices, stops, buffers,
traps, speed limiters of lifts, safety devices on hooks and other similar devices;

**.49 Authorized crew person** is a member of the crew having an authority to perform functions related to operation of the ship, its components or ship’s technical facilities according to the applicable law of the Russian Federation.

1.2.2 Stresses mentioned in the present Part of the Rules are interpreted as equivalent stresses \( \sigma_{eq} \), MPa, calculated by formula 1.2.2.

\[
\sigma_{eq} = \sqrt{\sigma^2 + 3\tau^2},
\]

where \( \sigma \) — normal stresses in the section under consideration, MPa;

\( \tau \) — tangential stresses in section under consideration, MPa.

Strength conditions shall be checked by these stresses.

1.2.3 In the present part of the Rules, permissible stresses which shall be compared with the stresses calculated while checking the strength conditions of ship appliances and deck machinery components are established as portions of the yield point of used material; Here, unless otherwise established by the present part of the Rules, the yield point shall not be taken more than 0.7 of the tensile strength of the same material.

1.2.4 Requirements to ships of М-СII class apply also to ships of М-СII4,5 class, unless otherwise required by the present part of the Rules.

1.3 OPERATING CONDITIONS

1.3.1 Ship appliances, deck machinery and equipment shall be designed to maintain their serviceability at heel and trim values as specified in 1.3 Part IV of the Rules as well as at ambient air temperatures given in Table 1.3.1.

### 1.5 STEEL WIREropes, Natural AND SYNTHETIC FIBRE ROPES

#### General requirements

1.5.1 Ropes shall be made and tested in accordance with national standards in organizations having the River Register's Recognition Certificate. Testing results shall be included into manufacturer's quality control document (see 1.2.1.2 Part X of the Rules).  

1.5.2 For running rigging the steel wire ropes with one organic core shall be used, the number of wires being not less than 114. Ropes with more than one organic core may be used subject to technical justification. It is recommended to use the ropes with the calculated tensile strength from 1275 to 1770 MPa with the diameter of wires in external strands of not less than 0.6 mm.  

For standing rigging steel wire ropes with one or more organic cores shall be used with the diameter of wires in external strands of not less than 1 mm, the number of wires being not less than 42. It is recommended to use the ropes with the calculated tensile strength from 1275 to 1670 MPa.  

The wires of running and standing rigging shall be provided with zinc coating.  

1.5.3 Wire splicing is not permitted.  

1.5.4 The ropes shall be marked in accordance with national standards.  

#### Steel wire ropes

1.5.5 For the manufacture of ropes wire of round cross-section shall be used with anti-corrosive coating and a tensile strength of 1180 to 1770 MPa.  

1.5.6 The organic fibre core of ropes shall be manila, sizal, hemp or synthetic fibre. Ropes with the nominal diameter exceeding 12 mm shall have at least three-strand core.  

1.5.7 The wires of a finished rope shall be covered with a lubricant.

---

1. GOST 30055, GOST 3069, GOST 3241.
Cores of organic fibre shall be impregnated or lubricated with anti-corrosive and anti-rot substances non-soluble in water and containing no acids or alkalis. The lubricant for the ropes and the impregnant for the organic-fibre cores shall be compatible by their physical and chemical properties.

1.5.8 After manufacture each rope shall undergo the breaking test throughout its length. The breaking test as a whole shall be performed on a tearing machine with the distance between the clamps not less than 50 rope diameters. If during testing the rope breaks less than 50 mm away from the clamp the test shall be repeated.

The test results shall comply with the requirements of GOST 3069 and GOST 3241.

1.5.9 If the breaking load cannot be reached due to insufficient power of the tearing machine during breaking tests for a rope as a whole the tensile strength may be determined based on tensile tests for all rope wires. In such a case, breaking strength of a rope as a whole is determined by the following formula:

\[
F = \sum_{i} \left[ \left( \sum_{m} F_m \right) \frac{n}{z} \right],
\]

where

- \( c \) — wire efficiency factor for the rope which is adopted on the basis of GOST 3069 and GOST 3241 or calculated as the ratio of the breaking load of the rope as a whole required by specified national standards to the total breaking load of all the rope wires;
- \( i \) — number of groups of wires of the same diameter;
- \( m \) — number of tensile tested wires from each group of a particular diameter, subjected to tensile testing with test results meeting requirements of GOST 3069 and GOST 3241;
- \( F_m \) — the maximum load preceding breaking of the specimen when performing tensile test of one wire, kN;
- \( n \) — number of wires in each group of a particular diameter;
- \( z \) — number of wires from each group of a particular diameter subjected to tensile testing.

1.5.10 The rope diameter shall not exceed the nominal value by more than 6%.

The rope diameter shall be measured on a slack rope perpendicular to its axis between two opposite strands in two positions.

1.5.11 Twisting and bending of strands, falling back, crossing, corrosion and breaking of wires in strands that prevent using the rope according to its intended purpose are not permitted.

When bends or burn-off spots are removed from the ends of non-spinning ropes the strands and wires therein shall not uncoil.

Ropes of natural and synthetic fibre

1.5.12 The breaking strength is determined during test for a rope as a whole or based on tensile tests of all fibres in the rope. In a latter case, breaking strength of a rope as a whole is determined by the following formula:

\[
F = c n \sum_{m} \frac{F_m}{z},
\]

where

- \( c \) is fibre efficiency factor for the rope which shall be adopted based on GOST 30055 or calculated as the ratio of the required by specified national standard breaking strength of the rope as a whole to the total breaking strength of all fibres in the rope;
- \( m \) — number of tensile tested fibers subjected to tensile testing with test results meeting requirements of GOST 30055;
- \( F_m \) — the maximum load preceding the destruction of the specimen at tensile testing of a single fibre, kN;
- \( n \) — number of fibres in the rope;
- \( z \) — number of fibres subjected to tensile testing which is taken to be equal to: 0.5\( n \) — for rope with circumference of up to 80 mm; 0.3\( n \) — for ropes with circumference from 80 to 115 mm; 0.1\( n \) — for ropes with circumference over 115 mm.

1.5.13 Ropes of synthetic fibre shall undergo testing to determine elongation at the breaking.

The percentage elongation of a rope at the breaking \( A, \% \), is determined by the formula:
\[ A = 100 \left( \frac{l_p - l_0}{l_0} \right), \]  
where \( l_0 \) — initial length of tested rope specimen, cm; 
\( l_p \) — length of the same rope specimen under the load equal to the breaking strength on the rope as a whole, which is specified in GOST 25552, cm.

1.5.14 On the surface of a finished rope no brown spots, mould, fused areas and smell of fume or rot shall be detectable.

The colour of the rope shall be uniform along its whole length and shall correspond to that of the yam or synthetic fibre of which the rope is manufactured.

1.6 REQUIREMENTS TO DECK MACHINERY

1.6.1 Construction and design of the deck machinery shall provide the ship’s operation under operating conditions specified in 1.3 Part IV of the Rules and in 1.3.1.

1.6.2 The deck machinery of oil tankers shall be located above dry compartments with gas-tight enclosures.

1.6.3 Elements of breaking devices of the deck machinery shall be resistant to water and oil products exposure. Brake pads shall be heat resistant up to the temperature 250°C. Permissible heat-resistance of connections between the brake pad and the supporting structure shall exceed the heating in the connection in all possible operating modes of the mechanism.

1.6.4 Fasteners of moving parts of mechanisms and devices, and also fasteners installed in hardly accessible places shall have fittings or be so designed as to prevent its spontaneous slackening and unravelling. Moving parts of the machinery shall be closed by protecting housings.

1.6.5 The structure and material of the deck machinery elements (locking devices, brake blocks etc.) installed in explosive spaces and areas (see 1.4 Part III of the Rules), shall preclude spark formation.

1.6.6 Rubbing assemblies of moving part of machinery and appliances shall be provided with lubrication devices. These devices shall be accessible and safe for maintenance during the operation of the machinery.

1.6.7 Safety and protective devices shall be so designed and installed so that in case of their actuation they are not hazardous both as regards fire and for the attending personnel.

1.6.8 Heating surfaces of the machinery with the risk of fire shall be fitted with fire-retardant insulation, or design measures shall be taken to prevent the ingress of fuel and oil on them.

Heat insulation shall be covered by metallic housing or fuel- and oil-proof composition.

1.6.9 Parts of machinery contacting with environment stimulating corrosion shall be manufactured of anti-corrosion material or protective corrosion-resistant coatings shall be applied to their surfaces.

Units and parts of mechanisms which are made of materials with different electric potentials and which may contact with aggressive media, shall be protected against electrolytic corrosion.

1.6.10 Machinery control devices, remote and automatic control systems shall meet the requirements of Part IV of the Rules.

1.6.11 Deck machinery control devices shall be so designed that lifting is executed by rightward rotation of the handwheel or by forward movement of the lever and lowering — by leftward rotation of the handwheel or backward movement of the lever.

Brakes shall be locked by rightward rotation of handwheels and unlocked by leftward rotation.

1.6.12 Machinery driven from a power source and manually driven shall be equipped with an interlocking device preventing simultaneous operation of the drives.

1.6.13 Hand forces required for movement of control levers and handwheels shall be set
depending on the frequency of application of manual drives.

If the control devices are being used for a short time, the hand force shall be not more than 160 N and the foot force – not more than 300 N. Force up to 490 N (for example, for the uncoupling device) is allowed as maximum valid for one-time force applied by one person in the vertical direction to the lever handles.

1.6.14 Winches shall provide the required nominal tractive force when the rope is positioned at the middle layer of coiling.

Their safety margin specified in these Rules shall be determined for the nominal tractive force for the rope position on the middle layer of coiling. In other cases, the safety margin shall be not less than as big as twice.

1.6.15 Manual-driven winches shall reach the nominal tractive force in the rope under action of the hand force of 160 N for each operator. When the hand force is as great as five and the rope is on the lower layer of coiling, the tractive force shall not exceed 85% breaking strength at the lowest layer of coiling.

1.6.16 The drums shall have ledges which shall be extended above the upper layer of coiling for not less than 2.5 times the rope diameter and not less than 1.5 the rope diameter above the last layer of coiled rope.

1.6.17 Hydraulic drives shall be protected by means of safety valves with the actuation pressure from 1.1 to 1.5 times the working pressure set by the manufacturer. Safety devices shall be so designed that their sealing is possible. The working fluid drained from the safety valve shall be directed to the suction pipeline or to the hydraulic reservoir.

1.6.18 The elements of hydraulic drives being under load shall be strength-checked for the application of forces corresponding to the working pressure, here, the equivalent stresses in the elements shall not exceed 0.4 of the yield point of the element.

1.6.19 Stresses in structural elements of the working cylinders induced by internal pressure shall not exceed 0.33 of the yield point of the material.

Safety margin at longitudinal bending shall be at least 5 at flexibility ratio above 60.

1.6.20 Devices for full deaeration shall be provided while hydraulic drive is being filled with the working fluid and also for its leakage replenishment and drainage.

The inner chamber of the hydraulic reservoir shall be open to atmosphere only through a filter (breather).

1.6.21 A level indicator of the lower and the upper level marks and a minimum level gauge shall be fitted on the hydraulic reservoir for the control of the working fluid level.

1.6.22 The hydraulic systems shall be provided with filters in order to remove resins and mechanical impurities from the working fluid.

It shall be possible to clean filters without stopping the working fluid circulation for permanently operating hydraulic systems providing the safe motion of a ship.

1.6.23 Suction and drainage pipelines of the main and standby pumps shall be located in the hydraulic reservoir so that the standby pump is capable to operate in the event of unintended drainage of the working fluid.

1.6.24 Drip trays shall be provided at places of possible leakage of the working fluid from the hydraulic equipment.

1.6.25 Hydraulic systems and pipelines shall meet requirements of 10.2 Part IV of the Rules.

1.6.26 After manufacture, elements of deck machinery and hydraulic drives shall be subject t hydraulic tests in accordance with 7.2.13 to 7.2.16 of RTSC.

1.7 EQUIPMENT NUMBER

1.7.1 Equipment number $N_{eq}$ is calculated by the following formula, $m^2$:

$$N_{eq} = L(B + H) + k \sum_{i=1}^{n} (l_i h_i), \quad (1.7.1-1)$$
where $L$, $B$, $H$ — design dimensions of the ship, m;
$k$ — coefficient assigned in accordance with 1.7.2 to 1.7.3;
$l$ — length of separate superstructures and deckhouses, m;
$h$ — average height of separate superstructures and deckhouses, m.

Equipment number of catamaran-type ships shall be determined by the following formula:

$$N_{eq} = 2L(B_{hull} + T) + (L + B_{ship})(H - T) + k \sum_{i=1}^{n} (l_i h_i),$$

(1.7.1-2)

where $B_{hull}$ — width of one hull body, m;
$B_{ship}$ — width of a ship, m;
$H$ — side depth, m;
$T$ — load draught, m.

1.7.2 Coefficient $k$ shall be assumed equal to 1.0 for ships with the total length of superstructures and deckhouses, located on all decks, exceeding a half of the ship’s length and 0.5 for ships with the total length being in the range of 0.25 to 0.5 of the ship’s length. The superstructures and deckhouses may be neglected for calculation of equipment number at the total length of the superstructures and deckhouses less than 0.25 of the ship’s length.

1.7.3 For hydrofoil craft, hovercraft and skimming ships the value of coefficient $k$ shall be assumed as less as twice comparing to those given in 1.7.2. Hydrofoils are neglected when determining the equipment number.

Note. For hydrofoil craft and hovercraft when there is no freeboard deck a superstructure is considered as a part of the ship above the lower edge of window cuttings.

1.7.4 For ships carrying cargoes on deck parameter $\sum_{i=1}^{n} (l_i h_i)$ in the formula (1.7.1-1) shall be calculated by multiplication of the side projection length of cargo stowed on the deck together with cargo limiting structures by its average height, and coefficient $k$ shall be assumed equal to 0.5 for ships intended for transportation of bulk cargoes only, and 1.0 for transportation of other deck cargoes.

1.7.5 In mud dredgers the towers, bucket frames and chutes secured for voyage shall be considered in the equipment number as deckhouses which side surface area is determined along the overall contour.
2 STEERING GEAR

2.1 GENERAL REQUIREMENTS

2.1.1 Requirements of the present Section of the Rules apply to steering gears with rudders (simple, balanced, semi-balanced), nozzles (turning, non-turning), and also to thrusters, steering means of pod drives, waterjet and vertical axis propellers.

2.1.2 All self-propelled ships shall be equipped with a steering gear. Non-self-propelled ships intended for towing by rope shall be equipped with fixed stabilizers.

Stabilizers may be omitted in floating objects and non-self-propelled ships intended for navigation only by pushing.

2.1.3 Steering gears shall provide manoeuvrability parameters as specified in Part II of the Rules.

2.1.4 In case of failure in main drive or main power source, the time of transition to the standby drive or the time of power supply pause shall not exceed 5 s.

2.2 RUDDER AND NOZZLE

2.2.1 The rudder blade and the nozzle shall be made of steel with carbon content not more than 0.22%.

Construction of the nozzle may be either welded or cast-welded. The carbon content in forgings and castings shall be not more than 0.25%.

2.2.2 The plate thickness of streamlined rudder blade casing $t$ shall be not less than determined by formula, mm.

$$t = s a \sqrt{\frac{p}{R_{eH}}} + \Delta s,$$

where $s = 32.6 - 7.56 \left( \frac{a}{b} \right)^2$;

$b$ — distance between horizontal stiffeners or vertical diaphragms, whichever is less, m;

$a$ — distance between horizontal stiffeners or vertical diaphragms, whichever is less, m;

$p$ — design pressure on a rudder blade plating, kPa, determined in accordance with 2.2.3;

$R_{eH}$ — the yield stress of the rudder plating material, in MPa.

$\Delta s = 0.6$ — corrosion allowance, mm.

2.2.3 Design pressure on a rudder blade plating, $p$, kPa, shall be taken equal to the greater value of pressures on the pressure ($p_{ps}$) and suction ($p_{ss}$) side of the rudder profile:

for a plating area falling into the propeller jet and located within 0.35 the rudder blade width from its leading edge

$$p_{ps} = 0.5 (1.706C_1 + 1.538) \rho V_A^2 + 9.81 T$$

$$p_{ss} = 0.5 (5.505C_1 + 0.939) \rho V_A^2$$

(2.2.3-1)

for a plating area falling into the propeller jet and located within 0.65 the rudder blade width from its trailing edge

$$p_{ps} = 0.5 (0.734C_1 + 0.662) \rho V_A^2 + 9.81 T$$

$$p_{ss} = 0.5 (2.369C_1 + 2.622) \rho V_A^2$$

(2.2.3-2)

for a plating area not falling into the propeller jet and located within 0.35 the rudder blade width from its leading edge

$$p_{ps} = 0.5 \rho V_A^2 + 9.81 T$$

$$p_{ss} = 2.5 \rho V_A^2$$

(2.2.3-3)

for a plating area not falling into the propeller jet and located within 0.65 the rudder blade width from its trailing edge

$$p_{ps} = 0.25 \rho V_A^2 + 9.81 T$$

$$p_{ss} = 1.25 \rho V_A^2$$

(2.2.3-4)
where \( C_T = 8 T_p \left( \frac{\rho V_A^2 \pi D^2}{2} \right) \) — propeller loading factor;

\( T_p \) — propeller thrust, kN;

\( \rho \) — water density, t/m\(^3\);

\( V_A = V (1 - W_f) \) — propulsion and steering system inflow velocity, m/s

\( V \) — design speed of a ship in loaded condition (for pushboats — together with the convoy), m/s;

\( W_f \) — wake factor for straight motion of the ship by calculation of propulsion ability;

\( D \) — propeller diameter, m;

\( T \) — ship draught, m.

Pressure \( p_{ss} \) shall not be taken to be more than 96.9 kPa.

Jet diameter is taken to be equal to propeller diameter.

2.2.4 In order to prevent resonance, natural oscillation frequencies of the first tone of the rudder plating plates shall exceed the propeller blade frequency which is the product of a number of propeller blades by shaft revolution frequency by at least 50%.

Natural oscillation frequencies of the first tone of the rudder plating plates shall be determined in accordance with requirements of 2.6.10 and 2.6.11 Part I of the Rules as for the plate washed by liquid from one side.

2.2.5 The edge plate thickness of the rudder blade and stabilizer shall be not less than 1.3 times the shell thickness determined according to 2.2.2.

2.2.6 The plate thickness of lamellar rudder blade casing \( t_{\text{lam}} \) shall be not less than determined by formula, mm:

\[
t_{\text{lam}} = k d_0 + 4, \quad (2.2.6)
\]

where \( k \) — factor taken equal for ships of classes:

- M-СП, М-ПР and М 0.080
- O and О-ПР 0.055
- P, Л 0.030

\( d_0 \) — rudder stock diameter, mm, determined according to 2.3.1 or 2.3.3 at \( R_eH = 260 \) MPa.

The least thickness of nozzle internal plating \( t_3 \) shall be not less than determined by formula, mm:

\[
t_3 = 1.25 t_1. \quad (2.2.7-2)
\]

2.2.8 Inner plating of the hollow nozzle in the middle part \( t_3 \) shall have a strengthened belt with thickness not less than determined by formula, mm:

\[
t_3 = 2 t_2. \quad (2.2.8)
\]

Plates of the strengthened belt are recommended to be made of stainless steel.

2.2.9 The plating thickness of streamlined rudder blade, hollow nozzle and its stabilizer shall be not less than shell plating thickness of the ship’s aft extremity.

2.2.10 The plating thickness of the rudder blade and the nozzle with stabilizer for ships with ice strengthening shall be increased by 20% as compared with that determined in accordance with 2.2.2, 2.2.3, 2.2.5 to 2.2.9.

2.2.11 The plating of the rudder blade and the stabilizer shall be strengthened from the inside by vertical stiffeners and horizontal diaphragms.

2.2.12 The nozzle plating shall be strengthened from the inside by longitudinal stiffeners and circular diaphragms.

At least four longitudinal diaphragms uniformly distributed along the circumference of the nozzle shall be provided.

2.2.13 Stiffener and diaphragm thickness shall be not less than plate thickness of streamlined rudder (stabilizer) or the nozzle shell plating.

2.2.14 Cut-outs shall be provided in stiffeners and diaphragms.
2.2.15 Plugs made of anti-corrosion material shall be provided in the rudder blade edge plates, in the lowermost and the uppermost points of the nozzle.

2.2.16 The rudder blade and the nozzle shall not protrude beyond the ship overall dimensions. When it is impracticable, protective arrangements shall be provided (housings, crinolines).

2.2.17 The rudder and the nozzle shall be so located as to prevent their damage due to stroke on ground when ship sails with the maximum design stern trim.

Note. The rudder and the nozzle intended for work on shallow water are to be designed with the lower support.

2.2.18 The plating thickness of fixed stabilizer installed instead of the rudder shall be determined in accordance with the requirements of 2.2.2, 2.2.3, 2.2.5, 2.2.9, 2.2.10. The design of fixed stabilizer shall meet the requirements of 2.2.11 to 2.2.14, 2.2.16.

2.3 RUDDER STOCK AND RUDDERPIECE

2.3.1 The diameter of the rudder stock and the nozzle in the area of lower supporting bearing shall be proved by the calculation carried out in accordance with requirements of the present Section. Hydrodynamic loads, bending moments, shear forces and support reaction forces acting in the stock-rudder system are to be calculated in accordance with Appendix 1.

2.3.2 The full ahead speed shall be taken as the design speed: for self-propelled ships — not less than 3.5 m/s, and for non-self-propelled ships — not less than 3.0 m/s.

The design astern speed shall be taken not less than 60% of the design ahead speed.

2.3.3 If there are no hydrodynamic calculations, the rudder stock diameter in the area of lower supporting bearing shall be not less than determined by formulas, mm:

for suspended rudder (Fig. 2.3.3-1)

\[ d_0' = 46.2 \cdot \sqrt[3]{k_2 M_{\text{torque}}^2 + M_b^2 / \left(9.81 \cdot 10^{-3} R_{\text{eh}}\right)} \]  

(2.3.3-1)

for rudder with lower support on sternframe heel (Fig. 2.3.3-2)

\[ d_0'' = 46.2 \cdot \sqrt[3]{k_2 M_{\text{torque}} / \left(9.81 \cdot 10^{-3} R_{\text{eh}}\right)} \]  

(2.3.3-2)

for rudder with pins on sternframe hinges

\[ d_0''' = 46.2 \cdot \sqrt[3]{k_2 M_{\text{torque}} / \left(9.81 \cdot 10^{-3} R_{\text{eh}}\right)} \]  

(2.3.3-3)

where \( k_2 \) — safety factor of the rudder stock material taken equal for ships of classes: M-ПР, О-ПР, М and О 2.5
2.3.4 Minimum permissible external diameter of hollow rudder stock, mm, is determined by the formula:

\[ d_{\text{outer}} = \alpha d_0, \]  

(2.3.4)

where \( \alpha \) — coefficient taken from Table 2.3.4 depending on the set ratio of the rudder stock wall thickness to the external diameter \((\delta/d_{\text{outer}})\).

**Table 2.3.4**

2.3.6 The rudder stock strength shall be checked for maximum forces induced by steering machines in case of rudder or nozzle seizure.

In this case, the design stresses shall not exceed \( 0.8R_{\text{yH}} \) or \( 0.6R_m \), where \( R_m \) is tensile strength of rudder stock material.

2.3.7 For ships intended for navigation in broken ice the diameters of the rudder stock design cross-sections calculated in accordance with 2.3.1 and 2.3.3 shall be increased by 15%.

2.3.8 Rudder stocks and rudder pieces may be forged or welded.
Cast-welded and cast-forged constructions are permissible, with the diameter of cast part of the rudder stock being increased by 15% as compared with the design diameter of forged rudder stock.

For ships less than 25 m in length the rudder stocks and rudder pieces may be made of rolled steel.

2.3.9 The rudder piece cross-section area in the upper part shall be equal to the rudder stock cross-section area. The rudder piece cross-section area below the upper edge of the rudder blade may be smoothly reduced down to 50% of cross-section area in the upper part.

Connection of the rudder stock with the rudder blade or steerable nozzle shall be equal in strength to the rudder stock.

2.3.10 Streamlined hollow rudders may have no rudder piece.

In this case the constructions substituting the rudder piece are continuous vertical diaphragms of the rudder blade with adjacent plating of rectangular or tubular cross-section as shown in Fig. 2.3.10.

\[ F = 0.3d^2 \]

where \( d \) — rudder stock diameter determined according to 2.3.1 or 2.3.3, mm.

2.3.11 The rudder blade or steerable nozzle with the rudder stock shall be connected by means of a horizontal flange or other structure (conic, stirrup etc.) which ensures the required connection properties.

For ships with a length of 10 m and less with manual steering drive the connection of the rudder stock with the rudder blade may be welded.

2.3.12 Connecting bolts (studs) shall be tightly fitted. The number of tightly fitted bolts shall be at least two for keyed joints. Minimum permissible total cross-section area or all bolts is determined by the formula, mm²:

\[ F_d = 0.3d_o^2 \]

2.3.13 Fastening joints of the rudder stock and the rudder blade or steerable nozzle shall be reliably locked to prevent spontaneous unscrewing.

2.3.14 The distance from the edge of bolt hole to the outer edge of connecting flange shall be not less than 0.65\( d_o \), where \( d_o \) is the bolt diameter.

2.3.15 Flange thickness shall be not less than the connecting bolt diameter.

2.3.16 A radius of the fillet at the junction of the rudder stock with the flange shall be not less than 0.12\( d_o \) (\( d_o \) — see 2.3.12).
For conic connection of the rudder stock with the rudder blade or the nozzle the length of cone shall be not less than 1.5 the rudder stock diameter, and the conicity – not more than 1:10. The conic part of the rudder stock shall change into the cylindrical part without a shoulder.

A key shall be placed in the conic connection which dimensions shall be calculated for the case of maximum hydrodynamic torque transfer acting on the rudder stock or steerable nozzle. The key slot shall have skishaped exits.

Plain bearings or rolling bearings may serve as the rudder stock supports.

Plain bearing sleeve height \( h_{\text{bush}} \), mm, shall be determined by the formula:

\[
h_{\text{bush}} = 1000B_H/(pd_1),
\]

(2.3.19)

where \( B_H \) — assumed reaction of the rudder stock support while calculating the rudder stock – rudder piece bar for bending determined according to 2.3.20, kN;

\( p \) — permissible contact pressure for bearing materials taken from Table 2.3.19, MPa;

\( d_1 \) — diameter of the rudder stock in the support (including facing, if any), mm.

In any case, the rudder stock bearing sleeve supporting surface height shall be not less than 0.8\( d_1 \).

Minimum assumed design reaction from the rudder stock side shall be determined by the formula, kN:

\[
B_{\text{low}} = R \left( 0.5I_{10} + I_{30} + I_{40} \right)/I_{40} ;
\]

(2.3.20-1)

for the rudder with lower support

\[
B_{\text{low}} = 0.549 R .
\]

(2.3.20-2)

Here \( R, I_{10}, I_{30}, I_{40} \) shall be taken in accordance with 2.3.3.

Standard rolling bearings may be used for the rudder stock supports provided their reliable lubrication and protection against water.

The rudder stock sealings shall be designed to prevent leakage of lubricants from supporting units of bearings.

Measures shall be taken to prevent leakage of lubricants from supporting units of bearings.

The helmport tube shall be so designed as to prevent the ingress of sea water into the ship’s hull.

Glands situated above the load waterline shall be accessible for inspection and service afloat.

The elements of the helmport tube subject to loads of rudder stock or steerable nozzle shall be sized so that the occurring stresses do not exceed 0.35 \( R_eH \).

The height of bosses of easily put-on quadrants and auxiliary tillers shall be not less than 0.8 times the diameter of the rudder stock head.

The boss external diameter shall be not less than 1.6 times the diameter of the rudder stock head.

Split bosses shall be fixed from both sides with at least two bolts and have two keys. The keys shall be arranged at the angle of 90° to the jointing plane.

Connection of the steering machine or transmission gear with parts attached to the rudder stock shall be such as to prevent damage of the steering drive at axial displacement of the rudder stock by not more than 0.1 times the rudder stock diameter.

Lower journal of rudder stock for ships of M-CTI class shall be protected with
lining coating made of stainless steel, copper alloys or other method of corrosion protection.

Keyed taper connection of rudder stock with rudder blade or steerable nozzle shall be protected from corrosion.

2.4 STEERING DRIVES

Steering devices available with steering drives

2.4.1 The ship steering gear shall be fitted with two drives: main drive and standby drive.

2.4.2 A standby drive may be omitted in ships with several rudders or nozzles driven by separately controlled machines.

2.4.3 Main and standby steering drives shall be so arranged that any one of them can work despite the damage of the other. It is allowed to have common parts of a power drive to the rudder stock (tiller, quadrant, cylinder block).

2.4.4 The main steering drive control system shall be independent of the standby steering drive control system. It is allowed to have common steering wheel or control handle.

2.4.5 The main and standby drives may be manually controlled. In this cases, requirements of 2.4.14 to 2.4.17 shall be met. In all other cases the steering drive shall be driven from the power source.

2.4.6 The standby steering drive shall provide the rudder or steerable nozzle being put over to the same maximum angle as the main steering drive.

2.4.7 Rope for steering line pilotage shall be flexible, galvanized, cross-twisted and unravelling.

2.4.8 Main and standby steering drive control stations shall be fitted with rudder (steerable nozzle) position indicators.

2.4.9 If main and standby drives are hydraulic, each of them shall have a pump with independent motor and the drive pipelines shall be laid apart as far as practicable.

2.4.10 If main and standby drives are electric, their supply and control systems shall be independent of each other. Each of these two drives shall have its own electric motor.

Drive power

2.4.11 The power of the main steering drive shall be sufficient to put the rudder stock (steerable nozzles) over to the angle from 35° of either side to 35° of the other side in not longer than 30 s at maximum speed with the ship running ahead and the draught corresponding to the load waterline.

2.4.12 The power of the standby steering drive shall be sufficient to put the rudder stock (steerable nozzles) over to the angle from 20° of either side to 20° of the other side in not longer than 60 s at ahead speed equal to 0.6 times the maximum one and the draught corresponding to the load waterline.

2.4.13 Steering drive motors shall allow an overload by torque equal to 1.5 times the design torque for 1 min.

Manual and standby steering drives

2.4.14 The main manual steering drive shall be of self-braking design or be fitted with an automatic brake.

The main manual steering drive shall provide the requirements of 2.4.11 when being operated by one person who produces a force on the steering wheel handle not more than 120 N with not more than 25 revolutions per one wheel turn.

2.4.15 The main manual steering drive shall be of self-braking design or be fitted with an automatic locking device.

The standby manual steering drive shall comply with the requirements of 2.4.12 when operating with a force on the handle not more than 160 N per each operator with not more than 25 revolutions per one wheel turn.

2.4.16 The standby steering drive shall be independent of the main steering drive and shall act directly on the rudder stock if possible.
2.4.17 The steering wheels of the main and standby manual non-self-braking drives shall have external rims.

**Mechanical steering drives with remote control**

2.4.18 Chain cables, pull rods and galvanized steel ropes which are included in the steering line convoy pilotage shall be fitted with devices for taking slake of a rope; moreover, tightening springs shall be fitted on each side in the steering line pilotage.

2.4.19 Rudder indicators (supports, transmissions, joints, couplings) shall be designed so as to prevent seizure or damage of their parts due to the hull deformation because of cargo movement or waves.

2.4.20 Transmissions of mechanical steering gears of oil tankers intended for transportation, pumping and storage of liquids with a flash point of 60 °C and below shall be led above the deck in chutes or ducts. Construction of rubbing units and parts of these drives shall prevent spark formation.

**Hydraulic steering drives**

2.4.21 Hydraulic systems of main and standby steering drives and their pump units shall be independent of each other. When the pump of the standby steering drive is operated by an auxiliary motor which is not continuously in operation, the operation of this pump shall be provided by a buffer system during the motor start.

2.4.22 Main and standby steering drive systems may have common parts, as a rule, cylinders provided that such systems may operate independently of each other. Each hydraulic steering system shall be provided with a separate hydraulic tank equipped with low oil level indicator and alarm in accordance with 1.6.21.

2.4.23 Hydraulic steering systems shall not be connected with other hydraulic systems.

Flexible hoses shall be used if required for dampening of vibrations and providing for free motion of the hydraulic system components. In this case flexible hoses shall comply with requirements of 10.2.22 Part IV of the Rules and be designed for pressure at least 1.5 of the working pressure.

2.4.24 Connection of the started pump and its switch-off without any valve reversal shall be provided in the hydraulic drive of the steering device.

**Protection against overload and reverse rotation**

2.4.25 The manual steering drive may be fitted with buffer springs instead of overload protection devices.

When the manual steering drive is used as a standby drive, overload protection need not be fitted.

2.4.26 In ships of M-CP1, M-PIP, M, O-PIP and O class shock absorbers rated for at least twice nominal load shall be included in all steering drives other than hydraulic ones.

2.4.27 Hydraulic steering drives shall be equipped with overload protection devices. The safety valves specified in 1.6.17 may be used as overload protection devices.

2.4.28 Pumps of hydraulic steering machines shall be fitted with either protection devices preventing the reverse rotation of switched-off pump or automatically operating device preventing the liquid flow through the switched-off pump.

**Braking device**

2.4.29 The steering gear shall be fitted with a brake or other device providing the rudder (steerable nozzle) confinement in place in any position under the action of torque from the rudder side not taking into account the friction in the rudder stock bearings.

2.4.30 A special braking device may be omitted for hydraulic steering drives if their pistons or blades may be locked by closing of oil line valves.

**Limit switches, rudder limiters, rudder (steerable nozzle) position indicators**

2.4.31 Each mechanical steering drive shall be fitted with a device (limit switch) stopping
its operation before the rudder reaches the rudder turn limiters. Limit switches shall be adjusted for putting the rudder over to an angle not less than 35° and for rotating the steerable nozzle to an angle not less than 30°.

2.4.32 Steering gears shall be fitted with rudder and steerable nozzle turn limiters. The limiters shall provide for putting the rudder over and rotating the steerable nozzle to an angle greater by 1.5° than the angle to which the limit switches are adjusted.

2.4.33 All parts of limiters including those which are parts of the steering drive, shall be designed for forces corresponding to the maximum back moment determined by the formula, kN-m:

\[ M_{\text{max}} = 1.132 \cdot 10^{-7} d_{\text{rad}}^3 R_{\text{st}}, \]

(2.4.33)

where \( d_{\text{rad}} \) — rudder stock diameter in the least cross-section, m;

\( R_{\text{st}} \) — yield point of the rudder stock material, MPa.

Stresses in the limiter parts shall not exceed 0.95 times the yield point of the material.

2.4.34 In ships of M-СП, M-ПП, M, O-ПП and O class a fixing device shall be installed to prevent spontaneous turning of the rudder and steerable nozzle disconnected from the steering machine.

2.4.35 Steering machinery shall be fitted with remote indicators of the rudder position. The scale for the determination of actual rudder position with scale factor not more than 1° shall be fitted on the steering drive quadrant, on parallels of the hydraulic steering machine or on parts rigidly connected with the rudder stock.

2.4.36 Strength of parts of main and standby steering drives being under load shall be checked when subject to forces corresponding to the design torque. Stresses in the parts shall not exceed 0.4 of tensile strength of the part material (\( R_{\text{ut}} \)).

2.4.37 Stresses in parts common for main and standby steering drives (tiller, quadrant, reduction gear) shall not exceed 0.8 times the stresses allowed by 2.4.36.

2.4.38 Parts of steering drives which are not protected against overload by safety devices provided in 2.4.25 to 2.4.28 shall have the strength indices not less than the rudder stock strength indices.

2.4.39 In case stipulated in 2.4.27 the strength of the parts shall be checked when the forces corresponding to the safety valve opening pressure are applied; in this case equivalent stresses in the parts shall not exceed 0.95 times the yield point of the part material.

2.5 THRUSTER

2.5.1 Passenger and self-propelled cargo ships with the lateral area on the centreline exceeding 800 m² shall be equipped with thrusters.

Note. The lateral area of the ship includes lateral areas of the hull above and below the waterline, as well as of deck cargo.

Specific thrust of a thruster of passenger and self-propelled cargo ships shall be not less than specified in accordance with 6.9.3 Part III of the Rules.

2.5.2 The thruster shall be so located as to produce thrust in all possible cases of the ship loading.

2.5.3 Thruster compartments shall be watertight.

2.5.4 Thrust direction indicator shall be fitted on the thruster control panel.

2.6 CONTROL OF THRUSTERS, WATER-JET AND VERTICAL AXIS PROPELLERS

2.6.1 The independent main and standby drives shall be provided for the device which adjusts the direction of thrust of thrusters, water-jet propellers, vertical axis propellers and bowthrusters with electric, hydraulic or pneumatic remote control. These drives shall comply with requirements of 2.1 and 2.4.14 to 2.4.17.
2.6.2 The requirement 2.6.1 is not applicable if pod drives, propulsors, thrusters are not required to ensure turning capacity, directional stability and manoeuvrability with propellers not in operation and under wind conditions in accordance with requirements of Part II of the Rules. The requirement 2.6.1 is also not applicable if pod drives, propulsors, thrusters are required along with the main function to ensure manoeuvrability parameter only — stopway in case of an emergency stop of the ship.

2.6.3 In case of failure of the main drive of the thrust direction adjustment system (steering control) of the thruster the duration of switch to the standby drive shall not exceed 5 seconds.

If the ship is fitted with two or more thrusters, the standby drive is not required.

2.6.4 If the ship is fitted with two or more fully steerable thrusters, then a separate control is to be provided for each thruster. If the ship is fitted with two or more thrusters with limited angle of rotation, then it is allowed to use both separate and joint control of the thrusters.
3 ANCHOR ARRANGEMENT

3.1 GENERAL REQUIREMENTS

3.1.1 The present Section of the Rules covers standards of anchor equipment and anchor chain cables, as well as requirements to the machinery and elements of anchor arrangements.

3.1.2 Every ship other than mentioned in 3.1.3 shall be equipped with an anchor arrangement for holding the ship at the place when she is anchored.

3.1.3 Floating objects, as well as pushed non-self-propelled ships of P and J class may not be fitted with an anchor arrangement provided that the holding power (see 3.1.4 and 3.3.6) of tugboat/pusher's anchor arrangement is provided as specified in 1.4.2, Appendix 8 of RTSC, and provided that a shipowner follows the requirements specified for anchoring of convoys and safety of mooring at berthing facilities and on outer roads.

3.1.4 Holding power \( T_{\text{hold}} \), N, of the mooring pontoon used for anchoring of convoys or individual barges (sections) on outer roads shall be determined by the following formula:

\[
T_{\text{hold}} = 3.5g \sum m_{\text{anch}},
\]

(3.1.4)

where \( g \) — acceleration due to gravity, \( \text{m/s}^2 \);

\( \sum m_{\text{anch}}, \text{kg} \), — total mass of bower anchors of the greatest pushed convoy calculated by formula (3.3.2).

3.1.5 Anchor equipment of floating docks, floating cranes, oil-transfer stations shall be substantiated in a ship design depending on nature and features of her service.

The required conditions (depth, flow speed, wind speed), at which anchoring of any of the above ship types shall be provided, are assigned by the design specification.

3.1.6 The requirements of the present Section, unless otherwise stated, apply to Hall's anchors (GOST 761) which are normal holding power anchors.

When using Matrosov anchors (GOST 8497) their weight shall be taken equal to a half of the weight calculated in accordance with GOST 25496.

When increased holding power anchors (GOST 25496) their weight shall be taken equal in accordance with GOST 25496.

Sizes of chains are determined in accordance with 3.2.8 to 3.2.9 for a weight of an anchor calculated in accordance with 3.2.1.

3.1.7 Cable chain lockers of oil tankers (when located in explosive spaces and areas) shall be gas-tight and be fitted with arrangements for water filling.

3.2 ANCHOR, ANCHOR CHAIN

AND WIRE ROPE OUTFIT

3.2.1 Total weight of bow anchors \( \Sigma m_{\text{anch}} \) with normal holding power (see 3.1.6) for self-propelled, non-self-propelled and towing displacement ships shall be determined by the following formula:

\[
\Sigma m_{\text{anch}} = k_1k_2N_{\text{eq}},
\]

(3.2.1)

where \( N_{\text{eq}}, \text{m}^2 \), — equipment number (see 1.7);

\( k_1 \) — coefficient which accounts for forces acting on the ship when anchored to be taken based on data or determined by formulas given in Table 3.2.1-1.

\( k_2 \) — coefficient which accounts for requirements to anchor equipment due to water basin category to be taken based on data or determined by formulas given in Table 3.2.1-2.

The calculated values of \( \Sigma m_{\text{anch}} \) are rounded to the nearest greater value of weight \( M_{\text{anch}} \) for industry manufactured anchor of dimension-type series regulated by national standards\(^1\).

\(^1\) GOST 761, GOST 25496.
The calculated values of $m_{anch}$ are rounded to the nearest greater value of weight $M_{anch}$ for industrial anchor of dimension-type series regulated by GOST 8497.

### 3.2.3 Dredgers may be fitted with one bowing anchor of a weight equal to at least one half of a total weight determined in accordance with 3.2.1. On self-propelled dredgers anchor arrangement shall be fitted in the bow end and on non-self-propelled dredgers - in the extremity which is opposite to that where the main dredger working arrangement is fitted (dredging pipe, bailer frame etc.).

### 3.2.4 Stern anchor arrangements of ships other than tug-and-pushboats (see 3.2.5) and self-propelled ships (see 3.2.6) are installed at shipowners' option.

Where bower anchor arrangement cannot be located in ships with a length less than 25 m other than tug-and-pushboats, such
ships may be fitted with aft anchor arrangement only.

3.2.5 In tug-and-push boats fitted with the bow anchor arrangement according to standards for common towing vessels (see 3.2.1), aft anchor arrangement shall be also provided (see 3.3).

3.2.6 Self-propelled ships with equipment number of 1000 m² (see 1.7) and over shall be fitted with the stern anchor arrangement in addition to the bower anchor arrangement, when:

1. navigation area of those ships includes areas without current or with a low current rate. Weight of the aft anchor for such ships shall be not less than 0.25 of total mass of bow anchors;

2. navigation area of those ships includes numerous fairway sections which do not allow the ship for turning to come to bow anchors against the current due to its width. The stern anchor weight in this case shall be at least 0.4 of the total weight of bow anchors;

3. ship is of Ì-ÑÏ class. The stern anchor weight of such a ship shall be at least 0.25 of the total weight of bow anchors.

3.2.7 Weight of each of two installed bow anchors shall be equal to a half of a total weight of bow anchors

3.2.8 Length $L_{anch}$ of the anchor chain of one bow anchor is determined as follows;

1. The approximate total length of bow anchor chains is calculated by the following formula:

$$L_{anch} = \alpha \left[ b + c \ln \left( \frac{N_c}{N} \right) \right],$$

where $k$ — coefficient equal to:

1.25 for ships of M class;

1 for ships of other classes;

$b$ and $c$ — coefficients to be taken from Table 3.2.8.

2. Obtained value $L_{anch}$ shall be rounded for ships equipped with two bow anchors (see 3.2.1) to the nearest greater value $L_{anch}$, multiple of shot length (25 m), and for ships equipped with one bow anchor to the nearest value $L_{anch}$, from the range of 25, 30, 40, 50, 60 and 75 m.

For ships of M-ΠP and O-ΠP class with equipment number of 1000 m² and over except tugboats, the total length of anchor chains shall be increased by one shot length;

3. If total length of anchor chains of two bow anchors is characterized with odd number of shots, then chain length of one bow anchor $L_{anch}$ is taken equal to one half of $L_{anch}$.

If total length of anchor chains of two bow anchors is characterized with odd number of shots, then length of one of chains shall be taken one shot more and connected to a heavier anchor if anchors are different in weight.

The anchor chain cable length for self-propelled ships equipped with stern anchor arrangement in addition to bow anchor arrangement shall be at least 75% of the shorter chain length of the bow anchors.

3.2.9 Anchor chain diameter shall be determined as follows;

1. The approximate value $k_{str}$ of anchor chain diameter is calculated:

$$k_{str} = c + d M_{anch} + e M_{anch}^2 + f M_{anch}^{1.5},$$

(3.2.9.1-1)

where $M_{anch}$ — weight of an anchor to be fitted on the ship (see 3.2.1), for which the anchor chain is intended, kg;

for studless anchor chains, mm,

\[ k_{str} = a_1 + b_1 \frac{M_{anch}}{f(M_{anch})}, \]  
(3.2.9.1-2)

for ships of П and Λ class \( a_1 = 5.071, \) \( b_1 = 0.234 \) shall be taken, for ships of М-СП, М-ПР, О-ПР, М and О: \( a_1 = 6.197, \) \( b_1 = 0.253; \)

.2 The approximate values of anchor chain diameter shall be rounded to the nearest value from dimension-type range of diameters regulated by GOST 228.

The anchor chain diameter for ships of М-СП 4.5 class when a weight of an anchor is 2500 kg and less shall be set according to Table 3.2.9.1 similarly to ships of М-СП class. For the larger weight of anchor, stud link chains of strength category 2, with diameter of 46, 48, 50 and 52 shall be used when anchor weight is 2700, 3000, 3300 and 3600 kg, correspondingly.

3.2.10 When using cast chain cables instead of welded ones, their diameter may be reduced by 12%.

3.2.11 Using of steel, synthetic or hemp ropes instead of chains except for dynamically supported craft, where chain cables can be replaced with steel wire ropes, is allowed in ships of О and М class only for stern anchors and in ships of О class less than 25 m in length and ships of Λ and П class — for bow anchors provided that the following conditions are met:

.1 chain cable diameter to be replaced by a steel or synthetic rope shall be not over than 22 mm, and a chain cable diameter to be replaced by a hemp rope — not over than 14 mm;

.2 ropes shall be flexible and of the same strength as the chain cable of the required diameter, their length shall be at least 20% greater than that of the anchor chain to be replaced;

.3 steel wire ropes shall be galvanized and hemp ropes shall be tarred;

.4 the rope shall be connected to the anchor by means of a chain cable section of the same strength as the rope and of a length sufficient for securing the anchor for voyage by means of chain stopper. The chain cable section is not required, if a design of the anchor arrangement provides other stopper device for securing the raised anchor.

3.2.12 In tug-and-push boats with capacity up to 590 kW inclusive equipped with towing winches, anchor chain cables may be replaced with steel wire ropes in the stern anchor arrangement.

On non-self-propelled industrial ships of all classes equipped with bower winches which ensure rope slippage at loose drum anchor, chain cables of a diameter up to 31 mm may be replaced with steel wire ropes. In both cases the requirements of 3.2.11.2 and 3.2.11.4 shall be met.

3.2.13 For ships with equipment number of 1000 m² and over engaged on coastal navigation of the Kara Sea, weight of anchors determined in accordance with 3.2.1 shall be increased by 20% and length of anchor chain cables determined in accordance with 3.2.8 — by 25%.

3.2.14 Anchor equipment of О class ships navigating in Obskaya Guba up to the Novy Port shall be determined according to 3.2.1 for ships of М class.

3.2.15 For ships of О class navigating on estuaries of the biggest rivers (the Amur, the Enisey) the length of anchor chain cables shall be increased as compared to that determined according to 3.2.8 by at least one shot.

3.2.16 For ships of П class intended for navigation in basins with the current velocity
of 6 to 9 km/h, the total weight of anchors shall be increased by 25% as compared to that determined according to 3.2.1, and with the current velocity over 9 km/h — by 55%. Here, total length of anchor chains for ships with the equipment number of 500 m² and over shall be increased by one shot.

3.2.17 For ships of Ï class intended for navigation in basins with the current velocity of 6 to 9 km/h, the total weight of anchors shall be increased by 15% as compared to that determined according to 3.2.1, and with the current velocity over 9 km/h — by 45%. Here, total length of anchor chains for ships with the equipment number of 500 m² and over shall be increased by one shot.

For all ships of Ï class being operated on river channels and reaches with the current velocity up to 2 km/h, the weight of anchors may be assigned by rounding the calculated weight \( m_{anch} \) to the nearest value from dimension-type range regulated by national standards\(^1\), here, the length of anchor chain may not exceed 25 m.

For self-propelled ships of Ï class with the equipment number of 450 m² and less, navigating on river channels and reaches with the current velocity up to 2 km/h, there may be provided one bow anchor the weight of which shall be not less than 0.5 of the calculated weight of two anchors.

The anchor weight may be similarly reduced in ships operating on ferries or permanently engaged on carriages within a port or jetty water areas related to P and Ï categories in a distance of not more than 5 km from the port or jetty.

3.2.18 For hydrofoil craft, hovercraft and skimmers of M class the anchor weight, chain cable length and breaking load of a rope shall be increased by 25% in comparison with those taken in accordance with 3.2.2 for ships of O class.

3.2.19 For hydrofoil craft, hovercraft and skimmers navigating on river parts with current velocity over 6 km/h and with stone ground the anchor weight shall be twice increased in comparison with that determined according to 3.2.2.

3.2.20 The anchor chain cable length for dynamically supported craft shall be determined as follows:

\[
l_{anch} = a_3 + b_3 N^c_3,
\]

where \( a_3, b_3, c_3 \) — coefficients adopted from Table 3.2.20.1.

<table>
<thead>

<td>0.324</td>
</tr>
</tbody>
</table>

The obtained value \( l_{anch} \) shall be rounded upwards and designated as \( L_{anch} \).

When determining breaking strength of the anchor chain cable the anchor weight shall be taken twice as that determined in accordance with 3.2.2.

3.3 ANCHOR EQUIPMENT OF PUSHED CONVOYS

3.3.1 When assigning anchor equipment of pushed convoys, a dead-water pushed convoy formed according to scheme T+1+1 (pushboat + barge + barge) is taken as a design convoy.

3.3.2 Total weight of bow anchors \( \sum m_{anch} \), kg, of a pushed convoy is defined by the following formula:

\[
\sum m_{anch} = k_c k_{str} \left[ L(B + H) + k \sum_{i=1}^{n} (l_i h_i) \right],
\]

where \( L \) and \( B \) — dimensions of a convoy in the waterline plane, m;

\( H \) — design depth (for the greatest barge of the convoy), m;

\( n \) — number of barges in the convoy;

\( k \) — coefficient for the case of a barge without the equipment.

\( L \) and \( B \) are determined according to the formula:

\[
L(B + H) = \frac{a}{b} \left[ \frac{a}{b} + \frac{b}{c} \right] + \frac{b}{c},
\]

where \( a, b, c \) — coefficients from Table 3.2.20.1.

1 GOST 761, GOST 8497
and breadth of side silhouette of a cargo on deck, m;

- \( k \) — coefficient taken equal to 0.5 for carriage of bulk cargoes and to 1.0 for carriage of other deck cargoes;
- \( k_c \) — coefficient assigned according to 3.3.3;
- \( k_{str} \) — coefficient assigned according to 3.3.4.

### 3.3.3 Coefficient \( k_c \) for pushed convoys

Coefficient \( k_c \) for pushed convoys shall be taken according to Table 3.3.3.

### 3.3.4 Coefficient \( k_{str} \)

Coefficient \( k_{str} \) shall be taken depending on the height \( z_{str} \), m, of the windage centre above the water surface, basin category and current velocity.

For \( 1.25 \, \text{m} \leq z_{str} \leq 4.0 \, \text{m} \) coefficient \( k_{str} \) shall be determined by the following formula:

\[
k_{str} = 1 - A \left( 4.0 - z_{str} \right),
\]

where \( A \) — coefficient taken according to Table 3.3.4

For \( z_{str} < 1.25 \, \text{m} \) coefficient \( k_{str} \) shall be determined by formula (3.3.4) where \( z_{str} \) is taken equal to 1.25 m.

For \( z_{str} > 4.0 \, \text{m} \) coefficient \( k_{str} \) shall be taken equal to 1.0.

### 3.3.5 When assigning weight of each of two bow anchors and two stern anchors, refer to 3.2.1 to 3.2.3, 3.2.6, 3.2.7, 3.2.16 to 3.2.19.

### 3.3.6 Total weight of stern anchors (anchor) of a pushboat shall be taken equal to 0.8 of the weight of bow anchors of the pushed convoy.

### 3.3.7 Aft and middle sections of a convoy may be equipped with one bow anchor with weight equal that of one bow anchor of the head section.

### 3.3.8 A length of each bow and aft chain cable of a pushed convoy shall be equal to a total length of the pushboat and one barge of the pushed convoy, but not less than 50 m and not more than 150 m.

### 3.3.9 In pushed convoys operating in estuaries of the rivers Ob, Lena and Amur of O category, the chain cable length shall be increased in comparison with design length at least by one shot.

### 3.4 SECURING ATTACHMENTS FOR ANCHORS AND ANCHOR CHAIN CABLES

#### 3.4.1 Two stoppers shall be provided for each anchor chain cable: one for securing of the chain cable at anchorage and the other one for securing of the raised anchor. An anchor hoisting gear brake may be used as the stopper device for securing the chain cable at anchorage.

Cam, friction or chain anchor stoppers shall be used for securing of raised anchor. For Matrosov anchors up to 25 kg and Hall’s anchors up to 50 kg one stopper device is permissible ensuring riding the ship at anchor. Bollards and cleats may be used as stoppers.

#### 3.4.2 Inboard shots of anchor chains or bitter ends of ropes shall be securely attached to the hull and fitted with detachable joints in order to enable releasing of these ends from easily accessible place at tight chain cable or rope.

Attachment elements of the chain cables and ropes connection and of their detachable joints shall be of the same strength as the chain cable or the rope.

The capacity of chain lockers shall be sufficient for free arrangement of the whole anchor chain.

In ships less than 25 m in length bitter ends of synthetic or hemp ropes need not be fitted with detachable joints.
3.4.3 Anchor hawses and their location shall comply with the following requirements:
1. inner hawse pipe diameter shall not be less than 10 chain cable diameters and the wall thickness shall not be less than 0.4 of the chain cable diameter;
2. easy entering of the anchor shank into the hawse pipe and easy taking off the hawse pipe when the chain cable is released due to the gravity force shall be provided;
3. bend of the chain cable when passing through the stopper and the hawse pipe shall be minimal. If the small bend is not practicable, lead roll may be fitted.

3.5 ANCHOR MACHINERY

General requirements
3.5.1 When dropping and hoisting the anchors having a weight of 50 kg and over as well as holding the ship at anchorage a capstan or windlass shall be provided. When anchor weight is 150 kg and over that machinery shall be fitted with chain sprockets.
3.5.2 When chains are replaced by ropes, anchor winches may be used. Towing winches may be used as anchor hoisting gear.
3.5.3 Hydraulically driven anchor machinery shall comply with the requirements of 1.6.17 to 1.6.26.

Drive
3.5.4 The drive engine power of the anchor machinery arrangement shall be sufficient for hauling the ship to the anchor, breaking out and hoisting of any of the anchors at a speed not less than 0.12 m/s with the nominal pull on the sprocket, H equal to:
\[ F_t = 22.6m d^2 \]
where \( m \) — strength factor taken equal for:
- standard stud link chains 1
- studless link chains 0.9
\( d \) — the chain diameter, mm.
3.5.5 The drive shall provide heaving-in of the anchor chain at a speed and pull specified in 3.5.4 for a period at least 30 min without interruption and dropping of one anchor for the design anchorage depth.
3.5.6 The starting moment of the anchor machinery drive shall create a pull on the sprocket at still anchor chain of at least \( 2F_t \).
3.5.7 As the anchor approaches the hawse, the drive shall provide for heaving-in speed max. 0.12 m/s.
3.5.8 The anchor machinery drive shall provide for simultaneous hoisting of freely suspended anchors from one-half of the design anchorage depth.
3.5.9 The manual drive shall provide heaving-in speed of at least 0.042 m/s with a pull on the sprocket according to the requirements of 3.5.4. The pull applied to handles shall be max. 160 N per one operator.
When using reciprocating manual drives the pull shall be max. 200 N per one operator.
3.5.10 Piping of hydraulic systems of anchor machinery connected with piping of other hydraulic systems shall be served by two independent pump sets; each of the pump sets shall ensure the operation of anchor machinery with the nominal pull and the nominal heaving-in speed of the anchor chain.
3.5.11 If the machinery drive is capable of developing a torque bringing to stresses in the machinery elements exceeding 0.95 of the yield point, protection shall be provided against exceeding the mentioned torque which shall be fitted between the drive and the machinery.
3.5.12 Anchor machinery of ships of M-C1 class shall provide simultaneous hoisting of two freely suspended bow anchors from 33 m depth with a chain diameter up to 16 mm inclusive and from 40 m depth with a chain diameter over 16 mm.

Brakes and clutches
3.5.13 The anchor machinery shall be fitted with disengaging clutches arranged between the sprocket and its drive shaft. The anchor machinery shall be fitted with brakes.
The anchor machinery with electrical or diesel drive shall be fitted with automatic
brakes arranged on the drive shaft and being actuated when the power is switched off or the drive fails.

In case of self-braking gear no automatic brakes are required.

3.5.14 An automatic brake shall ensure a breaking torque corresponding to a force on the sprocket of at least \(2F_1\) where \(F_1\), see 3.5.4.

3.5.15 Each chain sprocket shall be fitted with a brake, the braking torque of which shall correspond to a force in the chain on the sprocket of at least \(0.3F_{\text{test}}\) (\(F_{\text{test}}\)— testing load of the anchor chain cable), and for manually-driven machinery – at least \(2F_1\).

The force applied to the brake drive handle shall not exceed 490 N.

**Chain sprockets**

3.5.16 Chain sprockets shall have at least five cams.

For horizontal shaft sprockets the wrapping angle shall be not less than 115°, while for vertical shaft sprockets – not less than 150°.

3.5.17 The chain sprockets shall ensure passing of joining links in both horizontal and vertical positions.

The chain sprockets of vertical anchor winches shall ensure passing the joining links in the vertical position.

**Strength checking**

3.5.18 The machinery elements subject to loading shall be checked for strength when being affected by forces corresponding to the drive maximum torque or the moment of the extreme protection setting. The reference stresses in the elements shall not exceed 0.95 of the yield stress of the element material.

At the action of the nominal pull force the stresses shall not exceed 0.4 of the yield stress of the element material.

3.5.19 The anchor machinery elements being loaded at braked sprocket shall be checked for strength under action of breaking load of the chain cable. Stresses shall not exceed 0.95 of the yield stress of the element material.

**Additional requirements**

3.5.20 Anchor machinery intended for mooring operations, the requirements of the present Chapter as well as requirements of 4.3 shall be met.

**3.6 REMOTE-CONTROLLED ANCHOR RELEASE DEVICE**

3.6.1 In self-propelled ships over 60 m in length, non-propelled pushed ships intended for carriage of inflammable liquids and pushboats, the hoisting gear break of bow starboard anchor, and on pushboats also the break of stern anchor shall be fitted with a remote-controlled anchor release device. The remote-controlled release device shall prevent from spontaneous anchor release.

3.6.2 The remote-controlled anchor release device shall provide the following:

1. control from the wheelhouse (on non-self-propelled ships — from the pushboat wheelhouse) of release of the bow starboard anchor and for pushboats — also stern anchor as well as indication of the released chain cable;
2. stopping the anchor chain from the wheelhouse at any released chain cable;
3. the duration of the anchor chain from the wheelhouse at any released chain cable;

3.6.3 Stoppers and other anchor equipment for which remote control is provided shall also be fitted with means of local manual control.

3.6.4 Anchor appliances and the associated means of local manual control shall be designed to ensure normal operation of anchor arrangement in the event of failure of separate elements or the whole remote control system.

**3.7 ANCHOR CHAIN CABLES AND THEIR ACCESSORIES**

3.7.1 Anchor chain cables and their accessories shall be made of rolled steel manufac-
tured and tested in accordance with requirements of 2.5 Part X of the Rules. The material of forged chains and accessories shall comply with the requirements of 2.6, and that of cast chain cables — with the requirements of 2.7 Part X of the Rules.

Chains and accessories shall be tested in accordance with requirements of Appendix 2. The design and dimensions of chain links and its accessories shall comply with GOST 228.

3.7.2 Chain links are manufactured from rolled steel bars by flash butt welding; they may be manufactured also by drop forging or steel casting.

Studless links of 26-mm diameter and less may be manufactured by pressure contact butt welding.

3.7.3 Accessories, kenter and joining shackles, swivels and swivel shackles shall be forged or cast and shall comply with requirements at least for steel of grade 2 according to GOST 228.

The above accessories may be also manufactured by welding.

3.7.4 According to the grade of steel, condition of supply of chain cables and accessories shall comply with Table 3.7.4.

<table>

The heat treatment of chain links and accessories shall be performed prior to breaking load and proof load testing.

3.7.5 The studs shall be made of rolled, forged or cast carbon steel similar to that of the given chain links. The studs must be located in the link centrally and perpendicular to longitudinal axis of the link. The studs of the final links at each end of any length may also be located off-centre to facilitate the insertion of joining links and shackles. The following tolerances are permitted provided that the stud fits tightly and its ends lie practically flush against the inside of the link: maximum off-centre distance \( X = 0.1d \), angle \( \alpha \) a not exceeding 4°.

Tolerances are determined according to Fig. 3.7.5.

![Fig. 3.7.5 Tolerances for fitting of studs](image)

\[
X = 0.5(A - a)
\]

3.7.6 Allowable tolerances of a shot length measured over a length of any 5 links shall not exceed +2.5 % of the nominal length. Measurements shall be performed on the chain under tension after proof load testing.

The following tolerances are allowed for chain accessories: for diameter +5%, -0; for other dimensions ±2.5%.

3.7.7 The welding of studs shall be carried out in accordance with procedure approved by the River Register with regard to the following conditions:

- studs shall be made of steel specified in 3.7.5;
- the studs shall be welded at one end only, which is opposite to the link weld. The stud ends must fit the inside of the link without appreciable gap;
- welding is performed preferably in the downhand position by qualified welders having the Approval Certificate using welding consumables required by the procedure;
- welding is performed prior to the final heat treatment of the chain cable;

3.7.8 The mechanical properties of finished chain shall comply with Table 3.7.8 and be specified in the quality control document.

1 Impact tests of material for grade 2 chain cables may be omitted if the chain cable is subject to heat treatment.
2 Percentage reduction of cross-sectional area is not regulated.
3 Impact tests for chain cable of grade 3 may be carried out at $–20$ $^\circ$C.

3.7.9 Marking of the chain shall be made on the outermost links of each shot length; it shall include the certificate number, chain grade and the River Register brand. The arrangement of the marking symbols shall be as in Fig. 3.7.9. Marking of the chain accessories shall be made on each item; it shall include the certificate number, grade and the River Register brand.
4 MOORING ARRANGEMENT

4.1 GENERAL PROVISIONS

4.1.1 Every ship shall be fitted with mooring arrangements for warping to shore or floating berths structures and reliable attachment of the ship to them.

4.1.2 Selection of number, type of machinery and elements of the mooring arrangements, and also their arrangement on board shall be carried out by a designer in accordance with design features and the ship purpose subject to the requirements of present Section of the Rules.

4.2 MOORING EQUIPMENT

4.2.1 Mooring bollards shall be made of steel or cast iron. For small ships equipped only by natural fibre or synthetic fibre ropes, bollards made of light alloys may be used.

4.2.2 The outside diameter of the bollard column shall be not less than ten diameters of the steel wire rope or at least one circumference of a natural fibre or synthetic fibre rope.

4.2.3 Bollards shall be installed on foundations which shall be fixed on the deck and be attached to the ship framing. It is allowed to weld bollards to strengthened plates of the deck flooring. No side bollards welded to the deck flooring are allowed in cargo ships.

Securing of the side in these ships shall be calculated for forces arising while towing and pushing ships by two wads.

4.2.4 Bollards, mooring chocks and other elements of mooring equipment as well as their foundations shall be so designed that stresses in the elements do not exceed 0.95 times the yield point of their material due to acting of force equal to the breaking strength of the mooring rope for which they are intended.

4.2.5 Mooring bollards located in explosive spaces and areas (see 1.4 Part III of the Rules), shall be installed on foundations designed so as to provide natural air circulation under the bollards.

4.2.6 Hull structures in way of the mooring equipment installation shall be supported by ordinary framing or stiffeners.

4.2.7 For hauling mooring ropes the mooring machinery may be used (mooring capstans, mooring winches etc.) or other deck machinery (windlasses, cargo winches etc.) fitted with mooring drums.

4.3 MOORING MACHINERY

Drive

4.3.1 A drive of the mooring machinery shall provide continuous hauling of a mooring rope for at least 30 min at a nominal tractive force and nominal speed specified in the manufacturer's technical documentation. Hauling speed of a mooring rope shall not exceed 0.3 m/s at the nominal tractive force. Moreover, it shall be possible to haul a mooring rope with a speed not exceeding 0.15 m/s.

4.3.2 The drive of the mooring machinery shall be able to create force as great as twice and more of the nominal tractive force for 15 s.

4.3.3 When the drive maximum moment can induce stresses in elements of the mooring machinery exceeding those indicated in 4.3.6 to 4.3.7, the overload protection shall be provided.

Brakes

4.3.4 Mooring machinery shall be equipped with an automatic normally closed brake. The brake shall hold the mooring drum in fixed
condition while a static force not less than 1.5 times of the mooring machinery tractive force is being applied to the rope.

4.3.5 Automatic mooring winches shall be equipped with brakes installed on the drum which are capable to withstand the rope breaking load.

**Strength checking**

4.3.6 Strength of loaded elements of the mooring machinery shall be checked under action of forces corresponding to the drive maximum moment or a moment corresponding to limit protection setting. The equivalent stresses shall not exceed 0.95 the yield point of the material. When the nominal tractive force is applied, stresses in the elements shall not exceed 0.4 of the yield point of the material.

4.3.7 The shaft (rudder stock) of the mooring machinery, its supports, fastening devices for its attachment to the foundation shall be checked by strength calculation for the case when bending force acts on the mooring drum and is equal to the rope breaking load. Here, the stresses occurred shall not exceed 0.95 times the yield stress of the material.

**Automatic mooring machinery**

4.3.8 Automatic mooring machinery shall be capable of being manually controlled as well.

4.3.9 Automatic mooring machinery shall be equipped with:

.1 audible warning alarm which is actuated at maximum permissible length of hauled-off rope;

.2 an indicator of actual value of the tractive force applied to the mooring rope during the automatic mode of operation of the machinery.

4.3.10 Strength of parts of the automatic mooring machinery being under load at braked drum shall be checked for action of the rope breaking load. Here, stresses in the parts shall not exceed 0.95 of the yield point of the material.

**4.4 MOORING ROPES**

4.4.1 Mooring ropes may be made of steel, natural fibres or synthetic fibres.

4.4.2 Breaking load $F_{br}$, kN, of the mooring rope shall be not less than:

- for ships with equipment number of 100 to 1000
  \[
  F_{br} = 0.147 N_e + 24.5
  \]
  \[(4.4.2-1)\]

- for ships with equipment number more than 1000
  \[
  F_{br} = 171 + 3.92 \times 10^{-2} (N_e - 1000)
  \]
  \[(4.4.2-2)\]

where $N_e$ — equipment number calculated in accordance with 1.7.

4.4.3 Number and length of mooring ropes shall be selected depending on the ship type and operating conditions. However, there shall be at least three mooring ropes on the ship:

- length of the first rope shall be at least $L + 20$ but max. $100$ m, where $L$ is the design length of a ship, m;

- length of the second rope shall be at least two thirds the length of the first rope;

- length of the third rope shall be at least one third the length of the first rope.

For ships with length $L$ less than $20$ m, the third rope is not required.

4.4.4 Steel wire mooring ropes shall not be used or stored in explosive spaces and areas (see 1.4 Part III of the Rules).

4.4.5 For non-crewed non-self-propelled ships, mooring ropes may be stored on tugboats and pushboats engaged on operations with them. In this case, tugboats and pushboats shall be completed with mooring ropes according to 4.4.3, mooring ropes of non-self-propelled ships are not taken into account.
5 TOWING AND COUPLING ARRANGEMENTS

5.1 TOWING ARRANGEMENT

5.1.1 Towing arrangement of tugs and tug-and-push boats shall include:
.1 at least two devices for towing rope securing: the main device and the reserve one. Towing rope may be also secured by means of:
  towing winch and towing hook;
  towing hook and towing bollards or bitts;
  towing winch and towing bollards or bitts;
  towing rope;
  towing arches and other rope guides;
  towing rope limiters.

Notes: 1. Towing hooks may be used instead of towing bollards or bitts, and towing winch — instead of towing hook.
  2. Where two towing winches of the same type or two towing hooks of the same type are installed in a tug, one of them is considered as the main and another — as the reserve one.

5.1.2 Tugs and tug-and-push boats of M class with main engines with output over 300 kW, of O, P and J class with main engines with output of 440 kW and over shall be fitted with mechanically driven towing winches.

5.1.3 Tugboats of M class with main engines with output over 440 kW shall be fitted with automatic towing winches.

5.1.4 Ships of all other types with main engines with output over 300 kW, with towing arrangements and not equipped with towing winches, shall be fitted with arrangements for hauling and laying of towing ropes.

5.1.5 Number and arrangement of towing bollards, bitts, mooring chocks, guiding blocks, stops shall correspond to the design features and general arrangement of the main towing equipment (winches, hooks).

5.1.6 Every self-propelled and non-self-propelled ship shall be fitted with arrangement allowing its towing, including the following equipment:
.1 two towing bollards or bitts situated in the fore and aft ship extremities;
.2 towing hawses for passing the towing ropes through the bulwarks.

5.1.7 Floating cranes, landing stages, industrial ships and other ships with transom extremities shall be fitted with two pairs of bollards or bitts installed in the extremities on either side.

5.1.8 It is allowed to replace towing hawses with roller fairleads or guiding bollards.

5.1.9 Tugboats of М-СП, М-ПР and О-ПР class shall be fitted with automatic towing winches with a towing rope at least 500 meters long.

5.2 TOWING WINCHES

5.2.1 Towing winches shall be fitted with brake with a holding capacity less than the breaking load of a towing rope.

5.2.2 Strength of the load-carrying parts of the towing winch shall be checked when the maximum drive moment is applied. Here, stresses in the parts shall not exceed 0.95 of the yield point of the material.

When the nominal tractive force is applied to the middle layer of rope coiling on the drum, stresses in the parts shall not exceed 0.4 the yield point of the material.

5.2.3 Strength of parts of the towing winch being under load at locked rope drum shall be checked when the load equal to the breaking load of the towing rope is applied on external layer of coiling.
Here, stresses in the parts shall not exceed 0.95 of the yield point of the material.

5.2.4 Automatic mooring winches shall be equipped with:

.1 automatic adjustment device of the towing rope tension This automatic device shall ensure release of the rope when tractive force on the winch exceeds the maximum permissible value; hauling of the rope when the tractive force is reduced below the minimum permissible value and holding of the rope for tractive forces within the specified range of permissible values from maximum to minimum. The indicator of a current tractive force applied shall be installed near the winch and in the wheelhouse;

.2 automatic normally closed brake (see 4.3.4);

.3 towing winch remote control device/system ensuring the following operations: control from the wheelhouse: speed and direction of rotation; towing drum activation/deactivation; release of the towing rope; emergency stop; emergency drop of the towing rope; control/indication of parameters from remote control station; length of hauled-off rope; rope tension.

5.2.5 Audible warning alarm shall be provided which is actuated at maximum permissible length of hauled-off rope.

5.2.6 It shall be possible to slacken the towing rope freely both from the local control station and from the wheelhouse.

5.2.7 Winch drums shall be equipped with a cable layer.

5.2.8 Drum brake driven by any energy source shall be manually operated as well.

5.3 TOWING HOOKS

5.3.1 A ship may be fitted with standard folding towing hooks of opened and closed types, with spring shock absorbers and without them, with mechanical and hydraulic locks.

Tugboats and tug-and-push boats of M and O class, and also tugboats of P and J class with main engines with output over 300 kW shall be fitted with hooks of folding type with spring shock absorbers when the towing hooks are applied as main means.

Hooks of non-folding type may be used as the main means for securing of the towing rope on towed ships and as reserve means in tugboats.

5.3.2 All carrying elements of the towing hook and parts securing it to the hull shall be designed for the breaking load of the towing rope taken by calculation. Stresses in these shall not exceed 0.95 the yield point of the material.

5.3.3 Load at which the shock absorber spring is compressed against the stop shall be not less than 1.3 times the nominal traction on the hook.

5.3.4 The cramp irons of the towing hooks shall be solid-forged. Relative elongation of the hook material shall be not less than 18% on five-fold sample and the yield point — not less than 245 MPa.

5.3.5 Prior to installation on board the ship, the towing hooks shall be tested by test load equal to doubled design tractive force on the hook determined for ships in mooring mode.

5.3.6 Attachment of the towing hook to the ship structures shall be of such design that at any possible towing angles the hook is not subject to the bending forces in the horizontal plane and does not touch any hull structures within the set angle of side stops, directly or by the rope thimble.

5.3.7 When in non-working position, the towing hook shall be secured for voyage.

5.3.8 Towing rope release shall be possible from two stations:

.1 from the wheelhouse (remote control);

.2 from the local station located in the immediate vicinity of the towing hook in a safe area.
5.3.9 Towing rope releasing arrangement shall operate in the range of loads on the hook from zero to the breaking load at any possible rope deviation from the centreline.

5.4 TOWING EQUIPMENT

Bollards, bitts, rope locks

5.4.1 Bollards, bitts and towing arrangement machinery shall be installed on foundations which shall be fixed on the deck and connected with the hull framing.

Deck shall be strengthened in way of installation of the foundations.

Bollards located in explosive spaces and areas of the second category of explosion risk shall be installed on foundations so designed as to provide natural air circulation under the bollards.

5.4.2 The outside diameter of the bollard or bitt column shall be not less than ten diameters of the steel wire rope or not less than one circumference of the natural fibre rope.

5.4.3 Rope locks shall be designed so as to withstand a load equal to a half of design tractive force on the hook.

Towing arches

5.4.4 In the after part of tugboats in way of possible displacement of the towing rope towing arches shall be installed in the transverse direction of the ship from side to side or other structures guiding the rope. The number of towing arches shall be determined for each tug depending on the length of its after part.

5.4.5 The height of the towing arches and protective rails shall ensure the safe work and movement of the crew in way of possible displacement of the towing rope.

5.4.6 The towing arches, supporting counterforts and other parts of the towing arrangement being touched by the towing rope are to be made of pipes or other proper profile with the rounding radius not less than the towing rope diameter.

5.4.7 In all ships equipped with the towing arrangement the side limiters of towing rope shall be fitted.

5.4.8 The side limiters of the towing rope shall be designed to take the load equal to the breaking load of the towing rope. Stresses in carrying elements of the limiters and also in the fastenings securing them to the ship’s hull or other structures shall not exceed 0.95 times the yield point of the material.

5.5 TOWING HOOKS

5.5.1 Strength characteristics of the towing ropes shall be determined depending on the design tractive force on the hook in the mooring mode established by hydrodynamic calculation or agreed by the River Register or by prototype and the results of trials of lead ships. If such calculations are not performed or a prototype is not available, the tractive force on the hook \( F \), kN, shall be assumed not less than the value calculated by the following formula:

\[
F = 0.16P_e, \quad (5.5.1)
\]

where \( P_e \) — the total output of main engines, kW.

5.5.2 Minimum permissible breaking load, kN, of the rope as a whole used for towing on the hook shall be not less than determined by the following formula:

\[
F_0 = kF, \quad (5.5.2)
\]

where \( F \) — design tractive force on the hook, kN;

\( k \) — safety factor equal to:

- for design tractive force on the hook up to 120 kN 5
- for design tractive force on the hook of 120 kN and more 4
- for ropes of automatic towing winches 3
- for ropes of natural and synthetic fibre 6

Note. For tug-and pushboats, safety factor \( K \) shall be at least equal to for design tractor force on the hook:

- less than 120 kN 4
- 120 kN and more 3
5.5.3 The length of the towing rope is selected depending on the area of navigation, but shall be not less than 180 m for ships of M class, 100 m for ships of O class and 60 m for ships of P and J class.

5.5.4 Steel wire ropes used for towing shall have not less than 144 wires and 7 fibre cores, and when using automatic towing winches — 216 wires and 1 fibre core with tensile strength of wires of 1177 to 1373 MPa.

Ropes must be untwistable in all cases. Wires shall be galvanized.

5.5.5 Manila ropes with increased strength may be used as the towing ropes. It is allowed to use three-rowed, ordinary and special tarred hemp ropes, and also ropes made of synthetic fibres — three-rowed, with circumference up to 200 mm.

5.5.6 Each rope shall be provided with a splice from one end, either with a thimble or without it, or a mark (on one end or both ends). A splice without thimble is allowed only when the towing rope is being fixed on the columns of a bollard or a bitt.

5.5.7 No steel towing ropes may be used or stowed in explosive spaces and areas.

5.6 COUPLING ARRANGEMENTS

5.6.1 Coupling arrangements of the pushed convoys shall have sufficient strength to operate at standardized wave height corresponding to a category of operating basin, maximum permissible operating rolling and pitch amplitudes to be determined in accordance with 2.4 Part II of the Rules, maximum speed of putting the rudder or other means of ship steering (for example, steerable nozzle, steering column, waterjet damper) from side to side at full speed of the convoy at any azimuth to rolling as well as for different loading conditions.

5.6.2 Calculations for the determination of bending moment due to the joined action of hydrodynamic forces due to wheellover, rolling and side wave pressure, and also for determination of the design loads \( P_d \) acting in connections of the coupling arrangements shall be submitted to the River Register for review.

5.6.3 Strength calculation of elements of the coupling arrangement shall be carried out by permissible stresses which shall be taken equal to 0.63 times the yield point of the material of the elements. Breaking load of ropes shall be at least 1.5\( P_d \).

5.6.4 The test load for bench tests of the coupling arrangement shall be not less than 1.5\( P_d \).

5.6.5 The prototype model of the coupling arrangement shall be tested on the bench with the test load of 1.5\( P_d \) and instrument measurements (strain-gauging) of the essential elements.

The prototype model is considered suitable for carrying out on board operational tests, if the stresses in the elements during testing by the test load does not exceed 0.95 times the yield point of the material.

5.6.6 The requirements of 5.6.7 to 5.6.12 applicable for two-hinged design of coupling arrangement of pushed convoys, ships of M-СП, М-ΠР and О-ΠР class operating with restrictions of a wave height \( 3.5 \text{ m} \geq h \geq 2.0 \text{ m} \).

Two-hinged design of coupling arrangement is such design that a pusher coupled with a barge can move freely with one degree of freedom relatively to the barge (turning of the convoy vessels relatively to horizontal axis being perpendicular to the centre line of the convoy).

5.6.7 Coupling devices of pushed river-sea navigation convoys shall possess sufficient strength for operation in sea areas at maximum speed of putting rudders or steerable nozzles from side to side at the maximum speed of a convoy and any azimuth to rolling.
5.6.8 Design loads applied to hinged coupling device shall be not less than those calculated by formulas, kN:

for longitudinal load

\[ P_x = 5C_x \rho g h \frac{L}{\sqrt{b}} \lambda^2 (1 + 5 Fr) \times \left[ 1 + 0.8 \left( \sin 2 \epsilon + \sin \epsilon \right) / \sqrt{b} \right], \]

(5.6.8-1)

for transverse load

\[ P_y = C_y \rho g h \frac{L}{\sqrt{b}} \lambda^2 (1 + 5 Fr) \sin^3 \epsilon / \sqrt{b}, \]

(5.6.8-2)

for vertical load

\[ P_z = 5C_z \rho g h \frac{L}{\sqrt{b}} \lambda^2 (1 + 9 Fr) \times \left[ 1 + 0.35 \left( \sin 2 \epsilon + \sin \epsilon \right) / \sqrt{b} \right], \]

(5.6.8-3)

where \( C_x, C_y, C_z \) — coefficients of longitudinal, transverse and vertical loads determined by formulas of Table 5.6.8 with regard to parameters \( h, \lambda \) and \( l_{hin} \):

- \( \rho \) — water density, t/m³;
- \( g \) — acceleration due to gravity:
  \( g = 9.81 \text{ m/s}^2 \);
- \( h \) — wave height, m;
- \( L, B, T, D \) — relative length, breadth, draught and water displacement of a pushed convoy determined by the formulas:
  \[ L = L_1 + L_2 \]  \[ B = B_1 + B_2 \]  \[ T = T_1 + T_2 \]  \[ D = D_1 + D_2 \]

(5.6.8-4)

\( L_1, B_1, T_1, D_1 \) — length, breadth, draught at design waterline of a barge respectively, in meters, and its water displacement, in m³;

\( L_2, B_2, T_2, D_2 \) — length, breadth, draught at design waterline of a tugboat respectively, in meters, and its water displacement, m³;

\( \lambda \) — wavelength, m;

\( \epsilon \) — azimuth (0° to 89°—following sea; 91° to 180°—head sea);

\( Fr = V / \sqrt{g(L_1 - L_2)} \) — Froude number;

\( V \) — speed of a pushed convoy, m/s;

\( 2b \) — distance between hinged coupling devices, m;

\[ l_{hin} = l_{m2} / (l_{m1} + l_{m2}) \] — relative value of position of the hinged coupling device for pushed convoys 0.10 ≤ \( l_{hin} \) ≤ 0.35;

\( l_{m1}, l_{m2} \) — distance between the hinged coupling device and the centre of gravity of a barge and a tugboat respectively, m.

5.6.9 When design of coupling arrangement of a pushed convoy is other than two-hinged, calculation of design loads on its structural members is performed based on procedures agreed upon with the River Register for compliance with requirements of the Rules.

5.6.10 Strength calculations of coupling arrangement elements shall be done on the basis of permissible stresses which shall be taken equal to 0.63 of the yield stress of the material.
5.6.11 Test load for bench tests of coupling arrangements shall be at least 1.5 of the design load.

When test load is applied, the greatest stresses in the coupling arrangement elements shall not exceed 0.95 of the yield stress of the material.

5.6.12 When parameters $h \lambda$ and $\bar{p}$ are other than prescribed by the Rules, design loads on a coupling arrangement may be determined by calculated method based on procedure agreed upon with the River Register for compliance with requirements of the Rules.

Design of coupling arrangements

5.6.13 Materials used for manufacture of coupling arrangements shall comply with requirements of Part X of the Rules.

Carbon steel for welded parts of the coupling arrangements shall contain no more than 0.22% of carbon. Weldability of low-alloy steels shall be documented by the manufacturer.

5.6.14 All steel forgings and castings as well as essential parts with intersecting welds or welds being apart from each other for 5 times thickness of the welded part or less, are subject to heat treatment after manufacture. The heat treatment type is established depending on the chemical composition, purpose and dimensions of the item according to RTSC.

5.6.15 Coupling arrangement shall provide the convoy coupling when the barge is non-attended. The coupling shall be performed from the local control station or remotely from the wheelhouse of the pushboat.

5.6.16 The coupling arrangement shall provide discoupling of vessels in the convoy at the rated waves when any one compartment of a barge is flooded and is at static heel of 15°.

5.6.17 When navigating on waves with height corresponding to operating basin category, the contact between hull structures of convoy sections shall be excluded.

5.6.18 Free clearances in connections shall not allow angular backlash of coupling arrangement more than 0.06°, when shock absorbers are not available, and 0.10° when they are available.

5.6.19 Bolt connections of the coupling arrangement with foundations shall comprise elements (templet bolts, pins, wedge rests etc.) taking shearing forces. Bolts shall be so tightened as to prevent discoupling of the connection when the design shear forces are applied. Nuts of the foundation bolts shall be locked to prevent self-unscrewing.

5.6.20 Coupling locks, tightening arrangements and other coupling equipment with shock absorbers shall remain workable at the momentary unloading of fully compressed shock absorber.

5.6.21 Coupling locks of falling type shall be fitted with locks for their securing for voyage.

5.6.22 Main parts of hull structures of the coupling arrangement (stops, coupling girders, supporting members, foundations) shall have smooth transition with solid hull structures.

5.6.23 Thickness of contact surfaces of thrust members shall be assigned depending on the design force according to Table 5.6.23. Edges of the contact members shall be rounded.

Thrust girders and thrusts shall be designed as plates with bearing surfaces.

5.6.24 Coupling device shall not be extended beyond the plane of the fender bars to prevent touching the structural elements of other ships and quays at mooring and locking. Fender bars enclosing the coupling arrange-
ment from the board side, and also extending girders located between the stops are recommended to be installed on shock absorbers or be made of damping material.

5.6.25 The coupling arrangement shall provide emergency discoupling of ships when the load in the members exceeding working load \( P_w \).

Note. For two-locked couplings, ships may be discoupled when the load is less than design load in the members.

5.6.26 Locks of the automatic coupling device shall close automatically when the ship is touched by another ship and open by manual drive from the local control station. In pushboats a device for the lock opening shall be provided in the wheelhouse.

5.6.27 Lock movement limiters shall be provided at the lower end of vertical coupling and guiding girders.

5.6.28 Where the coupling system is hydraulically driven, the drive when in closed position shall be stopped by mechanical brake equipped with remote indication of its actuation at the coupling device local control station and at the control station in the wheelhouse of the pushboat.

5.6.29 Two-hinged coupling arrangements for ships of М-СП, М-ПР and О-ПР class shall be located as far as practicable from the centreline of a convoy in order to reduce stresses in coupling joints.

5.6.30 The coupling arrangement shall allow for discoupling of vessels in the convoy under wind and waves conditions at loads not less than working loads.

5.7 INTERLOCKING ARRANGEMENTS

General requirements

5.7.1 Requirements of the present Chapter apply to end interlocking arrangements with longitudinal flexible members and longitudinal rigid connections.

5.7.2 Any interlocking arrangements at all possible operating loads shall provide for rigid connection of ships in a convoy and prevent longitudinal and transverse displacement of ships relative to each other so that this group of ships may be considered as a single shipping unit.

5.7.3 Pushboats, cargo pushboats and barges in the pushed convoy in front of which the other barges are located shall be provided with interlocking arrangement in the bow part.

The pushed barges shall be provided with interlocking arrangement in their after part.

5.7.4 Provision shall be made for connection of a ship with both loaded and light barges.

5.7.5 Interlocking arrangement elements shall not protrude beyond the overall hull breadth.

5.7.6 Interlocking and tension arrangements shall be designed and equipped so that the personnel shall be able to connect the pushboat and barges without errors and undue efforts and time consumption.

The pushboats shall be provided with pushing arrangement in their front part designed and equipped to allow the pushboat to take a specified position relative to the pushed barges from the start of interlocking manoeuvres.

The ships shall be interlocked to provide a safe passage for the personnel from one ship to another.

The interlocking arrangement and its connecting members shall withstand forces which may occur when the ship is navigating in the water basins where its operation is allowed and transmit the load from these forces on strong hull members.

5.7.7 Provision shall be made for an adequate number of coupling joints to comply with requirements of 5.7.2 and 5.7.6.

Coupling forces and dimensions of interlocking arrangement elements

5.7.8 Dimensions of longitudinal flexible and rigid members of interlocking arrangements specified in 5.7.1 for convoys and
groups shall be determined with regard to adequate safety margin and coupling forces applied (Fig. 5.7.8), kN, calculated by the following formulas:

1. coupling joint is located between the pushboat and barges or other ships:
   \[ F_{sb} = C_s P_e \cdot 10^{-3} L_s / B_s \]  \hspace{1cm} (5.7.8.1)

2. coupling joint is located between self-propelled cargo pushboat and pushed ship:
   \[ F_{st} = C_{pB} P_e \cdot 10^{-3} L_s / H_k \]  \hspace{1cm} (5.7.8.2)

3. coupling joint is located between pushed ships:
   \[ F_{sl} = C_{pb} P_e \cdot 10^{-3} L_s / H_k' \]  \hspace{1cm} (5.7.8.3)

where
- \( F_{sb}, F_{st}, F_{sl} \) — longitudinal member coupling force;
- \( C_s = 130 \div 270 \) — empirical factor determined in accordance with basin category and operating conditions;
- \( C_{pB} = 60 \div 80 \) — empirical factor determined in accordance with basin category and operating conditions;
- \( P_e \) — the total output of main engines, kW;
- \( L_s \) — distance between the pushboat aft and coupling joint, m;
- \( L'_s \) — distance between the pushboat aft and coupling joint located between the first pushed ship and coupled ships directly in front of it, m;
- \( H_k, H'_k \) — longitudinal member lever arm, m;
- \( B_s \) — pushboat breadth, m.

5.7.9 As a basis for determining dimensions of other longitudinal members in the coupling joints between pushed ships, the coupling force shall be used which is calculated by formula (5.7.8.3).

5.7.10 There shall be at least two coupling joints for longitudinal coupling of individual ships.

Fig. 5.7.8. Coupling force and lever arm of interlocking arrangement longitudinal member
Each coupling joint shall be sized so that it is capable of withstanding coupling forces calculated by formulas (5.7.8.1), (5.7.8.2) and (5.7.8.3).

Coupling joints shall be located as far as practicable from the centre line of a convoy in order to reduce forces in coupling joints.

In case of rigid connection one coupling joint is allowed provided that it ensures reliable connection between ships.

5.7.11 Strength in each rope used for ship interlocking is to be determined with regard to rope arrangement in a lash. The total breaking strength of ropes shall be at least 1.5 the load acting in the coupling joint members.

Each rope being used shall be laid on bollards or similar equipment max. by three turns and shall be capable of being hauled for different ways of its expected use.

5.7.12 In case of pushboat designed for pushing of several barges in a convoy with a single pushed barge, design coupling force is to be calculated by formula (5.7.8.2).

5.7.13 The ships designed for supporting motion of interlocked group shall be equipped with bollards or similar arrangements which quantity and layout ensures compliance with requirements of 5.7.2. Mooring bollards and other similar equipment for ships interlocking shall be used only if they withstand coupling forces applied to them in an extreme case and their quantity is adequate for unhampered normal mooring operations.

5.7.14 The towing arrangement of pushed barges shall comply with requirements of 5.1 to 5.5.

Special requirements to coupling arrangements for bendable convoys

5.7.15 A coupling arrangement for bendable convoys shall allow for rigid connection of ships.

5.7.16 A coupling arrangement for bendable convoys shall be equipped with a drive allowing for bending of a convoy. The coupling arrangement drive shall also provide for fail-safe return of the convoy to position before bending or in the straightened position.

5.7.17 Where the drive from power source (including hydraulic or electric) is used in a coupling arrangement, provision shall be made for an independent standby drive or power source.

5.7.18 Where the main drive is hydraulic and the standby is a manual hydraulically operated drive, each drive shall operate independently.

Where main and standby drives are hydraulic, provision shall be made for a pump with independent power source for each drive.

Piping, valves, controls of both drives shall be independent. However, these two drives may have common structural elements, for example, cylinder block.

5.7.19 If main and standby drives are electric, their supply and control systems shall be independent of each other. Each of these two drives shall have its own electric motor.

5.7.20 Where electric motor or coupling arrangement standby drive pump is fed from auxiliary engine and its startup operation requires more than 5 s, the buffer device shall ensure operation of electric motor or standby drive pump for the period of startup of auxiliary engine.

5.7.21 Provision shall be made for monitoring and control of coupling arrangement for bendable convoys from the wheelhouse at least for bending and straightening operation.

The control stations shall be provided with visual alarm indicating the operation of coupling arrangement drive and allowing for determination what drive is activated.

Visual and audible signals shall be provided to the control station in case of accidental trip or failure in a coupling arrangement power-operated drive.
6 CARGO HANDLING APPLIANCES

6.1 GENERAL PROVISIONS

6.1.1 The present part of the Rules applies to cargo handling appliances designed for loading, unloading and transfer of cargo:
1. upper structures of the floating cranes;
2. ship’s derricks;
3. cranes mounted on floating docks;
4. cargo booms;
5. electrically-driven lifts with load capacity of 250 kg and above intended for lifting and lowering of cargoes in a cabin which is moved by means of cables (ropes) with the speed not exceeding 1.0 m/s.

6.1.2 The requirements of the present Section are not applied to the cargo-handling machinery intended for operations with fishing tools and handling of fishery, for loading and discharging of ship equipment, supply and ship’s stock equipment, for hydraulic, dredging and ship lifting operations; they are not also applied to the handling devices of a group of special equipment (warping, cross-dredging, frame-hoisting, grabbing winches, etc.), hand tackles of machinery spaces, grabbing devices (grabs, platforms, cargo nets, slings, etc.), lifts with load capacity of less than 250 kg, as well as auxiliary devices which are not parts of lifts: turnbuckles, hooks, sockets, turnpikes.

6.2 GENERAL TECHNICAL REQUIREMENTS

6.2.1 The cargo handling appliances installed on the open decks shall be so designed as to provide their safe operation in the range of ambient temperatures from minus 20 to plus 40 °C, unless otherwise provided in technical documentation.

The cargo handling appliances shall be designed for operation with the ship listed to 5° and trimmed to 2° at the maximum jib radius.

6.2.2 The fixed axles supporting the drums, blocks, wheels, rollers and other rotating parts shall be fastened and locked.

6.2.3 All bolt, key and wedge connections of the cargo handling gear shall be locked against inadvertent loosening and disconnection.

6.2.4 Loose gear and cargo-gripping devices shall be attached so that any bending or twisting is excluded and swivels may be used to prevent this.

The swivels may be arranged with a ball or roller support to enable regular lubrication.

6.2.5 The ends of ropes attached to the metal structures or components shall be fitted with thimbles or be built in the rope sockets or clamps. The ends of ropes attached to the winch drums may be without thimbles or sockets. The rope shall be secured on a drum. Pressing devices using force of friction shall be at least two.

6.2.6 The controls of the machinery of the cargo handling appliances shall be so made and fitted that the direction of movement of the handles, levers or wheels is correspondent to the resultant movement of the load, for example pulling the upright lever, lifting the slanted lever, turning the control wheel clockwise shall correspond to lifting the load; turning the control wheel clockwise or shifting the lever to the right shall correspond to the right-hand slew; pulling the upright lever, lifting the slanted lever, turning the control wheel clockwise shall correspond to decrease of jib radius.

Handles, levers or wheels shall be marked and be easy in use and provided with means of fixing them in the neutral position and when step-controlled, in the operational position. The term “fixing” means keeping the handle in definite positions when the force
required for shifting the handle out of these positions is greater than the force required for moving the handle between the fixed positions.

The force to be applied for operation of controls shall not exceed 120 N in case of manual drive and 300 N in case of foot drive.

The force required for change of predetermined positions of control handles, wheels, pedals and other controls shall not exceed 40 N (see also 1.6.13).

The machinery and installation controls shall be marked with their function.

The wheels shall be provided with inscription and symbol (arrow) indicating direction of their revolution for opening and/or operating the equipment.

The travel of the control lever, mm, shall not exceed:

- for manual control 600
- for foot control 250

The push-buttons shall be provided with spring-loaded or other means for self-return to "stop" position when the operator removes his hand or relaxes its force. This means shall not require application of forces which can cause tiredness of the operator.

6.2.7 The controls of the cargo handling appliances (controllers, knife-switches, push-buttons) designed for transportation of dangerous cargoes (explosives, acids, radioactive substances and other substances covered by definition in 2.2.33 Part 0 of the Rules), as well as controls used in the portable remote control shall be provided with means for self-return to zero (neutral) position. Cargo-handling appliances intended for any purpose shall be provided with self-return controls.

If, with remote control, the operator does not see the winch drum, provision shall be made for arrangements ensuring the correct reeling of the rope onto the drum.

6.2.8 The valves connecting the deck steam line to cargo machinery shall be arranged close to the latter, be accessible at any time and easily closed by hand.

6.2.9 Power, hydraulic and steam drives, machinery, gear drives, systems and piping and electrical equipment, components, as well as loose ones, shall comply with the requirements of this and the other Parts of the Rules.

6.2.10 The cargo-handling cranes shall be provided with safety devices to prevent the falling of the load or uncontrolled movement of the derrick or crane when switching the crane machinery and disconnecting machinery from the drives or in case of power supply interruption of power drives and control circuits.

6.2.11 The hoisting and topping machinery shall be so made that lowering the cargo or the boom is possible with the help of the drive only. In the emergency, provision shall be made for means enabling safe lowering and stopping the cargo.

6.2.12 All the machinery of the cargo handling appliance except for the screw-driven machinery with self-braking or machinery driven with hydraulic cylinders provided with the pilot controlled check valves shall be equipped with the automatic brake providing braking with the safety factor as specified in the relevant paragraphs of the present Section of the Rules.

The safety factor of braking is the ratio of the torque exerted by the brake to the static torque created on the braking shaft by the maximum design tension in the rope (for machinery performing hoisting and luffing crane jibs) and for machinery with the rigid kinematic coupling by the design value of the inertia loads (the machinery used for turning and moving cranes and for luffing crane jibs).

Design shall be such that the operating solenoid could not be excited by the return electromotive force from any engine, by parasitic or stray currents or by the puncture of insulation. In emergency, when power supply of electric drives of the hoisting machinery is interrupted, provision shall be made for manual release of brakes.

Brakes shall be of the closed-band type, unless otherwise specified in the relevant paragraphs of the Rules. Brakes shall be applied smoothly, without shocks, be provided
with means of adjustment and enable replacement of the friction parts.

Forces applied to the adjustable brakes shall not exceed 160 N on the handle or lever and 310 N on the brake pedal. For brakes used regularly in the normal duty cycle, the above stated forces shall be reduced at least by two times. Brake pedals shall have a non-slip surface.

Where several items of machinery are served by one drive, brakes shall be fitted on each item.

If there is a brake between the motor and the drive it shall be placed from the side of the drive. Means shall be provided for keeping the adjustable disconnected brakes in the closed position. The braking forces induced by brake loads are not permitted.

The brake springs shall be of a push type and provided with the guides such as bushes or holders.

The brake drum (pulley) shall be protected against water, snow, ice, oils or fats unless the brake is designed for operation without such protection.

6.2.13 The hoisting and topping machinery of the cargo handling appliances, designed specially for loading, unloading and transportation of dangerous cargoes shall be provided with two independent of each other brakes of the closed-band type ensuring the holding of cargo (boom) in stopping the power supply.

The brakes can be designed for consecutive operation.

When there is a coupling between motor and reduction gear one brake shall be fitted on the half-coupling located from the side of the reduction gear or on the shaft of reduction gear. The second brake may be placed on the motor shaft or at any point of the driving mechanism. The brakes shall be located in such a way that in order to check reliable operation of the brake the other brake may be disconnected.

6.2.14 The width of winch drums shall be such that the number of rope layers reeled up onto the drum shall not be more than three. For winches equipped with cable layers or rope clamps with grooves, drums capable of reeling on more than three layers may be used.

In calculating the winch strength, the tensile strength of the rope upper layer shall be used for determination of the torque. Diameters of drums shall be not less than 18 rope diameters. The drums of the motor-driven winches where the rope is reeled onto the drum in a single layer, shall have screw-shaped grooves. Flanges of drums and those of grooved multi-layered drums shall have such outside diameters that will permit the flange to extend at least 2.5 rope diameters above the upper layer of the rope.

Angle of feeding the rope on the drum yoke shall not exceed 4° to the plane perpendicular to the longitudinal axis of the drum.

With the cargo-gripping device at the lowest operating position, there must remain not less than three turns of rope on the drum; this also relates to the drums of the luffing crane jibs machinery in their respective extreme positions. For drums where the rope is reeled onto the drum in a single layer, at least two turns shall remain.

6.2.15 In electrically-driven cargo handling appliances the power supply to motors after interruption shall not be possible until the corresponding handles, wheels, and levers of control stations are set in zero (neutral) position. It is recommended that means for signalling availability of voltage in the power line as well as for visual signalling of switching on and switching off the electric drive are provided on the control post or near it.

Hydraulic and pneumatic drive control systems shall be equipped with arrangements preventing power supply after the outage to the hydraulic and pneumatic systems (power cylinders) until the controls are set in zero (neutral) position. It is recommended that means for signalling availability of voltage in the power line (ambient pressure) and switching on and switching off drives are provided.

6.2.16 Faults in the control system of the electric drives shall not cause unauthorized starting or continuation of running of the drives (instead of immediate stopping), changing the direction of their rotation or di-
rection of motion of actuators or releasing the brakes, or their remaining released.

6.2.17 The control circuits of the independent electric drives of topping winches and preventer guy winches shall be such that any possibility of switching on or continuing the operation of the drives with the load hooked is excluded.

6.2.18 A safety button or an emergency switch for disconnecting the electric drive main circuit shall be provided within reach of the operator's hand, immediately at the control station of the cargo handling appliance. They shall be painted red and bear an inscription “Stop”.

6.2.19 A switch may be provided in the main circuit of the cargo handling gear accessible for authorized persons from the ship’s staff only, otherwise, a means shall be provided for locking the switch in the “off” position.

6.2.20 It is not permitted to use bare trolley wires for feeding current to travelling cargo-handling appliances.

6.2.21 Any possibility of switching on the electric drive inadvertently shall be excluded. The motor of each machinery or hydraulic pump shall start as soon as the control handle moves from the neutral position.

6.2.22 Electric drives of the cargo handling appliances fitted with artificial ventilation shall be provided with locking arrangement shall be provided not to make the drive starting or continuing its running possible when the ventilation is cut off.

6.2.23 To prevent spark formation during cargo handling operations on board of oil tankers, oil recovery vessels, ships carrying hazardous cargoes, the loose gears (cargo hooks, shackles, swivels, chains, etc.) shall be of a sparkproof type.

6.2.24 Pivoting part of the ship’s derricks except the boom shall not project outboard the ship’s hull.

Ship’s derricks shall be positioned so as to avoid cargo transferring above the stationary accommodation ladders and their gangway platforms.

6.3 MATERIALS, HEAT TREATMENT AND WELDING

6.3.1 The materials used in the manufacture of the stress-bearing metal structures, parts and machinery of cargo handling appliances, as well as lifts, heat treatment of forgings and castings, as well as welding, shall comply with the requirements of Part X of the Rules.

6.3.2 All stress-bearing elements of metal structures, machinery and gear except for those specified in 6.3.3, shall be manufactured from steel.

6.3.3 Cast iron and steel may be used for manufacture of the following items:

1. toothed, worm and travelling wheels (cast iron is permitted only for the hand-operated cargo handling appliances);
2. worm wheels with a bronze rim;
3. load drums and whipping drums of winches, gear boxes and sheaves of blocks;
4. brake shoes, drum brackets and bearing bodies;
5. cable sheaves and wedges of pressed clips of the ropes in lifts.

6.3.4 Steel grade depending on ambient temperature shall be selected in accordance with the Fig. 6.3.4.

6.3.5 The killed steel shall be used for stress-bearing elements of gear. The quality grade of steel shall ensure operation of the cargo handling appliances on the open decks at the temperatures below zero. Steel for stress-bearing elements of loose gear shall have the certified elongation after testing five samples not less than 20%.

6.3.6 Steel used for manufacture of chains for cargo handling appliances intended for operation at temperatures below minus 20 °C shall meet the requirements for steel grade 2 or 3 referred to in Table 2.5.7, Part X of the Rules.
Selection of steel grade

The chains for which no heat treatment is required for improvement of quality or increase of strength shall be normalized after manufacture.

6.3.7 All steel castings and forgings as part of gear of cargo handling appliances, as well as welded items with stressed intersecting welded joints or those max. 20 mm apart shall be subject to heat treatment for stress relieving (castings from alloyed steels shall be quenched and tempered, castings and forgings from carbon steels shall be quenched and tempered or normalized and electrically welded items shall be annealed).

Heat treatment of gear shall be carried out in enclosed (muffle) furnaces. The heat treatment procedure is established depending on the grade of steel, purpose and dimensions of gear.

Heat treatment shall be confirmed by the manufacturer’s document.

6.3.8 Higher strength materials (see 2.2 Part X of the Rules) for components and fixtures are allowed with regard to the prescribed operating temperatures. It shall be ensured that the relative elongation of the final product material at the normal temperature shall be not less than 12%.

6.3.9 The dimensions of the fillet welds shall be set as small as possible by reasons of strength or process conditions. The leg length of the fillet weld shall not be less than 4 mm and max. 1,2 of the least thickness of the welded items. The length of the fillet weld shall be not less than 50 mm.

Fillet welds up to 300 mm long used for tee-joints of the essential items are subject to non-destructive testing along the whole length (see 8.3 Pat X of the Rules).

6.3.10 Round- and ring-shaped items of small diameter (chains, rod shrouds) shall be joined by resistance welding.

6.3.11 Butt welded joints of tubular, box-shaped elements shall be made with complete penetration to the weld joint root but when the welded joints are not accessible this shall be made using the steel gasket plate.

6.3.12 In structures with enclosed circuit where access from inside is not provided the use of plug welds is permitted for fastening the closing plate on the inside framing (diaphragms).

6.4 CALCULATIONS, DESIGN LOADS AND STRESSES

6.4.1 Methods of calculation of forces and stresses in elements of the cargo handling appliances are developed by the designer and approved by the River Register.

6.4.2 The design load of the ship’s derricks and floating cranes is determined by summing up the following:

1. load weight of lifted cargo and the loose gripping gear;
2. self-weight of crane structures;
3. wind load acting on the deck crane and cargo in the longitudinal and transverse directions. Wind load is determined in accordance with the national standards\(^1\) and depends on the dynamic wind pressure assumed due to

---

\(^1\) GOST 25938, GOST 1451.
the combinations of upper structures design loads (see 6.4.12 and 6.4.13). Stress calculations for the components of the crane shall include angles of inclinations specified in 6.4.6. For cranes intended for operation at rolling the design loads shall meet the requirements of 6.4.7, 6.4.12 and 6.4.13;

4 loads due to the swinging of the cargo and inclination of the ship (pontoon).

6.4.3 In calculating the wind load, the wind side of the crane is assumed as the surface area perpendicular to the horizontal direction of the wind due to the design features of the crane. For continuous-sided constructions it is the area outlined by the contour of the construction, and for latticed constructions it is the area outlined by the contour of the construction and diminished by the area of gaps between the beams.

For cranes with equally high beams running at different levels (continuous-sided and latticed), one behind another, and with the distance between the beams less than the beam height, the wind side shall be assumed as the total area of the front beam; if the distance between the beams is equal to the height of the beam or more, but less than its double height, the wind side shall be the total area of the front beam and 50 per cent of the area of each sequent beam; if the distance between the beams is equal to the double height of the beam or more, the wind side shall be the total area of all the beams. Portions of rear beams not covered by the front beam shall be fully included in calculations.

For tubular constructions the design wind side may be reduced by multiplying it by the correction factor of 0.75.

The design wind area of the load \( A \) is the actual area outlined by the contour of the load to be lifted with the crane. It can also be assumed due to the static data. With no data available the following formula may be applied, m²:

\[
A = -0.881 + 3.726Q - 0.63Q \ln Q + 0.0028Q^2 - 1.595\sqrt{Q} \ln Q,
\]

where \( Q \) — lifting capacity, t.

The formula (6.4.3) is applicable in the range of lifting capacity varying from 0.05 to 100 t.

6.4.4 A combined allowance for sheave friction and wire rope stiffness shall be taken as equal to 5% per plain sheave and to 2% per roller bearing.

Variation of forces in the structural components of the cargo gear when the ropes are being pulled through the blocks shall be considered for the motion or motions that are the most unfavourable for the gear (hoisting or lowering the load or topping the boom).

6.4.5 Where special measures, for example ballasting of the ship, are provided to reduce the heel angles when working with heavy-lift derricks, these measures shall be taken into consideration in calculating the resultant load on the guy.

6.4.6 Stress calculations for structural members of ship's derricks and floating cranes shall be made both at static angles of heel and trim of 5° and 2°, respectively, and during the work in sea. If, under conditions of service, the angles of heel and trim are greater than those stated above, the actual values shall be taken for calculation.

6.4.7 Stress calculations for structural members of ship's derricks and floating cranes shall be made also when the possibility of rolling in still water as a result of wind gusts or dropping of the load is taken into consideration.

6.4.8 The absence of a risk of jack-knifing of the derrick crane booms on rope suspension to the side opposite to its outreach shall be confirmed by the calculations or the functional test.

The jack-knifing is unlikely to occur if there is a positive tension (more 30 min) in the boom ropes when the outreach of the boom is minimum and the inclination of the boom to the side opposite to its outreach is the least that could occur in service (but not less than angles of heel and trim of 5° and 2°, respectively), the wind pressure from the side of the outreach being as specified in 6.4.2.3.
6.4.9 In calculating stresses in the compressed beams and compressed beams with the applied bending moment, the effect of the longitudinal forces shall be considered with due degree of precision allowing for the eccentricity of their application, structural flexure and initial camber due to their self-weight per stress value.

6.4.10 The design modulus of elasticity for steel wire ropes shall be taken equal to 98 GPa.

6.4.11 In calculating the strength of the riveted or bolted structures, the cross-sectional areas and section moduli shall be determined with regard to surface area covered by holes. In stability calculations the surface area covered by holes shall not be taken into account.

6.4.12 The design loads for the upper structures shall be taken as follows:

.1 load weight of lifted cargo and loose gripping gear;
.2 self-weight of structures and equipment arranged on these structures;
.3 wind load (due to dynamic wind pressure on the load and metal structures) shall be taken not less than 400 Pa for maximum loads in working condition, not less than 125 Pa for load drop and not less than 2000 Pa for maximum load in non-working condition. The design dynamic wind pressure in non-working condition may be reduced if data on wind load of the water area and actual conditions of service of the upper structures of the floating crane is submitted, but in all cases, it is taken at least 1000 Pa;
.4 inertia forces, resulting from hoisting (lowering) the load with the hoisting device, when operating in acceleration (deceleration) duty. Dynamic load factor shall be calculated by a method approved by the River Register for compliance with requirements of the Rules; in any case, its value for the upper structures shall be not less than 1.15, when operating in still water, and not less than 1.4 when operating at rolling;
.5 inertia forces arising from deceleration (acceleration) of jib luffing, slewing or machinery travel as well as load swinging in still water and at rolling. These forces are taken into account based on data on angles of deviation of load, determined by method approved by the River Register for compliance with requirements of the Rules; in all cases, the angles shall be not less than 3° far and wide the boom at a time. The angles shall be counted off from the vertical with maximum dynamic heel of the upper structure;
.6 centrifugal inertia forces resulting from the upper structure turn;
.7 vertical inertia forces acting on the load in case of rolling. These forces are considered by means of dynamic load factor, determined by a method approved by the River Register for compliance with requirements of the Rules. In all cases the value of dynamic load factor shall be taken at least 1.25.

6.4.13 The combinations of design loads of the upper structures shall be taken as follows:

.1 normal loads in working condition. The loads to be included in the calculations are: weight load of lifted load masses and cargo-gripping devices, mass of components of cargo-handling appliance, inertia forces in case of smooth starting and braking, the average wind pressure complying with the dynamic wind pressure on the construction and the cargo 250 Pa. It is considered in calculation of endurance (fatigue strength) of the upper structure carried out by a method approved by the River Register for compliance with requirements of the Rules. The obtained value of safety factor shall be determined by the calculation given in 6.4.13.2;
.2 maximum loads in working condition.

Case I. The upper structure is motionless (the hoisting machinery alone is working); the hoisting machinery operates for lifting the load from the ground (deck) or for braking while lowering the load, drop of load.

The loads to be included in the calculations are: weight load of lifted load masses and cargo-gripping devices allowing for the maximum dynamic load factor; mass of components of cargo-handling appliance; inertia loads resulted from the drop of load and from ship's rolling in sea and in still water; wind
pressure on the crane structure and the load in the operating condition; load resulted from swinging of cargo on the flexible suspension with the maximum vertical tilt angle 16°.

The dynamic load factor shall be calculated with due account to the maximum speed of load handling, rigidity of the structure (the ropes included) and the structure and load masses both for hoisting (tearing off) and braking (when lowering) the load.

In determining the load, slewing component of the floating crane upper structure shall be considered when two movements are combined:

- lifting — lowering of cargo and crane slewing;
- crane slewing and luffing;
- hoisting — lowering of cargo and luffing.

Case 2. The upper structure when the load is in motion (traveling, luffing or slewing), one of the mechanisms operating in acceleration or deceleration duty.

The loads to be included in the calculations are: weight load of lifted load masses and cargo-gripping devices and mass of components of cargo-handling appliance with due allowance for the shock factor while moving along the track, inertia forces resulted from rolling; maximum horizontal inertia forces of masses of the upper structure and the load allowing for skidding of wheels, disconnection of limiting moment couplings or other design features; wind pressure on the upper structure and the load in the operating condition and load resulted from swinging of the cargo on flexible suspension.

The shock factor is determined depending on the travelling speed and availability of the rail joints;

- maximum load under non-working condition.

The loads to be included in the calculations are: the self-weight of construction components and wind pressure corresponding to the dynamic pressure on the construction in non-working condition.

In well-founded cases, owing to peculiarities of service or the upper structure the design loads may be required, which will differ from those stated above.

**6.5 ALLOWABLE STRESSES, SAFETY FACTORS AND STABILITY RESERVES**

6.5.1 The stresses in metal structures of the ship’s derricks and floating cranes when subject to the action of the design loads shall not exceed the allowable values as specified in Table 6.5.1 with regard to requirements of 6.5.2 to 6.5.5.

<tr>
<td>$\geq$ 75</td>
<td>0.60</td>
<td>1.67</td>
<td>1.17</td>
</tr>
</tbody>
</table>

Note. Intermediate values of parameters are determined by linear interpolation.

For manually operated cargo-handling appliances the allowable stresses may be taken equal to 0.6 of the yield stress of the material $R_{th}$.

The safe working load (SWL) (see 1.2.1.17) of ropes (wire, natural fibre and synthetic) shall not exceed the design breaking load divided by the safety factor in accordance with Table 6.5.7-2 and Table 6.5.8.

6.5.2 The values of allowable stresses as specified in Table 6.5.1 include the dynamic load factors determined by the following formula:

$$\psi_l = 0.7 R_{th} / \sigma,$$  \hspace{1cm} (6.5.2-1)

where $\psi_l$ — standard dynamic factor obtained as the ratio of the maximum expected dynamic load to the static stress when subjected to design loads.

When the maximum cargo hoisting or lowering speed is more than $1.33(\psi_l - 1)$, m/s...
the dynamic load factor must be verified by calculation using the formula:

$$\psi = 1 + 0.318 \sqrt{f_a}$$, \hspace{1cm} (6.5.2-2)

where $\psi$ — dynamic factor obtained as the ratio of the dynamic load to its static value;

$v$ — maximum speed of load movement, m/s;

$f_a$ — calculated vertical shifting of the load suspension point (including variations in the rope length) under the action of static force induced by cargo weight equal to the lifting capacity, m.

If the calculated dynamic load factor $\psi$ exceeds $\psi_l$, the allowable stresses as specified in Table 6.5.1 shall be multiplied by $\psi_l/\psi$. If the calculated dynamic load factor is equal to or less than $\psi_N$, the allowable stresses are assumed to be equal to those given in Table 6.5.1.

6.5.3 In calculating the allowable stresses in metal structures, the design yield stress to be taken with regard to its value as established in national standard for material or technical documentation; in all cases, however, it shall be taken max. 0.70 of the minimum tensile strength (ultimate resistance) established in the technical documentation developed by the designer and approved by the River Register.

6.5.4 The requirements of 6.5.2 apply to tensile, compression and bending stresses as well as equivalent stresses. The values of transition coefficients to allowable stresses for other types of deformation, as well as for calculation of welded, riveted and bolt joints shall be taken according to Tables 6.5.4-1 to 6.5.4-3.

Transition coefficients are applicable if the holes for rivets and finished bolts after reaming are drilled in the joined items at one go or separately through jib plates. Allowable stresses for field rivets shall be reduced up to 10%. Allowable stresses for flat-top countersunk-head rivets and for raised-top countersunk-head rivets shall be reduced up to 20%. As initial values for calculating of allowable stresses for rivet and bolt joints, allowable stresses determined for tension and cut due to the yield stress of material for rivets and bolts, and for crumpling — due to the yield stress of material of metal structures shall be assumed.

6.5.5 The design and scantlings of the loose gear shall be such as to exclude residual deformations and breaking when tested with an ultimate load. For items which are manufactured based on technical documentation approved by the River Register are considered as satisfying this requirement. The allowable stresses in the non-standard fixed gear shall not exceed the allowable stresses assumed for metal structures (see 6.5.1 to 6.5.4).

6.5.6 The safety factor of chains of cargo-gripping devices relative to breaking load shall be at least 4.

Load factor $K$ used in Table 6.5.7-1 is determined by the formula:

$$K = \sum_{i=1}^{n} t_i \left( \frac{P_i}{P_{\text{max}}} \right)^3 \sum_{i=1}^{n} t_i$$  \hspace{1cm} (6.5.7)

where $t_i$ — average duration of use of the mechanism at partial load levels, h:

$$t_i = t_1, t_2, ..., t_n;$$

$$\sum_{i=1}^{n} t_i$$ — total duration of use of the mechanism with various load levels, h:

$$\sum_{i=1}^{n} t_i = t_1 + t_2 + ... + t_n;$$

$P_i$ — load levels with average duration $t_i$ at general application of the given mechanism, H:

$$P_i = P_1, P_2, ..., P_n;$$

$n$ — the total number of levels of loadings;

$P_{\text{max}}$ — value of the greatest load applied to the mechanism, N.

6.5.8 The safety factor of the natural fibre ropes relative to breaking load of the rope as a whole shall be not less than the values given in Table 6.5.8, and that of the synthetic fibre ropes not less than 10.

6.5.9 The stability factor shall not be less than the safety factor (relative to yield point) for the compression of the same element.

6.5.10 The compressed beams shall be checked for overall stability and their thin-walled elements, for local stability.

Beams subject to transverse bending shall be checked for overall stability and their vertical walls and compressed belts for local-stability.

6.5.11 In calculating the buckling strength of beams compressed axially shall be taken of the initial eccentricity of the longitudinal forces and the initial bend; the total value of both shall not be less than 0.001 of the beam length.

6.5.12 Flexibility of each portion of the axially compressed fabricated beams, taken
between the connecting members (strips or lattices) shall be not more than 40.

6.5.13 Flexibility of compressed and expanded members of metallic structures shall not exceed the values given in Table 6.5.13.

**Table 6.5.13**

In calculating flexibility the design length shall be included in the calculations with due allowance for the type of end fixing. The flexibility shall be calculated within the plane of main inertia moments.

6.5.14 The design loads in metallic constructions of the upper structures of floating cranes shall not exceed the allowable values given in Table 6.5.14 with due regard for requirements of 6.5.3 and 6.5.4.

**Table 6.5.14**

</table>

For the upper structures of simple construction the allowable stresses shall be taken in accordance with 6.5.1.

**6.6 STRENGTH CALCULATION OF CARGO-HANDLING MACHINERY**

6.6.1 In calculating, the following shall be taken into account:

1. Safety factors of machinery items shall be so that no after-effects or deformations (except manufacturing defects) remain after testing the machinery with a proof load in accordance with the present Rules;
2. In calculating the design loads on items of the machinery, the loads on cargo handling appliances and conditions for which stresses in the structural elements were determined (see 6.4 and 6.5) shall be included;
3. Safety factors of machinery items shall not be less than those obtained for the metal structures of cargo handling appliances according to 6.5.

**6.7 GENERAL REQUIREMENTS TO CRANES**

6.7.1 Cranes shall be designed and installed in such a way as to obviate the risk of jack-knifing (see also 6.10.1).

6.7.2 Cranes with derricks on rope suspension shall be designed in such a way as to obviate the risk of jack-knifing of the derrick to the side opposite to the outreach; due account shall be taken of heel and trim which are likely to be encountered in service including the use of limiting stops (see also 6.4.8).

6.7.3 The design of cranes must enable them to be securely attached to the ship’s hull. The hull framing shall be adequately stiffened in the place where a crane will be installed.

6.7.4 Provision shall be made to ensure efficient fastening of cranes, their booms when stowed for sea (see GOST 25938).

**6.8 SAFETY DEVICES OF CRANES**

6.8.1 The cranes shall be provided with limit switches that automatically come into action to stop the following machinery in the extreme positions:

1. Hoisting;
2. Jib luffing;
3. Travel of the crane and its crab;
4. Slewing of the crane (for cranes with the limited slewing angle);
5. Interlocking of the grab in the uppermost position if the whole rope of the closing winch is hauled.
The possibility of the reverse movement must be provided for the above items after the limit switches have operated.

Where closing switches are provided for shunting the limit switches (e.g. for lowering the jib when the crane is being stowed for sea), only the authorized persons from the ship’s staff shall be admitted to them.

On cranes where the jib, when lowering, superimposes on the cargo-gripping device, the hoisting machinery shall be switched off simultaneously with the topping machinery adjusted to jib lowering.

6.8.2 On cranes where the safe working load varies with jib radii, an automatic indicator of safe working load corresponding to the appropriate radii shall be provided. The indicator scale shall be visible for operator from his workplace.

6.8.3 The cranes stability of which depends upon the load position on the hook shall be provided with limit load switches automatically disconnecting the crane hoisting and jib luffing machinery when an attempt is made to lift the load exceeding the safe working load of the crane for a given outreach by more than 10%. The possibility of lowering of the load and jib decreasing shall be provided after the limit load switches have operated.

Limit load switches may be fitted on cranes of other types.

6.8.4 Cranes with varying jib radii and constant safe working load over the whole radius shall be provided with limit-load switches of hoisting machinery.

The limit load switch shall actuate to prevent lifting the load with weight exceeding safe working load by more than 10%. After limit load switch actuation the lowering of the load shall be provided.

Short-time overloading (up to 0.5 ±0.1 s) shall not cause the limit-load switch to actuate.

6.8.5 The cargo handling appliances with the stationary control station or radio and telecontrol shall be equipped with audible warning device which shall be put into operation by the operator at any time. The audible warning signal shall be clear and distinctive among other audible signals and operation noises.

6.9 MACHINERY OF THE CRANES

6.9.1 The safety factor of braking for the hoisting machinery shall not be less than 1.5. For topping (luffing) machinery the safety factor of braking shall not be less than 2; the static moment on the braking shaft due to the weight of the load, weight of the jib and the counterbalance, shall be determined for such a position of the jib in which the moment is maximum.

In case of two or more brakes at a drive, the safety factor of braking shall be set at an assumption that all the load is hold by one brake.

The safety factor of braking of each of these brakes shall not be less than 1.25 at simultaneous operation of all brakes. If operation of brakes is not simultaneous, the safety factors of braking shall be taken the same as for individual brakes.

6.9.2 Slewing and travelling motion brakes shall act automatically or be controlled; the open-type brake may be used subject to technical justification.

The safety factor of braking shall not be less than 1.0.

The safety factor of braking for the upper structures of the floating cranes and for the cranes intended for operation at rolling shall be not less than 1.5.

Hand-braked slewing and travelling motion machinery shall be provided with stops against uncontrolled slewing or movement of the cranes.

6.10 Travelling of Cranes

6.10.1 Stability of the travelling cranes shall be ensured under all conditions, whether in service or not. The stability shall be checked in accordance with procedures developed by the designer and approved by the River Register.

6.10.2 Travelling cranes shall be provided with permanent anchoring devices or reverse rollers.
Travelling cranes shall be provided with efficient anticreeping devices (detachable anchoring devices, etc.).

6.10.3 Fastening of cranes when stowed for sea shall be such to prevent any movement of the crane.

6.10.4 Running wheels of the crane travelling machinery shall be designed or fitted to prevent their derailment. Fastening of rails to the ship’s framing shall withstand the worst combination of service loads.

6.10.5 Frames of the travelling cranes shall be provided with bearing struts arranged at a distance of not more than 20 mm from the rails and may be used as supports in case of breaking of wheels or axles. These struts shall be designed for the maximum permissible load.

6.10.6 Power-driven travelling cranes shall be provided with buffers against possible contact with stops. The buffers may be fitted on stops.

6.10.7 The stops shall be provided at both ends of the railway designed to withstand the impact of crane moving with the maximum working load at the nominal speed.

6.10.8 If several cranes travel at one railway, they shall be provided with stops so as to prevent collision.

6.11 COUNTERBALANCES AND METAL STRUCTURES OF CRANES

6.11.1 The crane counterbalance shall be designed to prevent specified weight change in service. Separate cargoes in the counterbalance shall be fastened to exclude their displacement.

6.11.2 The adjustable counterbalances shall either move automatically when the jib radii are being changed or be provided with a counterbalance position indicator. In case of adjustable counterbalance moving, the possibility of its jamming shall be excluded. It is recommended to provide the interlocking of the jib radii in case of failure in the adjustable counterbalance.

6.11.3 The thickness of walls of stress-bearing elements of crane metal structures which are readily accessible for inspection and maintenance from all sides shall not be less than 4 mm; the thickness of walls of box-type or tubular metal structures inaccessible for inspection and maintenance from the inside shall be at least 6 mm.

The maximum structural camber of the crane boom shall not exceed $1/1500$ of its length, both in the plane of suspension and in the plane normal to it.

6.11.4 The construction liable to loads, especially to vibration load, dangerous for breaking away rivet heads shall be avoided. Tensile stresses in rivets with countersunk or half-countersunk heads shall not be allowed.

The holes for rivets and finished bolts shall be drilled in the joined items at one go or separately through jib plates.

The diameter of rivets and bolts used in the stress bearing items connections shall not be less than 12 mm.

The maximum thickness of riveted items shall not exceed five diameters of the rivet.

The number of rivets securing the item in the assembly or arranged on either side of the joint shall be at least two.

6.12 CRANE CABS

6.12.1 Stationary crane control stations shall be positioned in specially equipped cabs.

6.12.2 Crane cabs shall be positioned in a way as to provide the operator with the possibility to observe the gripping appliances and the cargo during the whole cycle of crane operation. The operator shall be provided with 230° horizontal area of view from his working place. It is recommended to increase the angle up to 270°.

6.12.3 The cab shall be positioned in such a way as to preclude the possibility of cab damage in case of abruption or other damages of constructions supporting the jib (cables, ties, etc.).

6.12.4 Crane cabs shall be closed from all sides. View area surfaces shall be glazed.
possibility of glass surfaces cleaning shall be provided, as well as their heating to prevent sweat or icing. Lower glass surfaces, where the operator can get on, shall be protected with gratings withstanding human weight. The cab shall be provided with ventilation and heating system in accordance with national standards\(^1\).

The requirements concerning cab closing from all sides are not applicable to ship’s der- ricks.

6.12.5 Crane cab dimensions shall provide free access to the equipment.

6.12.6 The door of the cab shall open outside and be provided with a fenced platform located in front of the door. Provision shall be also made for a cab locking device if the operator is absent.

6.12.7 Cab access and entry shall not be blocked up by machinery, cables and other appliances.

The leading of cargo and jib ropes through the crane cab, as well as the positioning of drums for ropes winding are not allowed.

6.12.8 The crane cab shall be equipped with the stationary adjustable seat in regard to the height and horizontal plane.

6.12.9 The cab of the floating crane shall be at least 1.9 m high; the height of cabs of ship’s derricks may be reduced down to 1.5 m where the sitting posture of the operator is implied.

In floating cranes cabs the possibility of presence of at least one person except the operator is to be implied.

6.13 UPPER STRUCTURES OF THE FLOATING CRANES.
CRANES MOUNTED ON FLOATING DOCKS

6.13.1 The upper structures of floating cranes and cranes installed on floating docks are subject to all the requirements of the present Section of the Rules applied to the cranes, as well as to additional requirements specified in 6.13.2 to 6.13.11.

6.13.2 In case of inclinations permissible for the floating crane in service, the counterbalance and slewing element of the crane, except the jib, shall not extend outboard.

The accommodation and service spaces shall be located away from the cargo transferring area and their entrances - away from the cargo transferring area at least 1000 mm from the maximum extending members of the slewing element. Moreover, if it is possible, the entrances shall be led to the area opposite to the slewing area of the crane.

6.13.3 The upper structures shall be provided with safety arrangements which comply with the requirements of 6.8.1 to 6.8.4.

6.13.4 Self-weight of the jib appliance shall be balanced by means of the counterbalance.

6.13.5 The wall thickness of the stress-bearing elements of metallic structures shall be at least, mm:
- for profiles painted from the inside and outside: 5.0
- for closed box sections: 6.0
- for hot-rolled or extruded tubes with hermetically closed ends: 5.0

6.13.6 The thickness of the profile plate in welded structures shall be not less than 30 mm and not less than 50 mm in riveted and bolted structures.

6.13.7 The ratio of the drum (block) and rope diameters shall be determined with regard to operation mode of the crane machinery (see Table 6.5.7-1). The least allowable values of this ratio in accordance to the mode are indicated in Table 6.13.7.

6.13.8 The metallic structures shall be so designed as to provide an access for their examination from inside. Enclosed cavities of metallic structures inaccessible for the examination shall be subjected to air pressure test with the excessive pressure of 0.03 MPa; foaming solution shall also be applied to the outside walls of structures. Technical condition of metallic structures forming enclosed cavities may be checked using non-destructive test methods. In such a case, tests are omitted.

\(^{1}\) GOST 5534, GOST 12.1.005.

6.13.9 The upper structure of the prototype floating crane intended for operation at rolling shall be subject to the full-scale tests in natural conditions with maximum values of rolling and wind pressure.

6.13.10 The upper structure of the serial floating crane intended for operation at rolling shall be additionally tested with the proof load equal to 1.4 of the safe working load with maximum radius of the jib along the ship. The proof load shall be applied statically. The time of keeping the upper structure under the load shall be at least 5 min.

6.13.11 Static and dynamic tests of cranes are performed in accordance with 7.2.9 and 7.2.11 RTSC.

### 6.14 GEARS OF THE CRANES

6.14.1 The mating of parts in movable joints shall ensure the correct adjoining of bearing surfaces with the minimum permissible radial and axial clearances in service.

6.14.2 The safe working load (SWL) of the loose gear other than blocks shall be defined as maximum load (weight) for which the gear is designed.

6.14.3 Fixed gear shall be so attached to the metal framework as to ensure required strength and uniform distribution of forces in the metal structure members.

6.14.4 The cargo hooks and shackles shall be forged. The hooks used in cargo handling operations shall be so designed as to exclude any possibility of slipping off slings or catching the projected structures while lifting the load. The cargo hooks, shackles and their fastening parts shall not have any protruding parts and sharp edges.

For cranes with safe working load of 10 t and more, ramshorn hooks may be used, which shall meet the requirements imposed to cargo hooks of standard design. Ramshorn hooks for floating cranes and cargo handling appliances installed on industrial ships may be designed without special arrangement for protection from slipping off slings or catching the projected structures.

6.14.5 Swivels of cargo hooks and blocks are to be forged. The nut of the swivel shall be efficiently secured against turning on the thread.

6.14.6 The shackles shall be forged straight with pins that are screwed into the eye plates or secured with nuts. Pins or nuts shall be locked.

Club shackles may be used as cargo shackles and also for the natural and synthetic fibre ropes.

The shackles for securing the components in cargo suspension system (hooks, counterweights, triangular bars and chains) shall have pins with half-countersunk heads without nuts.

The shackles shall be so arranged as to ensure the correct fitting of pins and to prevent twisting of the rope.

6.14.7 The block shall be made so that the rope will not be jammed between the block cheek plates and the sheave.

Axles of sheaves shall be locked against turning and axial displacement. The block sheaves supported by plain bearings shall be provided with bushes made of antifriction materials (e.g. bronze).

The eyes and lugs of the blocks shall be forged integral with the latter; the nuts of swivels shall be locked. Blocks with open hooks shall not be used in cargo handling appliances.
The diameter of sheaves for wire ropes measured in the bottom of the groove shall not be less than 14 times the rope diameter for ropes movable under load, and at least 9 times the rope diameter for ropes fixed under load.

The diameter of sheaves intended for use with natural or synthetic fibre ropes shall not be less than 5 times the diameter of the rope.

The groove shall be so shaped as to accept the rope tightly and without jamming.

The diameter of the sheave and the shape of the groove shall be assumed basing on the diameter of the rope with the minimum acceptable calculated tensile strength of wires.

The depth of the sheave grooves shall be more than 1.4 of the rope diameter depending on the purpose and place of installation of the sheave and in any case shall be at least one rope diameter.

The groove bottom shall have circular contour forming a segment with an angle of at least 120°. The radius of the groove shall exceed the rope radius by at least 10%.

6.14.8 The triangular and multiangular plates used for connection of ropes or chains shall be so thick as to suit the shackles secured to them and to leave a minimum clearance enabling shackles to move easily; symmetrically welded reinforcing pads may be used.

6.14.9 Forged eye ends and screwed forks shall be forged integral with the rigging screws; use of rigging screws with hooks is not allowed. The design of the rigging screws shall ensure locking of tightened screws.

The fork may be fastened on the thread and locked subject to technical justification.

6.14.10 Thimbles shall be made of steel by smith forging or punching. Cast-in thimbles may be used subject to technical justification.

6.14.11 Chains used in cargo handling appliances, where not covered by this Section of the Rules shall comply with the requirements of 3.7 and be electric-welded (contact welding) or forge-welded.

Short link chains with terminal links for attachment (calibrated chains, when used on sprocket wheels) are to be used as cargo chains.

6.14.12 Connecting links (of anchor chain links type) in cargo handling appliances may be used for fastening the ropes and chains to the metal structures and components.

Connecting links shall be forged. The joint shall be designed to provide reliable connection of the both halves of link and stopping to prevent their spontaneous disconnection.

The link installation shall provide their free movement in the holes of the components to be connected and prevent the link operation with cocking.

6.15 SHIP’S LIFTS

6.15.1 When designing cargo ship’s lifts, follow Guidelines P.005-2004 “Technical requirements to cargo ship’s lifts”.

6.16 CARGO BOOMS

6.16.1 When designing cargo booms, the requirements of 6.1 to 6.14 shall be observed.

6.17 DOCUMENTS AND MARKING

6.17.1 Cargo-handling appliances manufactured at technical supervision of the River Register shall be provided with the Cargo Handling Survey Report.

6.17.2 Each loose gear, except lifts, tested with a proof load and accepted shall be marked and stamped by the manufacturer’s technical control service. The marking shall contain the following data:

1. cargo weight, corresponding to safe working load (stated after the inscription “SWL”), t;
2. month and year of test;
3. individual identification symbol of the item;
4. stamp of the manufacturer;
5. steel quality grade mark in accordance with Table 6.17.3.5.

The stamps shall be positioned on items as follows:
blocks, on the strap or, if there is no strap, on the cheek plate between the eye and the sheave axle pin;

swivels, on the wide side of the bow-piece close to the eye Shank;

swivel of blocks, on the side surface close to the pin;

hooks, on any side close to the eye, on ramshorn hooks — on wide portion between the horns; rope sockets — on the tapered portion; cross-heads of blocks — in the middle of the side surface;

shackles, on any side of the shackle close to the eye;

connecting chains, on one side surface; identification number — on the centre insert of the lock;

rigging screws, on tubular body; identification number — on the eye or lug;

chains, on end link of each union end. Where small dimensions of items make stamping difficult, the date of test may be omitted.

6.17.3 Cranes, if the results of the examination are satisfactory, shall be marked with:

.1 safe working load, t;

.2 month and year of test;

.3 identification number;

.4 stamp of the River Register (if tested under the River Register supervision) and manufacturer’s stamp.

In addition to above mentioned data, marking shall be also applied in accordance with paragraph 14 of Technical Regulations1.

6.17.4 All cargo handling appliances tested with a proof load shall, if the results of the examination are satisfactory, be marked with:

.1 safe working load, t, the allowable maximum and minimum jib radii; where the safe working load varies with the jib radii - the maximum and the minimum jib radii for each appropriate safe working load (see Table 6.17.4.1);

6.17.5 The places of marking shall be distinctly painted.

The stamp shall have a rounded outline to avoid concentration of stresses and shall not be put at welded areas.

6.17.6 If it is found that marking according to 6.17.4.1 is unnecessary large, data on in-

---

1Technical Regulations on Safety of Inland Marine Transport Facilities approved by Decree of the

Intermediate values of the safe working load of the crane may be reduced.

In such cases, the cranes where the safe working load varies with jib radii shall be provided with a metal plate containing jib radii for each appropriate safe working load.

The marks shall be made with paint, in Arabic figures at least 80 mm high.

On metal structures of cranes the marks shall be punched or welded on.
7 HOISTABLE WHEELHOUSES

7.1 GENERAL PROVISIONS

7.1.1 A hoistable wheelhouse and its hoisting and lowering arrangement shall be designed so that to prevent a risk of human injury due to unprovoked contact of wheelhouse with persons on board.

Provision shall be made for immediate unlocking of fixing devices for all service conditions as well as in case of emergency power cut-off to wheelhouse hoisting and lowering arrangement.

7.1.2 Hoisting and lowering of the wheelhouse shall not impede the operations performed from the wheelhouse.

7.1.3 The wheelhouse shall be lowered at all service conditions by one person from the deckhouse. Emergency lowering shall be performed both from deckhouse and from a separate control station located outside the deckhouse. The possibility of lowering a wheelhouse shall be excluded under rolling conditions.

7.2 TECHNICAL REQUIREMENTS TO DESIGN OF HOISTING AND LOWERING ARRANGEMENT

7.2.1 The drive gear of the arrangement shall be designed for lifted load equal at least 1.5 times the weight of fully equipped wheelhouse with watch personnel.

7.2.2 The hoisting and lowering arrangement shall be designed to stop and hold the wheelhouse in any specified position, provision shall be made for safe entrance and exit from the wheelhouse.

7.2.3 The hoisting gear of the wheelhouse shall operate without jamming at all possible cases of asymmetric load as well as at all heel and trim angles which may occur in normal operation of the ship.

7.2.4 The hoisting gear shall ensure transient slowing down of the wheelhouse when reaching the upper and lower utmost positions or buffer devices shall be provided.

7.3 TECHNICAL REQUIREMENTS TO HOISTING ARRANGEMENT DRIVE

7.3.1 The hoisting and lowering arrangement of the wheelhouse shall have a power drive capable of operating at all normal service conditions.

The wheelhouse shall be lowered by power drive or under action of its own weight.

7.3.2 The wheelhouse shall be equipped with emergency lowering arrangement which actuates independently of the main hoisting and lowering drive.

The emergency lowering arrangement shall be designed to provide for a smooth and controlled lowering of the wheelhouse under action of its own weight.

7.3.3 The hoisting and lowering arrangement of the wheelhouse shall ensure its emergency lowering at a speed at least equal to lowering speed under normal service conditions using main power-operated hoisting and lowering drive (see 7.3.1).

7.3.4 No self-braking hoisting gears are allowed.
8 LIFE-SAVING APPLIANCES

8.1 GENERAL REQUIREMENTS

8.1.1 The present Section of the Rules establishes standards for equipment of inland navigation ships with life-saving appliances as well as requirements for their stowage and arrangement on board a ship.

8.1.2 Standards of supply of ships with life-saving appliances are assigned on condition that a ship is intended to operate in basins of a category corresponding with her class.

8.1.3 For non-crewed non-self-propelled ships not intended for carrying people, life-saving appliances may be omitted.

8.1.4 In ships operating northwards 66°30' N. L. and in the Baikal lake and being equipped with free-fall liferafts not fitted with devices which provide boarding without getting into the water, an immersion suit shall be provided for each crew member engaged in rescue operations on such liferafts.

8.1.5 Life-saving appliances used on board ships shall have compliance certificates of the River Register.

8.1.6 Unless otherwise specified in this Section, collective and individual life-saving appliances shall:

.1 not be damaged in stowage at air temperature from –30 to +50 °C;
.2 be operable at water temperature from 0 °C to 30 °C;
.3 be rot-proof, corrosion-resistant and withstand water, oil, oil products or fungal exposure during service life;
.4 be resistant to deterioration (maintain its qualities) where exposed to sunlight during service life;
.5 be coloured orange which assists in detection;
.6 be fitted with retro-reflective material where it will assist in detection, with due regard of the requirements of the present Section;
.7 retain properties as required by the present Section when used at rolling (if designed for such a purpose);
.8 provide for safe launching by one person from its onboard location (for collective life-saving appliances).

8.1.7 The service life of life-saving appliances and outfit items which are subject to deterioration with age shall be determined. Such life-saving appliances and outfit items shall be marked with a means determining their age or the date by which they shall be replaced.

8.1.8 Materials used for manufacture of life-saving appliances and arrangements as well as welded structures shall comply with the requirements of Part X of the Rules.

8.1.9 Requirements of the present Section other than those stated in 8.1.6 to 8.1.8, 8.2.2.2, 8.2.16, 8.4.1, 8.4.15, 8.4.17, 8.4.19, 8.4.21, 8.4.24 to 8.4.27, 8.4.31, 8.4.35 to 8.4.51, 8.4.54 to 8.4.56, 8.5.5 to 8.5.7, 8.9.3, 8.9.5, 8.9.6, 8.10.4, 8.10.6, 8.10.8 and 8.10.17 apply also to ships in service.

8.1.10 If prior to approval of the Rules, the ship is not covered by requirements similar to those of this Section, when performing re-equipment, modernization or re-classification of such a ship life-saving appliances shall be brought in conformity with requirements of the present Section of the Rules.

8.1.11 Hull of a landing-stage, fire-watch craft or jetty pontoon throughout the periphery in the waterline area shall be guarded by a rescue handrail which is to be attached to the hull in the points located at a distance 0.5 – 1 m from each other.

8.1.12 Passenger ships, crew boats and special purpose ships shall be equipped with ar-
rangements for safe disembarkation in shallow water, on shore or on the other ship.

8.1.13 Inflatable life-saving appliances on board ships shall comply with the following requirements:

.1 comprise at least two separate pneumatic chambers;

.2 be automatically inflated when launched, manual pumping of chambers shall be provided;

.3 take and retain a stable trim regardless of the load even in case of half inflated pneumatic chambers.

8.1.14 The requirements of 8.2.13 to 8.2.20, 8.3.5, 8.4.22 to 8.4.25, 8.5.21 to 8.5.22, 8.6 are mandatory for ships engaged on coastal voyages. Ships engaged on international voyages as well as passenger ships of III-IV class regardless of the type of voyages (coastal or international) shall comply with the requirements of the International Convention for the Safety of Life at Sea, 1974, as amended (SOLAS), and the International Life-Saving Appliance Code (LSA Code), 1997.

Ships which navigate in areas of Northern Sea Route shall comply with requirements of navigation in the water area of the Northern Sea Route approved by the Order of the Ministry of Transport of Russia No.7 dated 17.01.2013.

8.1.15 On board the ships in service the life-saving appliances or means, after their replacement or additional introduction, shall comply with the requirements of 8.4 to 8.10.

8.2 STANDARDS FOR EQUIPPING WITH COLLECTIVE LIFE-SAVING APPLIANCES

8.2.1 Passenger ships, crew boats, special purpose ships, self-propelled and non-self-propelled ferries shall be equipped with collective life-saving appliances according to the standards specified in Table 8.2.1 with due regard of 8.2.12 and 8.3.6.

In these ships intended for operation in basins of P, O categories southwards 66°30' S.L. lifeboats may be replaced with liferafts provided that 8.2.3 is met.

* Norm of supply on each side

When using the data in Table 8.2.2, the following shall be considered:

.1 Dry cargo ships (85 m long and longer) shall be fitted with semi-enclosed or enclosed lifeboats which comply with the requirements of LSA Code.

Instead of the above mentioned lifeboats, cargo ships may be fitted with one or more lifeboats being launched by a free fall from the after part, of appropriate design, with total capacity sufficient for the total number of
persons on board the ship. The ship shall be additionally provided with one or more liferafts of the same capacity on each side, on one side the liferafts shall be served by launching arrangements;

.2 oil tankers for oil cargoes with flash point of 60 °C and below shall be fitted with fire-protected lifeboats complying with requirements of 8.4.52 to 8.4.56;

.3 in tugboats, ice breakers and industrial ships less than 85 m in length lifeboats may be replaced with liferafts;

.4 in dry cargo ships less than 85 m in length as well as tugboats, ice breakers, industrial ships all liferafts shall be of the same capacity. Where the liferafts cannot be moved from side to side, the liferaft capacity on each side shall be at least 150%.

Note. The possibility of moving liferafts from side to side is considered ensures when liferafts are located as such to provide for their free movement from side to side at a single deck level, the total weight of one liferaft shall be less than 185 kg.

8.2.3 Passenger ships of M-ПП and M class and more than 30 m in length shall be equipped with engined lifeboat.

Passenger ships more than 30 m in length intended for operation in basins of M, O-ПП and O category or lakes, reservoirs and areas with sea navigation conditions of P category shall be equipped with at least one engined lifeboat or rescue boat for towing all liferafts. The rest lifeboats may be replaced with liferafts.

8.2.4 Equipment of hydrofoil craft, hovercraft and skimming ships with collective life-saving appliances shall comply with the standards specified in Table 8.2.4.

* For ships entering lakes and reservoirs of P category as well as in river estuaries of О category with sea navigation conditions.

In ships less than 30 m in length intended for operation in basins of M and O categories and ships over 30 m in length intended for operation in a basin of P category equipped with lifeboats for 100% of persons, liferafts may be omitted.

8.2.6 Non-passenger ships permitted for carriage of organized groups of people shall be equipped with collective life-saving appliances according to Table 8.2.5 with due regard of the total number of persons on board.

8.2.7 In ships mentioned in 8.2.5 which are intended for operation in basins of M and O categories other than oil tankers intended for oil transportation with flash point of 60°C and below, lifeboats may be replaced with liferafts.

8.2.8 Equipment of non-self-propelled other than oil tankers with collective life-saving appliances shall comply with the standards specified in Table 8.2.8, the requirements of 8.1.3 and 8.2.9 shall be fulfilled.

8.2.9 In non-self-propelled ships intended for operation in basins of P and JI categories other than those mentioned in 8.2.1, collective life-saving appliances may be omitted.

8.2.10 Passenger ships of M-ΠΠ, O-ΠΠ, M and O class over 30 m in length in which free-fall liferafts are applied, shall be provided with embarkation slides preventing people from getting into the water. This requirement does not apply to ships in which boarding on the liferafts is carried out from the deck located less than 1.5 m above the waterline corresponding to the minimum operational draught.

8.2.11 Ships intended for operation in the Baikal lake or permanent operation in the Onega and the Ladoga lakes, ships intended for operation in basins of M and O categories northwards 66°30’, passenger ships and crew boats intended for operation in basins of P category in the Ob river northwards 66°35’, and other areas northwards 66°30’ shall be equipped with lifeboats and liferafts for 100% of persons onboard.

8.2.12 Where capacity of lifeboats provided on board the ship exceeds the established standards, a number of liferafts or life-saving buoyancy aids may be reduced to the number corresponding to the total number of persons provided with collective life-saving appliances.

Where capacity of liferafts exceeds the established standards, a number of life-saving devices may be reduced to the total number corresponding to the total number of persons provided with collective life-saving appliances.

8.2.13 Ships of M-СП class shall be fitted with a rescue boat (see 8.6). One of lifeboats may be considered as a rescue boat if it complies with the requirements for rescue boats.

8.2.14 Equipment of passenger ships, crew boats and special purpose ships of М-ΠΠ and О-ΠΠ class with life-saving appliances shall be taken according to the standards specified for passenger ships operating in basins of Μ category.

8.2.15 Equipment of cargo vessels, tugboats, catcher boats and self-propelled industrial ships of M-ΠΠ and O-ΠΠ class with life-saving appliances shall comply with standards specified in Table 8.2.15.

Table 8.2.15  Standards for equipping cargo vessels, tugboats, catcher boats and self-propelled industrial ships of M-ΠΠ and O-ΠΠ class with life-saving appliances

<table>
<thead>
<tr>

<td>lifeboats</td>
</tr>
<tr>
<td>≤30</td>
<td>50*</td>
</tr>
<tr>
<td>&gt;30</td>
<td>100*</td>
</tr>
</tbody>
</table>

* Norm of supply on each side

Notes. 1. In ships less than 30 m in length lifeboats may be replaced with liferafts.
2. In ships with length from 30 to 85 m lifeboats may be replaced with liferafts (for 100% of persons on each side), all liferafts shall be of the same capacity.
3. In ships with length of 85 m and more 50% of lifeboats may be replaced with liferafts provided that at least one lifeboat is provided on each side.

8.2.16 Oil tankers intended for carriage of oil products with a flash point of 60°C and below shall be fitted with fire-protected lifeboats.

8.2.17 Crewed non-self-propelled ships shall be fitted with life-saving appliances as the following:
for ships of M-ΠΠ class as for self-propelled cargo vessels of M class;
for ships of O-ΠΠ class as for non-self-propelled cargo vessels of М class.

8.2.18 Hydrofoil craft of M-ΠΠ and O-ΠΠ class shall be fitted with life-saving appliances according to the standards specified for hovercraft of Μ class.

8.2.19 For ships of М-ΠΠ class intended for operation in the Laptev Sea and in the East Siberian Sea in the area from the estuary of the Jana River to the estuary of the Kolyma River, collective life-saving appliances shall meet the requirements for ships of М-СП class.
8.2.20 For cargo ships of М-СП, М-ПП and О-ПП class where the horizontal distance from the extreme end of the stem or stern of the ship to the nearest end of the closest collective life-saving means is more than 100 m shall carry, in addition to life-saving appliances required by 8.2.2 and 8.2.15, a liferaft for at least 4 persons stowed as far forward or aft as practicable, or one liferaft as far forward and another liferaft as far aft as practicable. This liferaft or liferafts shall be securely fastened so as to permit manual release.

8.3 STANDARDS FOR EQUIPPING WITH INDIVIDUAL LIFE-SAVING APPLIANCES

8.3.1 All ships shall be provided with lifejackets for 100% of persons on board.

In floating objects moored on shore provided with deck ladders ensuring safe evacuation of people on shore, lifejackets may be omitted.

8.3.2 Ships of М, О, Р and ІІ class as well as cargo ships, tugboats, catcher boats and self-propelled industrial ships of М-ПП and О-ПП class shall be provided with additional lifejackets for 2% of people on board.

Ships of М-СП, М-ПП, О-ПП, М and О class shall be provided with additional lifejackets in the wheelhouse and the machinery space for the attending personnel in a number equal to a number of the persons on duty.

Lifejackets shall be arranged in readily accessible areas. Stowage positions of lifejackets shall be clearly indicated with inscriptions.

8.3.3 Hydrofoil craft of М-СП, М-ПП and О-ПП class shall be provided with additional lifejackets for 5% of people onboard.

8.3.4 Provision shall be made for lifejackets suitable for children with weight from 15 to 35 kg inclusive, at least 10% of the number of passengers onboard. At least 100% children onboard shall be provided with children lifejackets.

8.3.5 Equipment of ships with lifebuoys shall comply with the standards specified in Table 8.3.5.

8.3.6 Self-propelled and non-self-propelled ferries intended for operation on crossroads on rivers and canals of Р and ІІ categories are allowed to be equipped with one lifebuoy per each 5 m of the overall length of the ferry; here, life-saving appliances provided by Table 8.2.1 are not required.

8.3.7 Floating objects of 30 m and less in length shall be equipped with two lifebuoys on each deck, and those over 30 m in length – with four lifebuoys on each deck. One of the lifebuoys located on the main deck shall be equipped with a lifeline.

8.3.8 In ships up to 30 m in length intended for navigation in basins of Р, Р and ІІ categories all life-saving buoyancy aids may be replaced with lifebuoys assuming that one lifebuoy may hold two persons; here, lifebuoys required by Table 8.3.5 may be considered.

8.3.9 An immersion suit shall be provided for each crew member of a rescue boat for ships of М-СП class.

8.3.10 Ships of М-СП class shall be fitted with immersion suits for each person being rescued on free-fall liferafts when embarkation facilities to liferafts without getting into water are not available on board the ship.

8.4 LIFEBOATS

General requirements

8.4.1 Strength of lifeboats and lifting hooks for ships of М, О, Р and ІІ class shall be sufficient to provide for their launching when loaded with full permitted complement of persons and equipment.

The strength of lifeboats and lifting hooks for ships of М-СП, М-ПП and О-ПП class shall be sufficient to withstand the load as specified in this paragraph without residual deformation after its removal:

1. For metallic lifeboats – 1.25 times the total weight of such a lifeboat with a full complement of people and equipment; or

2. For non-metallic lifeboards – 2 times the total weight of such a lifeboat with a full complement of people and equipment; or

</tbody>
</table>

* Standard of supply on each deck at each side.

1 At least two lifebuoys shall be fitted with self-activating smoke signals.

2 One on each side of a ship.

3 All exposed deck areas intended for passengers shall be provided with lifebuoys on both sides of the ship with maximum 20 m spacing between them. Passenger ships in service are to be equipped with lifebuoys as per the requirements of the present note by the time of ordinary survey of the ship but not later than 19.07.2021.

Each lifeboat for ships of М-СП, М-ПП and О-ПП class launched by means of falls shall have a sufficient strength to withstand an impact on the ship side when fully completed with people and equipment and fitted with skids or fender bars when moving in a direction normal to the ship side at a speed of at least 3.5 m/s as well as drop into water from height of at least 3 m. This requirement does not apply to freefall lifeboats.

Points for lifeboat hanging shall be located in such a way as to ensure lifeboat launching in fully loaded condition without loss of stability.

**8.4.2** The lifeboat filled with water up to the top edge of a gunwale with a full complement of persons and equipment shall keep buoyancy and stability. Here, the lifeboat shall not have a list and the freeboard shall be not less than 20 mm.

The lifeboat shall keep stability and stable trim when held by people being in water in a complement not exceeding that as indicated on its marking in accordance with 8.4.11.

**8.4.3** Stability of the lifeboat is considered sufficient when the residual freeboard is at least 100 mm when the lifeboat is loaded with 50% of the number of persons permitted to accommodate seated to one side of the centreline.
8.4.4 Buoyancy of the lifeboat filled with water with a specified complement of persons and equipment shall be ensured by buoyancy of the material of the lifeboat or by water-tight air boxes or buoyant material.

Material of the lifeboat and elements which ensure buoyancy (water-tight air boxes, benches, buoyant material) shall comply with requirements of 8.1.6.

The ships of М-СП, М-ПР and О-ПР class shall be additionally provided with buoyant material in a quantity ensuring the buoyancy force of 280 N per person out of complement allowed for accommodation in the lifeboat. The buoyant material shall not be fitted outside the lifeboat except the material provided in excess of the required above mentioned quantity.

8.4.5 Length of the water-tight air boxes shall not exceed 600 mm. Air boxes of up to 1200 mm in length may be fitted provided that transverse tight bulkheads and longitudinal stiffeners are arranged inside.

8.4.6 In order to ensure lifeboat damage stability (see 8.4.2) the air boxes or buoyant material shall be arranged along the sides. Where it is impracticable, they may be located in the bow, the stern and the midship under thwarts but not by the bottom.

8.4.7 Where detachable boxes are installed, the easy replacement, protection against damage shall be provided and their shifting shall be avoided.

8.4.8 Freeboard of the lifeboat in fully loaded condition shall be not less than 0.4 of its side depth.

8.4.9 The number of persons permitted to be accommodated in the lifeboat is preliminary defined by gross capacity taking at least 0.226 m³ per person. Finally, the number of persons shall be established at testing to determine the number of adults which may accommodate in the lifeboat so as not to obstruct rowing and conning.

8.4.10 Surface of the gunwale and the sheer strake at a width of 150 mm shall be painted with orange colour.

8.4.11 On the sheer strake at either sides in the bow of the lifeboat a water-proof marking shall be made indicating a ship’s name, a shipowner, main dimensions of the lifeboat, permissible number of people to be accommodated and date of testing.

8.4.12 Lifeboats shall be so designed or be fitted with special arrangements as to provide a possibility of boarding of helpless people out of water.

8.4.13 Lifeboat equipment shall be taken according to the standards specified in Table 8.4.13. Items of lifeboat equipment shall have an appropriate package and excepting boat-hooks be adequately secured on assigned places in the lifeboat and be stowed in boxes and compartments. The equipment shall be so secured as not to interfere with the abandonment procedures.

When using the data in Table 8.2.2, the following shall be considered:

1. strength of sea anchor, hawser and tripping line specified in 8 Table 8.4.13 shall be adequate for all sea conditions;

2. a painter specified in 9 Table 8.4.13 shall be of at least 14 mm in diameter with a breaking load not less than 0.35 of the lifeboat’s weight with full complement of persons, equipment and the engine and of length not less than twice the distance from the stowage position of the lifeboat on board the ship to the waterline of the ship in the lightest sea-going condition in sea water or 15 m, whichever is the greater. One painter attached to the release device shall be placed at the forward end of the lifeboat and the other shall be firmly secured at or near the stem of the lifeboat and be ready for use;

3. watertight electric torch specified in 19 Table 8.4.13 shall be suitable for Morse signalling and be available with one spare set of batteries and one spare bulb in watertight packaging;

4. illustrated table of the life-saving signals specified in 21 Table 8.4.13 shall be either in waterproof packaging or made of waterproof material;

</tbody>
</table>

1 Only for rowboats.  
2 For lifeboats of ships entering reservoirs of P category.  
3 One hatchet at each end of the lifeboat.  
4 Watertight receptacles containing a total of 3 L of fresh water for each person the lifeboat is permitted to accommodate, or only 2 L for each person, if there is a de-salting apparatus in the lifeboat capable of producing 1 L of fresh water for each person for 2 days.  
5 Food ration totalling not less than 10 MJ for each person the lifeboat is permitted to accommodate in air- and watertight packaging.  
6 Only for lifeboats with engine.
8.4.13 A searchlight specified in 33 Table 8.4.13 shall be capable of effectively illuminating a light-coloured object at night having a width of 18 m at a distance of 180 m for a period of 6 hours including continuous operation for at least 3 h. If the searchlight is fixed, it shall be installed to allow turning by 360° in horizontal plane and tilting in vertical plane by 90° upwards and 30° downwards from horizontal plane.

8.4.14 Equipment of lifeboats of ships of M-IIP class shall correspond to standards adopted for ships of M-CP class excepting items required in subparagraphs 15 and 20 Table 8.4.13 and equipment of liferafts of those ships shall be taken according to 8.5.20 in any area of navigation.

Equipment for lifeboats and liferafts of ships of O-IIP class shall be taken according to the standards for ships of M class.

8.4.15 The engine of the lifeboat shall be fitted with a reverse reduction gear or another device enabling to move astern and an arrangement disconnecting the propeller (shaft) and engine.

8.4.16 The engine of the lifeboat shall be started manually within 2 min in any conditions possible during the lifeboat operation. A force on the engine handle shall not exceed 160 N per person.

Additional devices and appliances are allowed to facilitate the engine start.

8.4.17 The engine output shall provide lifeboat ahead speed with full complement of persons and equipment on calm water of at least 11 km/h and not more than 15 km/h.

Fuel store shall be sufficient for the engine operation for at least 2 hours at running mode. Built-in or portable capacities depending on the engine type (built-in or hinged) shall be provided for the fuel storage.

8.4.18 The engine and relevant appliances shall be protected in such a way that faultless operation is provided at flooding of the lifeboat up to the crankshaft axis line.

8.4.19 The propeller shall be located and guarded so that to ensure safety of people in water and prevent its damage by floating objects.

8.4.20 The engine, reverse reduction gear and hinged technical facilities shall be protected with casing made of material with low flame-spread characteristics (see 2.1.3.1 Part III of the Rules) or of non-combustible material.

Provision shall be made to protect people against accidental contact with hot or moving parts and protect the engine against environmental exposure. Provision shall be made for means of reduction of engine noises.

Starter batteries shall be arranged in watertight boxes ventilated with regard to 10.12.19 Part IV of the Rules.

8.4.21 Pipelines of systems serving the engine (fuel, lubrication, cooling) shall be protected against mechanical damages. Fixed fuel tanks on lifeboats shall be equipped with stop valves fitted on the fuel tank or fuel pipeline directly at the fuel tank. These valves shall be readily accessible. The air intake duct (ducts) of the engine and its exhaust system shall be designed to prevent the ingress of foreign objects and sea water in the engine. Insulation of exhaust system elements shall comply with the requirements of 1.9.2 Part IV of the Rules.

8.4.22 The engine start manual made of water-proof material shall be provided in the engined lifeboat.

8.4.23 Cleats shall be installed at sides of the engined lifeboat near the stern to ensure the towing of liferafts.

8.4.24 Handrails and buoyant grabline with floats attached to be held by a person in water shall be provided on the outer surface around the lifeboat above its waterline except for area in way of rudder and propeller.

8.4.25 The lifeboat shall be equipped with at least one bleed valve in way of the lowest hull point which shall be capable of opening automatically for draining water from the lifeboat when not in water and closing automatically when the lifeboat is in water. The bleed valves shall be accessible from inside of the
lifeboat and their location shall be clearly marked.

Each valve shall be fitted with a cap or plug for its closing with lanyards or chains attached to the lifeboat. This requirement does not apply to freefall lifeboats.

8.4.26 The lifeboat shall be provided with rudder and tiller.

Where a lifeboat is equipped with a steering wheel or other rudder remote control arrangement, provision shall be made for steering the lifeboat by means of a tiller in case of their failure. The tiller shall be permanently installed on the rudder stock or connected to it. However, where a lifeboat is equipped with the rudder remote control arrangement, the tiller may be of removable type and be kept attached near the rudder stock. The rudder and tiller shall be designed so that to prevent their damage during operation of launch and recovery arrangement or propeller.

8.4.27 The lifeboats shall be provided with embarkation ladder allowing the people in water to board the lifeboat through any access hatch. The lower step of ladder shall be at least 0.4 m below the lifeboat in the light condition.

The lifeboat shall be designed so that to allow the helpless people to be boarded from water or on stretchers.

All surface of the lifeboat which may be used for walking shall have a non-slip coating.

8.4.28 Both sides of lifeboats of ships of М-СП, М-ПП and О-ПП class in the bow end shall be marked with the following:

1. inscriptions indicating actual main dimensions of the lifeboat and the number of persons the lifeboat is permitted to accommodate made with indelible paint;

2. the name and port of registry of the ship which the lifeboat belongs to in block Latin letters; The name of ship which the lifeboat belongs to and its number shall be made so as to be visible from above.

8.4.29 Outer plating of the lifeboat’s hull of ships of М-СП, М-ПП and О-ПП class, exterior of folding and rigid enclosures and interior of that part of the lifeboat covered by the canopy shall be coloured orange.

**Partially enclosed lifeboats**

8.4.30 Partially enclosed lifeboats shall comply with requirements of 8.4.1 to 8.4.29 and 8.4.31 to 8.4.33.

8.4.31 A partially enclosed lifeboat shall have rigid water-tight enclosures extending for not less than 20% of its length from stem and aft end. The lifeboat shall be provided with permanently attached folding canopy which covers the people in the lifeboat together with the rigid enclosures to protect them against bad weather and environmental exposure.

The lifeboat shall be provided with entrances in front and aft ends and from each side. Entrances in rigid enclosures shall be water-tight when closed.

The canopy shall:

1. be provided with appropriate rigid sections or supports for its installation;

2. be fitted by max. 2 persons for max. 2 min;

3. ensure insulation of undercanopy space by at least two layers of material separated with air gap or other means with similar heat-insulating properties. Provision shall be made for means preventing water accumulation in the air gap;

4. have an external surface of distinctive colour and the internal surface causing no irritation to people in the lifeboat;

5. be provided with entrances equipped with adjustable enclosures which are capable of being opened and closed from inside and outside to provide ventilation but preventing the ingress of water, wind and cold in the lifeboat. Provision shall be made for arrangements allowing the entrances to be kept in opened and closed positions;

6. permanently pass a sufficient air for people in the lifeboat when the entrances are closed;

7. be provided with arrangement for collecting rainwater;

8. be capable of being abandoned by people in case of capsizing.
8.4.32 The internal surface of the lifeboat shall be of the light colour causing no discomfort for people in the lifeboat.

8.4.33 Where a lifeboat is equipped with stationary two-way VHF radiotelephone apparatus, this apparatus shall be arranged in an adequately sized wheelhouse to accommodate radiotelephone apparatus and operator. No separate wheelhouse is required if the lifeboat is designed to provide for a protected area so that not to impede its performance when the lifeboat is flooded up to upper thwart level.

Totally enclosed lifeboats

8.4.34 Totally enclosed lifeboats shall comply with requirements of 8.4.1 to 8.4.29 and 8.4.35 to 8.4.41.

8.4.35 Each totally enclosed lifeboat shall be provided with rigid water-tight enclosure allowing it to be completely covered.

The enclosure shall:

1. protect people in the lifeboat against heat and cold;
2. provide access to the lifeboat through hatches capable of being tightly closed;
3. arrange the access hatches so that the launch and recovery operations are possible without disembarkation of people. This requirement does not apply to freefall lifeboats;
4. be capable of opening and closing of access hatch covers from outside and inside. Hatch covers shall be kept opened;
5. provide for rowing. This requirement does not apply to freefall lifeboats;
6. be able to support the capsized lifeboats when hatches are closed with a full complement of people, equipment and technical facilities without any water leakage;
7. be provided with portholes and window capable of transmitting daylight inside when hatches are closed;
8. have an orange external surface and light internal surface;
9. be provided with handrails for people moving outside the lifeboat and which may be used during embarkation and disembarkation;
10. provide for passage of people from entrance to their seats without climbing over transverse thwarts and other obstacles;
11. provide for air pressure inside the lifeboat at engine operation when the entrances are closed which is not more or less than atmospheric pressure by more than 20 GPa.

8.4.36 The safety belts shall be provided at each clearly indicated area of the seat. Each set of safety belts for a seat shall be of colour in contrast with those in adjacent seats. The safety belts shall be designed to keep the person with weight of 100 kg in place when the lifeboat is capsized. This requirement does not apply to freefall lifeboats.

8.4.37 The stability of a lifeboat shall be so that it is capable of righting when totally or partially completed with people and equipment, all its entries and openings are tightly closed and safety belts are fastened.

8.4.38 After damage in any area below the waterline, the lifeboat shall be capable of supporting the full complement of people and equipment and its stability shall be so that it shall be capable of automatically positioning so that to be abandoned from the escape above the water level in case of capsizing. When the lifeboat is in a stable flooded condition, water level inside the lifeboat shall be max. 500 mm above any seat.

8.4.39 All engine exhaust pipes, air channels and other openings shall be designed to prevent ingress of water in the engine in case of capsizing and righting of the lifeboat.

8.4.40 The engine and associated arrangements shall provide stable operation in any position during capsizing and after righting of the lifeboat or shall be capable of being stopped automatically at capsizing and then being restarted after righting of the lifeboat. The fuel system shall be designed to prevent fuel leakage from the engine, the lubrication system shall be designed to prevent leakage of more than 250 mL of lubrication oil in case of capsizing of the lifeboat.

8.4.41 The air-cooled engines shall be provided with air ductworks for intake of cooling
Freefall lifeboats

8.4.42 Freefall lifeboats shall comply with requirements of 8.4.34 to 8.4.41 and 8.4.43 to 8.4.50.

8.4.43 The capacity of a freefall lifeboat is determined with regard to number of persons with average weight of 75 kg (82.5 kg for lifeboats of passenger ships) for which seats may be provided arranged not to impede operation of lifeboat propulsion arrangements and any other equipment. The seats shall be provided with foot support. The seats shall be arranged and designed to prevent a risk of injuries during launching. Passage between seats shall have clear width of at least 430 mm and be provided with non-slip coating.

8.4.44 The angle between seat pan and seatback shall be at least 90°. The seat width shall be at least 430 mm. Clear opening forward of the seatback measured perpendicular to the seatback shall be at least 650 mm. The seat back height above the pan shall be at least 1.075 m. The seats shall provide height to shoulders measured along the seat back equal at least 760 mm. The foot support shall be oriented so that the angle of inclination of support plane shall be at least half the angle of inclination of seat pan. The support shall be at least 330 mm long.

8.4.45 Each seat of the freefall lifeboat shall be provided with safety belts of contrast colour capable of keeping a person with weight of 100 kg in place when launching the lifeboat by freefalling and when the lifeboat is capsized. The safety belts shall be provided with fasteners capable of being unbuckled when belts are tensioned.

8.4.46 Each freefall lifeboat with a full complement of equipment for any of the following loading conditions:

- with a full designed complement of people;
- with a complement of people located so that the centre of its gravity is as far forward as practicable;
- with a complement of people located so that the centre of its gravity is as far aft as practicable;
- with a complement of launching crew only shall be capable of immediately running away from the ship right after its dropping into water and shall not contact with the ship after launching by free falling at trim of up to 10° by bow and heel of up to 20° either side from the permissible height of installation.

8.4.47 Oil tankers, chemical tankers and gas carriers of M-CII class shall be capable of launching of the lifeboat at a final heel angle above 20° if this angle does not exceed the maximum permissible heel angle under dynamic effect of a heeling moment due to wind and waves.

8.4.48 Each freefall lifeboat shall be capable of withstanding a launch by free falling from height 1.3 times the permissible height of installation, with a full complement of equipment and people according to its capacity.

8.4.49 Each freefall lifeboat shall be designed so that to protect people and equipment against hazardous accelerations which occur at its launching from permissible height into calm water at adverse trim of up to 10° and heel of up to 20° either side, with a full complement according to 8.4.46.

8.4.50 Each freefall lifeboat shall be provided with release system which shall:

- be provided with two independent and capable of being controlled from inside of the lifeboat arrangements for actuation of the system painted with different colours other than that of the internal surface;
- be designed so that to provide release at any loading conditions - from light condition to loading at least 200% the standard load produced by the weight of fully completed lifeboat with a complement of people corresponding to its capacity;
- be adequately protected against accidental or early use;
4 be designed so that the release system may be tested without launching of the lifeboat;
5 be designed so that to provide a safety factor equal to 6 times tensile strength of the materials used.

**Lifeboats with self-contained air support system**

8.4.51 Lifeboats with self-contained air support system shall comply with requirements of 8.4.34 to 8.4.41 and shall be equipped with compressed air system. The volume of compressed air cylinders of this system shall be sufficient for safety of people and uninterruptible operation of engine for at least 10 min with all entrances and openings closed. Within this period, air pressure inside the lifeboat shall not drop below or exceed the ambient atmospheric pressure by more than 20 GPa. Air supply system shall be provided with indicators permanently indicating the supply air pressure.

**Fire-protected lifeboats**

8.4.52 A fire-protected lifeboat shall comply with requirements of 8.4.51 and in addition, protect the complement of people allowed to be accommodated being in water in the area of continuous oil fires all around the lifeboat within at least 8 min.

8.4.53 The lifeboat shall be equipped with performance manual during fire as well as set of medicines against burns and carbon dioxide intoxication (see GOST R 53451).

8.4.54 In conditions specified in 8.4.52, carbon monoxide concentration inside the lifeboat shall not exceed 0.2 mg/L, carbon dioxide concentration – 3% by volume.

8.4.55 The lifeboat equipped with the water sprinkling system for firefighting shall comply with the following requirements:

1 the system shall be supplied with seawater fed from self-priming pump. Provision shall be made for switch on and shut off of water supply for sprinkling of lifeboat external surface;

2 water intake arrangement of the water sprinkling system shall be designed to prevent ingress of combustible liquids from the water surface into the system;

3 the system shall be capable of being washed with fresh water and be fully drained.

8.4.56 Water sprinkling system or thermal insulation of the lifeboat shall provide air temperature inside the fire-protected lifeboat at the headlevel of a sitting person max. 60 °C in conditions mentioned in 8.4.52.

**8.5 LIFERAFTS**

8.5.1 A liferaft shall be so designed that neither the liferaft nor its equipment are damaged after dropping into the water from a height of at least 10 m.

8.5.2 The liferaft shall be capable of withstanding a jump of a person having a mass of 75 kg on it from a height of 4.5 m above the bottom both with and without the canopy erected.

The liferaft shall keep stable trim when held by people being in water in a complement not exceeding that as indicated on its marking in accordance with 8.5.19.

8.5.3 Design of the liferaft and its equipment shall enable it of being towed at a speed of 5.5 km/h on calm water with the design number of persons and equipment. Herewith, the liferaft shall keep stability.

8.5.4 Buoyancy chambers of inflatable liferaft shall be divided into at least two separate compartments, each inflated through a non-return inflation valve on each compartment. The buoyancy chambers shall be so arranged that, in the event of any one of the compartments being damaged or failing to inflate, the intact compartments shall be able to support, with positive freeboard, over the liferaft’s entire periphery, the design number of persons, each having a weight of 75 kg and seated in their normal position.

Buoyancy of a rigid liferaft shall be ensured by means of buoyant material located as close as possible to the liferaft edges. The buoyant material shall be low spreading flame or have
a relevant coating (see 1.2.1.16 Part III of the Rules).

8.5.5 The liferaft of free-fall type shall be so designed that the capsized floating inflated raft may be turned over by one person in water after that this raft may be capable of being used effectively as when it is floating in a right position.

8.5.6 Liferafts for ships of М-СШ, М-ПР, М and О-ПР class shall be equipped with a canopy which shall:

.1 protect people from drops, cold and wind;
.2 provide adequate ventilation;
.3 have a viewing port;
.4 have entrances fitted with simple and efficient closing arrangements;
.5 have sufficient headroom for sitting occupants.

8.5.7 The liferaft shall be fitted with lifelines securely becketed around the inside and outside periphery of the liferaft as well as with means of drawing it up to a ship side and holding during the embarkation.

8.5.8 If the float-free arrangements use a weak link, it shall:

.1 not be broken by the force required to pull the painter from the liferaft container;
.2 be of sufficient strength to permit the inflation of the liferaft;
.3 break under a strain equal to 0.105n, but of not more than 2.2±0.4 kN, where \( n \) is liferaft capacity, persons.

8.5.9 If the float-free arrangements use a hydrostatic release unit, it shall:

.1 be so designed to prevent its incorrect operation. Galvanizing or other forms of metallic coating on parts of the hydrostatic release unit not permitted;
.2 automatically release the liferaft from a ship at a depth of not more than 4 m;
.3 have drains to prevent the accumulation of water in the hydrostatic chamber when the unit is in its normal position;
.4 be designed to prevent release the liferaft from a ship when seas wash over the unit;
.5 be permanently marked on the unit or identification plate attached to the unit with the date of manufacture, type and serial number and whether the unit is suitable for use with liferafts designed for not less than 25 persons;
.6 be such that each part connected to the painter and associated arrangements has a strength of not less than that required for the painter.

8.5.10 Liferaft equipment shall comprise the following:

.1 a first-aid kit in a waterproof case capable of being closed tightly after use (see GOST R 53451);
.2 two buoyant oars (paddles);
.3 a bailer;
.4 rescue buoyancy aid attached to buoyant line 15 m long;
.5 repair tool set for patching up of punctures in the buoyant chamber (for inflatable liferafts);
.6 manual bellows for topping up (for inflatable liferafts);
.7 six hand flares for ships operating in basins of M category and three hand flares operating in basins of O category;
.8 one whistle or equivalent sound signal means;
.9 two sponges;
.10 knife with a handle made of buoyant material, attached and stored on the face side of the canopy close to the attaching point of the painter to the liferaft;
.11 individual thermal protection aids (see 1.2.1.20) sufficient for at least 10% of the number of persons the liferaft is permitted to accommodate but not less than two.

Note. The individual heat-reflecting means shall be included in the supply of liferafts for ships operating northwards 66°30’ and in the Baikal lake.

8.5.11 A number of persons admitted for accommodation in a liferaft shall be equal to the least of the following values:

.1 the greatest number obtained from division of volume of main buoyant elements in inflated condition, \( m^3 \), on inflatable liferafts
or a volume of buoyant material, m³, on rigid liferafts, by 0.096;

.2 the greatest integer obtained from division of internal horizontal area of the bottom section, m², (including transverse thwarts) by 0.315;

.3 number of persons each having weight of 75 kg wearing immersion suits (for ships operating northwards 66°30’ and in the Baikal lake) and lifejackets which may be seated in their normal position not obstructing the use of liferaft equipment.

In any case, capacity of liferafts shall be at least 4.

8.5.12 The liferaft shall be equipped with a device to facilitate boarding from the water.

In way of one entrance, provision shall be made for semi-rigid boarding ramp capable of withstanding a load of 980 N and allowing the people in water to climb the liferaft. The ramp shall be fitted so as to prevent gas leakage from liferaft in case of damage. On the davit-launched liferaft with several entrances, provision shall be made for a boarding ramp near entrance opposite to the side which is used for drawing the raft up to the ship's side and where arrangements for boarding from ship to the raft are available.

Entrances not equipped with boarding ramp shall be provided with embarkation ladder with the lower step at least 0.4 m below the waterline of the liferaft in light condition.

Inside the liferaft provision shall be made for arrangements allowing the people to board the liferaft from the ship.

8.5.13 The bottom of the liferaft shall be waterproof and shall be capable to provide sufficient insulation against cold.

8.5.14 Non-toxic gas shall be used for inflating a liferaft. The liferaft shall be inflated to the working condition within 1 min at an ambient temperature of +20 °C and within max. 3 min at an ambient temperature of minus 30 °C.

8.5.15 Any liferaft shall be designed to be used afloat for at least 3 days.

8.5.16 Inflatable liferafts shall be capable of topping up inflatable elements by manual bellows.

8.5.17 Each inflatable liferaft shall be surveyed and restowed (see Appendix 7, RSSS) at least every twelve months.

8.5.18 Inflatable liferaft shall be packed in a container or a water-tight case of weatherproof type. The container or case together with stowed liferaft shall keep positive buoyancy for at least 20 min.

The weight of stowed liferaft on board ships not equipped with liferaft launching arrangements shall not exceed 80 kg.

The liferaft shall be packed in a container so that after dropping into water and release from container it shall be capable of inflating while being in upright position.

8.5.19 Marking of the inflated liferaft, case or container shall be clearly legible throughout their specified life and contain data on number of accommodated persons, brand and type, serial number, date of manufacture, name and address of manufacturer or trademark, weight, inspection and test intervals, disposal method.

Marking of the case or container shall include brief manual for bringing the liferaft in service condition.

8.5.20 Items of liferaft equipment for ships of M-CII class shall be compact and small-size, be packed and adequately secured on regular places in the raft.

The liferaft equipment shall include the following items:

.1 buoyant rescue ring attached to a buoyant line at least 30 m long;

.2 knife of the non-folding type having a buoyant handle attached by a lanyard and stowed in a pocket on the exterior of the canopy near the point at which the painter is attached to the liferaft. The liferafts permitted to accommodate 13 persons or more shall be provided with a second knife which may be of folding type;

.3 buoyant bailer;

.4 two sponges;
a sea anchor with a shock-resistant hawser and a tripping line. The sea anchor shall be permanently attached to the liferaft so that when the liferaft inflates and is waterborne it will cause the liferaft to lie oriented to the wind in the most stable manner. The strength of the sea anchor, hawser and tripping line shall be adequate for all sea conditions. The sea anchor shall be fitted with swivels at each end of the line and preclude turning inside-out between its shroud lines;

.6 two buoyant oars (paddles);

.7 a first-aid kit in a waterproof case capable of being closed tightly after use;

.8 signal whistle or equivalent sound signal;

.9 six hand flares;

.10 watertight electric torch suitable for Morse signalling together with a spare set of batteries and a spare bulb in watertight packaging;

.11 instructions on how to survive in the liferaft;

.12 instructions for immediate actions;

.13 individual thermal protection aids (see 1.2.1.20) sufficient for at least 10% of the number of persons the liferaft is permitted to accommodate but not less than two.

8.5.21 The marking in liferafts for ships of M-CII class equipped in accordance with 8.5.20 shall be “C PACK” in block capitals.

8.5.22 For ships of M-CII class the equipment of each liferaft shall be stowed in a container secured inside the liferaft except the cases when the container is an integral part of the liferaft, is permanently attached to the latter and is capable of floating in water for at least 30 min without damage to its contents.

8.6 REQUIREMENTS FOR RESCUE BOATS

8.6.1 Rescue boats shall comply with the following requirements:

.1 have a document issued by the River Register on compliance with the Rules as well as marking in accordance with 8.4.28;

.2 in addition, marking of inflated rescue boats shall contain a serial number, the manufacturer’s name or trade mark and the date of manufacture;

.3 unless the rescue boat of rigid construction has adequate sheer, it shall be provided with a bow cover extending for not less than 15% of its length;

.4 totally enclosed rescue boat shall be of self-righting type and comply with the requirements of national standards. Partially enclosed rescue boat shall be of automatically self-bailing type or be provided with effective means of bailing;

.5 enclosure of the rescue boat shall have railings to provide a passage outside the enclosure. In addition, partially enclosed rescue boat shall have a handrail at least 600 mm high in its open part;

.6 the rescue boat shall have a control station providing free view in all directions for the helmsman;

.7 the rescue boat shall be capable of manoeuvring at speeds up to 6 knots and maintaining that speed for a period of at least 4 h;

.8 rescue boats shall have sufficient mobility and manoeuvrability in a seaway to enable persons to be retrieved from the water, marshal liferafts and tow the largest liferaft carried in the ship when loaded with its full complement of persons and equipment;

.9 the rescue boat shall be fitted with an inboard engine or outboard motor;

.10 rescue boats shall be fitted with fixed arrangements for towing which shall be sufficiently strong to marshal or tow liferafts as required by 8.6.1.8;

.11 the buoyancy of an inflated rescue boat shall be provided by either a single buoyancy tube subdivided into at least five separate compartments of approximately equal volume or two separate buoyancy tubes neither exceeding 60% of the total volume;

.12 the buoyancy tubes forming the boundary of the inflated rescue boat shall on inflation provide a volume of not less than 0.17 m³ for each person the rescue boat is permitted to accommodate;

1 GOST R 53451 and GOST 52638.
.13 Each buoyancy compartment of the inflated rescue boat shall be fitted with a non-return valve for manual inflation and means for deflation;

.14 Underneath the bottom and on vulnerable places on the outside of the inflated rescue boat rubbing strips shall be provided;

.15 Where a transom is fitted, it shall not be inset by more than 20% of the overall length of the inflated rescue boat;

.16 Suitable patches shall be provided for securing the painters fore and aft and the becketed lifelines inside and outside the boat;

.17 The inflated rescue boat shall be maintained at all times in a fully inflated condition;

.18 Preparation and launching of the rescue boats shall be performed within max. 5 min.

8.6.2 Items of rescue boat equipment shall be packed and be secured on regular places in the rescue boat.

The equipment of each rescue boat shall include:

.1 At least two buoyant oars and one steering oar with pins or crutches provided for each oar;

.2 A boat-hook;

.3 A buoyant bailer and a bucket;

.4 A knife (of a safe type for inflated rescue boats);

.5 Two buoyant heaving lines 30 m in length with lifebuoys;

.6 A binnacle containing an efficient compass with luminous card or provided with suitable means of illumination of the diameter sufficient for normal reading the indications;

.7 A sea anchor and tripping line with a hawser of adequate strength not less than 10 m in length;

.8 A painter of sufficient length and strength so attached at the forward end of the rescue boat that to be released quickly for releasing when the rescue boat is in motion;

.9 Buoyant line, not less than 50 m in length, of sufficient strength to tow a liferaft;

.10 Electric torch of water-proof type suitable for Morze signalling together with a spare set of batteries and a spare bulb;

.11 Signal whistle or equivalent sound signal;

.12 A first-aid kit in a waterproof case;

.13 Searchlight capable of illuminating a light-coloured object at night having a width of 18 m at a distance of 180 m for a period of 6 hours including continuous working for at least 3 h;

.14 Individual thermal protection aids sufficient for at least 10% of the number of persons the rescue boat is permitted to accommodate but not less than two, whichever is the greater;

.15 Radar reflector;

.16 Additionally for inflated rescue boats: two sponges, manually operated bellows or pump, a repair kit for repairing punctures in a suitable container, a safety boat-hook.

8.7 LIFE-SAVING BUOYANCY AIDS

8.7.1 Carrying capacity of a life-saving buoyancy aid shall be sufficient for supporting of the design number of persons being in the water and grabbing it.

8.7.2 The number of persons \( n \), supported by the buoyancy aid shall be taken as the least of the values calculated by the formulas:

\[
 n = \frac{P_{\text{aid}}}{P_1}; \quad (8.7.2-1)
\]

\[
 n = \frac{Q}{q_1}, \quad (8.7.2-2)
\]

where \( P_{\text{aid}} \) — aid periphery, m;

\( P_1 \) — permissible periphery length per one person, \( P_1 = 0.3 \) m;

\( Q \) — carrying capacity, N;

\( q_1 \) — carrying capacity per one person, \( q_1 = 142 \) N.

8.7.3 Strength of the buoyancy aid shall be such as no damages may occur after dropping it into the water from a height of at least 10 m which may affect its performance characteristics.

8.7.4 The life-saving buoyancy aid shall maintain stability regardless of the side being above when afloat.

8.7.5 Floodability (buoyancy) of the aid shall be provided by air boxes or other equivalent floating means. The life-saving buoyancy
aid shall support a metallic weight of 7.5 kg in fresh water for 24 h.

8.7.6 The life-saving buoyancy aid shall be fitted with a lifeline, buoyant or fitted with floats becketed around the periphery of the aid with sags, the number of which shall correspond to the number of supported persons.

8.7.7 The life-saving buoyancy aid shall be coloured orange. An inscription “Life-saving buoyancy aid” shall be made on a visible place of the aid and the design number of persons and the name of a ship shall be indicated.

8.7.8 Each life-saving buoyancy aid shall be fitted with a towing line at least 18 m in length and diameter of at least 8 mm. The towing line shall be becketed to the aids in such a way that it may be towed. The life-saving buoyancy aid shall be fitted with a device to secure towing line of another life-saving buoyancy aid.

8.8 LIFEBOYS, LIFEJACKETS AND IMMERSION SUITS

8.8.1 Construction of lifebuoys, lifejackets, immersion suits and individual heat-reflecting means shall meet national standards¹ as well as requirements of 8.8.2 to 8.8.25.

8.8.2 The materials for lifejackets, lifebuoys, immersion suits and individual heat-reflecting means shall comply with requirements of 8.1.6.

Lifejackets, lifebuoys, immersion suits and individual heat-reflecting means shall not sustain burning or continue melting after being totally enveloped in a fire for a period of 2 s.

8.8.3 Lifebuoys shall:

.1 have an inner diameter of not less than 400 mm;
.2 be made of buoyant material; the life-buoy buoyancy shall not depend upon any loose materials or inflatable air chambers;
.3 be capable of supporting not less than 14.5 kg of steel or cast iron in fresh water for a period of 24 h;
.4 have a weight of at least 2.5 kg;
.5 be designed so as to withstand a drop into the water from the height of 10 m without impairing its performance characteristics and damaging of the outfit attached;
.6 be fitted with a grabline not less than 9.5 mm in diameter and not less than 4 times the outside diameter of the body of the buoy in length secured at four equidistant points;
.7 strips of retro-reflecting material at least 100×50 mm shall be fitted at both sides of the lifebuoy at four equidistant points.

8.8.4 Lifebuoy shall bear an inscription with the name of the ship, port of registry and testing stamp.

8.8.5 Grabline becketed to the lifebuoy shall be:

.1 of diameter at least 8 mm and not less than 27.5 m in length;
.2 non-twisting;
.3 have a breaking strength of at least 5 kN.

8.8.6 Self-igniting buoys shall be becketed to the lifebuoy with a line of 1.5 m in length. The burning period of automatically igniting light shall be not less than 45 min with luminous intensity of 2 cd. The buoys shall be coloured orange and automatically igniting light shall be white coloured and shall burn continuously at all directions of the upper hemisphere or provide flashes with frequency of at least 50 and max. 70 flashes per minute with effective luminous intensity of 2 cd.

8.8.7 Construction of a lifejacket for adult shall be such as:

.1 persons, completely unfamiliar with the lifejacket, can correctly use it without any assistance, guidance or prior demonstration;
.2 it is comfortable to wear;
.3 it allows the wearer to jump from the height of at least 4.5 m without injury and without dislodging or damaging the lifejacket;
.4 it allows the wearer to swim for a short distance and board a lifeboat or a liferaft.

8.8.8 The lifejacket shall have sufficient buoyancy and stability in calm fresh water to:

¹ GOST 22336, GOST 19815, GOST 54596.
support above the water surface the head of an exhausted or unconscious person in order to lift the mouth not less than 120 mm clear of the water with the body inclined backwards at an angle of not less than 20° from the vertical position;

turn the body of an unconscious person in the water from any position to one where the mouth is clear of the water in not more than 5 s.

8.8.9 The lifejacket shall have buoyancy which is not reduced by more than 5% after 24 h submersion.

8.8.10 Lifejackets and lifebuoys shall be orange in colour and be fitted with retro-reflecting material in those places where it assists in detection.

Each side of the lifejacket that may be the outer one shall be provided with at least three strips of retro-reflecting material of 50×100 mm in dimension; two of those strips shall be located on outer part and one of them on a collar.

8.8.11 Each lifejacket shall be fitted with a whistle fastened to it with a lace.

Each lifejacket shall be fitted with an electric search light of white colour which shall meet the following requirements:

luminous intensity shall be at least 0.75 cd in all directions of the upper hemisphere;
energy source shall be capable of providing the required luminous intensity for at least 8 h of continuous operation;
electric light shall be readily visible when attached to the lifejacket in the largest part of the upper hemisphere segment.

Where the electric search light is of flashing type, in addition to requirements mentioned in this paragraph, it shall meet the following requirements:
be equipped with manual switch;
flash frequency shall be at least 50 and max. 70 flashes per minute;
effective luminous intensity shall be at least 0.75 cd.

8.8.12 The lifejacket shall bear the name of the ship and a testing stamp.

8.8.13 A child lifejacket shall have the same design and characteristics as an adult lifejacket. In addition to afore-mentioned requirements it shall:

have such construction as it can be adjusted for the child body;

lift the mouth of an exhausted or unconscious child clear of the water;

assist a child to board a collective life-saving appliance.

8.8.14 A child lifejacket shall bear an indelible inscription “Child” and marking indicating the limits of child’s height or weight.

8.8.15 The immersion suit shall be made of waterproof materials and comply with the following requirements:

it shall be capable of being unpacked and donned without assistance within max. 2 min taking into account donning of any associated clothing, donning of a lifejacket if the immersion suit shall be worn in conjunction with a lifejacket;

it shall cover the whole body with the exception of the face. Hands shall also be covered unless permanently attached gloves are provided;

it shall be provided with arrangements to minimize or reduce free air in the legs of the suit;

following the jump from a height of not less than 4.5 m, the ingress of water into the suit shall not exceed 500 g.

8.8.16 An immersion suit which also complies with the requirements of 8.8.7 to 8.8.9 may be classified as a lifejacket.

8.8.17 An immersion suit which shall permit the person wearing it or a lifejacket, if the immersion suit shall be worn in conjunction with a lifejacket, to:

climb up and down a vertical ladder of at least 5 m in length;

perform normal duties during abandonment;

jump from a height of not less than 4.5 m into water without damaging or dislodging the immersion suit or being injured;
4. Swim a distance through the water from the ship to survival craft and board a survival craft.

8.8.18 An immersion suit which has buoyancy and is designed to be worn without a lifejacket shall be fitted with a whistle and electric search light complying with requirements of 8.8.11.

8.8.19 If the immersion suit shall be worn in conjunction with a lifejacket, the lifejacket shall be worn over the immersion suit. The immersion suit shall be so designed to allow a person wearing such an immersion suit to don a lifejacket without any assistance.

8.8.20 An immersion suit with or without a lifejacket if the immersion suit shall be worn in conjunction with a lifejacket, shall provide sufficient thermal protection following one jump by the wearer into the water from a height of 4.5 m to ensure that when it is worn for a period of 6 h in calm circulating water at a temperature of 0 to 2°C the wearer's body core temperature does not fall by more than 2°C.

8.8.21 The design of immersion suit or immersion suit with a lifejacket shall allow a person to turn in fresh water from a face-down to a face-up position in not more than 5 s.

8.8.22 An immersion suit made of material which has no inherent insulation with warm clothing may be used as an immersion suit. Such an immersion suit shall be:

1. Marked with instructions that it shall be worn in conjunction with warm clothing;

2. So constructed that when worn in conjunction with warm clothing and with a lifejacket if required, if the immersion suit continues to provide sufficient thermal protection, following one jump by the wearer into the water from a height of 4.5 m, to ensure that when it is worn for a period of 1 h in calm circulating water at a temperature of 5°C the wearer’s body core temperature does not fall by more than 2°C.

8.8.23 An individual thermal protective aid shall be made of waterproof material and be so constructed to reduce a heat loss from the wearer’s body when put on.

8.8.24 The individual thermal protective aid shall:

1. Cover the whole body with the exception of the face. Hands shall also be covered unless permanently attached gloves are provided;

2. Be capable of being unpacked and easily donned without assistance in the lifeboat or liferaft;

3. Permit the wearer to remove it in the water in not more than 2 min if it impairs ability to swim.

8.8.25 The individual thermal protective aid shall function properly at air temperature of minus 30°C to +20°C.

8.9 LAUNCHING APPLIANCES

8.9.1 Each launching appliance shall be capable of safe launching of life-saving appliances with full complement and design number of persons at static trim of up 5° and heel of 15° either way.

8.9.2 Each launching appliance shall be fitted with brakes being capable of stopping launching of the life-saving appliance and of holding it when loaded with the design number of persons and equipment.

8.9.3 The launching appliance and its related attachments shall be of sufficient strength to withstand a static test with a proof load not less than 1.5 times the maximum working load.

8.9.4 In ships of all classes lifeboats shall be installed under the boat davits. Where it is impossible, other equipment may be installed instead of davits subject to technical justification.

8.9.5 An arm of boat davits shall be so that at lifeboat launching from ships of M and O class without a heel a clearance of 0.3 ± 0.05 m is provided between a ship side or protruding parts (rubbing strip, extended deck etc.) and the lifeboat, and at least 0.15 m when launching lifeboats from ships of P class.
8.9.6 Strength of boat davits, falls, sheaves and other elements of the boat appliance shall be sufficient for safe boat launching and hoisting of a load of the weight kg,

\[ G = 1.25(Q + qn), \]

(8.9.6)

where \( Q \) — weight of the lifeboat with equipment, kg;
\( q \) — weight of one person (75 kg);
\( n \) — number of persons in the lifeboat for which the boat equal to:

at dumping, launching and recovery — a design number of persons on board;
at recovery — a number of persons on board for its maintenance purposes.

At strength calculations of elements of the boat appliances on board ships of M and O class a list of ship on either side of at least 15° and trim of at least 5° shall be considered.

Length of falls of tackles shall be sufficient for boat launching to the water at a list of a light ship on either side of 15° and trim of 5°. Herewith, at least three wraps of a rope shall remain on the boat winch drum.

8.9.7 Boat launching period shall not exceed 5 min including preparation for the launching and dumping over board.

The standard time does not consider the time required for embarkation.

8.9.8 The electrically-driven boat appliance shall be capable of recovering the lifeboat with equipment and persons for its maintenance purposes also by means of a manual drive.

8.9.9 Ships shall be equipped with appliances for dropping of inflatable liferafts. These appliances may be omitted when a weight of each liferaft does not exceed 80 kg.

8.9.10 Where the liferafts are stowed in hardly accessible places and no passages are provided to them on board ships less than 30 m in length, special effective remote-controlled dropping appliances shall be provided.

8.9.11 Steel wire ropes, natural and synthetic fibre ropes shall meet the requirements of 6.15 and buckles, swivels, screw turnbuckles and other loose components — the requirements of Section 5. Non-rotating and corrosion-resistant steel wire ropes shall be used as falls.

8.9.12 Embarkation ladders shall have free from sharp edges hard treads with a non-slip surface of a length not less than 450 mm and equally spaced in the horizontal position not less than 380 mm apart.

8.10 STOWAGE OF LIFE-SAVING APPLIANCES ON BOARD

8.10.1 Collective life-saving appliances shall be stowed as close as practicable to the water surface so as not to be damaged by wave hammering.

8.10.2 Collective life-saving appliances shall be stowed as close as practicable to the accommodation and service spaces in the safest places with regard to explosions, fires, touch by other ships, etc.

8.10.3 Collective life-saving appliances shall be so stowed that to avoid obstacles for mustering of people at embarkation stations, simultaneous boarding on launched life-saving appliances, dumping and launch of the life-saving appliances.

8.10.4 Collective life-saving appliances shall be stowed in way of wall-sided section of a ship’s side. They may be stowed also in the area where an angle between the vertical and tangent to outer shell plating laid in a framing plane at a level of waterline of light or ballasted ship does not exceed 45°.

When stowing side-launched lifeboats the following requirements are to be met:

1. bow extremity of the lifeboat shall not extend over the plane of the fore peak bulkhead;
2. after extremity of the lifeboat shall be located at a distance equal to at least its length forward of the propeller plane on ships with open propellers, and at least a half of its length on board ships with propellers in nozzles.

8.10.5 The lifeboat may be installed on the stern of a ship in the centre line plane, if provision is made to prevent the lifeboat against
damage by protruding parts of the propeller and the rudder or after structures during launching.

8.10.6 The lifeboat shall be installed on the keel-blocks, the shape of which shall correspond to its hull lines.

Keel-blocks shall be so designed as to provide launching of the lifeboat without preliminary hoisting.

8.10.7 For securing boats for navigation which are installed on the keel-blocks, lashes shall be provided.

8.10.8 Boarding of people to the lifeboats shall be provided directly from its stowage place; no dumping or launching of the lifeboat shall be required before launching.

8.10.9 Passenger ships shall have embarkation stations for boarding launched lifeboats and liferafts from the main deck, fitted with embarkation ladders.

Inflatable stairways may be used.

8.10.10 Liferafts and life-saving buoyancy aids shall be easily secured; life-saving appliances shall be so stowed as to be easily released and float free when a ship is immersed into the water.

8.10.11 Life-saving buoyancy aids and liferafts are recommended to be stowed so as they may be carried from one side to the other.

8.10.12 Life-saving buoyancy aids may be stored with one put over the other, with linings provided between the aids and measures are taken to prevent the aids from shifting at rolling or pitching.

8.10.13 Places of stowage of collective life-saving appliances, approaches to them and the water surface in the launching area shall be illuminated.

8.10.14 Lifebuoys shall be uniformly distributed along the port and starboard at visible and easily accessible places. Dead securing of lifebuoys which does not enable its free-floating when the ship is being flooded, is not permitted.

One lifebuoy shall be located in the immediate vicinity of wheelhouse.

8.10.15 Where ship’s outfit comprises two lifebuoys with lifelines or self-igniting buoys, such lifebuoys shall be stowed at the opposite sides.

8.10.16 Lifejackets for cabin passengers shall be stowed in cabins in easily accessible places.

8.10.17 Lifejackets for non-cabin passengers shall be distributed in easily accessible places. Not more than 20 lifejackets shall be stowed at the same place. An inscription “Lifejackets” shall be provided near lifejacket stowage places.

Child lifejackets shall be stowed separately, an inscription “Child lifejackets” shall be provided near lifejacket stowage places.

Stowage places of lifejackets shall be illuminated.

8.10.18 For all persons on board passenger ships with a length of 65 m and over or with three or more decks, mustering stations shall be provided which shall meet the following requirements:

1 be in the vicinity of, and permit ready access for all passengers to the embarkation stations of collective life-saving appliances unless in the same location;

2 the total area of mustering stations \( A \) shall be not less than the value calculated by the following formulas, m\(^2\):

for ships engaged on day voyages \[ A = 0.35 N_{\text{max}} \]

for cabin ships \[ A = 0.45 N_{\text{max}} \],

where \( N_{\text{max}} \) — maximum number of persons onboard;

3 the area of each single mustering station shall be at least 10 m\(^2\);

4 mustering stations shall be located on decks above emergency waterline;

5 mustering stations and evacuation areas shall provide ready access to life-saving appliances on any ship’s side;

6 mustering stations and evacuation areas shall be displayed in safety plan and prominently displayed on board the ship;
.7 if movable furniture is provided in the room where mustering stations are located, it shall be properly secured against slippage;

.8 if stationary seats or benches are provided in the room where mustering stations are located, when calculating the total area of mustering stations in accordance with 8.10.18.2, the corresponding number of persons may be neglected. However, a number of persons for which stationary seats or benches are considered shall not exceed a design number of persons for mustering stations in this room;

.9 requirements of 8.10.18.7 and 8.10.18.8 shall be complied with also for exposed areas of decks where mustering stations are located;

.10 where the ship is fitted with collective life-saving appliances, the design number of persons may be neglected when calculating the total area of mustering stations in accordance with 8.10.18.2;

.11 if the requirements of 8.10.18.8 to 8.10.18.10 are not met, the total area of mustering stations shall be adequate for accommodation of at least 50% passengers.
9 SIGNAL MEANS

9.1 GENERAL PROVISIONS

9.1.1 Requirements of the present Section apply to ships under design and construction as well as to ships in service.

9.1.2 The nomenclature and the location of navigation lights and daytime signal means for ships operating on inland waterways of Russia are defined by the Rules for Navigation on Inland Waterways of the Russian Federation and rules for navigation and berthing of ships in individual basins of inland waterways of the Russian Federation.

9.1.3 Inland navigation ships operating in areas with sea navigation conditions shall be equipped with navigation lights and sound signal means according to requirements for river-sea navigation ships.

9.1.4 Length, breadth and depth of a ship are length overall and maximum breadth and depth accordingly.

9.1.5 River-sea navigation ships shall be fitted with both signal means required for navigation in inland waterways and signal means required for navigation in sea areas in accordance with provisions of International Regulations for Preventing Collision at Sea (1972) regardless of the voyage type (coastal or international).

9.2 STANDARDS FOR EQUIPPING WITH NAVIGATION LIGHTS AND DAYTIME SIGNAL MEANS

9.2.1 Ships operating on inland waterways shall be equipped with navigation lights and daytime signal means according to the standards specified in Table 9.2.1-1, and ships operating in sea areas – to the standards specified in Table 9.2.1-2.

9.2.2 Navigation lights used in ships shall be electric ones.

9.2.3 Cargo motorships equipped for pushing shall be equipped with navigation lights provided in Table 9.2.1-1 for pushboats.

Table 9.2.1-1

Standards for equipping ships operating in inland waterways with navigation lights and daytime signal means

<table>

</tbody>
</table>

1 Self-propelled trailing suction hopper dredgers (TSHD) are fitted with three vertically located signs: two black balls with black cone in-between.
2 Ships belonging to the transport supervision service are fitted with a blue all-round flashlight.
3 Ships with length of 50 m and over are fitted with two white masthead lights.
4 Required for ships carrying dangerous goods.
5 Ships with a breadth of 5 m and less are fitted with one sternlight only.
6 Electrical flashing lights with incandescent lamps may be additionally fitted.
7 Fire-watch vessels, floating workshops and landing stages are fitted with one all-round white light on the mast and one all-round white light on the superstructure wall visible from the side of the navigational pass (for landing stages – one all-round white light on each side). One all-round white light is fitted on oil processing stations, pumping stations, industrial ships, berths and pontoons less than 50 m in length as well as on cable ferries.

8 Required for ships carrying dangerous goods and for oil processing stations. Dredgers shall be fitted with two all-round red lights (on the awning deck).

9 Required for dredgers, mud dredgers and ships engaged in underwater operations, sweeping the navigation pass, operation at the floating signs of navigational aids. In addition, mud dredges shall be fitted with two green all-round lights (on the awning deck). Ships engaged in diving operations and self-propelled trailing suction hopper dredger (TSHD) shall be fitted with two green all-round lights.

10 Required for water-displacement passenger vessels intended for permanent operation within the harbourage and at the crossings, self-propelled ferries as well as tugboats and pushboats servicing non-propelled ships at the crossings. Cable ferries shall be equipped with one yellow all-round light.

11 Required for self-propelled ships with a breadth over 5 m.

12 Required for mud dredgers and ships engaged in underwater operations, sweeping the navigation pass, operation at the floating signs of navigational aids. Ships engaged in diving operations shall be fitted with two flags “À” (shields).

13 Required for fishing vessels.

14 Required for pushed vessels.

15 Ships with length of up to 50 m may be fitted with one white all-round light.

</tr>
</tbody>
</table>

1 Ships of 50 m in length and over shall be fitted with two masthead lights.
2 Only for hovercraft
3 For passenger ships and other types of ships with gross tonnage over 150
4 For ships with length of 100 m and over.
5 If the length of towing rope is over 200 m — three masthead lights and a diamond
6 Not required for ships pushing ahead or towing alongside.
7 Not required for ships being pushed.
9.2.4 All ships shall be fitted with the following spare parts for navigation lights:
   .1 light filters, one for each coloured light unless coloured lens is applied in the light;
   .2 electric lamps, one for each electric light.

9.2.5 In self-propelled ships less than 7 m in length masthead lights and light impulsive (light) lamps are not required.

9.2.6 Tugboats and pushboats intended for work with non-self-propelled ships carrying oil products, explosives and dangerous substances are additionally fitted with a red masthead light and red all-round light.

9.2.7 Self-propelled ships of M-СП and M-ПП class shall be fitted with a set of spare electrical lanterns comprising masthead, side, stern, all-round lights for vessels not under command (see Table 9.2.1-2), all-round lights for ships at anchorage and aground, towing light.

9.2.8 All ships shall be provided with lights being placed at aground at the level of a floating sign:
   from side/sides where navigation pass is free – white all-round light on the part of the ship protruding into navigation pass.
   from the side where passage is impossible at night – three red all-round lights, at daytime – three readily visible black balls located vertically.

9.3 STANDARDS FOR EQUIPPING WITH PYROTECHNICAL SIGNAL MEANS

9.3.1 Pyrotechnical signal means include distress signal parachute rocket and a hand flare.

9.3.2 Navigational and technical requirements to pyrotechnic means shall comply with 9.6.

9.3.3 Self-propelled, non-self-propelled ships with a crew (except for floating objects) shall be equipped with pyrotechnic means according to the standards specified in Table 9.3.3.

<table>
<thead>
<tr>
<th>Name of signal means</th>

<tr>
<td>One-star rocket, green</td>
<td>6²</td>
</tr>
<tr>
<td>Hand flare, white (not required when daytime visual or audible alarm is available)</td>
<td>6²</td>
</tr>
</tbody>
</table>

¹ Pyrotechnical means are not required in non-crewed non-self-propelled ships.
² Recommended

9.3.4 Ships of P class entering water reservoirs of P category shall be equipped with the same pyrotechnic means as ships operating in basins of О category.

9.3.5 Equipment of lifeboats with pyrotechnic means shall be taken according to Section 8.

9.3.6 For launching distress rockets on port and starboard of a ship a special slotted cup inclined at an angle of 60 to 70° from the horizon to the outside shall be fitted on railing of the navigation bridge wings or a bulwark.
9.3.7 Hand flares shall not be used in oil tankers or other ships intended for carriage of oil products as well as in pushboats and tugboats towing and pushing non-self-propelled oil tankers. Instead of hand flares, these ships may be provided with parachute rockets in a quantity exceeding the standards specified in Table 9.3.3 by 50%.

9.3.8 Distress signal parachute rockets may be replaced with ship red six-star rockets.

9.4 STANDARDS FOR EQUIPPING WITH SOUND SIGNAL MEANS

9.4.1 All self-propelled ships shall be fitted with air typhons or steam whistles and bells for giving sound signals.

9.4.2 In ships less than 25 m in length and in ships of O, P and J class not fitted with air receivers or steam boilers electric horns may be used as the main sound signal instead of typhons or whistles. Bells in ships of 10 m in length or less may be omitted.

9.4.3 In ships of М-СІ, М-ПР, М class, electric horn may be used as auxiliary signal means.

9.4.4 In ships less than 20 m in length electric car horns may be used as the main sound signal.

9.4.5 In non-self-propelled ships a signal bell or a metal plate shall be provided. In non-self-propelled oil tankers a bell or a plate shall be made of non-ferrous metals.

In non-crewed ships sound signal is not required.

9.5 NAVIGATION AND TECHNICAL REQUIREMENTS TO NAVIGATION LIGHTS AND DAYTIME SIGNALS

9.5.1 Navigation lights designed for inland and river-sea navigation ships shall be manufactured in compliance with the technical documentation approved by the River Register.

9.5.2 Navigation lights of ships operating on inland waterways shall have light angles and range of visibility as specified in Table 9.5.2-1 with regard to the following:

.1 the range of visibility of masthead lights of self-propelled ships less than 20 m in length shall be at least, km:

<table>
<thead>

</table>

1. In vessels less than 20 m in length the minimum range of visibility is three nautical miles.
2. The minimum range of visibility of white sector is two nautical miles.
3. The range of visibility shall be at least one nautical mile but less than that of other all-round lights.

Signal lights required for navigation in sea areas as well as lights with double function (lights used at navigation both on inland waterways and in sea areas) shall comply with requirements established in Tables 9.5.2-2 and 9.5.2-3.

9.5.3 Horizontal luminous intensity $I_n$ of one flash of signal flashing lights specified in Tables 9.5.2-2 and 9.5.2-3 shall be at least, cd:

$$I_n = (0.2 + t_n)I_n$$  \(9.5.3\)

where $t_n$ — flash duration, s;
Table 9.5.2-3

</tbody>
</table>

\(^1\) Recommended for accompanying sound signals with light signals

Note: Lights are white coloured.

1 — luminous intensity determined in accordance with 9.5.15.

9.5.4 Visibility angles of lights specified in Table 9.5.2-1 in the vertical plane shall be at least 10° either side from a horizontal plane crossing the centre of a light source.

9.5.5 Navigation lights shall be designed for operation in conditions stated in 2.2 Part VI of the Rules.

9.5.6 Navigation lights shall be made of corrosion-resistant materials or be protected with anti-corrosive coatings.

9.5.7 The lanterns shall be of such design as to ensure drainage of condensate. Electric lanterns shall be of protected design in accordance with requirements of 2.3.6 Part VI of the Rules.

9.5.8 The navigation lights shall be so designed as to allow opening and closing of the lantern case as well as rapid change of electric lamps without using tools.

9.5.9 The lamps in the lanterns shall be located vertically and be in the lens focus. Measures shall be taken to prevent from self-unscrewing.

Two-filament lamps shall not be used in the navigation lights.

9.5.10 Inner surfaces of navigation lanterns shall be covered with a protective coating resistant to temperature and moisture which does not impair the colour and light characteristics of the lanterns.

9.5.11 The navigation lanterns may be fitted with lenses and plain glasses provided the minimum range of visibility meets the requirements of Tables 9.5.2-1 and 9.5.2-2 and the curve of vertical light distribution of the lantern – requirements of the present paragraph.

The inner and outer surfaces of the lenses and plain glasses shall be smooth, and the glass shall be free from foreign inclusions, blisters and chippings impairing the lantern characteristics.

The lenses of the navigation lanterns shall be so designed that the curve of vertical light distribution of the lantern shall ensure:

1. luminous intensity not less than specified in Table 9.5.15 within the range of visibility in the vertical plane up to 5° from the horizontal plane of symmetry of the lens;

2. not less than 60% of the luminous intensity specified in Table 9.5.15 within the range of visibility up to 7.5° on either side from the horizontal plane of symmetry of the lens.

The curve of horizontal light distribution of the side lights shall be such that lanterns fitted in the ship have the luminous intensity from right ahead, as prescribed in Table 9.5.15, which shall decrease and disappear between 1° and 3° outside the limit sectors.

For sternlights and masthead lights as well as arcs of 22.5° abaft the beam for sidelights the specified luminous intensity shall be maintained up to 5° within sectors prescribed in Tables 9.5.2-1 and 9.5.2-2. From 5° within the prescribed sectors the intensity may decrease by 50% up to the sector limit; then it shall gradually decrease to reach practical cut-off within not more than 5° outside the prescribed limits as specified in Tables 9.5.2-1 and 9.5.2-2.

9.5.12 The coloured light filters and lenses shall comply with the following requirements:

1. the colouring of the navigation lights may be obtained using appropriate light filters or coloured lenses. Plain coloured glasses may be used provided that the chromaticity of the filter is ensured over their whole surface.
Coloured lenses may be used subject to technical justification;
.2 the coloured light filters used in the navigation lights may be manufactured of glass coloured throughout its entire thickness or over the surface only.

The light filters may be manufactured of plastics provided all their characteristics are in all cases are at least equal to those of glass light filters;
.3 corner coordinates \( \alpha \) and \( \beta \) of the allowable zones for each colour are given in Table 9.5.12.3.

<table>
<thead>
<tr>

</tbody>
</table>

Here the colour of light is considered as a result obtained in the light filter – source of light optical system.

The luminous transmission factors of the coloured light filters shall have such values as to ensure the specified range of visibility of the lights according to the requirements of Tables 9.5.2-1, 9.5.2-2 and requirements of 9.5.11;
.4 the height and the length of the arc of a coloured light filter shall be such as to cover the whole inside surface of the lens;
.5 the inner and the outer surfaces of the light filters shall be free from notches and indentations, and the filter glass shall be free from blisters, foreign inclusions and drops degrading the characteristics of the lanterns;
.6 the light filters shall be fixed in the lanterns in such a way as to prevent their spontaneous shifting in course of their use on board.

9.5.13 Removable light filters shall be fitted with metal reinforcement throughout their periphery or other equivalent protection against chipping or mechanical damages which may occur during their use and storage.

9.5.14 The light filters of sidelights and their fittings shall be so designed as to avoid placing the red filter to the starboard lantern, and the green filter – to the port lantern.

9.5.15 The permissible luminous intensity \( I, \) cd, in the lanterns to ensure the range of visibility required in Table 9.5.2-1 shall be not less than that determined by the formula:

\[
I = 3.43 \cdot 10^6 T d^2 k^{-d}, \tag{9.5.15}
\]

where \( T \) — threshold factor, lux;
\( T = 2 \cdot 10^7 \) lux;
\( d \) — range of visibility of the light, nautical miles;
\( k \) — atmospheric transmission factor corresponding to meteorological visibility of approximately 13 nautical miles; \( k \) shall be taken equal to 0.8.

Luminous intensity values calculated by formula (9.5.15) are given in Table 9.5.15.

The maximum permissible luminous intensity of lanterns may be increased by more than 1.7 times as compared to values given in Table 9.5.15, but it shall not exceed 150 cd.

Reflectors in the navigation lanterns are not allowed.

9.5.16 A daytime signalling lamp (see GOST R ISO 25861) to be stowed in the wheelhouse or charthouse and be always ready for use shall meet the following requirements:
.1 daytime signalling lamp shall be so designed to remain operable under conditions specified in 2.2 Part VI of the Rules;
.2 At daytime, at atmospheric transmission factor of 0.8, range of visibility of light signals emitted by daytime signalling lamps shall be at least equal to that in Table 9.5.2-3 or correspond to luminous intensity of 60000 cd;

.3 Luminous intensity along the axis of the light beam of the daytime signalling lamps shall be at least 90% of maximum luminous intensity;

.4 Luminous intensity of the daytime signalling lamp shall be maximum at the centre of luminous intensity distribution and uniformly decrease from this centre to the distribution periphery;

.5 The half of the angle of deviation shall not exceed 9°, the tenth of the angle of deviation shall not exceed 14°;

.6 Colour characteristic of the white signal light shall be within angular coordinates specified in Table 9.5.12.3;

.7 The effective light area of the daytime signalling lamp shall be circular in shape. The total time of activation and deactivation shall not exceed 500 ms;

.8 The daytime signalling lamp shall be marked with its operating specifications;

.9 The daytime signalling lamp and storage battery required for its operation shall ensure safe operation and easy use by one person. Provision shall be made to use the daytime signalling lamp wearing gloves;

.10 The daytime signalling lamp shall be designed so as:

- to provide for safe installation of a light source (avoid threaded lampholders);
- to be able to replace a light source in the dark;
- to prevent condensate in the lamp;
- to ensure protection at least IP 56;

.11 Sighting device shall be fixed in parallel to optical axis of the lamp;

.12 All parts of the daytime signalling lamp shall be made of non-magnetic materials;

.13 The materials used in the lamp shall be suitable for temperature which may occur during its operation. Outer parts of the daytime signalling lamp shall be heated during operation up to the temperature which may result in injury of the operator when used manually;

.14 Each daytime signalling lamp shall be equipped with at least three spare light sources;

.15 The daytime signalling lamp shall be protected against short-circuit currents;

.16 Provision shall be made for powering of the daytime signalling lamp not only from ship’s main and standby electric power sources but also from other sources;

.17 The daytime signalling lamp shall be equipped with portable storage battery with the weight of max. 7.5 kg in total;

.18 Capacity of the portable storage battery shall be sufficient for operation of the daytime signalling lamp with at least 2 h;

.19 Provision shall be made for arrangements to protect against overcurrent, overvoltage and short-term accidental power source reverse polarity;

.20 When powered from different sources, provision shall be made for arrangements to switch from one power source to another. The daytime signalling lamp may not include such arrangements;

.21 The light source shall be marked with the name of the manufacturer, voltage and power consumption.

9.5.17 The manoeuvring lantern specified in Table 9.5.2-3 shall send flashing light signals within the whole manoeuvring period of the ship. The duration of each flash and the interval between flashes shall be about 1 s and the interval between successive signals – at least 10 s.

9.5.18 Signal shapes (daytime signals) shall be of black colour; the ball shall have a diameter of at least 0.6 m and the diamond shall consist of two cones with a common base with dimensions of each cone at least \( dh = 0.6 \times 0.6 \text{ m} \), where \( d \) is the diameter of the cone base and \( h \) the cone height.

9.5.19 The signal flags shall be made of special woolen cloth (bunting) or synthetic materials.
9.5.20 The signal flags shall be of square shape. The square side shall be at least 1000 mm, and for hand flags — at least 700 mm. In ships less than 25 m in length the flag side shall be at least 500 mm.

9.6 REQUIREMENTS TO PYROTECHNIC SIGNAL MEANS

9.6.1 The distress signal pyrotechnic means shall be safe in handling and during storage for the whole warranty period.

9.6.2 Pyrotechnic signal means shall be protected against moisture and mechanical damage. Storage cases for pyrotechnic signal means shall be capable of opening without using any tools.

9.6.3 Each pyrotechnic signal means shall bear the following made with indelible paint: stamp of the manufacturer, the date of manufacture, storage period, purpose and operating manual. On signal rockets the launching direction shall be indicated with an arrow.

9.6.4 Signal rockets shall be so designed as to ensure its launching both by hand (without using special arrangement) and using special arrangement.

9.6.5 All pyrotechnic signal means shall be vibration-resistant, moisture-resistant and non-extinguishable at a wind speed up to 30 m/s. They shall keep their properties at air temperature from –45 to +45 °C and be capable of operating at rain.

9.6.6 Characteristics of ship pyrotechnic signal means shall comply with the requirements of Table 9.6.6.

9.6.7 The parachute rocket shall have integral means of ignition and be so designed as not to cause discomfort to the operator when using it in accordance with the manufacturer’s instructions.

9.6.8 The hand flare shall:

.1 have integral means of ignition;

.2 be so designed as not to endanger the ship or collective life-saving appliance by burning or glowing residues when used in accordance with the manufacturer’s instructions;

.3 continue burning after having been immersed for 10 s under 0.1 m of water.

9.7 REQUIREMENTS TO SOUND SIGNAL MEANS

9.7.1 Whistles and typhons shall produce sound signals without sound level oscillations, hissing or other distortions. The beginning and the end of a signal shall be clearly audible.

9.7.2 The design and material of sound signal means for ships operating on inland waterways shall provide the range of audibility not less than that specified in Table 9.7.2.

9.7.3 Basic specifications of whistles for ships operating on sea areas shall comply with requirements of Table 9.7.3. The range of audibility shall be determined by such frequencies which may include the main and (or) one or several higher frequencies within 180 to 700 Hz ±1% which provide the required sound pressure levels.

9.7.4 A bell or gong of ships operating on sea areas or other facility with similar sound characteristics shall produce a sound pressure level of at least 110 dB at 1 m.

9.7.5 Bells and gongs of ships operating on sea areas shall be made of corrosion-resistant material and shall produce the sound of even tone.

No painting of the bell or gong is permitted. An outer diameter at the bell mouth shall be not less than 300 mm for ships with a length over 20 m and not less than 200 mm for ships with a length of 12 to 20 m. The total weight of movable (suspended) part of the bell (rod with striker) shall be at least 3% of the whole bell weight.

9.8 GENERAL REQUIREMENTS TO FITTING OF SIGNAL MEANS ON BOARD

9.8.1 The navigation lights shall be so located that during the whole lighting period no other lights or external illumination which may be taken for signal or navigation lights are visible.

9.8.2 Lights of all-round visibility (360°) in horizontal plane, excepting anchor lights, shall be so located as not to be obscured by masts, topmasts or superstructures within sectors of more than 6°. In this case, the lantern shall be considered as an all-round source of light with the diameter equal to the outside diameter of the source of light (filament of the lamp).

9.8.3 When the requirement of 9.8.2 cannot be met, it is permitted to install a system of lanterns for each light. Each of the systems shall be placed in the same horizontal plane. In this case measures shall be taken to prevent the lights of these lanterns from being seen separately in any direction.

9.8.4 All regular places of location of the navigation lights shall be provided with arrangements for their replacement and installation.

9.8.5 The accuracy of installation of the sector lights shall be controlled by their position as regards the centreline plane of a ship. The horizontality of installation of the lights shall be checked for ship’s fully loaded condition.

9.8.6 When several lights to be switched on simultaneously are placed on a mast one over the other on board ships operating in inland waterways, they shall be spaced not less than 1 m apart.

When lights are fitted in a vertical line one over the other on mast of the ships operating on inland waterways, the lights shall be spaced not less than 2 m apart and the lowest of these lights shall, except where a towing light is required, be not less than 4 m above the hull.

9.9 FITTING OF MASTHEAD AND MANOEUVRING LIGHTS

9.9.1 The masthead lights excepting lower ones on pushboats shall be located in the centreline plane of a ship. The vertical distance between the masthead light (lower masthead lights in tugboats and pushboats) and sidelights shall be at least 1 m.

9.9.2 The masthead lights in pushboats shall be located as an equilateral triangle with a side of 1 to 3 m with the base located downwards and the top in the centreline plane. The red masthead light shall be placed directly above the upper white masthead light regardless of requirements of 9.8.6.

9.9.3 The masthead lights on tugboats shall be placed on a mast vertically with due regard of 9.8.6.

9.9.4 On self-propelled ships of a length 50 m and over masthead lights shall be placed in the fore and aft at least 20 m apart. The vertical distance between them shall be such as under all normal conditions of trim the forward light is not less than 1 m lower than the after light; here, the forward masthead light may be located lower than the sidelights.
and the after light — abaft and not less than 1 m above them.

9.9.5 The forward masthead light on board ships operating in sea areas shall be placed on the foremost in the centreline of a ship at a height of at least 6 m above the main deck. When the breadth of a ship exceeds 6 m, then this light shall be placed at a height not less than the ship's breadth but no more than 12 m above the main deck.

9.9.6 The after masthead light of ships operating on sea areas shall be fitted in the centreline of the ship. The vertical distance between the forward and the after masthead lights shall be at least 4.5 m. The horizontal distance between these lights shall be at least 0.5 of the ship's length; the forward masthead light shall be fitted not be more 0.25 of the ship's length from the stem.

Where only one masthead light is prescribed for the self-propelled ship, this light shall be located ahead of the midship.

9.9.7 A ship which requires masts to be hinged in order to pass under bridges may be fitted with a reserve masthead light in the fore part; it may be placed below the sidelights. In a ship of 50 m and over in length this light may be permanently used as a forward masthead light provided the requirements of 9.9.4 are met.

9.9.8 All masthead lights shall be fitted with horizontal screens below to prevent persons in the wheelhouse and the deck from dazzling.

9.9.9 In ships operating in sea areas, the manoeuvring light shall be placed in the centreline and, as far as practicable, at a height of not less than 2 m from the forward masthead light; it shall be also placed at least 2 m higher or lower than the after masthead light.

In a ship fitted with only one masthead light the manoeuvring light shall be placed in a position where it can best be seen at a distance of at least 2 m in the vertical above the masthead light.

Where simultaneous actuation of light and sound signals is provided, separate actuation of light signals shall be also foreseen.

9.10 FITTING OF SIDELIGHTS

9.10.1 Sidelights (the red sidelight on the port and the green sidelight on the starboard) shall be clearly visible to the ships coming from the opposite direction and overtaken ships within the ranges of visibility defined in 9.5.2. The lanterns and their enclosures shall not extend beyond the overall breadth of a ship.

9.10.2 Sidelights shall be located in a horizontal line symmetrically to the centreline of a ship and placed in the following way:

.1 in open vessels — at least 0.5 m above the gunwale (in particular well-grounded cases the lantern may be placed at the gunwale level);

.2 in ships with a single-tier superstructure (deckhouse) — in its upper part;

.3 in ships with a double-tier or multi-tier superstructure — not lower than the wheelhouse deck.

9.10.3 Each sidelight shall be enclosed from the side by special lantern shield with two fore and aft transverse screens.

The distance between the outer edge of the protective glass or lens of the lanterns fitted in ships of 25 m in length and over and the after edge of the fore transverse screen shall be not less than 915 mm. The shield length for these lanterns shall be not less than 1 m.

The fore transverse screen shall be of such breadth that a line joining its outer edge and the centre of the light source is parallel to the centreline of the ship. The aft transverse screen shall be of such breadth as to mask completely the lantern from being seen across the stern, but not hinder showing its light to 22.5° abaft the beam.

9.10.4 The sidelights in self-propelled ships operating on sea areas shall be placed abaft the forward masthead light and above the hull at a height not greater than 0.75 of the height of the forward masthead light.

The sidelights in non-self-propelled ships operating on sea areas shall be placed in the fore part of the hull.

9.10.5 The side lanterns may be placed in recesses of the superstructures or deckhouses.
The dimensions of the recesses shall comply with the dimensions of the lantern shields; the recesses shall be fitted with the same screens as those of the lantern shield.

9.10.6 The inner surfaces of the lantern shield and recesses shall be painted matt black.

9.10.7 In ships less than 25 m in length and in hydrofoil craft and hovercraft the shield dimensions may be reduced or the shields may be omitted if the ranges of visibility of the lights defined by 9.5.2 are ensured.

9.11 FITTING OF STERNLIGHTS AND TOWING LIGHTS

9.11.1 In ships carrying one sternlight this lantern shall be located abaft the chimney or superstructure in the centreline of a ship and, as far as practicable, at the same height with sidelights but not above them.

9.11.2 In ships carrying three sternlights the upper one shall be placed as per 9.11.1 and the two lower ones — on the bulwark or after end walls of a bulkhead close as far as practicable to the sides in one horizontal line symmetrically to the centreline of the ship.

9.11.3 In ships operating in sea areas, the sternlight shall be placed in the centreline of a ship on the bulwark gunwale, after handrail or on the after wall of the poop deckhouse.

In tugboats operating on sea areas the sternlight may be placed on a chimney (false chimney, wall of the deckhouse) above the towing arrangement. In all cases the sternlight shall be placed lower than the side lights.

9.11.4 Towing light shall be placed in the centreline above the sternlight. The vertical distance between those lanterns shall be at least 0.5 m.

9.11.5 The towing lights in ships operating on sea areas shall be placed upper and/or lower the forward or after masthead lights with regard to 9.8.6.

9.11.6 Towing light in ships operating on sea areas shall be fitted above the sternlight with regard to 9.8.6.

9.12 FITTING OF ALL-ROUND AND ANCHORAGE SIDE LANTERNS

9.12.1 All-round lantern with white light for self-propelled ships operating on inland waterways used during anchorage shall be located in the ship's fore part. This lantern may be fitted on a mast, flagstaff or be hoisted on a stay.

9.12.2 All-round white lights (anchor lights) for ships operating on sea areas shall be placed in the fore and after parts of the vessel, the forward all-round white light shall be carried at a height of not less than 6 m above the hull. The stern all-round white light shall be placed not less than 4.5 m lower than the same forward light.

Where only one all-round lantern is required in accordance with Tables 9.5.2-1 and 9.5.2-2, it shall be placed in a position where it can best be seen.

All-round lanterns with white light may be installed either in fixed position on special uprights or by means of a special hoisting gear.

9.12.3 An all-round red light shall be placed higher than all-round white lights. This lantern shall not be located in one vertical line with anchorage lights.

9.12.4 In ships operating on sea areas two all-round red lights (“Vessel not under command”) shall be placed on a visible place in a vertical line one over the other with due regard of the requirements of 9.8.2, 9.8.3 and 9.8.6 either in fixed position or by means of a hoisting gear.

9.12.5 Yellow flashing all-round lantern shall be placed in a place where it can best be seen; it may be located in one vertical line with the masthead light above.

9.12.6 Side anchorage lanterns shall be placed at sides on the edges of the pilot bridge wings. In coastal vessels one anchorage side-light is fitted at the running side.
9.13 FITTING OF LIGHT IMPULSIVE (LIGHT) LAMPS

9.13.1 Light impulsive (light) lamps shall be fixed pairwise (fore and aft) at each side of a ship above the sidelights at the height not less than 0.5 m and in ships up to 12 m in length — at the height not less than 0.25 m from them.

9.13.2 The lamps shall be switched on separately of each other.

9.14 FITTING OF ALL-ROUND LANTERNS IN FISHING VESSELS

9.14.1 All-round lanterns in fishing vessels shall be placed vertically on the mast at mid-ship with the white lantern being located below red and green lanterns.

9.14.2 One white lantern and one red lantern shall be able to be switched on separately of each other.

9.15 FITTING OF NAVIGATION LIGHTS IN NON-SELF-PROPELLED SHIPS AND INDUSTRIAL SHIPS

9.15.1 Non-self-propelled ships shall be fitted with two fore and aft flagstaffs for installation of the masthead and white all-round lanterns. These lanterns shall be located in the centreline of a ship in the following way:

1. the masthead light — in the fore part, generally, 2 m above the deck;
2. white all-round lanterns — in the fore and after parts at least 2 m above the highest deck or 1 m above the deck cargo.

9.15.2 In oil tankers and ships carrying dangerous goods besides fore and after flagstaffs a mast for carrying red all-round light shall be fitted as per 9.12.2. This mast shall be equipped for hoisting the daytime signals.

9.15.3 White all-round lantern in landing stages, floating workshops, firewatch vessels shall be placed on a mast in the midship at least 2 m above the superstructure roof.

In oil processing stations over 50 m in length the lanterns shall be placed in the fore and aft parts. The red all-round lantern shall be located as per 9.12.2.

9.15.4 All-round lanterns in mud dredgers and ships engaged in underwater or diving operations shall be placed vertically on the mast. One white and one red all-round lanterns shall be able to be switched on separately of each other.

In mud dredgers one green all-round light shall be placed on the mast. In the fore and aft parts on each side 2 all-round lanterns, green and red, shall be located at the awning level.

9.16 FITTING OF SOUND SIGNAL MEANS

9.16.1 Steam whistles and air typhons shall be located at least 2.5 m above the uppermost deck and be raised over the surrounding objects located on the uppermost deck excepting masts and smoke funnels.

9.16.2 In ships less than 25 m in length sound signal means shall be located not lower than the wheelhouse roof (or directly on it).

9.16.3 The signal bell shall be located as far as practicable at fully clear parts in the fore part of the ship. The bell shall be freely hung up in such a manner as not to touch the surrounding objects in list conditions.

9.16.4 The gong shall be placed as near the after end of the ship as practicable in such a place where nothing will intercept the propagation of sound, and shall be hung up freely so as to avoid contact with nearby items in list conditions.

The gong beetle shall be kept in a special pocket to be fitted close to the gong.

9.17 STORAGE OF SPARE AND PORTABLE SIGNAL MEANS ON BOARD

9.17.1 For storage of non-fixed signal means and spare lanterns ships shall be fitted with special easily accessible store rooms, lockers or boxes which are recommended to be arranged in way of the wheelhouse.

9.17.2 Signal lantern rooms shall be fitted with metal shelves with arrangements for reliable securing of the lanterns to prevent their shifting at rolling.
9.17.3 For storage of signal flags special shelves shall be provided with separate clearly designated cells for each flag. The shelves shall be arranged in the wheelhouse or on the pilot bridge wings at a place protected against precipitation and direct sunlight.

9.17.4 For storage of signal pyrotechnical means gas-tight metal lockers shall be provided in way of the pilot bridge wings or in the wheelhouse. The lockers shall be fitted with tight doors opening outwards to the wheelhouse deck.

In ships less than 25 m in length a gas-tight metal locker for storage of pyrotechnical means may be arranged in the wheelhouse.
10 NAVIGATION OUTFIT

10.1 GENERAL PROVISIONS

10.1.1 The present Section of the Rules establishes standards of navigation outfit for ships.

10.1.2 Requirements of the present Section for navigation outfit completeness apply to ships under design and construction as well as to ships in service.

10.2 NAVIGATION OUTFIT STANDARDS

10.2.1 To determine navigation outfit standards ships are divided into three categories:

I — self-propelled ships with an overall length over 25 m;

II — self-propelled ships with an overall length of 25 m and less;

III — non-self-propelled ships.

10.2.2 Navigation outfit of ships shall be assigned according to the standards specified in Table 10.2.2 according to the navigation basin and ship categories.

10.2.3 Navigation outfit may be omitted:

in ships of 10 m and less in overall length navigating in basins of P and І класс categories;

in non-crewed ships of category III.

10.2.4 Inclinometer may be omitted in hydrofoil craft, hovercraft and skimming vessels.

10.2.5 Non-self-propelled ships of І класс, ІІ класс and ІІІ класс class carrying people on board shall be fitted with binoculars, manual sounding lead and an inclinometer.

11 EMERGENCY OUTFIT

11.1 GENERAL PROVISIONS

11.1.1 Requirements of the present Section apply to ships under design and construction as well as to ships in service. For the purposes of this Section, the length shall mean an overall length.

11.1.2 Emergency outfit is not required in ships of the following types:

- .1 non-crewed non-self-propelled ships;
- .2 non-self-propelled ships with a single-compartment floodability;
- .3 crewed non-self-propelled ships of P and І class less than 30 m in length;
- .4 non-self-propelled tankers regardless of the length;
- .5 passenger ships and ferries with one-hour trip or less;
- .6 coastal vessels;
- .7 self-propelled ships of О, І class with a number of crew members not more than three per trip;
- .8 self-propelled ships of P and І class with a length less than 25 m;
- .9 hydrofoil craft, hovercraft and skimming vessels.

Emergency outfit is not required for floating objects.

11.1.3 Tugboats and pushboats operating with non-self-propelled ships listed in 11.1.2, shall be fitted with emergency outfit as for ships having a group one position higher than the group of the given tugboat or pushboats (see 11.2.1). Tugboats and pushboats over 15 m in length regardless of 11.1.2.7 and 11.1.2.8 shall be fitted according to the standards for ships of Group V.

11.1.4 For non-self-propelled ships of М-СІ, М-ПІ and О-ПІ class emergency outfit shall be taken according to the standards specified in Table 11.2.2 for ships of Group VI. These ships are additionally fitted with a set of rigging tools according to the standards specified in Table 11.2.4.

11.1.5 Outfit items listed in Tables 11.2.2, 11.2.3 and 11.2.4 and available on board but intended for other purposes may be considered as emergency outfit items.

11.2 EMERGENCY OUTFIT STANDARDS FOR SHIPS

11.2.1 In order to determine the emergency outfit standards ships are divided into 10 groups:

I — self-propelled ships of М and О class with a length over 90 m;
II — self-propelled ships of М and О class with a length of 40 to 90 m inclusive;
III — self-propelled ships of М and О class with a length of 25 to 40 m inclusive and ships of P and І class over 70 m in length;
IV — self-propelled ships of P and І class with a length of 40 to 70 m inclusive;
V — self-propelled ships of P and І class with a length of 25 to 40 m inclusive and ships of М and О class with a length up to 25 m;
VI — non-self-propelled ships of М-СІ, М-ПІ, О-ПІ, M and О class;
VII — non-self-propelled ships of P and І class with a length of 30 m and over;
VIII — self-propelled ships of М-СІ and М-ПІ class with a length of 70 to 140 m;
IX — self-propelled ships of М-СІ and М-ПІ class with a length of 30 to 70 m inclusive and self-propelled ships of О-ПІ class with a length of 30 to 140 m;
X — self-propelled ships of М-СІ, М-ПІ and О-ПІ class with a length of less than 30 m.

11.2.2 In all ships other than listed in 11.1.2 the emergency outfit shall be available
according to the standards specified in Table 11.2.2.

**11.2.3** Set of fitter's tools specified in Table 11.2.2 shall be completed as per Table 11.2.3.

**Table 11.2.2**

#### 11.3 MATS

**11.3.1** Mats shall be made of tarpaulin with waterproof impregnation or other equivalent cloth. They shall be edged with four embedded thimbles at the corners. Cringles shall be also provided in quantity equal to the number of ropes specified in Table 11.3.2.

**11.3.2** Technical parameters and outfit of the mats shall be assigned as per standards stated in Table 11.3.2.

#### 11.3.3

The length of each sheet \( L_{sh} \), m, shall be determined by the following formula:

\[
L_{sh} = 1.6 \left( D + 0.5B \right),
\]

where \( D \) — side depth from the keel to the upper edge of the bulwark, m;

\( B \) — overall breadth of a ship, m.

The length of guy shall be at least \( 2L_{sh} \).

The length of control lanyard shall be equal to the sheet length.

The length of each keel hauling line \( L_{k,h,l} \), m, shall be determined by the following formula:

\[
L_{k,h,l} = 1.6 \left( 2D + 0.5B \right),
\]

The length of sheets, keel hauling lines, guys and lanyards for mats which shall be provided in ships as per 11.1.3, shall be calculated according to the dimensions of the biggest ship in a convoy.

#### 11.3.4

Mats shall be made of natural fibre strands and thrummed with natural spun line. A tarpaulin shall be sewed from the bottom side of the mat.

### 11.4 ARRANGEMENT OF EMERGENCY OUTFIT

**11.4.1** An emergency station shall be provided for arrangement of the emergency outfit located not lower than the main deck.

In ships less than 40 m in length the emergency station may be located lower than the main deck provided it is easily accessible.

As the emergency station a special space, box or assigned place on the deck or in the ship’s spaces may be used.

In ships less than 20 m in length the emergency outfit may be located in several spaces.

**11.4.2** Width of free passage before the emergency station shall be at least 0.8 m and in ships less than 30 m in length — at least 0.6 m.

### 11.5 MARKING

**11.5.1** Emergency outfit items or pack for their storage excepting mats shall be painted blue, totally or with a stripe.

</table>

The storage pack for emergency outfit shall bear clear inscription indicating the material, weight and permissible storage period of the outfit.

11.5.2 In the vicinity of the emergency station there shall be clearly visible inscription “Emergency station”. In addition, in the passages and on the decks the position indicators of the emergency station shall be provided.

Provision shall be made for lightning from emergency power source in the vicinity of the emergency station.

When the emergency outfit is stored in several spaces, the diagram of its location on board shall be placed in the wheelhouse.
12 WHEELHOUSE EQUIPMENT

12.1 GENERAL REQUIREMENTS

12.1.1 Control consoles fitted in the wheelhouse shall be provided with ship, engine, appliance, systems and equipment controls (levers, handles, wheels, button and key-operated switches, switches) as well as display and alarm devices and the requirements of 11.12 Part IV of the Rules shall be met.

12.1.2 Steering gear remote control system elements shall be arranged in the wheelhouse so that to the selected heading is visible to the navigator from the control station. If the mentioned remote control system is designed as disconnectable, provision shall be made for ON or OFF position indicators/indicator. The remote controls shall be arranged and manipulated in such a way to be easy to use by the navigator. Non-fixed equipment for remote control of such auxiliary (in terms of steering gear) arrangement as active bow rudders shall be used provided that control of these auxiliary arrangements may be any time transferred to the wheelhouse.

12.1.3 The wheelhouse shall be equipped with adjustable heating and ventilation system complying with requirements of 10.12 Part IV of the Rules. The arrangement for darkening of the wheelhouse shall not prevent its ventilation.
13 ADDITIONAL SHIP’S OUTFIT

13.1 GENERAL REQUIREMENTS

13.1.1 All crewed ships shall be equipped with loudhailer, boat hook and gangway 400 mm wide with a guardrail with the length according to the type and design features of the ship.

13.1.2 Ships of M-CP class shall be fitted with a line-throwing appliance with four projectiles and four lines.

14 EMBARKATION LADDERS FOR SHIPS OF M-CP, M-IP AND O-IP CLASSES

14.1 GENERAL REQUIREMENTS

14.1.1 Embarkation ladder shall be provided in every self-propelled ship near the muster station of the collective life-saving appliances being launched along the ship’s side.

This requirement does not apply to cargo and passenger ships with gross tonnage less than 500, in which boarding on the liferafts is carried out from the deck located less than 2 m (less than 1.5 m in passenger ships) above the waterline corresponding to the minimum operational draught.

14.1.2 Every self-propelled ship shall be fitted with a pilot embarkation ladder as well as arrangements for its installation on any side of a ship. The boarding place of the pilot shall be clearly marked.

14.1.3 In each place of installation of the pilot embarkation ladder there shall be a life-buoy with self-igniting buoy as well as throwing line.

14.1.4 The pilot embarkation ladder and the area outside the ship in the boarding place of the pilot shall be adequately illuminated.

14.1.5 Embarkation ladders shall be located outside the drainage outlet areas and, as far as practicable, outside the sharp lines of the ship; each ladder rung of the ladder shall be reliably set against the ship’s side.

When this requirement cannot be met due to design features of a ship (i.e., fender bars), measures shall be taken to ensure safe boarding.

14.1.6 Handrails shall be provided to ensure a safe passage from the deck to the embarkation ladder and vice versa.

14.1.7 Embarkation and pilot ladders shall comply with requirements of national standards, the ladder structure shall be continuous (not consist of separate sections) and have such length that to reach the water level at the place of installation at any operational draughts and trims of a ship as well as in conditions of list of 15° to the opposite side.

1 GOST R ISO 799, GOST R ISO 5489.
CALCULATION METHOD FOR HYDRODYNAMIC LOADS, BENDING MOMENTS, SHEAR FORCES AND SUPPORT REACTION FORCES ACTING IN THE STOCK-RUDDER SYSTEM

1 This Appendix establishes the method for accounting for a non-uniform nature of hydrodynamic load distribution over the height of ship's rudders and calculation methods for bending moments, shear forces and support reaction forces acting in the stock-rudder system.

2 Hydrodynamic loads (resultant of hydrodynamic forces and torque) acting on the rudder shall be determined based on experimental or calculation results for all possible range of rudder angles.

3 When calculating hydrodynamic forces acting on the rudder within the propeller jet or steerable nozzle, the effects of the ship's hull and propeller jet shall be taken into account.

4 When determining hydrodynamic forces acting on the rudder within the propeller jet or steerable nozzle experimentally, the compliance between load factors for model and full-scale propeller shall be ensured:

\[ C_T = \frac{8T_p}{\rho V_A^2 \pi D^2}, \]  
(A1.4)

where:
- \( T_p \) — propeller thrust, kN;
- \( \rho \) — water density, t/m³;
- \( V_A \) — propulsion and steering system inflow velocity, m/s;
- \( V \) — design speed of a ship in loaded condition (for pushboats — together with the convoy), m/s;
- \( W_f \) — wake factor for straight motion of the ship by calculation of propulsion ability;
- \( D \) — propeller diameter, m.

5 Bending moments, shear forces and support reaction forces acting in the stock-rudder system shall be calculated according to methods shown in Fig.A1.5-1 to A1.5-3.

Calculation shall be performed for such combination of hydrodynamic loads when the stock is subject to maximum equivalent stresses defined in accordance with 1.2.2 of this Part of the Rules.

Maximum unit load intensity \( q \), kN/m shall be calculated by the following formula:

\[ q = R \left[ l_{10} \left( \frac{0.45D}{l_{10}} - 0.975 \right) f + 0.95 \right], \]
(II1.5-1)

where:
- \( D \) — propeller diameter, m;
- \( l_{10} \), \( l_{10} \) — lengths of steering gear elements (see Fig. A1.5-1 to A1.5-3), m;
- \( R \) — resultant force on a rudder, kN;
- \( f \) — coefficient considering non-uniformity of load distribution for suspended rudders and rudders with support on sternframe heel determined by Table A1.5 depending on load factor \( C_T \) and relative height of the part of the rudder protruding from the jet \( \left( \frac{l_{10} - D}{l_{10}} \right) \).

For semi-suspended rudders, totally or partially falling into the propeller jet when the ship is moving ahead at \( \left( \frac{l_{10} - D}{l_{10}} \right) \leq 0.4 \), coefficient considering non-uniformity of load distribution shall be taken...
Fig. A1.5-1. Calculation method for moments, forces and reaction forces acting in the stock-suspended rudder system

Fig. A1.5-2 Calculation method for moments, forces and reaction forces acting in the system of stock and rudder with lower support on sternframe heel

\[ f = -1.625 \left[ \left( \frac{l_{10} - D}{l_{10}} \right)^2 \right] + 1.75 \left( \frac{l_{10} - D}{l_{10}} \right) + 0.65. \]  
\[ (A1.5-2) \]

For rudders totally beyond the propeller jet, $f$ is taken equal to 0.

Jet diameter is taken to be equal to propeller diameter.

For rudders downstream of the propeller, for the astern motion of the ship, $f$ is taken equal to 0.

Support rigidity factor $Z$, kN/m shall be determined as follows:

For support on sternframe heel

\[ Z = \frac{1}{u_b}; \]  
\[ (A1.5-3) \]

For support in the rudder horn

\[ Z = \frac{1}{(u_b + u_5 + u_6)}; \]  
\[ (A1.5-4) \]
Fig. A1.5-3. Calculation method for moments, forces and reaction forces acting in the system of stock and rudder with pins on sternframe hinges

where \( u_b \) — displacement of the support due to bending when the force of 1 kN is applied to the support centre:

\[
u_b = l_{50} \cdot 10^3 / (3EJ_{50})
\]

where \( u_s \) — displacement of the support due to shear when the force of 1 kN is applied to the support centre:

\[
u_s = l_{50} \cdot 10^3 / (GF)
\]

where \( u_t \) — displacement of the support due to horn torsion when the force of 1 kN is applied to the support centre:

\[
u_t = l_{50}l_{60} \cdot 10^3 / (Gl_t)
\]

\( E \) — Young’s modulus of the horn and sternframe heel material, MPa;

\( G \) — shear modulus of horn material, MPa;

\( F \) — average cross-sectional area of the rudder horn, m²;

\( J \) — average polar moment of inertia of cross-sectional area of the rudder horn, m⁴;

\( J_{10} - J_{60} \) — moments of inertia of appropriate sections of steering gear elements, m⁴.

Where a bending moment applied to the rudder stock is determined experimentally, the idealized law of load distribution over height as shown in Fig. A1.5-1 to A1.5-3 may be neglected.

6 When the lateral force from the steering drive is transmitted to the rudder stock, this force and corresponding bending moments shall be taken into account when stock strength is calculated.

7 When calculating the height of the plain bearing sleeve, assumed design reaction from the rudder stock being side \( b_h \) kN, for suspended rudder and rudder with lower support on sternframe heel shall be not less than determined by the formula:

\[
B_{sw} = \left[ R(\eta l_{10} + l_{30} + l_{40}) - B_{at}(l_{10} + l_{20} + l_{30} + l_{40}) \right] / l_{40},
\]

where \( \eta \) — nondimensional arm of bending moment (Table A1.7).

</table>

\( B_{at} \) shall be taken in accordance with 8, for suspended rudders, \( B_{at} = 0 \).

Element lengths \( l_{10}, l_{30}, l_{40} \) shall be determined in accordance with Fig. A1.5-1 and A1.5-2.

For the rudders with lower support on sternframe heel, calculation for \( \eta = 0.5 \) shall be additionally performed.
Reaction force in the sternframe heel, \( R \) — yield point of the stock material, kN, shall be determined by formula (A1.8), MPa.

\[
B_{str} = R \left( \eta l_{10} + l_{30} \right)^3 \left\{ 1 + 1.5 \left( l_{10} - \eta l_{10} + l_{20} \right) / \left( \eta l_{10} + l_{30} \right) + 
+ J_{10} J_{40} \left[ 1 + \left( l_{10} - \eta l_{10} + l_{20} \right) / \left( \eta l_{10} + l_{30} \right) \right] / \left[ J_{40} \left( \eta l_{10} + l_{30} \right) \right] \right\} / \left[ J_{10} J_{50} / J_{50} + \left( l_{10} + l_{30} + l_{20} \right)^3 + J_{10} J_{10} \left( l_{10} + l_{30} + l_{20} \right)^2 / J_{40} \right].
\]

(A1.8)
TESTS OF CHAINS AND ACCESSORIES

1 All finished chain cables shall undergo the tests specified in this Appendix in the presence of a Surveyor. Chain cables are allowed for testing if they are free from paint and anti-corrosive coating.

2 All chain links shall undergo visual examination.

All chain links and accessories shall have a clean surface consistent with the method of manufacture and be free from cracks, notches, foreign impurities and other defects impairing the use of the product as intended. The overflows or burrs on forgings shall be ground. The surface defects within the limits of admissible diameter tolerances established in the manufacturer's technical documentation shall be ground to ensure smooth transition of the surface. Hollows may be removed by means of local grinding up to 5% of the nominal link diameter or the item thickness.

The welds shall be free from defects which impair the use of the chain cable as intended. Undercuts, end craters and similar defects shall be ground off.

Allowable tolerances of chain links

3 Diameter tolerances in the elbow outside the link contact area shall not exceed values specified in Table A2.3.

4 Cross-sectional area of the chain link at elbow shall have no negative tolerances.

This area shall be calculated using a diameter determined as an arithmetic mean of four diameter values measured in the same cross section at different points of its outer contour.

<table>
<thead>
<tr>
<th>Nominal link diameter, mm</th>

</tr>
</tbody>
</table>

\(^1\) Positive diameter tolerances shall not exceed 5% of the nominal diameter.

5 Allowable tolerances of a shot length measured over a length of any 5 links shall not exceed +2.5 % of the nominal length. Measurements shall be performed on the chain under tension after proof load testing.

6 The following tolerances are allowed for chain accessories: for diameter +5 %, — 0 %; for other dimensions ±2.5 %.

Weldability tests

7 During type approval of the chain, in-process welding tests for the welding of chain studs shall be performed in accordance with Section 4 Appendix 10 Part X of the Rules.

Proof load test

8 Each length of chain cable (27.5 m) shall be subject to proof load test at the proof load specified in Tables A2.8-1 and A2.8-2.

### Breaking, tensile, impact tests

9 For breaking load testing in accordance with Tables A2.8-1 and A2.8-2 samples are taken from the chain cables in conformity with Table A2.9 which comprise at least three stud links or five studless links. The links concerned shall be made according to the same procedure and shall be welded and heat treated together with the chain cable. Samples are separated from the chain cable in the presence of a Surveyor.
In any case, from each fourth length or 100 m one specimen shall be taken for tensile test. Specimens are taken from each fourth length of the non-heat treated chain. The specimens shall be cut out as in Fig. A11.2.4.2 Appendix 11 Part X of the Rules on that side of the link which is opposite to the weld. Testing of the weld-cut specimens may be additionally performed: tensile testing across the weld and impact testing of a specimen with a notch through the weld.

If the adequate breaking load cannot be obtained due to insufficient capacity of the testing machine or large diameter of the chain cable, tensile and impact tests and investigation of microstructure of specimens made of chain links may be performed (see GOST 228).

If the results of the breaking load tensile do not comply with the requirements of Table A2.8-1, A2.8-2, the other specimen shall be taken from the same length. The tests are considered successful if the load corresponding to the required one specified in Table A2.8-1, A2.8-2 has been obtained.

If the results of repeated tests do not comply with requirements of Tables A2.8-1, A2.8-2, the length is rejected. At the manufacturer's discretion sample lengths may be taken from the remaining three lengths of the batch and subject the breaking load testing. If test results for at least one chain length do not comply with requirements of Tables A2.8-1, A2.8-2, the whole batch is rejected.

If the proof load test fails, the defective links/link shall be replaced, a new link/links shall undergo a local heat treatment and the proof load testing shall be repeated. The cause of link/links damage shall be determined.

For sampling an extra link shall be provided in a chain length (or some links for small-diameter chain). The extra link shall be manufactured similarly to the breaking load test specimen (see 9).

Test results shall comply with requirements of Table 3.7.8 of the Rules as well as requirements of this Appendix and shall be specified in the manufacturer's quality control document.

Tests of chain accessories

15 Chain accessories shall be tested in the presence of a Surveyor. Accessories are allowed for testing if they are free from paint and anti-corrosive coating.

16 All accessories shall undergo proof load tests according to Table A2.8-1.

17 For proof load testing according to Table A2.8-1, items shall be presented in batches. A batch of shackles, swivels, swivel shackles, enlarged and end links shall comprise of not more than 25 items, a batch of connecting links — of 50 items of the same grade and dimensions, made of metal of the same heat and heat treated in the same furnace charge.

One item out of each batch shall undergo tests; the use of tested items according to its purpose is not permitted.

18 Breaking load tests may be omitted, if: breaking load is confirmed by satisfactory results of initial tests at the manufacturer during survey of the organization in order to obtain the Recognition Certificate; results of mechanical tests of each batch performed in accordance with 19 comply with requirements of Table 3.7.8 of the Rules and items are subjected to non-destructive testing by organization with the Recognition Certificate issued by the River Register.

19 One tensile test specimen and one set of three impact test (KV) specimens (see Appendix 10 Part X of the Rules) cut out of specific sample or item as in Fig. A11.2.4.2 Appendix 11 Part X of the Rules shall be tested from each batch of items.

20 The results of mechanical tests shall comply with requirements of Table 3.7.8 of the Rules and shall be specified in the manufacturer’s quality control document.

1 GOST 18353, GOST R 51751
Part VI

ELECTRICAL EQUIPMENT
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 The present Part of the Rules applies to the electrical equipment of all classes of the ships, if otherwise is stated in the text of particular requirements.

1.1.2 The present Part of the Rules does not apply to electrical equipment intended for household, domestic and manufacturing purposes excepting:

.1 connected cables;
.2 protection, insulation, earthing, electromagnetic compatibility (only for the equipment installed in the spaces where the ship's radio communication and navigation means as well as the control systems of technical facilities having electronic components are operated) and equipment mounting means.

1.2 DOCUMENTATION

1.2.1 The following operational documents for electrical equipment shall be available onboard the ship:

.1 specifications;
.2 technical description and operating guidelines for shipboard electric drives (with diagrams);
.3 electric schematic diagram of generation and distribution of electric energy;
.4 electric schematic diagram of electric propulsion (for ships with electric propulsion);
.5 electric diagrams of main distribution devices (main switchboard, emergency switchboard, propulsion plant control panel etc.);
.6 electric schematic diagrams of charging line;
.7 calculations of the ship's electric power plant required power, generators quantity and power selection, as well as calculation of power of the emergency power supply sources;
.8 album of the switchboard front sides;
.9 electric schematic diagrams of power line, primary lighting line, secondary lighting line, minor emergency lighting (battery), signal and identification lights, starter circuits, special systems;
.10 technical description and operating guidelines for telephony, ship controls and other communication and signaling within the ship (with diagrams);
.11 electric diagrams of telephony connections, ship controls and other signaling within the ship;
.12 technical description and operating guidelines for navigation sets and instrumentation systems.

The following document approved by the River Register shall be available on board of bulk oil-carrying ships and other ships equivalent to them in addition to the documents specified in 1.2.1.1 – 1.2.1.12: “The layout of fire and explosion hazardous areas and spaces, list of electric installations in such areas”.

The availability of the documents specified in 1.2.1.1 – 1.2.1.12 is not required on board of the ships which do not have a crew, but the ship owner is to submit them on demand.
2 GENERAL REQUIREMENTS

2.1 DEFINITIONS AND EXPLANATIONS

2.1.1 In the present Part of the Rules the following terms and definitions are used:

1. **Emergency lighting** — lighting of ship's spaces and areas by means of lighting fixtures fed from the emergency or momentary emergency source of electric power.

2. **Emergency source of electric power** — electric power source intended for the necessary ship consumer's supply in the event of voltage break-off on the main distribution switchboard.

3. **Momentary emergency source of electric power** — electric power source intended for the necessary ship consumer's supply from the moment of voltage break-off in the main power source until the emergency diesel generator starts running.

4. **Antistatic earthing (bonding)** — electrostatic sparking safety device — electric connection which ensures potential equalization (bonding) of static electricity in structural parts of ship's equipment and hull by means of their direct electric contact or contact via earth wires.

5. **Shaft generator** — ship's generator of electric current driven from the ship's shaft line or from the main propulsion engine.

6. **Explosion hazardous area** — volume where explosive mixtures of air and gas or air and dust are present or may be generated. Explosion hazardous areas are subdivided into areas 0, 1 and 2.

7. **Galvanic spark safety** — condition of ship's equipment and systems when the probability of fire or explosion initiation caused by electric sparking during galvanic contact of the ship with onshore facilities or other ship is excluded. The galvanic contact in its turn may be caused by electro-chemical phenomena and vagabond currents water or ground.

8. **Ship's length** — ship's length at the design waterline.

9. **Protective earthing** — electrical connection of the equipment to the Earth. Onboard a ship such connection is attached to the hull.

10. **Ship's hull** — all metal parts of the ship, which are reliably connected with the outer metal plating. For the ships with non-conducting hull — a special copper sheet of at least 0.5 m² in area and at least 2 mm in thickness or a carbon steel sheet of at least 1.5 m² in area and at least 6 mm in thickness attached to the submerged part of the outer plating at light draught and used for earthing of all shipborne facilities.

11. **Small voltage** — a voltage which is not hazardous to the personnel. The safety condition is considered as satisfied, if the windings of the transformers, converters and other voltage-lowering devices are electrically separated and the value of the stepped-down voltage across these devices or electric power sources does not exceed:

   - 50 V between poles at direct current;
   - 50 V between phases or 30 V between phases and the hull at alternating current.

12. **Lightning divertor** — the upper part of lightning arrester intended for direct perception of atmospheric discharges.

13. **Essential facilities** — facilities, the normal operation of which provides the ship navigation safety, safety of people
and cargo onboard. Such facilities include those listed in 5.3.1.

14 Isolating transformer — a transformer intended to separate the electrical receiver feeding circuit from the primary electrical network.

15 Special electrical spaces — spaces or places intended for electrical equipment only and accessible only for attending personnel.

2.2 OPERATING CONDITIONS

2.2.1 The design of electrical equipment shall provide its operability at deviations of voltage and frequency from their nominal values specified in Table 2.2.1, unless otherwise specified in the present Part of the Rules.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Deviation from nominal values, %</th>
<th>Duration of short deviation, seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>AC voltage</td>
<td>+6</td>
<td>+15</td>

<tr>
<td></td>
<td>–10</td>
<td>–30</td>
</tr>
<tr>
<td>Frequency</td>
<td>±5</td>
<td>±10</td>
</tr>
<tr>
<td>DC voltage</td>
<td>±10</td>
<td>5</td>
</tr>
</tbody>
</table>

Note: When powered by accumulator battery which is operating into load in parallel with a charger, the long deviation is to be within the following limits: from +30 to –25 %.

When powered by accumulator battery for the equipment which is not connected to the battery during the charging process, the long deviation is to be within the following limits: from +20 to –25 %.

2.2.2 The values specified in Table 2.2.2 shall be taken as nominal operating temperatures of ambient air and cooling water for electrical equipment.

<table>
<thead>
<tr>
<th>Equipment location</th>
<th>Temperature, °C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Machinery spaces, galleys and special electrical spaces</td>

</tr>
<tr>
<td>Open decks</td>
<td>From +55 to –30</td>
</tr>
<tr>
<td>Other spaces and areas</td>
<td>From +40 to –10</td>
</tr>
</tbody>
</table>

2.2.3 Electrical equipment is to operate reliably at relative air humidity (80±3) % and temperature (40±2) °C, as well as at relative air humidity (95±1) % and temperature (25±2) °C.

2.2.4 Electrical equipment of ships of all classes, except for "P" class ships not operated at water storage basins and "J" class ships, is to operate reliably at a permanent list up to 15° and trim up to 5°, as well as at rolling motion up to 22.5° with the period of 7 – 9 seconds and pitching up to 10° from the horizontal line.

Emergency sources of electric power and electrical equipment fed from the emergency sources are to operate reliably at a permanent list up to 22.5° and trim up to 10°, as well as at simultaneous list and trim within the specified limits.

2.2.5 Electrical equipment is to operate reliably at vibrations with frequency of 2 – 80 Hz, amplitude of 0.1 – 1.0 mm and at impacts with acceleration of 5g with frequency of 40 – 80 impacts per minute.

2.2.6 (shall be considered to have lost force.)

2.3 STRUCTURAL REQUIREMENTS

2.3.1 The components of electrical equipment to be replaced while in operation shall provide easy dismantling and disassembly.

2.3.2 When using screw fastenings the screws and nuts shall be prevented from self-unscrewing and loss in places subject to frequent dismantling and opening.

2.3.3 Tightening gaskets of parts of the electrical equipment (detachable, opening, stuffing boxes etc.) are to correspond to the protective type of the equipment casing. Sealings are to be fastened to covers or housings.

2.3.4 Electrical equipment, where water may be condensed inside, is to be fitted with appropriate water drainage device. Drainage channels shall be provided inside the equip-
ment to drain water condensate out of all parts of the equipment.

Alive windings and parts of the equipment are to be so located or protected as to being prevented from the affection of water condensate inside the equipment.

2.3.5 Electrical equipment with forced ventilation intended for installation in the lower parts of wet spaces is to be fitted with a ventilation system which would prevent sucking of moisture and oil vapours inside the equipment.

2.3.6 Protection type of electrical equipment, depending on its location, is to be at least as specified in the Table 2.3.6.

2.4 MATERIALS

2.4.1 Structural parts of electrical equipment are to be made of strong fire retardant materials stable to affection of high humidity and oil vapours or be appropriately protected against it. Screws, nuts, hinges and other parts intended for fastening closings of electrical equipment located on the open deck and in spaces with high humidity are to be made of corrosion resistant materials or be fitted with reliable corrosion-proof covering.

2.4.2 All the alive parts of electrical devices are to be made of copper, copper alloys or other materials with the same physical characteristics with the exception of:

Notes: 1. For explosive spaces and areas the requirements for electrical equipment are given in 2.10, 16.2.4 – 16.2.6, 16.2.10, 16.3.4, 16.3.7.
2. If the protection level of electrical equipment is lower than the protection level required by the present Table, protective components (shields, screens, casings) shall be applied to ensure the safety of such equipment operation in its installation location.
3. In spaces and areas with explosive dust and similar spaces the equipment used shall be of IP66 protection level or equivalent explosion-proof equipment.
4. Designation of protection levels is specified in Appendix 1.
.1 resistor components which shall be made of materials with high mechanical strength, high resistivity and high temperature resistance;

.2 short-circuit windings of armatures of asynchronous motors made of aluminium or its alloys;

.3 coal brushes, metal-ceramics contacts, technical coal for slip rings and other similar parts when it is stipulated by the required properties of such devices;

.4 electrical equipment components directly attached to the hull used as a return wire in a single-wire system.

2.4.3 Insulation materials of parts being under voltage are to have appropriate dielectric strength, be able to withstand appearing of leakage current along its surface, be moisture-proof, oil-proof and have sufficient strength or be adequately protected.

2.4.4 To provide insulation of windings of machinery, apparatus and other essential facilities the insulation materials of B, F and H classes are to be used.

2.5 CONNECTIONS OF CURRENT-CARRYING PARTS

2.5.1 The minimal permissible cross-sectional area of wiring for inner mounting of distribution facilities including control and alarm measuring circuits shall be at least 0.75 mm². Cross-sectional area less than 0.75 mm² is allowed only for control, intercommunication, alarm and protection circuits, as well as electrical equipment.

The wire sections from busbars to protection devices not protected against short circuit shall be as short as possible.

2.5.2 Current-carrying parts shall be so attached that to avoid any additional mechanical loading; they shall not be attached by means of screws screwed directly into the insulation material.

2.5.3 The endings of stranded cores of cables and wires are to be treated properly depending on the type of the terminal used or to be fitted with cable tips. When soldering the tips no acids or other corrosion-active substances shall be used.

2.5.4 Insulated wires are to be laid and fastened so as not to decrease their insulation resistance and prevent them from damages caused by electrodynamic loads, vibrations and shocks. The cables are to be laid in straight lines without any crossings in their routes. The crossings are allowed only in: cable tails from the routes, paths through the bulkheads, spreading to electrical equipment.

2.5.5 Measures shall be taken to prevent the inadmissible temperature rise of insulated wire in normal operating conditions or during the period of cutting-off short-circuit current.

2.5.6 Insulated wires are to be connected to the terminals or busbars so as to prevent affection of inadmissible temperature on cables' insulation in normal operating conditions.

2.6 PROTECTIVE EARTHING

2.6.1 All non-alive metal parts of the electrical equipment, which are likely to be touched by attending personnel under service conditions, excepting those listed in 2.6.2, are to be earthed.

2.6.2 Protective earthing is not required for:

.1 electrical equipment with double or reinforced insulation;

.2 electrical equipment fed by low voltage current;

.3 metal parts of electrical equipment fastened in non-conducting material or passing therethrough and separated from the earthed and alive parts in such manner that under normal operating conditions these parts cannot become alive or contact with the earthed parts;

.4 housings of specially insulated bearings;

.5 lamp caps and fasteners for luminescent lamps, lamp shades, reflectors and guards attached to lamp holders or lighting fixtures made of or screwed into non-conducting material;

.6 cable clips;
small individual consumers fed from separating transformers.

2.6.3 Fixed electrical equipment, cable outer sheathes (armour) protecting from mechanical damage, cable outer sheathes (armour) and conductor shields used for shielding are to be earthed. Earthing is to be made by means of external wiring, earth core in the feeding cable or using direct electrical contact between the equipment casing and metal hull.

Earthing of electrical equipment and cable sheathes is considered adequately effective when the parameters specified in Table 2.6.3-1 are met.

<table>
<thead>

<td></td>
<td>0.02</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0.02</td>
</tr>
</tbody>
</table>

When external earth conductor is used for earthing, corrosion-resistant materials shall be used. The cross-sectional area of earth copper conductor is to be at least as specified in Table 2.6.3-2.

<table>
<thead>
<tr>
<th>Cross-sectional area of earth conductors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cross-sectional area of cable core connected to consumer, mm²</td>
</tr>
<tr>
<td>up to 2.5</td>
</tr>
<tr>
<td>from 2.5 to 120</td>
</tr>
</tbody>
</table>

When a cable core is used for earthing, its cross-sectional area is to be equal to: for cables with cross-sectional area up to 16 mm² inclusive – the nominal cross-sectional area of the main cable cores, and for cables with cross-sectional area over 16 mm² – equal at least to half cross-sectional area of the main cable core but not less than 16 mm². When feeding cable core is used for earthing, the resistance of earth circuit shall not exceed 0.4 Ohm.

2.6.4 Earth circuits of fixed equipment shall have no circuit-breakers.

2.6.5 Earthing of shields and metal armour of the cables is to be carried out in one of the following ways:

- 1 using a copper earth wire with cross-sectional area not less than 2.5 mm² for cables with core cross-sectional area up to 25 mm² and not less than 4 mm² for cables with core cross-sectional area over 25 mm²;
- 2 attaching the armour or metal sheath to the hull by means of firm, reliably adjoining clamp with good conductivity;
- 3 by means of cable gland rings provided that they are made of corrosion-resistant material and possess good conductivity.

Both cable ends are to be earthed. Cable sheathing of branched end circuits may be earthed at the feeding side solely.

2.6.6 Secondary windings of current- and voltage-measuring transformers are to be earthed.

2.6.7 External earth wires are to be accessible for monitoring and protected against mechanical damage.

2.6.8 Earth wires are to be connected to the metal hull or to earthing busbar by means of screws and bolts with at least 6 mm diameter.

Contact surfaces on the electrical equipment and the hull in places of adjoining of earth conductors are to be cleaned up to metal glitter and reliably protected against corrosion.

2.6.9 Superstructures from aluminium alloys insulated from the hull are to be earthed by means of at least two special wires with each cross-sectional area of not less than 16 mm², non-bringing to electrolytic corrosion in places of its connection with superstructure and hull. Such earthing connections are to be made in several places on the superstructure's perimeter, be accessible for observation and protected against damage.

2.6.10 Earthing of mobile or portable electrical equipment is to be made using a special core in flexible feeding cable by contact connection in the plug unit.
2.6.11 Earthing of electrical equipment on pipelines, compressed gas reservoirs and oil tanks is prohibited.

2.6.12 Casing of movable wheelhouse is to be earthed at least in two places by flexible copper wire laid separately from other wires going to the wheelhouse. This protective earthing may be at the same time a part of lightning arrestor, if the lightning divertor is installed on the wheelhouse.

2.6.13 Earthing shall be provided for static electricity discharging.

2.6.14 In ships with non-metal hull a special copper sheet with area not less than 0.5 m² and thickness not less than 2 mm or a carbon steel plate with area not less than 1.5 m² and thickness not less than 6 mm shall be used for earthing. Such sheet is to be attached to the submerged part of the outer plating at light draught and used for earthing of all shipborne facilities.

A metal stem or other metal structures of the ship immersed in water under any navigation condition may be used for earthing.

2.6.15 In the case when the ship’s technical facilities, assemblies or electrical equipment, which require earthing, are installed using shock absorbers or shock-absorbing mounts the earthing strip shall be connected without tension.

2.7 ELECTROMAGNETIC COMPATIBILITY

General requirements

2.7.1 The present requirements are applicable to electrical equipment, automation equipment, radio- and navigation equipment to ensure electromagnetic compatibility on board.

2.7.2 Failure-free performance of the equipment shall be ensured under conditions of interference having the following parameters:

1. static and variable (50 Hz) magnetic field in accordance with Table 2.7.2.1. The magnetic field resistance test shall be carried out using test generator and inductance coil generating the required magnetic field intensity;

<table>

2. harmonics of voltage in supply circuits in accordance with the higher harmonics diagram for ship mains to be found in Fig. 2.7.2.2 on logarithmic scale.

![Fig. 2.7.2.2. Diagram of higher harmonic components for ship mains: $U_c$ — actual circuit voltage; $U_n$ — voltage of n-order harmonic component](image)

2.7.3 The levels of electromagnetic interference and resistance to it shall not exceed the values specified in Tables 2.7.3-1 and 2.7.3-2.

2.7.4 On ships, for which the level of interference from power semiconductor converters cannot be limited in conformity with 2.7.3, the mains of automation radio and navigational equipment shall be galvanically isolated from the mains of those converters so that at least 40 dB are damped within the frequency range 0.01–30 MHz.

The power supply cables of equipment having the radio interference levels in excess of those stipulated by 2.7.3 shall be laid at least 0.2 m away from the cables of other equipment groups where the common cable run is longer than 1 m (see 2.7.11).

$^{*4}$ dBμV/m — value of radio interference field intensity to 1 μV/m.

Measures to ensure electromagnetic compatibility

2.7.5 To ensure protection of radioequipment against electromagnetic interference the requirements specified in Part VII of the Rules shall be taken into account.

2.7.6 For the purpose of dividing the power supply of the ship, rotary converters, transformers and filters shall be used.

2.7.7 Continuous screening shall be ensured, for this purpose cable screens shall be connected to the equipment casings, and it shall also be ensured in cable branch boxes, cable distribution boxes and in way of cable penetrations through the bulkheads.

2.7.8 The earthing installed for the purpose of interference protection shall have an electric resistance not greater than 0.02 Ohm, minimum length possible, shall be resistant to vibration and corrosion, and readily accessible for inspection.

2.7.9 Cable screens shall not be used as return conductors.

2.7.10 By the type of signals conveyed, the ship cables are subdivided in groups as follows:

.1 coaxial cables of radio receivers and conveying video signals with the level of signals 0.1 μV – 500 mV;

.2 screened or coaxial cables conveying analogue and digital signals with the level 0.1–115 V;

.3 screened cables of telephone and radio broadcasting apparatus, control and signaling with the level of signals 0.1–115 V;

.4 unscreened and located below the deck or screened and located above the deck cables of power and lighting network with the level of signals 10 – 1000 V;

.5 coaxial or screened cables of transmitting aerials of radio transmitters, radar installations, echo sounders and power semiconductor converters with the level of signals 10 – 1000 V.

2.7.11 Cables of the same group may be laid in the same cable run provided that interference-sensitive equipment is not influenced by the difference in the levels of signals conveyed. Where the cable lengths laid in parallel are in excess of 1 m, the cables (cable runs) of different groups shall be laid at least 0.1 m apart and their intersections shall be effected at right angles. Coaxial or screened cables of transmitting aerials of radio transmitters, radar installations, echo sounders and power semiconductor converters with the level of signals 10 – 1000 V shall be double-screened or laid inside a metal pipe, if they are coaxial. The outer screen shall be earthed as well as the principal cable screen.

Cables laid close to magnetic compasses shall not affect them and cause distortion of their readings.

2.7.12 When installing electrical equipment and laying cables the requirements of Part VIII of the Rules shall be taken into account to protect the navigational equipment from interference.

2.7.13 On board the ships built from the materials, which do not carry current, and where the installation of radio equipment is required, all cables shall be screened or otherwise protected from interference, and all the electrical equipment shall have specific devices for radio interference suppression.

2.7.14 In spaces where radio communication and navigation equipment is installed, as well as on the open decks and superstructures, which are not separated from antennae by a metal deck or bulkhead, all cables and wirings shall have continuous screening braid. All the telephone and other cables of the intercom (except for the end circuits of exclusive telephones) shall be screened.

### 2.8 ARRANGEMENT OF ELECTRICAL EQUIPMENT

2.8.1 Electrical equipment shall be installed in such a manner as to provide convenient
access to controls and to all components that require maintenance, inspection and replacement.

2.8.2 Electrical equipment under hatches, trunks, fittings or connecting devices of water, steam, oil, fuel and hydraulic systems, as well as in places subject to adverse conditions (temperature, oil, gas, salt water, hot steam). Arrangement of electrical equipment in such conditions is allowed if corresponding protection of electrical equipment and cable runs is provided. Electrical equipment shall be installed at a distance of not less than 100 mm from heat sources, which may heat up the components of electrical equipment above the permissible temperature.

2.8.3 The air-cooled electrical equipment shall be so located that the cooling air is not taken from bilges or other spaces wherein the air may be contaminated with substances having a harmful effect on insulation.

2.8.4 Electrical equipment installed in locations subject to vibration and shocks, which are heavier than those specified in 2.2.5, shall be so designed as to ensure its normal operation under these conditions or to be mounted on shock absorbers.

2.8.5 Electrical equipment shall be fixed in position in such a manner that the strength and impermeability of decks, bulkheads and skin are not impaired as a result of this.

2.8.6 Exposed parts of electrical equipment, which are under voltage, shall be located at a distance of not less than 300 mm in horizontal direction and 1200 mm in vertical direction from unprotected flammable materials.

2.8.7 Electrical equipment designed for operation under voltage above 500 V shall be installed in special electrical spaces.

Electrical equipment designed for operation under voltage above 500 V may be installed outside the special electrical spaces if the access to the current carrying parts is available only using special tools and after the voltage is removed. The doors of electric spaces and the covers of such electrical equipment shall have inscriptions specifying the voltage value.

2.8.8 It is strictly prohibited to mount the electrical equipment directly on the walls of tanks containing flammable liquids. The electrical equipment shall be installed at a distance of at least 75 mm from the tank walls.

The signaling and automation (level, pressure etc.) sensors may be mounted directly on the tank.

2.8.9 Electric engines designed for actuation of submersible pumps may be installed on open deck if their arrangement and construction comply with the requirements specified in the present chapter and in 2.3.6, 7.2.4, 7.8.2 and 16.2.

2.9 SPECIAL ELECTRIC SPACES

2.9.1 The doors of special electrical spaces shall be locked and open outwards or be sliding. From within the special electrical spaces the doors shall be open without a key, and from outside a warning inscription shall be provided.

2.9.2 Special electrical spaces shall not be adjacent to the tanks filled with flammable liquids.

2.9.3 No exits, side scuttles of the opening type or other openings are permissible from special electrical spaces into dangerous spaces.

2.9.4 Handrails of non-conducting material shall be installed in servicing areas of special electrical spaces when the open-type electrical equipment is used.

2.10 EXPLOSION-PROOF ELECTRICAL EQUIPMENT

2.10.1 The requirements of the present chapter are applicable to the electrical equipment installed onboard the ships in closed and semi-closed spaces where explosive mixtures of vapours, gases or dust with air may be formed. Semi-closed spaces — partially closed spaces located in a dangerous area at a distance up to 3 meters from tanks (compartments) or where cargo pumps and its systems, as well as pump hoses are located.
Semi-closed spaces have no forced air supply, and their natural ventilation is limited with partial bulkheads, sheds etc. Such spaces include paint stores, lamp rooms (for oil lamps), accumulator rooms and spaces containing tanks, pumps and piping for flammable liquids with a flash point below 60°C, holds of ships carrying dangerous goods and spaces of ammonia refrigerating plants.

Supplementary installation requirements for electrical equipment in oil tankers are specified in 16.2, and installation requirements for electrical equipment in the ships with holds and other spaces for carriage of transport means with filled fuel tanks, tank wagons and trunk tanks for flammable liquids are specified in 16.3.

2.10.2 In dangerous spaces and areas specified in 2.10.1 only the explosion-proof electrical equipment with explosion protection type complying with the category and group of mixture with the highest risk of explosion may be located, except for that specified in 2.10.3. electrical equipment in accumulator rooms shall be installed according to the requirements specified in 8.7.

Cables to tightly closed echo sounder oscillators shall be laid within the cofferdams in appropriately sealed steel watertight tubes at the required distance above the main deck.

Electrical engines of exhaust ventilators in refrigerating plant rooms and the lighting fixtures of stand-by lighting (see 15.2) shall have explosion-tight casing for explosive mixtures of categories and groups not lower than IIBT3 (see Appendix 2).

2.10.3 Electrical equipment to be installed in spaces where dust or fibres may generate an explosive mixture with air shall have the protection type not lower than IP65.

In cases when explosive fibre-air or dust-air mixture may be generated occasionally as a result of damage or leakage of operating technological devices or ventilation stop, electrical equipment of IP55 protection type may be installed.

Electrical equipment installed in such spaces shall have such casing that the temperature of its upper elements, vertical or inclined up to 60° from the horizontal, at prolonged operation is lower for at least 75°C than the smouldering temperature of dust present in those spaces (the smouldering temperature shall be determined for a dust layer of 5 mm thickness).

2.10.4 Explosion-proof lighting fixtures shall be installed in such a manner that to provide clear space of at least 100 mm around them except the place of their attachment.

2.10.5 Any electrical equipment located in explosive spaces and areas, except fire alarm detectors, is to be fitted with a switch to cut off the current carrying cores which is located in a safe place outside explosive spaces and areas.

2.10.6 In closed and semi-closed spaces, where no vapour or gas explosive mixtures can be generated, but having openings leading to explosive spaces the electrical equipment shall be of explosive-proof type.

2.10.7 In the holds intended for transportation of explosive cargoes in containers no electrical equipment or cabling may be located. If necessary, the electrical equipment located in such holds shall be of the following explosive-proof type:

1. spark-proof electrical circuit (Exi),
2. pressurized enclosure (Exp);
3. explosion-tight casing (Exd);
4. improved explosion-proof (Exe).

2.10.8 Cabling in explosive spaces and areas is allowed only for the electrical equipment located in those spaces and areas. Transit cables across such spaces and areas may be laid only when the requirements specified in 2.10.9 – 2.10.11 are met.

2.10.9 All the cables laid in explosive zones shall be covered with tight non-metal sheath with armour or other metal covering for mechanical protection and monitoring of cable core insulation.

The following wires and cables may be used in explosive zones:

1. wires with rubber or polyvinylchloride insulation;
2. wires with rubber or polyvinylchloride insulation in rubber, polyvinylchloride or metal sheath.

No cables with aluminium sheath or wires and cables with polyethylene insulation or sheath may be used.

2.10.10 Cables laid in explosive spaces and areas shall be protected against mechanical damage. Local cables led to accumulators may be laid open.

2.10.11 All metal sheathes of the cables laid across explosive spaces and areas or led to the equipment located therein shall be earthed on both ends.

2.10.12 Cables connected to the electrical equipment of "spark-proof electrical circuit" type are to comply with the following requirements:

1. spark-proof circuits shall be separated from other circuits;
2. the same cable shall not be used for spark-proof and spark-hazardous circuits;
3. cable core insulation of spark-proof circuits shall be of distinctive blue colour. It is allowed to mark with blue colour only the core ends;
4. cable cores of spark-proof circuits shall be protected against the effect of other cables on its spark-proof properties;
5. cables led to the electrical equipment of Exi protection type may be laid open and covered with a non-tight casing if protection from mechanical damage is required.

2.10.13 Cables laid in explosive spaces and areas shall have:

metal armour or braid covered with non-metallic sheath;
or lead sheath with additional mechanic protection;
or copper sheath or stainless steel sheath (for cables with mineral insulation only).

2.11 ADDITIONAL REQUIREMENTS FOR INSTALLATION OF ELECTRICAL EQUIPMENT IN PAINT STORES

2.11.1 Paint stores and ventilation ducts of these stores may be fitted only with the electrical equipment which is necessary for maintenance of these spaces.

This electrical equipment is to be explosion-proof and of the type specified in 2.10.7.

2.11.2 Minimal requirements to this equipment with regard to the explosion protection type are to correspond to the gas mixture category IIB and gas mixture group T3 (see Appendix 2).

2.11.3 Cables (transit or local) laid across the paint stores and spaces specified in 2.10 are to comply with 2.10.10.

2.11.4 Electrical equipment located in the open deck spaces within 1 m from the openings of forced and exhaust natural ventilation or within 3 m apart from the outer opening of exhaust artificial ventilation is to be of explosion-proof type according to 2.11.1.

2.11.5 Cables (transit or local) laid across the paint stores and spaces specified in 2.11.4 are to have metal armour or to be laid in metal pipes.
3.1 NUMBER AND CAPACITY OF MAIN SOURCES OF ELECTRICAL POWER

3.1.1 The number and capacity of the main sources of electric power are to be determined with due regard of the following operating conditions of the ship:

- 1 rate of speed;
- 2 maneuvering;
- 3 in the event of fire, hole in the hull or other conditions which impose the safety of navigation;
- 4 anchorage;
- 5 other operating conditions according to ship's purpose.

3.1.2 Every self-propelled ship shall be fitted with at least two main power sources. If these sources are generators, at least one of them shall have its own independent drive.

3.1.3 Capacity of the main electric power sources is to provide the power supply of essential facilities in the ship's operating conditions specified in 3.1.1.1; 3.1.1.2; 3.1.1.3 in the event of failure of one of the main power sources by the rest of them.

This requirement is not applied to the tugboats and pushers intended for service of the ships carrying flammable substances and liquids during the fire-extinguishing mode on the serviced ship (see 3.1.1.3).

3.1.4 Under normal operating conditions the capacity of electric power sources is to be sufficient to provide the start-up of the most powerful electric motor without spontaneous disengaging of other electric motors being in operation.

3.2 ACCUMULATOR BATTERY AS THE MAIN SOURCE OF ELECTRIC POWER

3.2.1 The accumulator battery may be considered as the main source of electric power solely when it can be charged from shipborne electric power source.

3.2.2 If the accumulator battery is operating in parallel with a charging set, then the ship is considered as fitted with two main electric power sources.

In that case every power source is to be supplied by its own feeder for the consumers supply and have its own protection.

3.2.3 If the accumulator battery is operating in parallel with a charging set, then its capacity is to be sufficient to supply the electric circuit in the event of generator failure, as well as to provide operation of essential facilities within 6 hours for "M" and "O" class ships and within 3 hours for "P" and "L" class ships. This requirement is not applied for the ships of "M-СП", "M-ПР" and "O-ПР".

3.2.4 On the ships where the accumulator battery is the sole main electric power source, its capacity is to be sufficient to provide the fulfillment of the requirements specified in 3.1.1 without recharging and within the following periods of time:

- 8 h — ships of "M-СП", "M-ПР", "O-ПР" classes;
- 6 h — ships of "M" и "O" classes;
- 3 h — ships of "P" и "L" classes.

3.2.5 When the accumulator battery and generator are operating in parallel, the latter shall be fitted with automatic voltage regulator preventing the rise of the accumulator battery charging current over the permitted value.
3.2.6 The generator (rectifier) operating in parallel with the accumulator battery is to have a capacity sufficient for the supply of all shipborne essential consumers and charging of the accumulator battery under normal operating conditions.

3.3 DRIVE OF GENERATORS
3.3.1 Engines intended for the generator drive are to comply with Section 2, Part IV of the Rules, as well as with the requirements specified in the present Chapter.
3.3.2 Diesel generators shall be designed for continuous operation.
3.3.3 Generator drive from the main non-reversible engines operating with variable frequency is allowed provided that the voltage is regulated within 85 – 100 % of the rating and the frequency – within 45 – 52.5 % Hz range.

If the frequency (voltage) of the shaft generators is decreasing after the minimal specified limits have been reached, the consumers which provide the running conditions safety (see Table 4.5.1) are to be switched to the accumulator battery designed for their supply within 15 minutes. Simultaneously one of the diesel generators is to be started automatically and to be connected to the busbars of the electric power plant and assume the load.

Shaft generators onboard the ships with the consumers which do not allow power interruption in operation (e.g. gyrocompass), as well as voltage and frequency oscillations within the limits stated above may be used only when the shaft generator and the diesel generator are operating in parallel.

3.4 AC GENERATOR VOLTAGE REGULATION
3.4.1 Every AC generator is to have a separate independent system for automatic voltage regulation.
3.4.2 AC sets are to be equipped with the voltage regulation systems which comply with the regulation curves of prime movers in such a manner that to maintain the voltage rating with 2.5% accuracy (up to 3.5% for emergency sets) when the load varies from idling up to the nominal with the nominal power ratio.

3.4.3 AC generators are to have the excitation margin sufficient to maintain the voltage rating within 2 minutes with 10% accuracy in the event of generator overload by current equal to 150% of the rated current and power ration equal to 0.6.

3.4.4 A sudden change in the balanced load of the generator running at the nominal revolution frequency and voltage shall not bring the rated voltage drop lower than 85% or rise above 120%. Afterwards the generator voltage shall be restored to the rating with a deviation not exceeding ± 3 % within the time period not longer than 1.5 s. For emergency sets the specified parameters may be increased up to 5 s and up to ± 4 % of voltage deviation.

When no exact data on the maximal values of sudden load, which may be connected additionally to the existing generator load, are available, the load, which is connected at idle speed and then disconnected, may be taken equal to 60% of the current rating with the power ratio of 0.4 or less.

3.5 DC GENERATOR VOLTAGE REGULATION
3.5.1 Shunt-wound DC generators are to have automatic voltage regulators.
3.5.2 Compound-wound generators are to have independent voltage regulating devices with the accuracy up to 1 % for generators with capacity up to 100 kW and up to 0.5% for those with capacity over 100 kW. The above indicated regulation limits are to be maintained both in cold and heated condition, as well as at any load within the generator working load range.

3.5.3 Voltage regulators of compound-wound generators are to enable reduction of the idling voltage for at least 10% below the rated generator voltage in cold condition with due regard of increase of the revolution frequency of the prime mover at idling.

3.5.4 Manual voltage regulators are to be so designed that the clockwise turn of its controls leads to the voltage increase.
3.5.5 Voltage regulators of shunt-wound generators are to be so designed that the exciting winding is shorted after the excitation has disappeared.

3.5.6 DC sets with compound-wound generators are to have such external characteristics that the voltage of the heated generator set for the rated value with the accuracy up to 1% at 20% load does not vary for more than 1.5% for generators with capacity of 50 kW and over and for 2.5% for those with lower capacity.

Voltage variation within 20 – 100% of the rated load of compound-wound generator shall not exceed the following values:
- 3% — for generators with capacity of 50 kW and over;
- 4% — for generators with capacity of more than 15 kW, but less than 50 kW;
- 5% — for generators with capacity of 15 kW and lower.

3.5.7 DC sets with shunt-wound generators are to have such external generator characteristics and automatic voltage regulators that the voltage is maintained with the accuracy of 2.5% when varying the load from idle to full loading.

3.6 LOAD DISTRIBUTION AT THE PARALLEL OPERATION OF THE GENERATORS

3.6.1 When the electric power sources are not designed for prolonged parallel operation on common busbars, provision shall be made for switching them to parallel operation for the period of load transfer from one generator to another.

3.6.2 When AC generators operate in parallel, the synchronization device is to be provided on the main distribution switchboard. When automatic synchronization is used, the reserve manual synchronization device is to be provided.

3.6.3 When several DC generators are installed, a magnetizing device is to be arranged in the main distribution switchboard.

3.6.4 The regulators of the driving motors of AC generators, designed for operation in parallel, are to have such characteristics that the generator active loads vary from the proportional capacity values of single generators for not more than 10% of the rated resistance load of the maximal generator operating in parallel within the range of 20 – 100% of the rating.

3.6.5 AC sets designed for operation in parallel are to be fitted with such reactive voltage drop compensation system that the distribution of reactive load among the generators varies from the values proportional to their capacities for not more than 10% of the rated reactive load of the maximal generator while the sets are operating in parallel.

3.6.6 The revolution frequency regulators of the driving motors of DC generators are to have such characteristics that the load of single generators when operating in parallel is distributed proportionally to the capacity of each generator so far as possible.

For the loads within 20 to 100% of the rated load, the load of single generators shall not differ from the value proportional to the capacity of the given generator for more than 10% of the rating of the maximal generator or on 20% of the rating of the minimal one of those operating in parallel.

For generators of the same capacity the load of any generator shall not differ from the value proportional to their capacity for more than 10% of the rating.

3.7 AUTOMATION OF ELECTRIC POWER STATIONS

3.7.1 The requirements of the present Chapter apply to ships with "A" character in the class formula.

3.7.2 The control systems of generator sets are to provide the following:
- automatic synchronization, acceptance and distribution of load;
- automatic switch-off of non-essential power consumers in the event of the generator overload or when one of the generators oper-
ating in parallel is overloaded due to emergency switching-off of other generator.

3.7.3 When the electric power is supplied by shaft generator, the latter shall be switched off automatically regardless of the voltage (frequency) during the remote start-up of diesel generator.

3.7.4 In the event of voltage cut-off in the ship network the essential consumers required for the ship control, which were in operation, are to be remotely switched on automatically after the voltage has been restored. Automatic start of these consumers shall be performed according to the preset programme preventing the running generators from overload.

3.7.5 When the generator sets are switched off at load decrease, measures shall be taken to prevent it at short-term load variations as per Table 2.2.1 or the forced operating mode of the generator is to be provided to prevent it from going to standby operation at load decrease.

3.7.6 When the standby generator sets are switched on automatically at overloading of the running sets, it shall be possible to determine the sequence of start of those sets.
4 EMERGENCY ELECTRICAL INSTALLATIONS

4.1 GENERAL REQUIREMENTS

4.1.1 The requirements of the present Section are applied to the emergency electrical installations onboard the inland navigation ships and the ships of combined (river – sea) navigation performing domestic voyages. The ships performing international voyages are subject to the requirements of international conventions.

4.2 EMERGENCY SOURCES OF ELECTRIC POWER

4.2.1 All ships are to be equipped with emergency source of electric power.

When the accumulator batteries are used as the main sources of electric power onboard the ship, one or a group of the accumulator batteries may be used as emergency source of electric power provided that its arrangement and capacity meet the requirements for emergency sources of electric power.

The capacity of the emergency source shall be sufficient for provision of power supply to all consumers, simultaneous operation of which is required for the safety of navigation when the main sources of electric power failed to supply voltage.

The emergency source shall provide electric power for emergency consumers listed in Table 4.5.1:

- on self-propelled ships of "M", "O", "P" and "JI" class within the time period specified in Table 4.2.1;
- on the ships of "M-СП" class with a gross tonnage of 300 and more, on the ships of "M-ПР" class designed for operation in the Laptev Sea and the East Siberian Sea from the estuary of the river Yana up to the estuary of the river Kolyma, on the ships of "M-ПР" and "O-ПР" class, where the emergency source supplies power to the navigational and radio equipment, during 12 hours;
- on the ships of "M-СП" class with a gross tonnage of less than 300 during 6 hours;
- on the ships of "M-ПР" and "O-ПР" class within the time period specified in Table 4.2.1 as for the ships of "M" and "O" class accordingly.

4.2.2 On the non-self-propelled ships and floating objects with shore power supply source as main source of electric power

</tr>
</tbody>
</table>
the emergency source of electric power shall supply the electric power to:

.1 upon availability of the crew — emergency lighting network (it is allowed to use portable electric torches instead of it) and signal side lights;

.2 if now crew is available — signal side lights.

The time of emergency source operation shall be as specified in 4.2.1.

4.2.3 Emergency consumers are to be supplied from the busbars of emergency distribution switchboards via separate feeders directly or via distribution switchboards or via electric power converter.

4.2.4 Emergency diesel generator is to have a system of automatic engine start and switching to the emergency distribution switchboard busbars in the event of voltage loss on the busbars of main distribution switchboard.

The time from the start signal activation to the moment of readiness to receive 100% load shall not exceed 30 seconds.

The emergency diesel generator starter onboard the ships of "M-СИП" class shall have two independent power sources. Each source is to ensure at least three starts.

4.2.5 No devices having effect on the start, operation and stop of the emergency diesel generator shall be present in the main distribution switchboard and central control station.

4.2.6 Onboard the ships equipped with a generator attached to the main engine and an accumulator battery operating in parallel with this generator, the abovementioned accumulator battery is considered as emergency source of electric power.

4.2.7 Onboard the ships equipped with emergency diesel generator an accumulator battery shall be present to be used as the emergency transitional (short-term) source of electric power.

4.2.8 Accumulator battery used as emergency or emergency transitional (short-term) source of electric power is to provide power supply to all consumers specified in Table 4.5.1 without recharging and voltage drop on its terminals lower than 0.9 of the rated one for the period of time not less than that specified in 4.2.1 as emergency source and for at least 30 minutes — as emergency transitional (short-term) source of electric power.

4.2.9 Accumulator batteries used as emergency or emergency transitional source of electric power are to be equipped with automatic connector to the emergency consumers' network in the event of voltage loss on the busbars of main distribution switchboard — for emergency source, and on the busbars of emergency distribution switchboard — for emergency transitional source. An automatic connection of accumulator batteries to the network when charging shall be provided also.

4.2.10 Emergency and emergency transitional sources of electric power are to have protection from short-circuit only.

When the diesel generator is used as the emergency source of electric power, it is required to use the warning system signaling the generator's overload. The warning devices are to be located at ship's control station or at central control station.

4.3 SPACES FOR EMERGENCY SOURCES OF ELECTRIC POWER

4.3.1 Emergency diesel generator, emergency distribution switchboard, accumulator battery for feeding the starter and the emergency set automation system, as well as emergency fuel storage tank are to be located in the same space.

Accumulator batteries of emergency source and emergency transitional (short-term) source of electric power shall not be located in one space with emergency distribution switchboard.

4.3.2 Onboard the ships of "М-СИП", "М-ПИП", "О-ПИП", "М" and "O" classes and onboard of all passenger ships the spaces for emergency sources and emergency transitional sources of electric power, as well as emergency distribution switchboard are to be lo-
cated above the watertight bulkhead deck, outside the trunks of machinery and boiler rooms and abaft the collision bulkhead. Exits from these spaces are to lead directly to the open deck.

Onboard the ships of "P" and "J" classes the emergency sources of electric power may be located in the machinery space.

4.3.3 Emergency diesel generator room is to be equipped with a heating system sufficient for the faultless start of emergency diesel generator.

Emergency accumulator battery room shall meet the requirements specified in 8.5 and 8.6.

4.4 DISTRIBUTION OF ELECTRIC POWER FROM EMERGENCY SOURCES

4.4.1 Failure of single emergency consumers of electric power in emergency situation (flooding, fire etc.) shall not affect the power supply of other consumers being in operation.

4.4.2 No switches are to be arranged in the circuits of the distribution switchboard of single emergency lighting fixtures except for the cases when the emergency distribution switchboard and emergency circuit are used for the main lighting.

Emergency electrical lighting in the wheelhouse is to be equipped with a switch-off device.

4.4.3 In normal operation the emergency distribution switchboard shall be fed from the main distribution switchboard, and the power supply line shall be protected from short-circuit current and overload. When the ship is moored at the quay the emergency generator may be used to supply power for the non-emergency consumers, in this case the connecting line shall be likewise protected in the emergency distribution switchboard.

4.5 EMERGENCY CONSUMERS OF ELECTRIC POWER

4.5.1 In emergency mode the consumers specified in Table 4.5.1 shall be fed from emergency or emergency transitional source of electric power.

4.5.2 Every lighting fixture and lamp holder of combined lighting fixture of the emergency lighting are to be marked red.

4.5.3 An indicator, displaying the charge level of accumulator battery used as emergency source of electric power, shall be arranged in the central control station or wheelhouse.

### Emergency consumers of electric power

| 3.11 Equipment of Automatic Identification System (onboard the ships built before 2002 the emergency accumulator battery shall provide 1 hour operation; onboard the ships built after 2002 – 6 hours operation) | + | + |

#### 4 Power consumers

4.1 Electric and electro-hydraulic rudder drive and its remote control system, as well as rudder indicators (operating time – 15 minutes)

4.2 Electric drives of watertight and fireproof doors together with their indicators and closing warning system

4.3 Electric drive of stationary emergency fire pump in accordance with 3.3.17 of Part III of the Rules (only when emergency diesel generator is installed)

4.4 Automatic pump of spray system (only for passenger ships of "M-CII" class, when emergency diesel generator is installed)

4.5 Emergency bilge pump and the equipment required for operation of the valves of bilge pumping system with electric remote control (only for passenger ships of "M-CII" class, when emergency diesel generator is installed)

4.6 Emergency means for leveling the elevator cabins with the deck during evacuation (only for passenger ships of "M-CII" class, when emergency diesel generator is installed)

#### 5 Means of communication and navigational equipment

5.1 Radio communication facilities specified in p. 3 of Part III of the Rules

5.2 Navigational equipment (only when emergency diesel generator is installed) except for magnetic compass (see p. 3.6 of the Table)

5.3 Navigational equipment of combined navigation (river – sea) ships
5 DISTRIBUTION OF ELECTRIC POWER

5.1 DISTRIBUTION SYSTEMS

5.1.1 The following systems of electric power distribution are allowed onboard the ships:

1. for three-phase alternating current:
   - three-wire insulated system;
   - four-wire insulated system.
   Application of three-phase four-wire distribution system with earthed neutral wire is allowed only for ships with shore power supply system as main source of electric power;
2. for single-phase alternating current:
   - two-wire systems insulated from the hull;
   - two-wire systems with one earthed wire — up to 30 V only;
3. for direct current:
   - two-wire systems insulated from the hull;
   - single-wire systems where the hull is used as return line — up to 30 V only.

5.1.2 In the three-wire insulated distribution systems the generator’s neutral may be earthed. The earthing shall be made via compensating unit near the generator or on the main distribution switchboard.

5.1.3 When using the single-wire distribution system the following conditions are to be met:

1. electric equipment within accumulator rooms, lamp rooms, store rooms and cargo holds is to be fed via two-wire system. Connection of negative wire with the hull is to be arranged outside the abovementioned spaces;
2. lighting fixtures of accommodation spaces (cabins, messes etc.), as well as signal lights, radio and navigational equipment are to be fed via two-wire system. The negative wire of these consumers is to be connected with the hull by means of earthing busbar of the feeding switchboard;
3. common terminals or a busbar for connection of negative connecting wiring of the group of electric power consumers are to be connected to the hull using separate wire with cross-sectional area chosen according to the total current of electric power consumers;
4. wire connection points to the metal hull are to be located in the areas and places with free access and monitoring of contact joints on framing parts or other massive parts of the hull.

It is prohibited to locate the connection points on the outer plating of the ship.

5.1.4 Three-phase alternating current consumers shall be connected in such a manner that phase current of different phases differs for not more than 15% under normal operating conditions.

5.1.5 In direct current systems where the hull is used as return line all the cables arranged in the area of magnetic compass are to have bipolar location (on two poles).

Leading and return wires are to be laid in the same cable or in the proximity to each other.

5.2 PERMISSIBLE VOLTAGE AND FREQUENCY

5.2.1 Voltage rating on the terminals of electric power sources designed for feeding the ship’s power mains shall not exceed the following values:

400 V — three-phase alternating current;
230 V — single-phase alternating current;
230 B — direct current.

</tbody>
</table>

1 380 V voltage is allowed when the parts being under voltage are not accessible without special tools.
2 220 V voltage is allowed provided that continuous automatic checking device for insulation of electric circuits is installed, which actuates a signal in the event of insulation decrease in permanently attended spaces (wheelhouse, machinery space, main distribution switchboard room etc.).
3 It is allowed to use portable tools with double insulation, which operates on 220 V power.

In the docks, as well as on the dredgers and other industrial ships it is allowed to use three-phase current of 10,000 V inclusive for special electrical high-power drives. In this case the electrical installation is to meet the requirements of Sections 14 and 17 of the present Part of the Rules.

AC frequency rating is to be taken for 50 Hz.

5.2.2 Voltage rating on consumers’ terminals shall not exceed the values specified in Table 5.2.2. Intersystem voltage is not regulated.

5.3 POWER SUPPLY OF ESSENTIAL FACILITIES

5.3.1 The following consumers are to be fed from the bushbars of the main distribution switchboard by separate feeders:
1. Electric drives of the steering gear;
2. Electric drives of the anchor gear;
3. Electric drives of fire pumps;
4. Electric drives of bilge pumps;
5. Electric drives of compressors;
6. Gyrocompass;
7. Cargo holds refrigerator panel;
8. Actuation system devices of electric propulsion plant;
9. Main lighting panels;
10. Radio station panel;
11. Navigation aids panel;
12. Navigation lights panel;
13. Sectional panels and supply distribution devices for other essential consumers grouped according to the principle of similarity of their functions;
14. Distribution devices built into the general ship control panels;
15. Fire-detecting automatic alarm station panel;
16. Electric drives of machinery providing operation of main power plant;
17. Panels of electric drives of cargo, mooring, boat and other arrangements, as well as ventilation and heating devices;
18. Charging device for starting and emergency accumulator batteries, as well as batteries supplying essential facilities;
19. Power supply panels of electric drives intended for closing of watertight doors and for the devices maintaining the fireproof doors in open position, as well as the panels of signaling devices which indicate the position and closing of watertight and fireproof doors.

Consumers specified in 5.3.1.6, 5.3.1.10, 5.3.1.12, 5.3.1.15, 5.3.1.16 and 5.3.1.19 may be fed from the distribution devices specified in 5.3.1.13 and 5.3.1.14 via separate feeders fitted with commutation devices (onboard the
5.3.2 If a ship is equipped with two or more mechanisms of the same purpose having electric drives specified in 5.3.1, then one of those electric drives is to be fed via a separate feeder from the main distribution switchboard. The electric drives of the rest of the mechanisms may be fed from the section boards or special distribution devices intended for feeding the essential consumers.

If the collecting busbars on the main distribution switchboard divided into sections having intersection disconnecting devices, then the electric drives of the mechanisms duplicating each other, special distribution devices having equal names, control panels or the same objects fed via two feeding lines shall be connected to the different sections of the main distribution switchboard.

5.3.3 Feeding circuits for smaller groups of consumers and their safety devices and switches shall be rated for the current not exceeding 16 A. These feeding circuits shall not feed lighting and heating devices simultaneously.

5.4 POWER SUPPLY OF ELECTRIC CONSUMERS OF PUSHED BARGES

5.4.1 Electric consumers of pushed barges are to be supplied as follows: from the pusher by means of a cable fixed on the pushed barge; between neighboring barges and the pusher – by means of flexible cable bridge sagging freely and being connected to the fixed circuit by means of a plug connection.

Multipolar plug connections and stranded cables may be used to supply several consumers. In this case single consumers are to be fed from stationary distribution devices.

5.4.2 A possibility to switch off the power supply onboard of the pushed barge is to be provided.

5.4.3 On pushed convoys the area of plug connections and the coupling gear shall be fitted with plates with warnings that the feeding cables shall be disconnected prior to disconnecting.

5.5 POWER SUPPLY FROM EXTERNAL SOURCE OF ELECTRIC POWER

5.5.1 If the ship network may be fed from external source of electric power, then the ship shall be equipped with external feeder switchboard.

5.5.2 The following facilities are to be provided in the external feeder switchboard:

1. terminals for external portable cable including neutral wire;
2. commutation and protection devices in the cable circuit to the main distribution switchboard (if the external feeder switchboard and the main distribution switchboard are less than 10 m apart from each other, the protection device is not obligatory);
3. signal lamps or voltmeter;
4. a device or a possibility to connect a device for checking polarity and phase sequence;
5. a plate indicating voltage, current type and frequency.

5.5.3 External feeder switchboard shall be connected with the main distribution switchboard by means of stationary laid cables.

5.5.4 Devices for mechanical fixation of the flexible cable tip laid to the switchboard, as well as cable suspensions are to be arranged in the proximity of the external feeder switchboard. Connecting cables shall not be tensioned.

5.5.5 The following facilities are to be provided in the main distribution switchboard in the feeding circuit from external source of electric power:

1. commutation and protection devices;
2. signal lamp and voltmeter;
3. antisingle-phasing device.

5.5.6 The requirements specified in 5.5.2.3 and 5.5.2.4 are not applicable for a ship supplied from external power source with current rating not exceeding 16 A.

5.5.7 If several ships are supplied from the common source of electric power, then each
ship is to be equipped with a device for disconnection from such power source.

**5.6 POWER SUPPLY TO OTHER SHIPS**

**5.6.1** Power supply to other ships shall be performed via separate lines protected with automatic switches or breakers through feeder switch boards of guarded construction according to their location onboard the ship. If the plug connections for 16 A of rated current are used for power supply of other ships, then it is required to provide connection/disconnection in no-voltage condition only (e. g. using switches or lockout devices).
6 DISTRIBUTION DEVICES, ELECTRICAL APPARATUS, TRANSFORMERS

6.1 DESIGN OF DISTRIBUTION SWITCHBOARDS

6.1.1 Frameworks, front panels and casings of main, emergency, sectional and group distributions switchboards shall be made of metal or other non-combustible material with fire retardant and self-extinguishing characteristics.

The generator section of the main distribution device is to be separated from the adjacent sections with divisions made of non-combustible material which prevent spark and flame spreading.

6.1.2 Detachable or opening parts of distribution switchboards intended for installation in locations accessible for unauthorized persons are to be locked with a special key which is the same for all distribution switchboards onboard the ship. The doors shall have a possibility to be fixed in open position.

6.1.3 The main and emergency distribution switchboards as well as the control panels are to be equipped with handrails on their front sides. The distribution switchboards accessible from the back side are to be additionally equipped with horizontal handrails located behind the switchboard.

Handrails shall be made of insulation materials. Firm sorts of wood are allowed for such application.

6.1.4 The panels of generator sections of main and emergency distribution switchboards are to be lightened with lighting fixtures fed from the corresponding generator's side in front of the generator switch.

The panels of distribution sections are to be lightened with lighting fixtures fed from the busbars.

No commutation devices are allowed in the lighting circuits.

6.1.5 The front side of the distribution switchboard panels is to be lightened in such a manner as not to interfere with monitoring the devices and not to dazzle.

6.1.6 Equipment, devices and facilities which require monitoring and maintenance shall be located on the switchboard not higher than 2 m.

6.1.7 Distribution devices designed for rated voltage higher than the low voltage, which are fitted with commutation and protection equipment and do not have a voltmeter installed, are to be equipped with a signaling lamp showing availability of voltage on the busbars.

6.1.8 The opening panels and doors, which have electric control equipment and measuring devices, are to be earthed at least with a flexible crosspiece.

Distribution device shall be equipped with at least one external earthing node. When the distribution device is sectional, then each section or casing shall have an independent earthing node.

6.1.9 Busbars and non-insulated wires in the distribution switchboards shall have dynamic and thermal stability when short-circuit currents occur in corresponding points of the circuit.

Electrical loads occurring in the busbars and in non-insulated wires at short circuit
shall be specified according to national standards.

6.1.10 Busbars and non-insulated wires of different polarity shall be painted with the following distinctive colours:

.1 red — for positive pole;
.2 dark blue — for negative pole;
.3 black or yellow-green — for earthing wire;
.4 light blue — for middle wire.

The equalizing wire shall be painted with the colour of the pole of its location with additional white transverse bands.

6.1.11 Busbars and non-insulated wires of different phases are to be marked with the following distinctive colours:

.1 yellow — for phase 1;
.2 green — for phase 2;
.3 purple — for phase 3;
.4 light blue — for neutral wire;
.5 yellow-green (transverse bands) — for earthing wire.

6.1.12 Busbars and non-insulated wires of separate phases or poles within the switchboard are to be located in the same way relatively to each other.

6.1.13 Equalizing busbars are to ensure for at least one half of the current rating of the major generator connected to the main distribution switchboard.

6.1.14 The maximal permissible load of busbars and non-insulated wires is specified in the Table 6.1.14.

The permissible temperature for busbars and non-insulated wires shall not exceed 90 °C.

The data specified in Table 6.1.14 are defined for the ambient temperature 40 °C under the following conditions:

.1 relative distance between the busbars is equal to their thickness;
.2 only the outer surface of the bunch is coloured.

If the ambient pressure differs from 40 °C or the busbars have a cross-section not specified in the Table 6.1.14, then the maximum permissible load shall be recalculated accordingly.

6.1.15 The busbars shall be connected in such a manner as to prevent corrosion in the places of their junction.

6.1.16 For light alarm indicating the status of shipborne facilities in the distribution switchboards or panels the signaling fixtures are to be used with the colour of lamps or lenses as specified in the Table 6.1.16.

6.1.17 If both alternative and direct current are used onboard the ship, then the electrical equipment shall be fed from separate distribution switchboards or from a distribution switchboard with a division or a distribution section where the voltage values are marked. The wiring diagrams of each switchboard shall be available in the distribution switchboards.

6.1.18 The design of the distribution switchboards shall provide space for mounting of external cable cores to the terminal clamps, block of terminal clamps and electrical connectors.

6.1.19 Signal lamps shall be fitted with signs and inscriptions specifying the signals' designation.

6.2 ELECTRICAL APPARATUS. GENERAL REQUIREMENTS

6.2.1 The switches with replaceable contacts are to be so designed that their replacement could be carried out using common tools without dismantling the switch or its main components.

6.2.2 All switches and disconnectors are to be fitted with mechanical or electrical indicators of "ON" position of the contacts being located in place where the apparatus is put in operation by the operator.

6.2.3 The location of the controller and bracket drums are to be clearly fixed; the neutral position is to be fixed more distinctly than other positions.

The controller and bracket drums are to have a scale and an indicator or a device indicating the "ON" position.

6.2.4 The direction of the motion of manual controls of the commutation or start-control devices is to be such that the clockwise rotation of the fly-wheel handle or upward or forward movement of the handle (lever) corresponds to the apparatus activation, start of electric motor, increase of the rotation speed, voltage rise etc.

For the control of lifting or lowering arrangements the clockwise rotation of the fly-wheel handle or movement of the handle (fly-wheel) towards the operator is to correspond
to lifting operation and counter-clockwise rotation of the fly-wheel handle or movement of the handle (lever) against the operator is to correspond to lowering operation.

6.2.5 The resistors are to be located and cooled in such a manner as to prevent other devices from heating above permissible temperatures caused by the resistors.

6.2.6 Tell-tale lamps as well as monitoring and recording instruments are to be protected against short-circuit current or fitted with the short-circuit current limiting devices.

It is allowed not to equip the tell-tale lamps with their own short-circuit current protection or short-circuit current limiting devices, if:

.1 the lamps are located in the common casing of the device;
.2 lamps are fed from the circuits laid inside the device casing;
.3 damage of the lamp circuit does not cause interruption of operation of essential facilities;
.4 the device circuit protection is designed for current not exceeding 25 A.

6.2.7 The voltage coils of the apparatus and controls are to be fitted with short-circuit current protective devices; however, they may have no protection if:

.1 the coils are installed in common casing of the device, have common protection and belong to the control system of the same device;
.2 the coils are fed from the device circuit, the protection of which is designed for current not exceeding 25 A.

6.2.8 Fastening of the wire or its tip to the coil block of electrical apparatus is to be made in such a manner that no forces from the connected wire could be transferred to the coil turns. The voltage coil taps are to be made of stranded flexible wire, except for the cases when the lead terminals are fastened directly on the coil shell.

6.2.9 Coils are to have name plates with their technical data.

6.2.10 The radio interference suppression capacitors installed in the circuits of the main and emergency distribution switchboards, generator circuits, as well as in the circuits of essential electric facilities shall be protected against short-circuit current.

6.3 MACHINE-DRIVEN ELECTRICAL APPARATUS

6.3.1 The drive gear of the current breakers shall be so designed that its contacts would be fixed in “ON” or “OFF” positions when the energy feeding the drive gear disappears.

6.3.2 The electrical drive is to provide correct activation of the circuit breaker under all load conditions at control voltage within 85 – 100 % of the rated current, and in case of alternating current — at frequency deviation from the nominal value a per 2.2.1 in addition to the above conditions.

6.3.3 The drive is to provide correct activation of the circuit breaker at the rated making current, ambient temperature +40 °C and hot winding of the drive when the control voltage is not lower than 85 % of the rated value.

6.3.4 Voltage drop down to 70% of the rated control voltage shall not cause the shutdown or reduction of pressure of the movable contacts below the minimal required one at ambient temperature of +40 °C and hot winding of the drive.

6.3.5 The design of the machine-driven circuit breaker shall provide manual control.

6.4 SELECTION OF ELECTRICAL APPARATUS

6.4.1 Electrical apparatus shall be selected in such a way that their rated voltage, load and permissible temperature would not be exceeded under normal operating conditions. Such apparatus shall withstand the rated overloads in transient modes without any damage or temperature rise up to dangerous values.

6.4.2 Rated breaking capacity of electrical apparatus designed for breaking the short-circuit-current is to be not less than the ex-
pected short-circuit current in the place of their installation in the event of shut-off.

6.4.3 Rated making capacity of automatic circuit breakers as well as switches that can be incorporated into a shorted circuit shall be not less than the expected maximal making current in the place of their installation in the event of short circuit.

6.4.4 Rated dynamic stability of electrical apparatus not designed for breaking the short-circuit-current shall be not less than the expected maximal short-circuit current in the place of its installation.

6.4.5 Thermal stability of electrical apparatus shall comply with the expected short-circuit current in the place of its installation as well as with the duration of the short circuit caused by the selective operation of the protection.

6.4.6 Automatic circuit breakers in the circuits of compound generators intended for operation in parallel are to have a pole in equalizing wire which is mechanically connected to other poles of the circuit breaker in such a way that it would switch on prior to connection of other poles to the busbars and would switch off after their disconnection.

6.4.7 The calculation of short-circuit currents shall be performed on the basis of national standard\(^1\) or according to the procedures approved by the River Register.

6.5 ELECTRICITY MEASUREMENT DEVICES

6.5.1 One voltmeter and one ammeter shall be fitted on the main and emergency distribution switchboards for each DC generator.

6.5.2 For each AC generator the following devices shall be fitted on the main and emergency distribution switchboards:

- .1 ammeter with a switch for current measuring in each phase;
- .2 voltmeter with a switch for measurement of phase and linear voltages;
- .3 frequency meter or double frequency meter for generators operating in parallel;
- .4 wattmeter — for capacity exceeding 50 kVA.

6.5.3 In the circuits of essential consumers with rated current of 20 A and more the ammeters are to be provided, which should be installed in close proximity to the consumer or at the remote control stations or in the main distribution switchboard.

It is allowed to use an ammeter with a switch but not more than for six consumers.

6.5.4 In the main and emergency distribution switchboards for each circuit of insulated systems an individual device for insulation measuring is to be installed. For all circuits of insulated systems it is allowed to use one displaying device which can be activated using a switch.

The insulation control devices are to check the circuit insulation permanently and send a light and sound signal (which can be switched off) to the engine room, central control station or the wheelhouse, when the insulation of the circuit increases up to 0.06 M at 100 V, and 0.2 M at 500 V.

The enclosure leakage current caused by the operation of the measuring device shall not exceed 30 mA in all conditions.

6.5.5 Measuring devices with at least the following scale limits are to be used:

- .1 voltmeters — 120 % of rated voltage;
- .2 ammeters for generators not operating in parallel and for consumers — 130 % of rated current;
- .3 ammeters for generators operating in parallel:
  - scale limit for load current — 130 % of rated current;
  - scale limit of reverse current — 15 % of rated current;
- .4 wattmeters for generators not operating in parallel — 130 % or rated power;
- .5 wattmeters for generators operating in parallel:
  - scale limit of load capacity — 130 %;
  - scale limit of reverse capacity — 15 %;

\(^1\) GOST R 51321.1
6. frequency meters — +10 % of rated frequency.

6.5.6 The rated values of voltage, current and power on the scales of measuring devices fitted in the circuits of electric power sources and essential consumers shall be marked with distinguishable marks or signals.

6.6 INSTALLATION OF APPARATUS AND MEASURING DEVICES

6.6.1 The switches shall be installed and connected to the power source in such a way that the movable contacts and all protecting and monitoring apparatus connected to the switch are not alive in off position.

6.6.2 The fuses in distribution switchboards shall be installed in such a way that to provide access and safety for service personnel when replacing fuse strips.

The fuses in distribution switchboards mounted on a foundation at the plating level shall be located not lower than 150 mm and not higher than 1800 mm from the plating.

If the circuit breakers are available in the distribution switchboard circuits, then the fuses shall be located between the busbars and the circuit breaker.

6.6.3 The feeding wire of screwing fuses shall be connected to the central terminal.

6.6.4 The fuses protecting poles or phases of the same circuit shall be installed close to each other either horizontally or vertically according to the design of the fuse.

The relative position of the fuses in AC circuit shall correspond to the sequence of phases either from left to right or downwards.

In the DC circuit the fuse of the positive pole shall be located to the right, from above or closer to the service personnel.

6.6.5 The manual drives of voltage regulators installed on the main or emergency distribution switchboards are to be located close to the measuring devices of corresponding generators.

6.6.6 Apparatus controls, devices, panels and coming-out circuits in distribution switchboards shall have corresponding inscriptions. The positions of commutation apparatus shall be indicated.

Irrespective of the availability of manufacturer's plate the fusing current and the release current setting shall be indicated near the fuses and current-limiting automatic circuit breakers.

6.6.7 Every feeder coming out of the distribution switchboard shall be fitted with protection and commutation devices.

It is allowed not to install the commutation apparatus in the secondary distribution boxes of lighting circuits which have common switch, as well as in the circuits of interlocking and alarm devices, switchboards local lighting which are protected with fuses.

6.6.8 Ammeters of compound generators intended for operation in parallel shall be installed in the circuit of the pole not connected to the equalizing wire.

6.6.9 The controls of generator apparatus shall be located not lower than 800 mm from the plating. The controls of other apparatus shall be located not lower than 300 mm from the plating.

6.7 PROTECTION DEVICES

6.7.1 The circuits outgoing from the distribution switchboards shall be protected against short-circuit currents and overloads by means of appropriate devices installed at the inception of each circuit as close as practicable to the feeding terminals. The overload protection of the circuit is not required when the consumers fed from the switchboard are fitted with individual overload protection devices, and the cable of the switchboard feeding circuit is rated on the maximal working current.

6.7.2 Protection devices are to comply with the characteristics of protected equipment in such a way that to be activated at prohibitive overloads.

6.7.3 Protection system is to be selective both on overload currents and short-circuit currents.

6.7.4 The protection against short-circuit current shall be installed in each insulated...
pole of DC system and in each phase of AC system. The short-circuit release current settings shall be chosen in accordance with calculations but not less than for 200% of consumers' rated current.

It is allowed to use the same protection devices to protect the electric circuits (cables) and consumers against the short circuit.

6.7.5 If the cross-sectional area of the cable is reduced at some sections of the feeding circuit, then additional protection shall be provided for each cable with reduced cross-sectional area in case the preceding protection device does not protect the cable with reduced cross-sectional area.

6.7.6 In the feeding circuits from the main distribution switchboard to the emergency distribution switchboard it is not allowed to use the protection devices which are not capable of immediate reactivation after protection operation.

6.7.7 It is not allowed to install the protection apparatus in the equalizing wire of DC generators.

6.7.8 Overload protection is to be installed in:
  .1 at least one pole or phase in two-wire system;
  .2 all phases in insulated four-wire system of three-phase current;
  .3 at least two phases in insulated three-wire system of three-phase current.

6.7.9 The casings of the fuses are to be of entirely closed type and not to allow the outside emission of arc, sparking or any other harmful effect on the adjacent structural elements when fusion occurs.

6.7.10 The casings of the fuses should provide the possibility to visually detect the fusion of the fuse.

6.7.11 The design of protection devices with screw caps shall prevent them from self-unscrewing.

6.8 LOCATION OF DISTRIBUTION SWITCHBOARDS

6.8.1 When a distribution switchboard of IP10 protection or lower is located in a special room, locker or recess, then such spaces are to be made of non-combustible material or have coating made of such material.

6.8.2 Location of pipelines and tanks close to the distribution devices is to comply with the requirements specified in 1.9.7 and 10.5.17, 10.5.18 of Part IV of the Rules.

6.8.3 The main distribution switchboard is to be located in the same vertical fire protection zone with the generators (see 1.2.1.8 of Part III of the Rules).

6.8.4 Distribution devices shall be protected against or removed from the sources of vibration and high temperature.

6.8.5 At the front and back sides of free-standing distribution switchboards (except for leaning-type switchboards) a passage shall be provided of at least 600 mm width for the switchboards of 3 m long and at least 800 mm for the longer switchboards.

6.8.6 As a rule, the distribution switchboards longer than 1.2 m shall be of free-standing type.

When using the leaning-type switchboards, the access to the parts which require maintenance shall be provided.

6.8.7 The space behind the free-standing distribution switchboards with open alive parts shall be enclosed and fitted with doors. The doors shall be opened from the inside without a key and from the outside using a key. The doors are to bear plates with warnings. A device holding the door in open position shall be provided.

6.8.8 Distribution switchboards longer than 3 m specified in 6.8.7 are to be provided with at least two doors for entering the space behind the switchboard from the space of its location. One of the doors may lead into the adjacent space.
6.9 STATIC POWER CONVERTERS

6.9.1 The requirements of the present chapter are applicable to the shipborne static power converters and other semiconductor power units as an addition to the requirements of other chapters of the present Part of the Rules.

6.9.2 The distortion factor $K_{\text{dist}}$ of the ship network is subject to the operation of the semiconductor power units and shall not exceed 10%.

The distortion factor is determined using the following formula, %

$$K_{\text{dist}} = 10^2 \sum_{n=2}^{\infty} \left( \frac{U_n}{U_1} \right)^2$$

(6.9.2)

where $U_n$ — active value of $n^{th}$ harmonic of distorted voltage;

$U_1$ — active value of 1$^{st}$ harmonic.

6.9.3 Electromagnetic interference generated by the semiconductor units including their feeders shall not exceed the values specified in 2.7.

6.9.4 The semiconducting converters shall have the air cooling (natural or forced) or the liquid cooling.

In the converters with the liquid cooling where the latter is in direct contact with unit’s parts a continuous monitoring of insulation resistance is to be ensured. A light and sound alarm shall be available in engine room to warn the watchkeeping of impermissible reduction of insulation resistance. Onboard the ships with unmanned engine room such alarm shall be available at the central station or the wheelhouse.

6.9.5 The semiconductor converters with forced cooling shall be fitted with a protection which reduces or shuts down the load in case of failure of cooling system or overheat of the latter.

A sound and light alarm is to be provided before activation of the protection. This alarm shall indicate that the temperature of the semiconductor converters exceeds the maximum permissible value and the cooling agent flow at the output of the cooling system disappears.

6.9.6 The semiconductor power units are to be protected against inner and outer overvoltage.

6.9.7 The blocks of semiconductor units shall be protected against short-circuit current. The protection of diodes and thyristors is to be separated from protection load circuit.

6.9.8 Where only one consumer is allowed, the load and the blocks of diodes and thyristors may have a common protection.

6.9.9 The semiconductor converters are to have a light alarm indicating the on/off condition of power and control circuits.

6.9.10 The power part of the semiconductor converters shall be electrically isolated from the control system.

6.10 TRANSFORMERS

6.10.1 Onboard the ships where the transformers are used for feeding the lighting circuits and essential facilities, at least two transformers are to be installed with such a capacity that in the event of failure of the highest capacity transformer the others would be capable to provide the ship’s total need in electric power under all operating conditions.

When using sectioned system of collecting busbars, the transformers are to be connected to different sections.

Onboard the ships of less than 25 m in length and on board the floating objects (except for passenger ships) it is allowed to install only one transformer.

6.10.2 Dry-type transformers are to be used on board the ships.

6.10.3 Short-circuit voltages of transformers operating in parallel are to be such as to limit the load deviation of every transformer from the value of appropriate capacity proportion for not more than 10% of the current rating of the given transformer.

6.10.4 Ratio of power ratings of transformers operating in parallel shall not exceed 3:1.
6.10.5 Transformer windings for primary and secondary voltages are to be electrically separated. This requirement is not applied to starting and excitation transformers.

6.10.6 In the single-phase and three-phase transformers intended for the ship network supply the voltage fluctuations at the active load within the limits from idling to rated load shall not exceed 5% per phase for transformers with capacity up to 5 kVA and 2.5% per phase for those with greater capacity.

6.10.7 The design of air-cooled and dry dielectric-cooled transformers shall ensure their capability to withstand 10% overload within 1 hour and 50% overload within 5 minutes.

6.10.8 Feeding circuits of transformers' primary windings are to be fitted with short-circuit current protective devices. Overload protection is to be provided only for transformers with capacity exceeding 6.3 kVA. Overload protective devices may be replaced with alarm devices.

6.10.9 If the transformers are intended for operation in parallel, the switches are to be installed which disconnect their primary and secondary windings (simultaneous disconnection is not obligatory).

When such transformers are fed from different sections of the main distribution switchboard which may be disconnected during operation, an interlocking is to be provided to prevent their parallel operation when disconnecting the sections of the main distribution switchboard.

6.10.10 The switching-over of current-measuring transformers is to be made in such a way that to prevent their secondary windings from being in an open circuit condition.

6.11 UNINTERRUPTIBLE POWER SOURCES

6.11.1 The uninterruptible power sources (UPS) complying with the requirements specified in 6.11.2 – 6.11.9 may be used as emergency or transitional sources of electrical power.

6.11.2 UPS type selection shall be appropriate to power supply requirements of the connected load.

6.11.3 UPS shall be provided with a bypass, which ensures power supply to connected load from the ship network if the inverter fails.

6.11.4 Each UPS shall be provided with light and sound alarm to be given in normally manned location for:

1. power supply failure to the connected load;
2. earth fault;
3. activation of battery protective device;
4. when the battery is being discharged;
5. when the bypass is in operation for online UPS.

6.11.5 The requirements for location of the UPS are similar to the requirements for the location of the emergency or transitional source of electrical power.

6.11.6 UPS with sealed batteries may be located in any space other than the accommodation space, provided that the ventilation of such space ensures at least three-time air circulation per hour.

6.11.7 UPS shall maintain rated voltage and frequency on the load side throughout the whole time necessary to supply the connected consumers.

6.11.8 On voltage recovery in the power supply circuit, the capacity of the UPS rectifier shall be sufficient to maintain rated voltage and frequency on the load side with simultaneous recharging the battery by the maximum possible charging current.

6.11.9 The accelerated (boost) charging of the UPS batteries by the maximum possible charging current shall be interlocked with the ventilation of the space where the UPS batteries are installed.
7 ELECTRICAL MACHINERY AND DRIVES

7.1 GENERAL REQUIREMENTS

7.1.1 Electrically driven machinery with remote or automatic control from combined stations are to have light alarm on the stations indicating the switching on of the drive.

7.1.2 When the devices and machinery have automatic, remote and local control, the automatic and remote control are to be switched off when the local control is activated. Local control is to be independent from the automatic and remote control.

7.2 ELECTRICAL MACHINERY

7.2.1 Ventilation doors for cooling air input to the electric machinery shall not be located below the flooring level.

7.2.2 Current drainage from the brush is to be carried out by means of flexible copper wire.

No brush-holder springs are allowed for current drainage.

7.2.3 The generators are to be so designed as to withstand the overcurrent specified in Table 7.2.3 after being heated up to the steady-state temperature corresponding to the power rating.

<table>
<thead>
<tr>
<th>Generator</th>

<td>50</td>
<td>15</td>
</tr>
</tbody>
</table>

7.2.4 The electric motors are to be so designed as to develop increased torques specified in 7.2.4 without stop or sudden change of the rotation speed.

7.2.5 The generators not intended for parallel operation shall have a protection against overcurrents and short circuits. Circuit breakers shall be used to protect every generator of more than 4 kW capacity.

7.2.6 Every generator intended for operation in parallel shall be protected against the following:

1. overload;
2. short circuit;
3. reverse current or power;
4. undervoltage.

<table>
<thead>
<tr>

It is recommended to use such devices for the generator overload protection which are fitted with overload alarm operating with time delay up to 15 minutes for the load from 100 to 110 % of current rating, and with the shut down of the generators with time delay corresponding to the thermal time constant of protected generator for the load from 100 to 150% of the current rating.

When setting the protection on 150% of the generator current rating, it is recommended for the time delay not to exceed 2 minutes for AC generator and 15 seconds for DC generator. At the load exceeding 150% of the current rating the generator should be shut down without any time delay.

Overload protection settings and time delays are to be selected in accordance with the overload characteristics of the generator prime mover in such a manner that the prime mover would be capable to develop the required output within the specified time delay. No protective devices which prevent from immediate restart of the generator are to be used for the generator overload protection.

7.2.7 Devices are to be provided which shut down automatically and selectively the consumers of less importance in the event of generators' overload. The consumers may be switched off in one or several steps depending on the generator's overload capacity.

7.2.8 The short-circuit protection of the generators for the systems with insulated zero point is to be provided in all phases or poles.

7.2.9 Protection of the generators intended for operation in parallel against reverse power or current is to correspond to the characteristics of the prime mover. The applicability range of protection against reverse current or power is to be in accordance with Table 7.2.9.

<table>
<thead>
<tr>

7.2.10 The undervoltage protection shall prevent the generators connection to the busbars prior to the moment when the generators' voltage stabilizes and reaches at least 80% of the voltage rating, as well as shut down the generators when the voltage across their terminals is reduced.

The undervoltage protection is to be activated with time delay for disconnecting the generators from the busbars when the voltage is reduced, and to be activated instantly in the event when the generator is connecting to the busbars prior to the moment when the abovementioned minimum voltage is reached.

7.2.11 The outgoing feeders of the distribution switchboards supplying electric motors of more than 0.5 kW power are to be fitted with protection devices against short-circuit current and overload, a well as the zero protection device if no automatic restart of motor is required.

The overload and zero protection devices are to be installed on the current collector or its starter.

Electric motors of less than 0.5 kW power shall be protected against short-circuit current.

7.2.12 AC motors are to be protected against overload in two phases.

DC motors are to be protected against overload in two poles.

7.2.13 Overload protection devices of electric motors are to be set so as to shut down the motor to be protected within 105–125 % of the current rating with time delay corresponding to the heat resistance characteristics of the protected electric motor.

7.2.14 For electric clutches the maximum torque in the field forcing mode shall not exceed the value equal to the double rated torque of the clutches.

7.3 INTERLOCKING OF ELECTRICAL DRIVES. SWITCHGEAR

7.3.1 Electrically and manually driven ship's facilities are to be fitted with interlocking device to prevent the drives from simultaneous operation.
7.3.2 If the technical facilities are required to operate in a specified sequence, then appropriate interlocking devices are to be used.

An interlocking switch-off device may be used provided that it is protected from spontaneous interlocking switching-off. An inscription indicating its purpose and forbidding its use by unauthorized personnel is to be located nearby.

7.3.3 Starting of the technical facilities, the electric motors or equipment of which require additional ventilation under normal operating conditions, is to be possible only when such ventilation is in operation.

7.3.4 The applied start-control equipment is to provide the start of electric motor only from the zero position.

7.3.5 The start-control equipment which shuts down the shunt excitation winding is to be fitted with field suppression devices.

7.3.6 Every electric motor with power of 0.5 kW and over as well as its start-control equipment are to be fitted with a power-off device. If the start-control equipment is mounted in the main distribution switchboard or in other distribution switchboard but in the same space and are visible from the place of electric motor location, then a switch mounted on a switchboard may be used for this purpose.

If the above requirements for the location of the start-control equipment are not practicable, the following is to be provided:

1. a device interlocking the switch on the distribution switchboard in off position, or
2. additional switch near the electric motor, or
3. protection devices in each pole or phase of start-control equipment which are located in such a manner as to be easily replaced.

7.4 SHUTDOWN SAFETY DEVICES

7.4.1 The control systems of technical facilities, the operation of which may create danger to the safety of people under certain conditions, shall be fitted with shutdown safety devices which ensure the power-off of electric drive.

7.4.2 The shutdown safety device is to be painted red and protected against occasional activation. An inscription indicating its purpose is to be located nearby.

7.4.3 The shutdown safety devices are to be located at the control stations or in other places ensuring safety of operation.

7.4.4 The electrical drives of technical facilities and devices, which require restriction of motion in order to prevent injuries or emergency situations, are to be fitted with terminal switches.

7.5 ELECTRIC DRIVE OF STEERING GEAR

7.5.1 The main and standby electrically driven steering gear are to be fed by separate lines from the main distribution switchboard of the electric power plant directly or via the switchboard of emergency diesel generator.

7.5.2 Every line is to be rated for supply of all electric motors that are connected to it and may operate simultaneously.

7.5.3 When the emergency and main power sources provide the same current type and voltage, then one of the lines specified in 7.5.1 is to be led across the emergency distribution switchboard.

7.5.4 When more than one power-generating sets of the steering gear are used, at least two steering gear control systems (independent from each other) are to be provided in the wheelhouse. Separate cables are to be led for such control systems.

Circuits used for both electrical drives are not to be combined in one device.

7.5.5 Protection apparatus of control circuits are to be connected behind the protection apparatus of the steering gear power set.

7.5.6 An alarm indicating the loss of voltage in the control circuit is to be provided.

7.5.7 Electric motors of electric or electrohydraulic steering gear are to be protected
against short circuit only. No undervoltage and overload protection are allowed. An alarm indicating the overload of electric motors is to be provided.

7.5.8 Automatic circuit breakers protecting electric motors of the steering gear against short-circuit current are to be set for instantaneous release: at current not less than 300% and not more than 400% of the current rating of electric motor under protection; for AC motors – at current exceeding 125% of the maximum starting current of the protected electric motor.

7.5.9 Starting devices are to provide repeated automatic start of electric motors after voltage restoration caused by interruption of power supply.

7.5.10 In the vicinity of main engine control stations, if any, or in the central control station, where available, as well as in the wheelhouse near the rudder control panel there shall be provided the devices indicating the voltage presence in the steering gear supply circuit, the steering gear overload and shutdown as well as when reaching the minimal oil level in the daily service tank of hydraulic system. The overload and shutdown alarm signals are to be both visible and audible.

7.5.11 Direction of the handwheel rotation and movement of the control device handle are to coincide with the selected direction of ship's movement.

When a push-button control is used, key-stroke of the button located on the right side makes the ship to move to the right and key-stroke of the button on the left side makes the ship to move to the left.

7.5.12 Electrical drive of the steering gear is to provide:

.1 a period from hard over to hard over within the time and angle specified in 2.4.11, 2.4.12, 2.4.31 of Part V of the Rules;

.2 continuous period from hard over to hard over within 30 minutes for every set at maximal ship's speed ahead and the draught corresponding to the load waterline;

.3 possibility of the electric motor stalling in energized condition within one minute after operation in a steady temperature conditions (only for steering gear with direct electrical drive).

7.5.13 The initial starting moment of the steering gear motor with direct electrical drive is to be not less than 200% of the rated one.

7.5.14 The end switches to limit the movement of the rudder or steering nozzle from hard over to hard over are to be provided in the control circuit of the electrical steering drive. It shall be possible to move the rudder in backward direction when one of them is activated.

7.5.15 When there are a number of control stations for electrical steering drive, a switch is to be provided for selecting only one station for operation.

7.5.16 The wheelhouse and all the control stations are to be fitted with rudder position indicators. For electrically or hydraulically driven steering gear the rudder position indicator sensor shall be driven either directly from the rudder stock or from a component being rigidly connected to the latter. The sensor is to be fed independently from the control system. The rudder position indicating system is to be fed by a separate feeder and be permanently in operation. Additional transmitters for automatic pilot facilities are to be fed by separate feeders and be electrically separated from that system.

7.6 ELECTRICAL DRIVE OF ANCHOR AND MOORING MACHINERY

7.6.1 When AC squirrel-cage electric motors are used, the electrical drives of the anchor and mooring machinery are to ensure the possibility of stalling of electric motor in energized condition at the rated voltage after 30 minutes of operation at the rated load for at least 30 s for anchor machinery and 15 s for mooring machinery. For the pole-changing motors this requirement is applicable for operation of the motors with the windings generating the maximal starting moment.
DC electric motors and AC wound-rotor electric motors are to withstand the above-mentioned stalling conditions but at the moment equal to 200% of the rated value, in this case the voltage may be lower than the rated one.

After stalling the temperature is not to rise by 30% above the permissible value under normal operating conditions.

7.6.2 Anchor and mooring capstans and mooring winches at the velocity stages intended for mooring operations only and not for anchor lifting are to be adequately protected against the overload protection of the electric motor.

**7.7 ELECTRICAL DRIVE OF BOAT WINCHES**

7.7.1 The controls of the boat winch electric drive are to be fitted with a self-return device to "Stop" position.

7.7.2 The electrical drive of the boat winch is to be prevented from being switched on when using the manual drive handle.

7.7.3 The power circuit switch of the electric motor is to be arranged in the vicinity of the boat winch control station.

7.7.4 The boat winch control station is to be located in such a way that the operator could observe the boat when it is being lifted from water to the place of arrangement.

**7.8 ELECTRIC PUMPS OF DRIVES AND VENTILATORS**

7.8.1 The feeding circuits of electrical drives of the fire pumps shall not contain the thermo-switch protection devices. The overload protection devices may be replaces with an alarm.

7.8.2 The electric motors of fuel and oil transfer pumps and separators are to be fitted with remote disconnecting switches located outside the spaces containing them and outside the trunks of machinery spaces but in close vicinity of exits from those spaces, as well as in the wheelhouse; onboard the ships with length less than 25 m the latter shall be fitted in the wheelhouse.

7.8.3 The remotely controlled fire pumps are to be fitted also with local control station.

7.8.4 Electric drives of ventilators in the machinery spaces, cargo holds, galleys and general shipboard ventilation are to be fitted with remote disconnecting device located in the wheelhouse.

Irrespective of the number of the disconnecting devices the electric motors of the galley stoves' exhaust ventilation are to be fitted with a disconnecting device located in the galley.

7.8.5 The supply and exhaust ventilation system for spaces protected by fire smothering system is to be automatically switched off after activation of the system.

7.8.6 The remote switching-off devices for the ventilators are to be fitted with visual alarm indicating that the electrical drive is stopped.

7.8.7 Activation of the ventilator electrical drive is to be accompanied with a visual alarm when remotely controlled.

**7.9 ELECTRICAL DRIVE AND ELECTRICAL EQUIPMENT OF CARGO HANDLING GEAR**

7.9.1 When the cargo handling gear has two independent electrically driven winches intended for joint lifting of a cargo, the electrical drive of these winches is to ensure simultaneous stop and braking of both winches in the event of deenergizing of one of them.

7.9.2 For power supply and control of movable cargo handling gear the automatically installed flexible hose cables shall be used. The use of bare (trolley) wires is not allowed.

7.9.3 The elevator is to be fitted with electromagnetic brake, end switches, limiters and grabs which automatically stop the cabin in the event of the rope rupture or excessive lowering speed.
When the cabin starts moving, it shall be prevented from being controlled by any buttons except the "Stop" button. An alarm indicating that the elevator is busy shall be provided at the control station.

7.9.4 The electrical drive of the elevator shall prevent its moving when the cabin doors are open, the rope is slack or the cabin is caught by the grabs.

7.10 ELECTRICAL DRIVE OF WHEELHOUSE HOISTING DEVICE

7.10.1 The electrical drive of the wheelhouse hoisting device shall have at least two shutdown devices, one in the wheelhouse, another – at the drive control station.

7.10.2 A light alarm is to be provided in the wheelhouse indicating the upper and lower end positions of the wheelhouse, as well as light and sound alarm indicating the movement of the wheelhouse.

An automatic shutdown of the hoisting device is to be provided in the end positions of the wheelhouse.

7.11 ELECTROMAGNETIC BRAKES

7.11.1 The brake is to be activated (braking) in the event of loss of voltage on the brake's coil.

7.11.2 Voltage drop down by 30% below the rated one shall not cause the actuation of the brake when it is in heated condition.

7.11.3 It shall be possible to unbrake the electromagnetic brakes manually.

7.11.4 The electromagnetic brakes are to have at least two pressure springs.

7.11.5 Shunt excitation windings of the compound excitation brakes are to maintain the brake in unbraked condition even when the current does not flow along the series winding.

7.11.6 Shunt excitation windings of the brake are to be made or protected in such a manner as to prevent their damage due to overvoltages generated when switching off the windings (see also 7.3.5).

7.12 ELECTRICAL DRIVE OF WATERTIGHT AND FIRE DOORS

7.12.1 Power supply of electrical drives and indicators of position and closure of watertight doors shall be taken from the main and emergency sources of electrical power in accordance with the requirements specified in 4.5.1 and 5.3.1.

7.12.2 Electrical equipment of watertight doors having no IP level shall be located above the bulkhead deck.

Electrical equipment of the door drives located below the bulkhead deck shall have the following IP levels:

- Electric motors and controls related thereto — IPX7;
- Door position indicator sensors and circuit elements related thereto — IPX8;
- Door movement sound alarm elements — IPX6.

7.12.3 Electric power, control, indication and alarm circuits shall be protected against fault in such a way that a failure in one door circuit will not cause a failure in any other door circuit. Short circuits or other faults in the alarm or indicator circuits of a door shall not result in a damage in the electric power and control circuits. The door design shall be such that the leakage of water into the electrical equipment located below the bulkhead deck will not cause the door to open.

7.12.4 A failure in the power operating or control circuits of a sliding watertight door shall not result in a closed door opening. Availability of power supply shall be continuously monitored. Loss of power supply in the power operating and control circuits shall activate a sound and light alarm in the central control room and the wheelhouse.

7.12.5 The electric drives of devices for holding the fire doors in open position (see 2.6.3 of Part III of the Rules) shall:

- be supplied from the main and emergency sources of electric power;
.2 be remotely controlled from the wheelhouse for closing the doors individually, in groups or all doors simultaneously;

.3 close automatically all the doors simultaneously in case of supply voltage loss;

.4 be so designed that any damage in the mechanism of closing any door could not render inoperative the systems of supply and operation of other doors.
8 ACCUMULATORS

8.1 DESIGN OF ACCUMULATORS

8.1.1 The storage-cell jars and opening closings are to be so designed that to prevent spilling and splashing of the electrolyte when the jar is inclined in any direction at an angle up to 40°.

The closings are to be made of strong and electrolyte-resistant material. The design of the closings is to prevent the increase of gas pressure in the accumulator.

8.1.2 Materials used for manufacturing of containers intended for accumulators are to be electrolyte-resistant. The accumulators are to be fixed inside the containers in such a way as to prevent their relative displacement.

8.1.3 The mastics used shall withstand the ambient temperature changes from –30 to +60 °C.

8.1.4 For the fully charged accumulators after 28 days storage in unloaded condition at the temperature (20±5) °C the capacity loss due to self-discharge shall not exceed 30% of the rated one for acid accumulators and 15% for alkaline accumulators.

8.2 PROTECTION OF ACCUMULATORS

8.2.1 The accumulator batteries, except for those intended for starting the internal combustion engines, are to be fitted with protection devices against short-circuit current.

8.2.2 Every accumulator charging system shall have an appropriate protection against batteries' discharge due to drop or loss of voltage feeding the charging device.

8.3 CHARGING DEVICES OF ACCUMULATOR BATTERIES

8.3.1 A charging device is to be provided for charging the accumulator batteries. This device is to charge the battery within 8 hours.

8.3.2 Charging device is to provide the possibility of measuring the charging current and voltage, as well as the possibility to indicate the charging rate at the battery outlet.

8.3.3 Onboard the ships with portable consumers fitted with accumulators it shall be possible to charge that accumulators.

8.3.4 It shall be possible to charge the starter battery of emergency diesel generator from the ship power network.

8.4 CAPACITY OF STARTER BATTERIES

8.4.1 The capacity of the starter accumulator battery is to provide at least 10 consecutive starts of each main engine starting from cold condition without recharging.

8.4.2 The starter accumulator batteries of main and auxiliary engines are to provide the power supply of controls, alarm devices and standard consumers of those engines' electricity.

Signal lights, lighting fixtures of main lighting, rudder indicators and low-capacity non-essential consumers may be connected to the starter battery.

The battery is to be of such capacity as to supply the required number of starts of every engine and connected consumers within at least 8 hours without recharging.
8.4.3 The starter battery of an auxiliary engine is to have such capacity as to provide not less than 6 consecutive starts of the engine starting from cold condition without recharging.

8.4.4 When calculating the capacity of the batteries the duration of every start is to be taken for at least 5 seconds.

8.4.5 The starter accumulator battery for internal combustion engines' start is to be fitted with a disconnecting switch in the beginning of the circuit from the accumulator side in order to disconnect the battery from consumers; such switch fitted in one pole is sufficient.

8.5 LOCATION OF ACCUMULATOR BATTERIES

8.5.1 The batteries for voltage over 50 V as well as those with charging capacity over 2 kW rated for the maximal charging current and the nominal voltage of accumulator with due regard of the charge characteristic of the charging device are to be located in accumulator rooms, recesses, containers accessible from the main deck.

The batteries that require capacity from 0.2 to 2 kW for charging may be located below the main deck in a locker or container.

The batteries with capacity lower than 0.2 kW may be located in any space onboard the ship, except for the wheelhouse, accommodation and service spaces, provided that they are protected against water and mechanical damages and do not adversely affect the nearby equipment.

8.5.2 Acid and alkaline accumulators are not to be located in the same space or container. The jars and devices intended for batteries with different electrolytes are to be located separately from each other.

8.5.3 The inner part of the accumulator room or container as well as all structural parts that can be adversely affected by electrolyte or gas are to have appropriate protection.

8.5.4 The accumulator batteries are to be fastened securely. When installing the single accumulators with jars made of conductive materials, the linings and spacers are to be made of non-hygroscopic insulation materials.

8.5.5 When installing the accumulator batteries or single accumulators, the linings and spacers between them are to be provided in order to ensure a clearance of at least 15 mm on all sides for air circulation.

8.5.6 The accumulator batteries are to be installed in such a way as to provide easy maintenance for replacement, control, tests, installing additional elements and cleaning the accumulators, and to be located in such a way as to provide a distance between the deck and the plugs of the upper tier not more than 1500 mm.

If the accumulators are installed on two or more shelves located one above the other, at least 50 mm clearance for air circulation is to be provided at the front and back sides of the shelves.

8.6 HEATING AND VENTILATION OF ACCUMULATOR ROOMS

8.6.1 The accumulator rooms where the temperature may be lower than +5 °C during operation shall be heated either with water or steam radiators or using heat supply from adjacent spaces.

8.6.2 The valves of the heating system are to be located outside the accumulator room.

8.6.3 The shipborne air conditioning system shall not be used for heating the accumulator rooms.

8.6.4 The accumulator rooms, lockers and containers are to be adequately ventilated thus preventing accumulation of explosive mixtures inside them. The ventilation system shall meet the requirements specified in 10.12 of Part IV of the Rules.

The ceiling in the accumulator room shall be even and with cavity-free structures, otherwise each cavity shall be individually ventilated to avoid dead zones.

8.6.5 The artificially ventilated accumulator rooms are to be fitted with devices preventing from activation of accumulator charging prior
to the activation of the ventilation. The charging is to be automatically shutdown after the shutdown of the ventilators.

8.7 PROTECTION AGAINST EXPLOSION

8.7.1 The explosion danger inscriptions are to be placed on the entrance doors to the accumulator rooms as well as on the accumulator containers and lockers.

8.7.2 The accumulator rooms may be fitted only with lighting fixtures with explosion-proof cover (Exd), which are to comply with the gas mixture category IIC and the gas mixture group T1 (see Appendix 2), as well as local cabling to accumulators and lighting fixtures.

Local cabling to accumulators may be laid without sheathing.
9 ELECTRICAL HEATING AND COOKING APPLIANCES

9.1 GENERAL REQUIREMENTS

9.1.1 The requirements of the present Section apply to galley electrical ovens, water heaters, heating pads, radiators and other heating and cooking appliances. The stationary type electrical heating appliances are allowed only.

9.1.2 The loaded structural parts of electrical heating appliances as well as the inner surfaces of their enclosures are to be made of non-combustible materials.

9.1.3 The electrical heating appliances are to be designed in such a way that the temperature of their handles or other components, which are used or likely to be touched by the attending personnel, does not exceed the values specified in Table 9.1.3.

9.1.4 The electrical heating devices and the water heaters are to be fitted with a device for automatic adjustment of temperature. The water heaters are to operate safely when being inclined in any direction at an angle up to 30° from the vertical.

9.1.5 The commutation facilities and switches of the heating appliances are to have clearly distinguishable indications of "on" / "off" positions as well as all other possible positions of the controller.

9.1.6 When the electrical heating appliances are not fitted with built-in switching-off devices, the spaces where such appliances are located are to have the corresponding switching-off devices.

9.1.7 The electric flowing liquid heaters are to have a thermal protection. Two thermo-regulators are to be provided in the heaters: one of them – a safety device, another – for adjustment.

9.1.8 The electrical heaters in oil and fuel tanks shall comply with the requirements specified in 16.2.32 – 16.2.34.

9.1.9 The stationary electrical heating appliances operating in automatic mode are to have a temperature protection.

A red light signal is to be provided near each appliance or on the appliance itself. This signal shall be activated simultaneously with the switching-on of the heating appliance. This signal shall not hinder the shipdriver.

9.2 HEATING APPLIANCES

9.2.1 The casings of heating appliances are to be so designed that no objects may be located on them.

</tbody>
</table>
9.2.2 The heating appliances intended for ship's spaces heating are to be of stationary type. The appliances are to be fitted with appropriate facilities that shutdown the power supply when the temperature of particular components exceeds the permissible values.

9.2.3 The galley heating appliances are to be so designed that to exclude the contact of cooking utensils with alive parts of the appliances, and the leakage of any liquid could not cause a short circuit or insulation damage.

9.2.4 The stationary heating appliances intended for 380 V voltage are to be of protected type in order to prevent any access to alive parts not using special tools. The casings are to have inscriptions indicating the voltage according to Table 5.2.2.

9.2.5 The electric water heaters are to be automatically shutdown when the water level is lower than the permissible one.

9.2.6 The electric radiant heaters for saunas shall be equipped with:
1. heat regulator – built-in or installed separately from the electric radiant heater – which switches off the heating elements when reaching the temperature of 120 °C;
2. red lights shall be installed on the control panel of the electric radiant heater and in the nearest ship's corridor or in the room of administrator on duty. These red lights shall be activated simultaneously with the power supply to the electric radiant heater.

9.2.7 The ironing rooms shall be fitted with a non-detachable connection of the iron via a packet switch with a signal lamp to be activated when the later is switched on and located near the entrance into the room.

9.3 SYSTEMS WITH HEATING CABLES

9.3.1 The systems using heating cables for removing ice and avoiding icing shall be provided for shipborne arrangements, equipment and spaces intended for:
- performing by ship of its main purpose;
- maintaining maneuverability and stability;
- crew safety (rafts, boats, ladders, guard rails etc.).

9.3.2 The heating capacity of such systems shall not be less than:
- 300 W/m² — for the spaces of open decks, helidecks, ladders and gangways,
- 200 W/m² — for superstructures,
- 50 W/m² — for guard rails with internal heating.

9.3.3 The switchboard for the said systems shall be equipped with:
- Wattmeter or ampermeter to indicate the total load;
- Name plate indicating the rated load of each circuit and the switchboard as a whole;
- Residual current device;
- Load signal lamps for each circuit.

9.3.4 The heating cables shall be protected against overload exceeding 125% of the rated current of the circuit. For the self-regulating cables the overload protection may be omitted.

9.3.5 The cables and the controls of the electric heating systems of the pipelines carrying combustible media, as well as of the pipelines located in dangerous spaces are to be of explosion-proof design.
10 LIGHTING AND NAVIGATION LIGHTS

10.1 GENERAL REQUIREMENTS

10.1.1 In all ship's spaces, places and areas where lighting is required for navigation safety, control of machinery and technical facilities, as well as appropriate habitability of passengers and crew the main stationary lighting fixtures are to be provided.

The list of spaces, places and areas where the emergency lighting fixtures are to be arranged in addition to the main ones is given in Table 4.5.1.

The lighting fixtures installed in those spaces and areas where their glass hoods may be exposed to mechanical damage are to be fitted with protective gratings.

10.1.2 The external lighting fixtures shall be installed in such a way as to avoid the unwanted light interference to the ship's navigation.

10.1.3 The accumulator rooms are to be illuminated with lighting fixtures located in the adjacent explosion-proof spaces through glazed gas-tight portholes or with the explosion-proof lighting fixtures located inside the space.

10.1.4 Where the spaces or places illuminated with luminescent lamps contain machinery with visible rotating parts, appropriate measures to avoid stroboscopic effect shall be taken.

10.1.5 The stationary lighting fixtures of the cargo holds are to be fed from a special distribution switchboard. This switchboard is to be fitted with control light alarm for individual lighting circuits in addition to the safety devices and switches.

10.1.6 The casings of devices are to be made of corrosion-resistant low flame-spreading materials having the adequate mechanical strength in accordance with 2.4.1. The casings of devices intended for installation on the open deck, in cooled spaces and other moist spaces are to be made of brass, bronze or equivalent alloys or fire-resistant plastics. When using steel or aluminium alloys for the casings, then a protection against corrosion is to be provided.

10.1.7 The insulation components which the current-carrying parts are fastened to are to be made of materials not emitting gasses igniting from electric sparks at the up to 500 °C.

10.1.8 The lighting fixtures installed on the combustible materials or in immediate vicinity to them shall be designed in such a way that the temperature on their surface does not exceed 90 °C.

10.1.9 Each lighting fixture is to have a marking indicating the maximum permissible power of the lamp.

10.1.10 All the work stations in the wheelhouse shall be fitted with lighting which allows adjustment of illumination and light direction. The brightness of light is to be sufficient for safe navigation. The adjustment of illumination density to the minimal level is to be provided.

10.1.11 The illumination required for continuous work in darkness and near the entrances into the wheelhouse is to be red and have adjustable brightness.
10.1.12 The illumination of spaces and working surfaces is subject to the sanitary regulations\(^1\).

10.2 SUPPLY OF MAIN LIGHTING CIRCUITS

10.2.1 The main lighting distribution switchboards are to be fed via separate feeders. Non-essential electric drives with capacity up to 0.25 kW and the single cabin electric heating pads with current rating up to 10 A may be fed from the said switchboards.

10.2.2 The protection devices of terminal branches of the lighting circuits are to be designed for the rated current not exceeding 16 A, the total load current of connected consumers shall not exceed 80% of the protected device rated current.

10.2.3 The terminal branch of the lighting circuit for accommodation and public spaces is to feed not more than:
- 10 lighting points at voltage up to 55 V;
- 14 lighting points at voltage up to 127 V;
- 24 lighting points at voltage up to 220 V.

A larger number of lighting points may be arranged provided that 10.2.2 is met and calculation sheets of voltage drop and cable cross-sections for all sections of the branched circuit are submitted to the River Register.

Cabin ventilators and other small consumers may be fed from lighting circuits.

For a daisy chain or ramp lighting schemes where lamp holders are located close to each other and are connected to the circuit without using flexible wires a larger (than specified above) number of lighting points may be connected to one circuit provided that the maximal working current in each circuit does not exceed 10 A.

10.2.4 The main lighting fixtures for corridors, machinery spaces, as well as lamps for messes, ladders and passages leading to boat deck on the passenger ships are to be fed via two independent feeders from different switchboards. The lighting fixtures are to be located in such a way as to provide the maximal possible evenness of illumination in the event of failure of one of the feeders.

10.2.5 The local lighting lamps in accommodation spaces and the sockets shall be fed from the lighting switchboard via separate feeder independent from the feeder of the common lighting lamps.

This requirement is not applied to individual plug transformers.

10.2.6 When the ship is divided into fire zones (see also 6.8.3), the lighting circuits of each zone are to be fed via separate feeder independent from those feeding the lighting circuits of other fire zones.

The lighting circuit cables shall be laid in such a way that the fire in one zone could not damage the cables feeding the circuits of other zones.

10.3 LIGHTING CIRCUIT BREAKERS

10.3.1 Two-pole circuit breakers shall be used in all lighting circuits.

Single-pole circuit breakers may be used in lighting circuits only at low voltage and for individual lighting fixtures in accommodation and service spaces.

10.3.2 The wheelhouse or other permanent watchkeeping station on the upper deck shall be fitted with centralized means of switching-off all the stationary external lighting fixtures.

10.3.3 The switches for lighting behind the free-standing switchboards are to be located in front of the passage to the backside the switchboard.

10.3.4 The lighting switches of refrigerator spaces, baths, shower rooms, saunas and other wet spaces are to be located outside those spaces.

10.3.5 The stationary lighting circuits in the cargo spaces are to be shutdown by means of multi-pole circuit breakers located outside the cargo area. The indicators of voltage presence in the circuits shall be provided.

\(^1\) Sanitary Regulations and Standards SanPin 2.5.2-703-98. «Inland and Combined (river – sea) Navigation Ships». 
10.4 PLUG-AND-SOCKET CONNECTIONS

10.4.1 The design of connector sockets of the socket outlets is to provide permanent pressure when being in contact with the plug pins.

10.4.2 Sockets for portable lamps and low-power household devices may be connected in groups as specified in 10.2.3.

10.4.3 Sockets intended for systems with voltage over 250 V are to be rated for current at least 16 A.

10.4.4 Plugs with slotted pins are not allowed for use. The pins of the plugs intended for current exceeding 10 A are to be cylindrical solid and hollow.

10.4.5 Sockets or plugs intended for connection of the consumers that require earthing are to have contacts for connection of earthing cores of the consumer cable. When inserting the plug into the socket outlet, the plug earthing part is to engage the socket earthing part up to the connection of current-carrying pins.

10.4.6 The socket outlets with housings of at least IP55 protection level are to be designed in such a way as to provide the required protection irrespective of whether the plug is in the socket or not.

10.4.7 The socket outlets intended for rated current over 16 A are to be fitted with switches which are to be assembled with the plug in such a way that the latter could be withdrawn from the socket only when the switch is in “off” position.

10.4.8 In the socket outlets without interlocking the clearances between contacts by air or via the insulation material are to be such that no short circuit could occur due to arcing over when withdrawing the plug loaded with current exceeding by 25% the rated one at the rated voltage.

10.4.9 The socket outlets and plugs are to be so designed as to prevent the possibility to insert only one current-carrying contact pin into the socket outlet or insert into the earthing jack. The socket outlets intended for connecting the motors (gears), the direction of rotation (operation) of which depends on the change of the phase or pole sequence, are to be designed in such a way as to prevent the possibility of sequence changing.

10.4.10 No safety devices shall be located in the socket outlets and plugs. This requirement is not applied to plug transformers.

10.4.11 The socket outlets fed by different voltages are to be designed in such a way as to prevent the insertion of plugs into the outlets for higher voltage.

10.4.12 The socket outlets on open decks are to be arranged in such a way as to prevent water penetration inside the outlets.

10.4.13 The purpose and feeding voltage of the socket outlets are to be indicated in the places of their location.

10.5 PORTABLE LIGHTING NETWORK

10.5.1 The socket outlets for portable lighting fixtures are to be located:

1. in the room of radio installation converters;
2. in the emergency generator set room;
3. in the steering and thruster rooms;
4. in the machinery spaces;
5. behind the main distribution switchboard;
6. in special electrical spaces;
7. in the wheelhouse;
8. in the radio room;
9. near the log and echo-sounder enclosures;
10. in the gyro compass room.

10.5.2 The socket outlets shall not be arranged lower than the plating in the machinery spaces.

10.6 GLOW DISCHARGE LAMPS

10.6.1 The throttles and capacitors shall be protected with earthed metal coatings.

10.6.2 The capacitors of 0.5 mcF and more are to be fitted with a discharge device which is to be designed in such a way that the ca-
Lighting and Navigation Lights

10.6.3 the throttles and transformers with high inductive impedance are to be installed as close as possible to the lamp which they are intended for.

10.6.4 The glow discharge lamps fed by the voltage exceeding 250 V are to have corresponding inscriptions indicating the voltage applied. All the alive components of such lamps are to be protected.

10.7 NAVIGATION LIGHTS

10.7.1 The navigation light panel shall be fed via two lines (intended solely for this purpose) directly or through a transformer: first line — from main distribution switchboard (see 5.3.1) or via emergency distribution switchboard (if available), second line — from the nearest group lighting panel or control panel.

Onboard the ships less than 25 m in length the navigation light panel may be fed via one line including the line from the ship's control panel.

10.7.2 The navigation lights controls may be installed on the panel located in the wheelhouse.

These devices may be fed from the panel if the latter is fed from the main distribution switchboard via two feeding lines.

The navigation lights shall be connected to the power supply network via flexible cable with plug-and-socket connector.

10.7.3 The following lanterns are to be fed from the navigation lights panel via separate feeding lines:

1. top lanterns (including the top light "triangle" on pushers);
2. side lanterns;
3. poop lantern in longitudinal central plane;
4. poop lanterns on boards;
5. towing lanterns.

The poop lanterns located on ship's sides, as well as the top light "triangle" on pushers may be combines and connected to the separate groups of the switchboard. In this case the checking alarm is to be activated when both single lantern and all the lanterns are extinct.

10.7.4 The lanterns not specified in 10.7.3 may be fed from separate distribution boxes or from the nearest lighting distribution switchboard or control panel.

The lanterns being risen temporarily may be fed from lighting sockets.

10.7.5 Onboard the ships, where the lanterns are connected to the accumulator battery operating in parallel with the charging set when the ship is moving, the standby power supply of the navigation lights panel is non-obligatory.

10.7.6 The navigation lights switchboard is to be located in the wheelhouse; the power supply switch is to be arranged in the vicinity of the switchboard unless it is arranged on the switchboard itself.

10.7.7 Every circuit of the navigation lights is to be protected on both wires (including ships with single-wire power distribution system); the circuits of the lanterns specified in 10.7.3 are to have an automatic light indicator of navigation lights operation.

The light indicator is to be designed and arranged in such a way that its damage would not cause the shutdown of the navigation light.

Regardless of the light alarm an audible alarm shall be provided, which is activated automatically when a navigation light fails and the switch is in "on" position.

The audible alarm may be omitted onboard the ships where control of the navigation lights operation is available directly in the wheelhouse.

10.7.8 The navigation lights network is to be designed in such a way as to provide operation of the lantern lamp when the pilot lamps on the switchboard of the navigation lights are damaged or unscrewed.

10.7.9 The voltage drop through the indicator element connected to the navigation lantern circuit shall not exceed 3% of the rated voltage.
10.8 PROJECTORS

10.8.1 The projector’s structure shall provide the following:

.1 installation of incandescent device or the illuminating device of the lamp in the focus of projector’s optics. The position of lampholder for different lamp types is to be indicated, and the extreme positions of the lampholder are to be limited;

.2 allowable horizontal turning, as well as up and down turning in relation to projector’s normal position. A possibility to fix the projector in any position is to be provided. The allowable turning of the projector is to be specified in the technical documentation for particular types or groups of projectors.

10.8.2 The projectors may be fitted with:

searching device for homing the projector onto the object;
remote control.

10.8.3 The internal wiring of projectors is to be made using high-temperature wires with cross section at least 0.75 mm².

10.8.4 The protective glass, diffusers and light filters of projectors are to be thermal-resistant.

10.8.5 The projector’s protection level is to be at least IP56.
11 INTERNAL COMMUNICATION AND ALARM

11.1 ELECTRIC TELEGRAPHS

11.1.1 Electric telegraphs are to be fitted with visual and audible alarm being fed from the emergency power source and indicating that the voltage disappears in the feeding circuit.

11.1.2 The scales of the telegraphs arranged in the wheelhouse are to have illumination with adjustable brightness.

11.1.3 The telegraphs are to be fed from the main distribution switchboard, navigation equipment switchboard or from ship's control station.

11.1.4 The control handle of command transmitter is to be arranged in such a way as to move in the same direction as the ship moves. As a rule, the vertical position of the handle shall correspond to "Stop" command.

11.1.5 When the electric telegraphs and remote control means are installed on the inclined control panels, the handle in "Stop" position may be inclined from the vertical.

11.1.6 When two or more columns with transceivers are located in the immediate vicinity to each other (on the same deck within the visibility limits), they are to ensure the command transmission from any of them and the acknowledgement of command by all of them simultaneously without any additional switching-over. The switching to control by the column not visible from the wheelhouse is to be performed using the switches located in the wheelhouse.

11.1.7 Every electric telegraph is to be fitted with audible alarm device sending the sound signal to the wheelhouse and the machinery space when transmitting a command and receiving acknowledgment. In the event of false command acknowledgment the sound signal shall not stop.

11.2 SERVICE INTERCOMMUNICATION

11.2.1 A two-way intercommunication is to be provided onboard the ship for conversation under normal and emergency conditions of ship operation.

11.2.2 Intercommunication shall provide the following:

1. communication between the wheelhouse and central control station, local control station of main engines, control stations of bow and stern anchor gear, local control station of the steering gear drive, local control station of electric propulsion motor, emergency distribution switchboard room, gyro room, smothering fire extinguishing station, captain's room;

2. communication between central or local control station of main engines and the accommodation spaces of engine room staff.

The separate two-way voice communication is not required if the communication device ensures the priority of call and conversation from the wheelhouse at any time.

11.2.3 An automatic power supply change-over to the emergency source is to be ensured in the event of loss of voltage from the main source of power supply.

11.2.4 Communications stations in the spaces with high noise level are to have additional light signalization indicating incoming call.
11.2.5 Damage or shutdown of one communications station shall not interrupt the operation of communication system.

11.2.6 The requirements specified in the present Chapter are not applied to the ships less than 25 m in length.

11.3 GENERAL ALARM

11.3.1 The ships, onboard of which the general alarm given by voice cannot be heard in all locations where people may be present, are to be fitted with electrical general alarm which ensures sufficient audibility of signals in all such spaces and areas.

11.3.2 The sound alarm is to be arranged:
   .1 in machinery spaces;
   .2 in public spaces of total area exceeding 100 m²;
   .3 on open decks;
   .4 in corridors of accommodation, service and public spaces.

The radio room is to be fitted with the general alarm red lamp located within the field of view of the operator instead of main sound alarm.

11.3.3 The general alarm is to be fed directly from the emergency accumulator battery or a single battery. The general alarm may be fed from the ship network provided that it is under voltage for 24-hour period under any operating conditions of the ship.

11.3.4 The sound devices of general alarm shall be located in such a way as to provide clear audibility of the signal in the given space. The sound devices installed in the spaces with high level of noise shall be fitted with light alarm. The sound of general alarm devices shall differ from the sound of other types of alarm.

11.3.5 The general alarm is to be activated by means of self-return contactor from both the wheel-house and the space intended for watchkeeping when mooring in a port, if any. The interlocking of the contactor in "on" position is to be provided.

The contactors shall have inscriptions specifying their purpose and indicating their positions – "on" or "off".

If the general alarm signal is not heard from the wheelhouse or central station, then a lamp for monitoring voltage supply to the general alarm circuit is to be installed in the contactor’s circuit.

11.3.6 No commutation facilities are allowed in the general alarm circuits except for the contactor specified in 11.3.5. It is allowed to use electromagnetic equipment activated by the contactor, but not more than one contactor may be arranged in each section.

11.3.7 The sound devices, switches and distribution devices of general alarm shall have identifying designations.

11.3.8 The feeding circuits of the general alarm are to be protected against short-circuit current only. The protection devices are to be fitted in both poles of the feeder, as well as in the circuits of each sound device.

11.4 FIRE ALARM

Fire detection alarm

11.4.1 Depending on the ship's type and design features the ships spaces are to be equipped with the following systems:
   .1 manual fire indicating alarm (passenger ships, ships carrying dangerous goods, ships with two or more decks);
   .2 automatic light and sound fire detection alarm (passenger ships, ships carrying dangerous goods, other self-propelled ships with a gross tonnage of 500 gross tons and more);
   .3 automatic light and sound alarm warning of activation of the smothering fire extinguishing system. This alarm is to be activated at least 30 seconds before the release of the extinguishing medium (spaces of the ships with crew consisting of more than two persons, where the people may be present permanently or periodically under normal operating conditions);
   .4 automatic light alarm in the wheelhouse and at the central control station which
indicates the presence of water pressure in the fire main.

11.4.2 The sensors of the automatic fire detection alarm are to be installed in the following spaces:
- in accommodation spaces of passenger ships;
- in pump rooms of oil tankers;
- in cargo spaces;
- in storage spaces for inflammable materials;
- in galleys and saunas;
- in machinery spaces if no continuous watch is available.

The sensors are to be installed above the main and emergency distribution switchboards, near the fuel pumps and boilers, above the main engines and diesel generators as well as in other spaces with the risk of fire.

The sensors installed in the passenger rooms shall activate also a sound signal in the location of their installation.

When installing the sensors the locations, where the air flow may affect their operation, should be avoided, as well as the locations where the sensor may be damaged. The sensors installed in the deckhead shall be located at a distance of at least 0.5 m from the bulkheads. If this requirement cannot be met due to the design of the cargo space, then it is possible to implement another solution on sensors installation. The installation of the sensors in the cargo space is to meet the requirements specified in Table 11.4.2.

**Table 11.4.2**

**Requirements for installation of sensors in cargo space**

<table>

<td>9</td>
<td>4.5</td>
</tr>
<tr>
<td>smoke</td>
<td>74</td>
<td>11</td>
<td>5.5</td>
</tr>
</tbody>
</table>

11.4.3 Onboard the passenger ships the smoke detectors are to be installed in all the between-deck interconnections, corridors and exit paths within the accommodation spaces.

11.4.4 The manual fire detectors of fire detection alarm are to be installed in the machinery spaces, corridors, lobbies, elevators, dining cabins and saloons with an area exceeding 50 m² and at least one detector per each deck.

11.4.5 The manual fire detectors are to be located in the vicinity of exits from the spaces in easily accessible and clearly visible places and not more than 20 m apart from each other.

Onboard the passenger ships the manual detectors are to be installed within each vertical fire zone, at least one at each ship’s side on each deck.

11.4.6 The manual fire detectors are to be painted red. The sensor’s button is to be under glass cap.

11.4.7 The reception devices of fire detection alarm and the activation devices of fire indicating alarm are to be installed in the wheelhouse or in the location of permanent watch (if any).

11.4.8 The automatic fire detection alarm system shall use sensors which are activated under the effect of heat or smoke and comply with the following requirements:
- .1 sensors, responding to the temperature rise at the rate of its increase not more than 1 °C per minute and depending on the place of their installation, are to be activated within the following temperature range:
  - Installation place | Temperature range, °C
  - spaces, where normal temperature does not exceed 45 °C | from 57 to 74
  - spaces with high temperature (galleys, drying areas etc.) | < 80 x 100
  - saunas | < 120 x 140
- .2 smoke detectors are to be activated before the smoke density value reaches the level when the light extinction exceeds 12.5 % per 1 m, but not less than 2 % per 1 m. Smoke detectors installed in the machinery space are to be activated at such smoke density when the light extinction reaches not more than 50% per 1 m;
- .3 after activation test the sensors shall return to their operation condition without replacement of any components.
11.4.9 An automatic switching of the power supply of the fire detection alarm system to the emergency power source in the event of voltage loss in the main ship network is to be provided (see p. 3.5 of Table 4.5.1).

11.4.10 The fire detection alarm sensors installed in the spaces, where explosive vapors may be accumulated, and the sensors exposed to the airflow evacuated from such spaces shall be used in accordance with 16.2.6 – 16.2.10.

11.4.11 The reception device of the fire detection alarm system shall provide the following:

1. any signal or damage of a circuit do not affect the normal operation of other circuits;
2. fire detection signal has priority over other signals received by the device and allows to determine the location of the space from which it has been sent. The signal is to be both light and sound;
3. device operation monitoring;
4. the circuits of the contact-type detectors of the automatic fire detection alarm operate for interruption;
5. a possibility to switch off the sound signals. In the event of subsequent signal receipt the previously switched off sound source shall be re-activated.

11.4.12 A failure in the fire detection alarm system shall initiate the activation of light and sound alarm.

11.4.13 The central control station is to be fitted with alarm of fire detection in the machinery spaces as well as with alarm indicating the release of fire extinguishing medium to the protected spaces.

11.4.14 The fire detection alarm systems, capable of remote determination of the location of the space wherefrom the fire detection signal has been sent, shall be designed in such a way as to:

1. the loop can not be damaged by fire in more than one point;
2. corresponding means are provided which maintain the loop in operating condition in the event of any damage (break, short circuit, earthing);
3. in the event of failure of electric components of the system or data corruption the system shall quickly restore its operability;
4. activation of the fire detector does not prevent the activation of any other detector and subsequent alarm signals.

11.4.15 It is allowed to use the automatic smoke detection air sampling system instead of the automatic fire detection alarm system. The requirements for the smoke detection system are specified in 5 of Part III of the Rules.

11.4.16 Each section with detectors shall be used by not more than one fire zone and cover not more than two decks located one above the other.

Warning alarm

11.4.17 The stationary fire extinguishing systems shall be fitted with systems (devices) indicating activation of every system by means of light and sound signals.

11.4.18 The warning signals shall be clearly visible and audible in the protected spaces and in the entrances into such spaces, as well as in the adjacent spaces when the doors are closed in the noisiest locations during at least 30 seconds. The warning signals shall differ from all other light and sound signals in the protected space.

11.4.19 A warning plate shall be arranged prominently at the entrance to the space where the extinguishing medium may penetrate. The following inscription is to be made on the plate with red colour on white background:
«ОСТОРОЖНО, СИСТЕМА ПОЖАРУШЕНИЯ! НЕЗАМЕДЛИТЕЛЬНО ПОКИНУТЬ ЭТО ПОМЕЩЕНИЕ ПРИ СИГНАЛЕ...(ОПИСАНИЕ СИГНАЛА)!»
Warning! Fire extinguishing system activated!
Leave the space immediately when [signal description] signal is activated!
11.5 PORThOLES OPENING ALARM

11.5.1 Onboard the passenger ships of all classes except for «І» class all the portholes, including the life saving portholes, installed in the hull shall be fitted with automatic alarm indicating their open position. This alarm is to be output to the wheelhouse.

11.6 MECHANICIANS CALL ALARM

11.6.1 Onboard the passenger ships of «О-ПР», «М-ПР» and «М-СП» classes in the mechanics’ accommodation spaces a sound alarm of mechanics’ emergency call is to be provided. This alarm shall be activated as follows:

- manually from the main engines control station in machinery space or from the central control station (if any);
- automatically when the signal of the warning alarm for the propulsion system is not answered.
12 CABLE NETWORK

12.1 GENERAL REQUIREMENTS

12.1.1 The cables used are to be flame retardant and have standard copper cores and be manufactured in accordance with the requirements of the present part of the Rules or according to the national standards\(^1\). The flame retardance tests of the cables are to be carried out in accordance with the requirements specified in Appendix 3.

12.1.2 The cross-sectional area of cable and wire cores used for alarm and communication circuits is to be at least 0.5 mm\(^2\). For portable electrical equipment flexible cables and cords with cross-sectional area of at least 0.75 mm\(^2\) shall be used. In all other cases the cables and wires shall have a cross-sectional area of at least 1 mm\(^2\).

12.1.3 The requirements on the minimum number of strands in the core of the cables used onboard the ships are specified in Table 12.1.3-1.

Connections of separate strands of the core shall be displaced from one another by not less than 500 mm along the length of the core.

Such connections shall not impair the mechanical and electrical properties of the strand nor change the cross-sectional area of the strand or the core.

The insulation of cable and wire cores is to be made of the insulating materials specified in Table 12.1.3-2.

12.1.4 The maximal permissible temperature for cable or wire core insulation is to be higher than the assumed ambient temperature by at least 10 °C.

12.1.5 In the places exposed to oil products or other aggressive media the cables to be used are to have a sheathing resistant to such media. The cables without such properties shall be either laid in pipes or be otherwise protected.

12.1.6 In the places, where the cables may be subject to mechanical damage, the cables with appropriate protective sheathing are to be used. The cables of other types used in such places are to be protected with special shrouds or to be laid in pipes.

12.1.7 The cables of telephone communication, alarm circuits indicating activation of fire smothering system, general alarm system and closing of watertight doors shall not be laid across the machinery or boiler spaces and other enclosed spaces with higher risk of fire except for the cases when the single devices of the above systems are located in such spaces.

*Wire temperature for calculation of permissible continuous load of the cable.

If this requirement can not be met due to the structure of the ship's spaces, then appropriate measures shall be taken to protect the cable network laid across the spaces with higher risk of fire.

12.1.8 The cores of standard cables shall not be used for power supply of the controls of essential facilities not connected with each other.

The simultaneous application of low voltage and operational voltages interrupting the low one is not allowed in the standard cable.

12.1.9 Non-insulated wires and busbars may be used for inner mounting of electrical equipment; non-insulated busways may be used for the electric power run provided that they are shielded reliably.

12.1.10 When the electric power source and the electrically-driven fire pump, including the emergency one, are located in different spaces separated by a tight or fire-resistant bulkhead, then the cable feeding the electric motor shall be noncombustible or adequately protected against fire.

12.2 SELECTION OF CABLES AND WIRES BY LOAD

12.2.1 If the permissible current load values for used types of cables and wires are not specified, then the permissible continuous loads are to comply with the values specified in Tables 12.2.1-1 – 12.2.1-4.

Table 12.2.1-1

appliances neither the simultaneity factors nor correction factors shall be used.

12.3 CHECKING OF CABLES BY VOLTAGE DROP

12.3.1 The voltage drop along the cable connecting generators with the main or emergency distribution switchboard shall not exceed 1 %.

12.3.2 The voltage drop between the main distribution switchboard and the consumer at the rated load shall not exceed:

- 5 % — for lighting and alarm consumers at voltage exceeding 50 V;
- 10 % — for lighting and alarm consumers at voltage 50 V and less;
- 7 % — for power consumers, heating and cooking appliances, as well as for navigation lights irrespective of the voltage;
- 10 % — for power consumers with short-term and intermittent short-term operation irrespective of the voltage.

At the short-term loads, e. g. When starting the electric motors, large voltage drops are allowed provided that it does not adversely affect the operation of the shipborne power plant.

12.3.3 The cables feeding the directly-started AC electric motors shall be so designed that the voltage drop on the motor terminals does not exceed 25% of the rated voltage when starting the motor.

12.3.4 The voltage drop along the cable feeding the panel of the radio station and the radio electronic navigation means, as well as the voltage drop along the cable intended for charging the accumulator batteries shall not exceed 5%.

12.4 LAYING AND FASTENING OF CABLES

12.4.1 The cables shall be laid, as far as possible, on strait and accessible routes in the places free from condensate or moisture effect.

The cable route is to be located at least 100 mm apart from the heat sources.

12.4.2 The pipes with cables shall be laid at least 50 mm apart from the inner bottom plating, fuel and oil tanks, and at least 20 mm apart from tight bulkheads, outer plating and decks.

For cables laid on shackle-bridges, panels or in cassettes the above distance is to be at least 75 mm.
12.4.3 Cables and wires shall not be laid through oil and fuel tanks except for cases specified in 16.2.7.

12.4.4 The cables with outer metal sheathing may be laid using structures made of light alloys or be fastened by shackles made of such metal only when a reliable anti-corrosion protection is provided.

12.4.5 Inside the cargo holds the cables shall be located in the upper part and laid in pipes or closed with strong coatings.

12.4.6 In the spaces specified in 2.10.3 the cables may be laid in extremely urgent cases in a sealed pipeline fitted with automatic control and alarm device which activates when the circuit insulation resistance decreases.

12.4.7 It is not recommended to lay the cables under the flooring of machinery spaces. If such laying cannot be avoided, then the cables shall be laid in metal pipes or in closed trunks (see 12.6).

12.4.8 The cables laid across the expansion joints in the hull structure are to be provided with expansion bends of a radius sufficient for such joint. The inner diameter of the bend is to be equal to at least 12 cable diameters.

When mounting the heating cable in the places of dismountable joints of the pipelines fitted with electric heating, the bends with a radius sufficient for dismounting the pipeline without damaging the heating cable are to be provided.

12.4.9 The cables with insulation of different heat resistance when arranged in common cable routes shall be laid in such a manner as to provide the insulation temperature of any cable in the route to be within the permissible limits.

12.4.10 The cables with protective sheathings having different properties shall not be laid in a common pipe, if those being less protected under these conditions may be exposed to damage. When laid in a common trunk such cables shall be separated from each other and fastened.

12.4.11 The main current cables of the electric propulsion machinery shall be laid at least 0.5 m apart from the lower voltage cables and cables of other purpose.

12.4.12 The cables from any of two power sources for essential consumers, e.g. steering gear, and all the control and alarm cables connected with each source are to be laid via different routes as far apart from each other in the vertical or horizontal as possible.

12.4.13 When laying the cables in pipes or trunks made of inflammable materials, the latter shall be protected against ignition by means of appropriate fire-protecting means (facing, covering or impregnation).

12.4.14 Neither cables nor wires shall be laid in thermal or acoustic insulation. Cables may be laid in the insulation layer provided that special trunks faced with non-combustible material are used. The cables shall be designed with due regard of corresponding load decrease and be accessible for examination or be located at least 20 mm apart from the trunk sides.

12.4.15 The cables laid in cooled spaces shall have protective sheathing made of material resistant to the cooling agent effect. If the cables are armoured, the armour shall be adequately protected against corrosion.

12.4.16 The cables laid in cooled spaces shall not be located under the heat insulation. They are to be fastened on perforated panels, made of zinc-coated steel for example, or on similar braces, which are to be installed in such a manner as to provide clearance between the panel back side and the cooled space plating. The cables sheathed with thermoplastic or elastomer are allowed for laying directly on the cooled space plating. When the space is faced with aluminium, the cables are to be protected against electrolytic processes.

When cables are introduced into spaces through the heat insulation, they are to be laid in pipes fitted with glands made of material protected against oxidation. The pipes are to be located at a right angle to the bulkhead.
12.4.17 When laying the cables the minimal bending radii of cables shall be met according to Table 12.4.17.

12.4.18 The cables are to be fastened by means of shackles, clamps, collars or other fastening means made of steel or other non-combustible or flame retardant material. The fastenings shall not cause damage of the cable sheathings.

12.4.19 When the cables are laid horizontally, the distance between their fastenings shall not exceed the values specified in Table 12.4.19. In case of vertical laying the distance may be increased by 25%.

12.4.20 The cables are to be fastened in such a manner as to prevent transmission of mechanical strains occurring in the cables to their inlets and connections.

12.4.21 The cable runs and the cables laid in parallel to the hull plating shall be fastened to the hull framing. On tight bulkheads and masts the cables are to be fastened using casettes, bridges etc.

12.4.22 The cables laid in parallel to the bulkheads subject to sweating are to be arranged on bridges or perforated panels in such a way as to provide clearance between the cables and the bulkheads.

12.4.23 The cable runs are to be laid with minimal number of crossings. Bridges are to be used in the places of cable crossings. A clearance of at least 5 mm is to be provided between the crossing runs.

12.4.24 The cable runs and the cables of essential consumers laid under the ceiling and bulkheads lining are to be closed with easily removable or opening panels or shields along the whole length. Other cables and the local ones may be laid under the lining without providing access to them.

12.4.25 The cables laid to the electrical equipment installed on shock absorbers shall not affect or restrict the operation of the latter. No load is to be applied to the cable at the maximal stroke of shock absorbers.

12.4.26 The cables on the surfaces of internal combustion engines, boilers or other equipment, which may cause overheat of the cable, shall be laid in such a way as to provide protection against external overheat, otherwise the cables suitable for the maximum possible ambient air temperature shall be used on such surfaces.

12.4.27 The cables laid on opened parts of the ship are to be protected against direct effect of solar radiation.

12.4.28 Laying of cables in the bulwarks or in the guard rail elements is not allowed.
12.5 CABLE PENETRATIONS THROUGH DECKS AND BULKHEADS AND THEIR SEALINGS

12.5.1 The cable penetrations via watertight, gastight and fire bulkheads as well as through the decks are to be sealed. Such sealings shall not decrease the tightness of the above bulkheads and decks. Strains occurring from the hull resilience shall not be transmitted to the cables.

12.5.2 When laying the cables through the non-watertight bulkheads or framing less than 6 mm thick, the holes for cables are to be bushed with facing or bushes protecting the cable against damage. If the bulkhead or framing is at least 6 mm thick, the bushes or facing are not required, however the edges of the penetration hole are to be rounded.

12.5.3 The cables shall be laid through the decks in the following ways:
1. in steel pipes raised above the deck for at least 900 mm in places where mechanical damage of the cable may occur, and to a height not less than that of the door coaming for the given space in other places;
2. in metal sockets or boxes additionally protected with cable jackets of a height not less then that specified in 12.5.3.1.

Sockets and boxes are to be filled with appropriate stuffing compounds, and the pipes are to have glands or be stuffed with cable compound.

12.5.4 The cable boxes in the watertight bulkheads and decks are to be filled with packing compounds having good adhesion with the inner surfaces of the boxes and cable sheathings, resistant to water and oil products, not shrinkable and not imposing tightness during long-term operation.

12.5.5 The sealings of cable penetrations through the fire-resistant bulkheads shall satisfy the fire-resistance test specified for the given type of bulkhead.

12.6 LAYING OF CABLES IN PIPES AND CONDUITS

12.6.1 Metal pipes or conduits with cables laid are to be protected against corrosion both from the inner and outer sides. The ends of pipes and conduits shall not cause the damage of cables when pulling in.

12.6.2 The radius of pipe's bend shall be not less than that permitted for the cable with the largest cross-section laid in it (see 12.4.17).

12.6.3 The total cross-sectional area of all cables defined using their outer diameters shall not exceed 40% of the inner cross-sectional area of the pipe.

12.6.4 The pipes are to be laid in such a way as to prevent water accumulation in them. The pipes are to be fitted with ventilation holes on the highest and lowest points, if possible, so that the air circulation is provided and vapour condensation is prevented. The sealed pipes are to be fitted bleeder plugs for condensate drainage in the lowest points.

12.6.5 The pipes are to be mechanically and electrically integral and earthed.

12.6.6 The cable pipes laid along the hull are to have compensation devices preventing their damage caused by hull deformation.

12.6.7 The cables laid in pipes vertically are to be fastened in such a way as to prevent cable damage by gravity.

12.6.8 It is allowed to use cable shrouds/trays made of flame-retardant plastic.

12.6.9 The cable shrouds/trays made of plastic shall be additionally fitted metal fastenings and clamps in order to prevent the falling of such shrouds and trays, together with the cables fastened, in the event of fire. The cable shrouds/trays made of plastic and laid on open decks shall be protected against UV emission.
12.7 CONNECTION AND JOINING OF THE CABLES

12.7.1 The ends of rubber-insulated cables to be inserted into machinery, apparatus, distribution devices and other equipment are to have appropriate contact, protection and sealing terminals which ensure reliable electrical contact, prevent the ingress of moisture inside the cable and protect the cable core insulation against mechanical damage and affection of air and oil vapours.

The cable cores connected to lighting fixtures, as well as to heating and cooking appliances shall have protected heat-proof terminals in order to avoid overheating of the cable.

12.7.2 Joining of cables in the places of their branching or connection is to be carried out inside the junction boxes using clamps.

12.7.3 The cable sheathings without protective terminals shall be inserted into a device for 3–5 mm, if the protective and sealing terminals are available – at least 10–15 mm.

12.7.4 In the places of cables and wires insertion, especially in the points of joining to the mobile elements and devices, means of cable slacking and kinking prevention are to be provided.

12.8 CABLE MARKING

12.8.1 The cables onboard the ship are to be marked in accordance with design documentation.

12.8.2 The marking method is to provide the safe keeping of the marking for the whole operation period of the cables.

12.8.3 Trunk cables shall be marked.
13 LIGHTNING PROTECTION DEVICES

13.1 GENERAL REQUIREMENTS

13.1.1 The ships are to be fitted with lightning conductors covering the protected zone (ship's open spaces where explosive gas-air mixtures may be present, explosive or inflammable cargoes, materials and equipment may be located or people may be present). The ships, where consequential effects of lightning strokes may cause fire or explosion, are to be fitted with lightning protection earthing devices.

Aerials shall not be used as lightning protection devices. Aerial facilities shall be installed lower than the lightning conductor.

13.1.2 The lightning conductor is to consist of lightning diverter, diverting wire and earth termination.

The lightning conductor may be omitted on metal masts if a reliable electrical contact with the metal hull or with the point of earthing is provided.

13.2 LIGHTNING DIVERTER

13.2.1 Onboard the metal hull ships the ship's vertically oriented structures (e.g. masts, half-masts, superstructure components etc.) shall be used as lightning diverters provided that reliable electrical contact between these structures and the metal hull is ensured.

Additional diverters shall be used only when the ship's structural elements do not ensure protection against lightning.

13.2.2 When electrical equipment is installed on top of the meal mast, an earthed lightning diverter is to be provided.

13.2.3 Every mast or topmast made of non-conducting material shall be fitted with earthed lightning diverter.

13.2.4 The lightning diverter is to be made of a rod with at least 12 mm in diameter. The rod may be made of copper, copper alloys or corrosion-protected steel. For aluminium masts the aluminium diverter is to be used. It is not allowed to mount aerials or other devices on the lightning diverters.

13.2.5 The lightning diverter is to be secured to the mast in such a way as to be raised above the mast top, or a device located over the top, for at least 300 mm.

13.3 DIVERTING WIRE

13.3.1 The diverting wire is to be made of a rod, strip or stranded wire with at least 70 mm² cross-sectional area when using copper or copper alloys, and at least 100 mm² when using steel; the steel wire is to be protected against corrosion.

13.3.2 The diverting wires are to be laid on the outer side of masts and superstructures as straight as possible and with the minimum number of bends which are to be smooth and have as large radius as possible.

13.3.3 The diverting wire shall not be laid through explosion-hazardous spaces and areas.

13.3.4 Onboard the non-metal hull ships the diverting wire is to be laid separately throughout its length (including its earthing connection) and shall not be connected to the busbars of protective and working earthing.
13.4 EARTHING

13.4.1 The diverting wire is to be attached to the hull (see 2.1.1.10).

13.4.2 Devices are to be provided for connection of the lightning conductor earthing or the metal hull with the shore earthing when the ship is in the dock or on the slipway.

13.4.3 Onboard the composite ships a metal stem or other metal structures submerged into water under all navigation conditions may be used for earthing.

13.5 LIGHTNING CONDUCTOR INTERNAL CONNECTIONS

13.5.1 Connections between lightning diverter, diverting wire and earthing are to be welded or bolted with clamps.

13.5.2 The contact surface area between the diverting wire and the diverter or earthing is to be at least 1000 mm². Connecting clamps and bolts are to be made of copper, copper alloys or corrosion-protected steel.

13.5.3 The resistance between the lightning conductor and the hull shall not exceed 0.03 Ohm.

13.6 LIGHTNING PROTECTION EARTHING DEVICES

13.6.1 The lightning protection earthing is to be provided for isolated metal structures, movable connections, pipelines, shields of power and communication lines, joints leading to explosion-hazardous spaces.

13.6.2 All the pipelines for oil products, as well as all other pipelines connected with explosion-hazardous spaces and located on the open deck areas or in the spaces without electromagnetic shielding shall be earthed to the hull at least each 10 m throughout their length.

All the pipelines located on the upper deck, where explosive gases may be present, and not connected with explosion-hazardous spaces shall be earthed to the hull at least each 30 m throughout their length.

13.6.3 Metal parts located near the diverting wires are to be earthed if none of them is located on earthed structure or connected otherwise with the hull. The devices or metal parts located up to 200 mm apart from diverting wires are to be connected with the diverting wire in such a way as to avoid sparking.

13.6.4 The connections of elements are to be accessible for monitoring and located in places where they are not subject to mechanical impacts.
14 ELECTRICAL EQUIPMENT WITH VOLTAGE OVER 1000 V

14.1 GENERAL REQUIREMENTS

14.1.1 The requirements of the present Section are applicable to the electrical equipment with voltage over 1000 V but less than 11000 V AC and are supplementary to the requirements specified in other Sections of the present Part of the Rules.

14.1.2 The insulating materials used for electrical equipment are to ensure 1500 Ohm insulation per 1 V of nominal voltage during ship's operation but not less than 2 M.

14.1.3 Warning inscriptions indicating voltage value are to be located in the vicinity of the entrance to the special electrical space. The casings of electrical equipment located outside special electrical spaces are to have warning inscriptions indicating voltage value.

14.2 DISTRIBUTION OF ELECTRIC POWER

14.2.1 The following electric power distribution systems are to be used:
- neutral earthed system;
- system with neutral connected to the hull via high-ohm resistor (reactor) provided that any possible current does not flow directly through any explosion-hazardous space or area.

14.2.2 The total earthing resistance of neutral point is to be selected in such a way that the short-circuit to hull current does not exceed the nominal current of the major generator in the given system but is at least three times greater than the current required for activation of each of applied protections against short circuit to the hull.

14.2.3 When the electric power is distributed from separate sections capable to operate autonomously, each of them is to have a separate earthing reactor.

14.2.4 The neutral points of generators intended for parallel operation may be connected together before the earthing resistor (reactor).

14.2.5 The neutral point of generator is to be earthed via resistor (reactor) on the distribution switchboard or directly near the generator.

14.2.6 The neutral wire of each generator is to be fitted with a disconnector by means of which the earthing of the generator's neutral point may be disconnected.

14.2.7 The nominal voltages of the electric power distribution systems are to comply with the requirements specified in Table 14.2.7.

<table>

<td>50/60</td>
</tr>
</tbody>
</table>

14.2.8 The power supply of the ship network from external power source shall be provided only for ships operated at anchorage, such as floating docks etc.
14.3 PROTECTION DEVICES

14.3.1 When different voltages are applied in the equipment, measures shall be taken to prevent lower voltage circuits from being supplied by a higher voltage.

14.3.2 All phases of AC systems are to be protected against overload.

14.3.3 The circuits with insulated neutral point are to be fitted with light and sound alarm indicating the earth fault.

14.3.4 The electrical machinery is to be fitted with temperature detectors in the stator windings. These detectors shall indicate when the temperature of windings exceeds the permissible limits.

14.3.5 Generators are to be protected against earth fault.

14.3.6 Generators are to be de-excited automatically after activation of the generator protection of any type.

14.3.7 Generators are to be protected against inner damages and short-circuit current in the cable connecting generators and the switchboard.

14.3.8 The transformers at high voltage side are to be protected with automatic circuit breakers against the short-circuit current.

14.3.9 The transformers at low voltage side are to be protected against overload.

14.3.10 The voltage measuring transformers are to be protected against the short-circuit current.

14.4 PROTECTIVE EARTHING

14.4.1 Metal casings of electrical equipment are to be earthed using external flexible wires with a cross-section designed for the single-phase short-circuit current but not less than 16 mm². Earthing wires are to be marked.

14.4.2 The earthing conductors may be joined by means of welding or bolts of at least 10 mm in diameter.

14.5 ARRANGEMENT AND PROTECTION LEVEL OF ELECTRICAL EQUIPMENT

14.5.1 The electrical equipment shall be arranged in special electrical spaces and have a protection level not less than IP23 (see also 14.6).

The terminal boxes of electrical machinery shall have at least IP44 protection level.

The electrical equipment may be arranged outside the electrical spaces provided that its protection level is at least IP44 and its live parts are accessible only in the absence of voltage or using special tools.

14.5.2 The special electrical space shall have a diagram specifying arrangement and connections of electrical equipment.

14.6 DISTRIBUTION DEVICES

14.6.1 The high-voltage distribution switchboards are to be locked with a special key different from the keys of the low-voltage distribution switchboards and devices.

The opening of doors or pulling out of single elements is to be possible only when the switchboard or the given element are disconnected from the power network.

14.6.2 The automatic circuit breakers used in the distribution switchboards are to be of pullout type.

The circuit breakers are to be fitted with a device that holds them in the pulled out position.

The fixed current-carrying disconnecting contacts are to be covered automatically with the insulating baffles when the circuit breaker is pulled out.

14.6.3 Protective earthing is to comply with the Rules of Electrical Installations Arrangement and with the requirements of national standards.

14.6.4 Passages are to be provided along the distribution switchboards in order to perform examination of the switchboard and electrical equipment. The passage is to be at

---

1 GOST 24040, GOST R 54585.
least 800 mm wide between the partition and the switchboard and at least 1000 mm between the parallel sections of the switchboard.

When such passages are intended for maintenance, then they are to be at least 1000 and 1200 mm wide respectively.

Such width is required regardless of type of protection against accidental touching made as solid doors, mesh or insulating handrails.

The doors, solid partitions and mesh partitions are to be of at least 1800 mm height.

Perforated or mesh partitions shall provide at least IP2X protection level.

The switchboards are to be fitted with two insulating handrails, one of them located along the switchboard at the height of 600 mm and another – at 1200 mm height.

14.6.5 The distance between the live parts being under voltage and the guard rails is to be at least as specified in Table 14.6.5.

<table>

14.6.7 The main distribution switchboard is to be fitted with disconnectors for splitting the collecting busbar system in at least two independent sections.

14.6.8 When a power source is required for the drive of the mechanism of automatic and other circuit breakers, then the power margin is to be sufficient for activation of all devices for at least two times.

14.7 TERMINAL BOXES

14.7.1 All the phase-ends of stator windings in generators and motors shall be brought out into the terminal box separated from the lower voltage box.

14.7.2 In the boxes, sockets and terminal boxes of electrical equipment no connections or wires for lower voltage are permitted.

14.8 TRANSFORMERS

14.8.1 The dry type transformers with earthed shields between higher and lower voltage windings are to be used.

14.8.2 De-energizing of the transformer from the high voltage side shall cause the switching off of the switch at the lower voltage side.

14.8.3 If an insulated neutral point is available at the lower voltage side of the transformer, then a spark trap device is to be provided between the neutral point of every transformer and the hull. The spark trap device shall be designed for not more than 80% of the minimal test voltage of the consumers fed from the given transformer.

14.8.4 The spark-gap may be connected in parallel with insulation monitoring apparatus for low-voltage equipment or a device detecting the insulation damage of that equipment. Such devices are not to impose the reliable operation of the spark-gap.

14.9 CABLE NETWORK

14.9.1 The three-phase current cable network shall be made of the three-core cables.

14.9.2 The cross-sectional area of the cable core for power circuits is to be at least 10 mm².
14.9.3 The design, type and permissible current loads of the cables used shall comply with the Rules of Electrical Installations Arrangement.

14.9.4 The cables are to be installed separately from the cables for voltage lower than 1000 V.

14.9.5 The following conditions are to be met when laying the cables:

1. Cable runs of different voltages may be laid jointly provided that the insulation of all cables laid jointly is designed for the highest voltage;

2. Cables are not to be laid across the accommodation spaces;

3. The clearance between the outer sheaths of the cables for different nominal voltages is to be at least the double outer diameter of the biggest one but at least 50 mm;

4. The cables laid outside the special electrical spaces are to be laid in earthed metal pipes or trunks or to be protected with earthed metal coatings.

Such cables may be laid without sheathing provided that they are fitted with solid metal armour which is to be earthed.

14.9.6 Installation of junction boxes as well as other types of connections aimed at elimination of cable breaks or extensions (splicing) is not allowed.
15 ELECTRICAL EQUIPMENT OF REFRIGERATING PLANTS

15.1 DISTRIBUTION OF ELECTRIC POWER

15.1.1 The electric drives of the refrigerating plants onboard the refrigerator ships are to be fed via separate feeders from the distribution switchboard of the refrigerator plant or from the main distribution switchboard. The refrigerating ventilators are to be fed from the distribution switchboard of the refrigerator plant or from other distribution switchboard fed from the main distribution switchboard. The generators' overload-protection device, specified in 7.2.7, is to shut down the drives of refrigerating plants after all the other consumers.

The electric drives of the emergency ventilators, specified in 9.7.7, Part IV of the Rules, shall not be fed from the same distribution switchboard as the electric drives of the main ventilators. The emergency ventilators' drive shall be fed from the main distribution switchboard or from the switchboard fed directly from the main one.

15.1.2 When using ammonia as the refrigerant, a device for emergency remote shut down of the refrigerating plant's distribution switchboard is to be provided in:

.1 control station of the refrigerating plant in the refrigerating machinery room;
.2 a place outside the spaces that may be filled with ammonia in the event of an accident in the refrigerating machinery room;
.3 outside near every exit from the refrigerating machinery room.

15.1.3 The devices for emergency remote shut down of the ammonia refrigerating plant's distribution switchboard are to simultaneously shut down the electric drives of the refrigerating compressors, when they are fed from the main distribution switchboard, to de-energize the main lighting circuit in the refrigerator machinery room and to actuate the electric drives of the emergency ventilators, the watering system, water screens and emergency lighting.

In addition, the devices intended for remote actuation of emergency ventilators, watering system, water screens and emergency lighting in any sequence without shutting down the refrigerating plant distribution switchboard shall be provided in the vicinity of the device for emergency remote shut down of the ammonia refrigerating plant's distribution switchboard.

15.2 VENTILATION AND EMERGENCY LIGHTING

15.2.1 When using ammonia as the refrigerant, the exhaust ventilators' electric motors of the emergency ventilation in the refrigerating machinery rooms installed in the exhaust channels are to be of explosion-proof type (see 2.10.2).

15.2.2 The ventilators' electric motors exposed to the air jet coming from the cooled spaces are to be of at least IP55 protection level.

15.2.3 When using ammonia as the refrigerant, then the explosion-proof lighting fixtures of emergency lighting (see 2.10.2) are to be provided in the refrigerating machinery rooms in addition to the main lighting. The emergency lighting is to be fed independently from the electric equipment and main lighting fixtures.
16 ADDITIONAL REQUIREMENTS FOR SPECIAL TYPES OF SHIPS

16.1 PASSENGER SHIPS

General requirements

16.1.1 The power supply systems of essential facilities (see 5.3) shall be designed in such a way that the fire in one vertical fire zone does not damage the power supply systems of the consumers located in any other vertical fire zone. This requirement is considered as fulfilled, when the main and emergency feeding lines of such consumers passing across any of such zones are located as far as possible from each other in vertical and horizontal directions.

16.1.2 The general alarm system is to consist of two separate groups: one for passengers and the other for the crew.

Passenger ships less than 25 m in length may be fitted with only one group of general alarm system.

16.1.3 The remote switches specified in 7.4, 7.7.3, 7.8.2 shall be protected against unauthorized access.

16.1.4 Onboard the ships fitted with remotely driven doors an indication of doors closing is to be provided in the wheelhouse. Such indication is to display the position of the doors (open/closed) by means of corresponding inscriptions.

A light and sound alarm is to be provided in the place of doors location. This alarm is to indicate the actuation of the closing drive and is to be active till the doors are completely closed.

Lighting

16.1.5 Only electrical equipment is to be used for lighting purposes.

16.1.6 The following spaces and areas are to be provided with lighting:

1. Life saving appliances storage areas, as well as the areas where such appliances are usually prepared for use;
2. Escape routes, areas designated for passengers including passages, entrances and exits, interconnecting corridors, elevators and deck ladders or hatches leading into accommodation spaces, as well as places where passenger rooms and accommodation spaces are located;
3. Places of markings location on the escape routes and emergency exits;
4. Other spaces designed for people with reduced mobility;
5. Places of fire extinguishers location and fire-fighting equipment control stations;
6. Areas of passengers, personnel and crew assembly in the event of emergency.

16.1.7 The emergency lighting for the following spaces and areas is to be provided in addition to that specified in 4.5.1:

1. Escape routes, passenger assembly areas including passages, entrances and exits, interconnecting corridors, elevators and deck ladders or hatches leading into accommodation spaces, as well as places where passenger rooms and accommodation spaces are located;
2. Spaces designed for people with reduced mobility.

16.1.8 In addition to the emergency lighting onboard the passenger ships including high-speed ships the escape routes in the areas with increased accident rate (corridors, ladders, exits, emergency exits) along their whole
length are to be marked with photoluminiscent or electric light signs indicating the escape direction.

16.1.9 In addition to that specified in 16.1.8 onboard the ships intended for transportation of persons with reduced mobility an additional visual and sound alarm and additional lighting are to be provided on the escape routes.

The lighting switches onboard the ships intended for transportation of persons with reduced mobility are to be arranged in accordance with the requirements of 5.2.8, Part XIII of the Rules.

16.1.10 The following requirements are applied for the escape light indicators and their location:

.1 all the escape light indicators shall have a colour (red or green) different from the surface of the deck or door on which they are arranged;

.2 in order to provide the observable outline along the whole escape route all the corridors shall be fitted with uninterruptible escape route marking except for those places where passages and doors to passenger rooms are located. The escape light indicators having observable outlines may be used for interruptible marking;

.3 the escape light indicators are to be arranged at least at one side of the corridor or on the wall not higher than 0.3 m above the deck or on the deck not more than 0.15 m apart from the wall. In the passages of more than 2 m width the escape light indicators shall be arranged at both sides;

.4 the escape light indicators in the dead-end corridors are to be made in the form of arrows with the distance of not more than 1 m from each other, or in the form of equivalent direction indicators showing the way to escape;

.5 the escape light indicators on all the ladders shall be arranged at least at one side of the corridor not higher than 0.3 m from the steps, that will allow to distinguish clearly every step for any person standing higher or lower of the given step. The escape light indicators shall be arranged at both sides, if the width of the ladder is 2 m or more;

.6 the escape light indicators shall lead to the handle of the exit door. Other doors shall not marked otherwise.

16.1.11 The electric escape light indicators are to meet the following requirements:

.1 the electric escape light indicators are to be connected to the emergency distribution switchboard in such a way that under normal conditions the power is supplied from the main power source and from the emergency one if required. In order to specify the power of the emergency source the electric escape light indicators shall be included into the list of emergency consumers;

.2 the electric escape light indicators are to be activated automatically or by one operation in the wheelhouse;

.3 the electric escape light indicators shall provide the following lighting parameters:

   indicators' active elements are to have the minimal brightness 10 cd/m²;

   point sources of midget lamps shall provide at least 150 mcd of average candle power of spherical surface with not more than 0.1 m distance between the lamps;

   point sources of LED systems shall have the minimal peak intensity 35 mcd. Angle of radiation shall be in accordance with the direction approximation and visibility. The distance between lamps is to be not more than 0.3 m;

   electro-luminescent systems shall operate during 30 minutes from the moment of shut down of the main power source to which they are to be connected in accordance with the requirements 16.1.11.1;

.4 all the electric escape light indicators shall be designed in such a way as to avoid the reduction of the escape routes marking efficiency in the event of failure of one lamp.

Safety equipment and devices

16.1.12 All passenger ships are to be equipped with intercommunication devices in accordance with 11.2 and Table 2.1.1, Part VII of the Rules. Such devices are to be provided in the service spaces and in the passenger assembly and evacuation areas where the direct communication with the wheelhouse is not available.

16.1.13 The loud-speaking communication system shall be audible in all the passenger
spaces. The system is to have power sufficient to make the communicated information clearly audible under the normal noise conditions. When the direct communication between the wheelhouse and the passenger areas and spaces is available, the loud-speaking system is not mandatory.

16.1.14 The ship shall be fitted with alert system, which is to include the following:

.1 alert system for the command personnel and the crew to be informed by the passengers, crew members or servicing personnel onboard the ship. The alert signals are to be sent only to the spaces intended for the command personnel and the crew. The alert signals may be switched off by the command personnel only. The alert signals may be activated from the following locations:

Every cabin;
corridors, elevators and stairtowers in such a way that the distance to the nearest alert switch does not exceed 10 m; every watertight compartment is to be fitted with at least one switch;
saloons, dining halls and other spaces intended for rest;
toilets intended for persons with reduced mobility;
machinery spaces, galleys and other fire dangerous spaces;
refrigerated dooms and other store spaces.
The alert switches are to be located at the height from 0.85 m to 1.10 m above the deck;

.2 alert system for passengers to be informed by the command personnel of the ship. The alert signals are to be clearly heard and distinguished without error in every space accessible by the passengers. The alert signals shall be available for activation from the wheelhouse and from the places where the crew members or the personnel are permanently present;

.3 alert system for the crew and servicing personnel to be informed by the command personnel. The alarm system specified in 11.3 is to be also audible in the spaces intended for crew members and servicing personnel rest, refrigerated rooms and other store spaces.

16.2 OIL TANKERS

General requirements

16.2.1 The requirements of the present Chapter apply to the electrical equipment of the following types of ships:

Bulk oil-carrying ships (see 2.2.61, Part 0 of the Rules) and equivalent to them (hereinafter — oil tankers);
ships intended for carriage of inflammable liquids and liquefied gases;
ships using neutral gas as fuel (see 1.1.1 of Interim technical requirements for ships using gas as fuel);
ships intended for work together with the abovementioned ships.

16.2.2 The spaces and areas in oil tankers are divided into explosive and non-explosive, fire-dangerous and fire-proof ones. The classification of explosive and fire-dangerous areas and spaces is given in 1.4, Part III of the Rules.

16.2.3 Distribution of electric power using hull as the return circuit as well as the systems with earthed neutral wire or pole is not allowed.

Protection level and protection types of electrical equipment

16.2.4 The level, explosion protection type, field of application and temperature class of electrical equipment shall comply with the national standard for explosion protected equipment¹ and have markings in accordance with Appendix 2.

16.2.5 In the explosive spaces and areas the installation of electrical equipment is not allowed except for:

.1 measuring, adjusting and warning devices of Exi spark-proof design;
.2 sensor, lamps and signal lanterns fitted with pressurized enclosure (Exp), with explosion-proof enclosure (Exd) or improved reliability against explosion (Exe);

¹ GOST R IEC 60079-0.
.3 Electric motors of improved reliability against explosion (Exe), fitted with explosion-proof enclosure (Exd) or with pressurized enclosure (Exp);
.4 Junction boxes of improved reliability against explosion (Exe) or fitted with explosion-proof enclosure (Exd);
.5 Fire alarm devices of explosion-proof design;
.6 Cables feeding the abovementioned equipment and devices provided that they are laid in steel pipes. The pipe connections to electrical equipment and to each other are to be gastight;
.7 Electric heating cables of explosion-proof design.
.8 Level and pressure sensors, monitoring devices and communication means of explosion-proof design (Exi) and cables connected to them.

16.2.6 The electrical equipment installed in the cofferdams of explosion hazardous areas adjacent to explosion hazardous cargo compartments and tanks is to be of Exi spark-proof design.

16.2.7 In the explosion hazardous areas on open deck above the cargo compartments and tanks along the whole breadth and within 3 m to the bow and to the stern from their end bulkheads and up to the height of 2.4 m above the deck it is allowed to install the following only:
- electrical equipment specified in 16.2.5 and 16.2.6;
- cable runs in gastight pipes.

16.2.8 The cables are to be laid in pipes in accordance with 12.6.

16.2.9 In the first category fire hazardous spaces the electrical equipment to be installed shall have the protection level not less than IP56.
In the second category fire hazardous spaces the electrical equipment to be installed shall have the protection level not less than IP55.

16.2.10 Onboard the ships carrying and pumping gasoline and crude oil in explosion hazardous spaces and areas the electrical equipment to be used shall be designed for operation in explosive mixtures of at least II B-T3 categories and groups (see Appendix 2).

**Electrical network and cable laying**

16.2.11 In explosive zones 0 and 1 the installation of the plug sockets is not allowed. In these spaces the hand lanterns of explosion-proof design with individual built-in power source may be used.

16.2.12 Portable electric hand tools and portable light operated in explosive areas shall be connected to power source outside such areas.

16.2.13 The cables in cargo compartments, tanks and cofferdams are to be laid in steel pipes having no connections in such spaces except for sealed connections with the equipment specified in 16.2.5.

16.2.14 Over the deck of cargo tanks outside the explosive areas the cables are to be laid in channels (trunks) or pipes in accordance with 12.4.

The cables in trunks are to be fastened in order to avoid side displacement.

When laying the cables in channels (trunks) across the explosive areas over the deck of the cargo compartments, the following requirements are to be met:
- The cables shall be laid in rows on the shaped protectors made of non-metal materials provided that their side displacement is not possible;
- The cables shall not contact with metal structures of the channel (trunk);
- The cables shall not be subject to permanent or reverse tensions caused by hull deformation; expansion loops shall be provided, the internal diameter of which shall be...
not less than 10 diameters of the cable having the largest diameter;

.4 the cables are to be protected against impact of the environment, waves, oil products and mechanical damages;

.5 the distance between cables and heat sources shall comply with the requirements of 12.4.1;

.6 the cable runs located in the gangways or in pipes within the space inside the zone 1, as well as the expansion loops shall not be arranged lower than 300 mm from the tanks' deck;

.7 all the metal sheathings or armour of the cables shall be earthed as per 2.10.11.

16.2.15 The flexible cables for portable electrical equipment used during oil skimming shall have metal braid covered with impermeable oversheath made of material resistant to oil products.

16.2.16 The cables shall be protected against oil products exposure.

16.2.17 In the devices for insulation measuring specified in 6.5.4 the ground leakage current shall not exceed 30 mA, and the inductance of ground connection in the device's circuit shall not exceed 60 mH.

**Lighting**

16.2.18 The pump room may be illuminated with explosion-proof lamps or through the tight portlights from the explosion-proof space. The portlight glass is to be at least 12 mm thick and be protected against mechanical damage with a guard mesh from both sides.

16.2.19 The pump room shall be fitted with at least two lighting groups fed via separated lines.

16.2.20 The explosion-proof lamps shall be arranged in such a way as to provide at least 100 mm clearance around them.

16.2.21 The lighting switches are to be located outside the explosion hazardous zones.

**Electrical heating**

16.2.22 Fixed electrical heating arrangements shall be located only outside the explosion hazardous zones 0, 1 and 2 of the oil tankers intended for carriage of inflammable liquids and liquefied gases with flash point up to 60 °C, and the pump rooms of the oil tankers intended for carriage of inflammable liquids and liquefied gases with flash point 60 °C and higher provided that the heating arrangements are fitted with thermoregulators.

**Earthing**

16.2.23 No current-carrying part is to be connected to the hull, other than earthings of condensers used for suppression of electrically induced radio interference, secondary windings of current transformers, as well as the insulation measuring and control devices.

16.2.24 All the electrical equipment irrespective of the nominal voltage value installed in the spaces and areas of explosion hazardous zones is to be earthed according to the requirements specified in 2.6.

16.2.25 Every oil tanker intended for carriage of inflammable liquids and liquefied gases shall be fitted with anti-static earthing devices for protection against sparking caused by static electricity.

The anti-static earthing is to be provided for all conducting (metal) parts of systems, particular devices and components (tanks, pumps, pipelines and pipe systems, routing and end accessories) with oil products, which are permanently or temporarily (washing devices or portable pumps) located in the explosion hazardous zones, spaces and areas.

16.2.26 When earthing the pipelines the continuity of earthing is to be provided. The pipelines shall be earthed to the hull at their beginning and end, as well as at each branch termination.

16.2.27 Special earthing for static electricity discharge is to be provided only when other types of earthing are not available (pro-
tective earthing, lightning-proof earthing, protection against radiointerference).

16.2.28 The structure of the anti-static earthing strips is to comply with the requirements for protective earthing of electrical equipment which are specified in 2.6.

The value of electric resistance between the hull and each of the elements isolated from each other shall not exceed $10^6$ Ohm, when the contact area of the instrument's measuring electrode (probe) and the surface of the equipment under test does not exceed 20 mm$^2$.

16.2.29 The following means of anti-static electricity discharge are to be provided at the entrances into the explosion hazardous zones, spaces and areas: unpainted handles, electrical plates, humid mats etc.

**Pump rooms**

16.2.30 It is required to provide interlocking of the power-on devices of electric motor of the cargo pump and electric drive of the pump room ventilation. Such interlocking is to provide the start of the electric motor only after the pump room is ventilated with the 10-fold air change.

16.2.31 Each electric motor of the cargo pumps is to be fitted with the remote shut down device located at the entrance into the pump room.

**Electric heating of viscous oil products**

16.2.32 The maximum temperature of the heating surface of the electric heater is to be at least by 10% lower than the flash point of the oil product to be heated.

16.2.33 The thickness of the oil product layer above the surface of the heating and current-carrying elements is to be at least 100 mm.

16.2.34 When the heating elements are isolated from the heated oil product, the insulation of the electric heater is to be at least 1 MOhm.

**16.3 SHIPS FOR CARRYING VEHICLES WITH FUEL IN THEIR TANKS AND ROAD TANKERS FOR INFLAMMABLE LIQUIDS**

16.3.1 The requirements of present Chapter apply to electrical equipment of holds and other spaces and areas intended for carriage onboard the cargo ships and ferries of vehicles with fuel in their tanks and road tankers for inflammable liquids.

16.3.2 The holds, spaces and areas specified in 16.3.1 are explosion hazardous spaces and areas.

16.3.3 The cables shall be protected against mechanical damage. The horizontally laid cables shall be arranged at the height of at least 450 mm above the flush deck or platform preventing from free penetration of gases below. Cable penetrations through the decks and bulkheads shall be gas-tight.

16.3.4 The electrical equipment installed in the exhaust ventilation ducts is to be explosion-proof — improved reliability against explosion (Exi, Åõð) or with explosion-proof enclosure (Exd).

16.3.5 The lighting fixtures installed in the holds and spaces specified in 16.3.1 shall be separated on at least two groups each of them being fed via different circuits.

16.3.6 In the holds and spaces located above the main deck, in the area located 450 mm above the deck or a platform preventing from free penetration of gases below it is allowed to install electrical equipment with at least IP55 level provided that the ventilation ensures the 10-fold air change per hour.

16.3.7 Electrical equipment with Exi, Exp, Exd and Exe protection types is to be installed in:

1. In the lower part of the spaces located above the main deck, in the area up to 450 mm above the deck a platform preventing from free penetration of gases below;

2. In the holds and spaces below the main deck.
16.4 SHIPS FOR CARRIAGE OF INSULATED CONTAINERS

Supply and distribution of electric power

16.4.1 The installed capacity of electrical equipment of insulated containers is to be taken for their rated power. The power consumption of electrical equipment of insulated container under nominal operating conditions shall not exceed 15 kW (18.75 kVA).

16.4.2 The device intended for protection for the generators against overload and specified in 7.2.7 shall provide the disconnection of insulated containers from the main distribution switchboard in the very end.

16.4.3 The electrical installations of insulated containers shall be connected to the special distribution facilities by means of plug sockets. These facilities are fed from the main distribution switchboard of the ship's power plant via separate feeders through the separating transformers.

16.4.4 The electric circuit of the plug sockets intended for feeding the electrical equipment of insulated containers is to have a nominal voltage of either 220/380 V of three-phase AC with 50 Hz frequency or 240/440 V of three-phase current with 60 Hz frequency.

Distribution devices and transformers

16.4.5 The secondary winding of separating transformers is to have an insulated neutral point.

16.4.6 Every distribution device shall be fitted with an apparatus to provide the following:

1. light alarm indicating voltage presence in the panels;
2. switching on/off of each feeder supplying the plug sockets;
3. protection against short-circuit currents in the outgoing feeders supplying the plug sockets;
4. measurement of the insulance value and the sound alarm indicating the invalid value of the latter.

Plug sockets and protective earthing

16.4.7 In the holds intended for carriage of insulated containers the plug sockets used for feeding the containers are to have at least IP 55, and IP 56 for open decks.

When electrical remote monitoring systems are used for monitoring the temperature, humidity and other parameters of insulated containers, it is allowed to install additional plug sockets in the holds or on the decks for connection of such monitoring devices.

16.4.8 The plug sockets for feeding the electrical equipment of insulated containers shall be fitted with a switch with interlocking preventing the connection and disconnection of the plug with the socket when the switch is in "ON" position. The plug socket is to have a plate indicating the voltage value.

16.4.9 The electrical equipment of insulated container is to be fed from the ship's electrical network at direct alternation of phases L1, L2, L3 according to the diagram given in Fig. 16.4.9.

16.4.10 The plug sockets intended for feeding the electrical equipment of insulated containers shall be designed for the following rated currents:

- 60 A — for 220 V, 50 Hz (or 240 V, 60 Hz);
- 32 A — for 380 V, 50 Hz (or 440 V, 60 Hz).

16.4.11 The design of plug connections shall prevent the possibility to connect the plugs for one voltage with the sockets for another voltage.

16.4.12 The plug socket intended for connection of earthing core of insulated con-
The container's flexible cable is to be earthed by means of earthing core of feeding line in the place where the power distribution facility of insulated containers is located.

16.5 CATAMARANS
16.5.1 At least one main power source is to be provided in each hull bode of a ship.
16.5.2 A main distribution switchboard is to be provided in each hull bode of a ship. However, only one main distribution switchboard may be provided if located above the main deck.
16.5.3 The busbars are to be sectioned according to the power supply of the hull bodies.
16.5.4 The emergency consumers of each hull body shall be fed from the emergency power source via separate feeders.

16.6 FLOATING CRANES
16.6.1 The accumulator rooms and boxes, as well as the emergency power source spaces in the floating cranes may be located below the main deck provided that the requirements of 4.3 and 8.5 are met.
16.6.2 In order to send the sound signals during cargo handling operations the crane is to be fitted with the sound alarm device to be controlled from the operator's cabin.
16.6.3 In order to prevent the spontaneous actuation of electric drive the zero protection is to be used.
16.6.4 The requirements for machinery and controls of cargo handling gear are specified in Chapter 6, Part V of the Rules.

16.7 FLOATING OBJECTS
16.7.1 At least two generators, main and auxiliary, used as main power sources shall be provided onboard the autonomous passenger floating objects and autonomous bulk oil-carrying floating objects. Additional power supply from external power source may be provided.
16.7.2 The supply and alarm systems of essential systems and facilities (see 5.3) onboard the floating hotels and hostels are to comply with the requirements specified in 16.1.1 – 16.1.2.
16.7.3 Every floating hotel is to be fitted with a stand-alone emergency power source which is capable to provide power for consumers during 30 minutes in accordance with 4.5.1.
16.7.4 When the floating objects is fed from the shore electric network with a dead-earthed neutral, all the ship circuits shall have a zero protection conductor with at least 50% of the phase conductor's admittance in all cases. The zero protection conductors shall be located within the same sheath with the phase conductors.
16.7.5 When the shore electric network with a dead-earthed neutral is used as a main power source, and the diesel generator – as the auxiliary one, the generator distribution system is to have a dead-earthed neutral.

16.8 DOCKS
Scope of application
16.8.1 The present Chapter applies to:
.1 electric drives and their control systems, monitoring and alarm systems which provide submergence and emergence of the dock;
.2 earthing facilities of a ship in the dock.
Protection level of electrical equipment casings
16.8.2 The protection level of the electrical equipment casings shall comply with Table 2.3.6 with due regard of the fact that the dry compartments of the dock superstructures are considered as spaces with high humidity IP 44, and the dry compartments and tunnels of pontoons and other similar spaces are considered as very wet spaces IP 55.

Earthing
16.8.3 Every docking ship is to be earthed to the dock hull with at least two special
16.8.4 In order to connect the dock hull with a shore earthing facility the dock is to be fitted with at least two flexible copper cables with a cross section of at least 70 mm$^2$ each and with devices for connection of these cables to the dock hull.

16.8.5 All the hull sections, pontoons, superstructures and similar dock structures are to be reliably electrically interconnected.

**Number and capacity of electrical power sources**

16.8.6 The main sources of electrical power for the docks shall be as follows:

- 1. generators;
- 2. shore electrical power system.

16.8.7 At least two generators shall be provided as the main electrical power sources for autonomous docks and a shore electrical power system in addition to them if necessary. For non-autonomous docks it is allowed to use only the shore electrical power system.

16.8.8 The capacity of the autonomous docks' main generators or the capacity fed from the shore power system is to be sufficient for providing the following operating conditions of the dock:

- 1. submergence;
- 2. entering a ship into the dock;
- 3. emergence;
- 4. emergency condition;
- 5. other conditions according to the dock's purpose.

16.8.9 The capacity of the autonomous docks' main generators shall provide safe submergence and emergence of the dock as well as entering and exiting of ships in the event of failure of one generator.

**Distribution of electric power**

16.8.10 In addition to those specified in 5.1.1 a single-wire AC or DC system may be used with the dock hull used as a return wire only for welding circuit, as well as for unsulance measuring and monitoring devices.

16.8.11 The following consumers are to be fed from the busbars of the main distribution switchboard via separate feeders in addition to 5.3.1:

- 1. control, alarm and monitoring system for dock submergence and emergence processes;
- 2. switchboards of electric drives of the ballast system outboard water valves;
- 3. feeder switchboards for welding plants;
- 4. feeder switchboards for docked ships.

16.8.12 Essential facilities and electric drives of machinery located in a superstructure not fitted with a power source shall be fed from a distribution switchboard arranged in such superstructure. Such switchboard shall be considered as an outer part of main distribution switchboard and shall be fed via two feeders from the latter. Cross section of each feeder is to be sufficient for feeding the essential facilities of the superstructure in the event of failure of one feeder. The feeding cable runs between the superstructures shall be laid in different spaces, if the dock's design allows it.

16.8.13 It is allowed to feed the navigation lights from the lighting switchboards.

16.8.14 When feeding a non-autonomous dock with voltage over 1 kV from the shore electrical network a device for connection of lower voltage feeder is to be provided in addition to such network. The device is to be designed for supply of power required when the dock is not in operation due to absence of repair works. The electric drive of at least one fire pump, which has the maximum capacity in comparison to others, is to be fed at full load, as well as all motors of clinket (valve) drives and lighting of the spaces are to be fed also.

When feeding a non-autonomous dock with voltage over 1 kV via two independent feeders, the low-voltage feeder is not required.

16.8.15 When feeding the dock from the low-voltage shore electrical network, two feeders and two power reception devices are
to be provided. One device — for feeding the consumers specified in 16.8.11, another — for consumers specified in 16.8.14.

16.8.16 The location and design of the devices for connecting the feeders from the shore electrical network shall:

.1 provide the cables laying at a distance from each other in order to avoid simultaneous damage of cables over 1 kV voltage and the low-voltage cables;

.2 prevent mechanical stress of the cables when submerging and emerging the dock;

.3 prevent the transmission of mechanical strains to the clamps to which the cables or wires are connected.

The devices intended for power reception from the shore electrical network should be located at different superstructures.

16.8.17 A warning sign indicating the voltage value is to be arranged prominently on the hull or on the door of the switchboard intended for power supply from external source.

16.8.18 The maximum permissible short-circuit power level is to be determined for every dock capable of being fed from the shore network. This level is to be indicated on the nameplate of the external source power switchboard.

16.8.19 The ships in the docks are to be fed from the power switchboards fixed in the dock.

16.8.20 Flexible cable feeding the docked ship is to have the cross section designed for the nominal current release setting on outgoing lines of the feeding switchboard of the docked ship.

Portable electrical lighting circuit

16.8.21 The plug sockets for portable lighting shall be installed in the following places in addition to those specified in 10.5:

.1 in the dry compartments of the superstructures, where the equipment and fittings of the submergence and emergence system are located;

.2 in the spaces on the safety deck, where the equipment of the submergence and emergence system is located;

.3 in the space of the central control station intended for control of submergence and emergence procedures;

.4 in the place of the mooring machinery electric drives location.

Service telephony

16.8.22 When other means of communication are not available, the telephones of the control group are to be provided. The telephones are to provide a clear two-way communication between the central control station and the following objects:

.1 mooring capstans control stations;

.2 emergency diesel generator room;

.3 main distribution switchboard room;

.4 main diesel generators room;

.5 transformer substation room;

.6 spaces where manual drives of the outboard water valves are installed;

.7 fire-fighting station.

Additionally, a paired communication is to be provided between the central control station and the machinery space.

16.8.23 It shall be possible to connect the telephone set to the shore telephone network.

General alarm

16.8.24 The general alarm is to be activated from the central control station room and from the room intended for attending personnel, if any.

Cable laying

16.8.25 When the slip deck is illuminated by lighting fixtures of water-proof type fed via the non-tight cables, then such cables are to be laid in a steel water-and-gastight pipes.

The pipes and their sealings shall be selected taking into account operation under pressure which shall be not less than the permissible pressure for the water-proof lighting fixture.
Channeling of electric power and installation of cable network at a single-wire distribution system

16.8.26 The points of connection of a conductor to the steel hull of the dock shall be easily accessible for monitoring and inspection of contact joints.

Such points shall be located on the structures having welding connection with the dock's hull.

16.8.27 Irrespective of electric power channeling system applied for welding circuit the welding station onboard the docked ship shall be fed via the two-wire system from the dock welding circuit.

It is not allowed to use the docked ship's hull as a return wire.

16.8.28 During the welding operations on the hull of the docked ship the cable with a potential opposite to electrode is to be connected to the hull in the vicinity of the welding area.

Emergency electrical installations

16.8.29 Every dock is to be fitted with emergency power source to provide power for all required consumers during at least 3 hours, and during 1 hour for non-autonomous dock.

16.8.30 The emergency source of electric power is to supply the consumers installed in the dock in accordance with 4.5.1, as well as the following consumers:

.1 electric drives of essential outboard water valves of the dock submergence and emergence system (opening and closing of the valves done at least twice);

.2 control and monitoring circuits of the submergence/emergence system;

.3 intercommunication and broadcasting means.

16.8.31 When the automatically started diesel generator is used as emergency power source, a local start shall be provided also.

16.8.32 All the emergency consumers shall be fed from the emergency distribution switchboard.

Where warranted the emergency diesel generator and the emergency distribution switchboard may be arranged in different spaces. It is allowed to use a section of the main distribution switchboard as an emergency distribution switchboard provided that the main distribution switchboard is located higher than the maximal permissible submergence line.

Electric drives of the dock submergence and emergence system

16.8.33 The electric drive of the outboard water valves of the submergence and emergence system shall not impair the valves' manual closing and opening. An interlocking device is to be provided which prevents the operation of electric drive when the valve is set to manual control.

16.8.34 The electric drive of the outboard water valve is to be fitted with local and remote indicators showing the end points of the valve. The drives of the outboard water valves distributing water by the pontoon sections shall be fitted with devices for adjusting the rate of valve opening.

16.8.35 When controlling the drives of the outboard water valves distributing water by the pontoon sections, it is recommended to provide both individual control of each valve and group control of portside and starboard valves.

16.8.36 The control circuits of the bilge (ballast) pump electric motor shall be fitted with local and remote control from the central post with indication of electric motor operation, and for electric motors with 20 A of nominal current and more (according to 6.5.3) — with monitoring of the motor load using the ammeter.

Equipment with voltage over 1 kV

16.8.37 The equipment with voltage over 1 kV shall comply with the requirements of Section 14 of the present Part of the Rules and with Rules of Electrical Installations Arrangement.

16.8.38 The equipment with voltage over 1 kV shall be arranged in special electrical spaces.
17 ELECTRICAL PROPULSION PLANTS

17.1 GENERAL REQUIREMENTS

17.1.1 The generators of electrical propulsion plants may be used for power supply of auxiliary electrical machinery and facilities provided that voltage and frequency are stable under all operating conditions including maneuvering in accordance with the requirements of 2.2.1.

17.1.2 Fixed lighting is to be provided below the electric motors of propulsion plants and the main generators.

17.1.3 Part of electrical propulsion machinery (motors and generators) located under the flooring shall have at least IP X6 protection level.

When they are located in a dry compartment or are protected against water by means of a water-tight foundation and when the compartment is fitted with an alarm indicating water penetration into it, then IP X3 protection level is to be provided.

17.1.4 It is allowed to feed the control, protection and alarm circuits of electric propulsion system from the exciters of the main electric propulsion machinery.

17.1.5 All the components of the DC electrical propulsion plant shall be designed for operation under the conditions of the propulsion motors stalling in "on" position during one minute.

17.2 SUPPLY VOLTAGE

17.2.1 The voltage value in the electrical propulsion plant system shall not exceed the values specified in Table 17.2.1.

17.3 ELECTRICAL MACHINERY

17.3.1 Main electrical machinery fitted with closed-circuit ventilation system shall be equipped with thermometers for monitoring the temperature of the outgoing air and water.

The electrical machinery fitted with closed-circuit cooling system shall be equipped with light and sound alarm warning of the loss of the cooling medium flow at the output of cooling system.

17.3.2 A light and sound alarm is to be provided. Such alarm is to be activated when the temperature of the main electrical machinery exceeds the values specified in the technical documentation.

17.3.3 The air-cooled electric propulsion motors shall be fitted with two forced ventilators. Each of such ventilators is to have capacity sufficient to provide normal operating conditions for electric motor.

A light alarm indicating that the ventilators are in operation and a sound alarm indicating their shut down shall be provided.

17.3.4 Each water-pumped air cooler of electrical machinery shall be fitted with valves on suction and discharge lines, as well as an air cooler drainage device.
17.3.5 The ventilation air lines of the generators and electric propulsion motors with capacity over 250 kW are to be fitted with temperature monitoring devices at the air outlet from the machinery. Such devices shall provide sound and light signals transmission to the central control station when the air temperature exceeds the permissible value.

17.3.6 When the ventilation system is disconnected, the incoming air shall be free from oil, water and dust.

17.3.7 The generators of electric propulsion plants and electric propulsion motors shall be fitted with a heating system to maintain the air temperature inside the machinery for at least 3 °C higher than the ambient temperature.

17.3.8 The DC electrical machinery designed for actuating the propulsion plants are to have inspection ports for observation over the commutator and the brushes without dismantling the covers.

17.3.9 For the armatures heavier than 1000 kg a possibility to process the commutator without removing the armature from the machinery is to be provided.

17.3.10 If the bearings of the electrical propulsion plant machinery are lubricated under pressure, then the lubricating system shall be fitted with auxiliary pumps.

17.3.11 The lubricating system of the propulsion plant electric motor is to be fitted with a filter and a daily tank which provides oil supply to the bearings under hydrostatic pressure during 15 minutes of operation with switched-off pump, when the normal lubrication of the bearings is not provided during the inertial movement of the ship.

17.3.12 The electrical machinery lubricating system shall be fitted with alarm system which sends the signals to the control stations in the event of pressure loss in the oil line and the increase of oil temperature at the outlet.

17.3.13 The bearings of generators and electric motors of propulsion plants are to be fitted with alarm indicating that the bearing brass temperature exceeds the permissible value.

17.3.14 The excitation system of the electric propulsion plant machinery shall be fed from at least two electric power converters. When one of the converters is damaged, the rest of them shall provide electric power on a full scale for excitation even at the increased load required for maneuvering.

It is allowed to feed the excitation system of electric propulsion plant machinery from the busbars of the main propulsion switchboard provided that the power supply is available under any conditions in accordance with the above requirements.

17.3.15 In the DC electric propulsion systems the disconnection or interruption of the excitation winding of electric motor is to be accompanied by voltage disappearance from the armature winding.

17.3.16 The excitation circuits shall be fitted with a damper of magnetic field energy activated in the event of sudden shut down of the excitation windings.

17.3.17 The excitation and automatic control systems are to be designed in such a manner as to protect the electric motors of propulsion plants against excessive increase of revolution frequency in the event of breakage or baring of the propeller screw.

17.3.18 The generators which operate with semiconductor converters shall be so designed as to operate at the level of harmonic components specified in generators' documentation. For this purpose a power reserve is to be provided sufficient for preventing from the generator's temperature rise which does not occur at normal sine load.

17.3.19 The stator windings of generators and electric propulsion motors with nominal capacity over 500 kVA shall be fitted with temperature sensors.

17.4 SWITCHES IN MAIN AND AUXILIARY CIRCUITS

17.4.1 No automatic circuit breakers are allowed in the excitation circuits, except for those which perform de-excitation of the ma-
chinery at short circuit or damage in the main current circuit.

17.4.2 When it is required to provide a specific sequence of commutation operations, a reliable interlocking preventing the incorrect commutations is to be provided.

17.4.3 The switches intended for immediate commutations in the circuits of electric propulsion plant at voltage off shall be fitted with an interlocking device preventing their shut down in live condition or false switching on.

17.5 PROTECTION IN THE ELECTRICAL PROPULSION PLANT CIRCUITS

17.5.1 The electrical propulsion plants are to be protected against earthing of the current-carrying parts. The leakage current in the protection device shall not exceed 20 mA.

17.5.2 It is not allowed to use fuses as protection devices in the main and excitation circuits of electric motors of propulsion plants.

17.5.3 When the DC generators of propulsion plant are connected in series, a protection device is to be provided to prevent from changing the direction of the generator set rotation in the event of partial or total loss of torque by the primary mover.

17.5.4 The electrical propulsion plant shall have a zero protection against spontaneous start after activation of any protection.

17.5.5 The electrical propulsion plant shall be protected against short-circuit currents and against overloads. A sound and light alarm is to be activated prior to the start of operation of the overload protection.

17.5.6 Measures shall be taken for limitation and use of electric power generated by electric motor of the propulsion plant at transient conditions or when changing the direction of the propeller screw rotation if this power may cause excessive increase of the primary movers revolution frequency.

In the electrical propulsion plant systems fitted with frequency converter and AC electric motor the energy recuperation to the generator’s busbars is allowed provided that other consumers connected to the busbars of the given generator may use this energy. In order to absorb the corresponding part of recuperated energy and speed up the electric propulsion motor braking when reversing it is allowed to use "braking resistors". The amount of recuperated energy shall be limited by the automated control system of electrical propulsion plant in order to prevent the speed up of primary motors rotation above the permissible limit.

17.5.7 At spontaneous shut down of a primary mover of a generator operating in parallel to the common busbars or to one electric motor of the propulsion plant this generator shall be automatically disconnected by all poles or phases without interruption of propulsion plant power supply.

17.5.8 In the AC systems the generators and the electric propulsion motors of 1000 kV A capacity and higher shall be fitted with differential protection.

17.5.9 The checking, alarm and effective control circuits of electric propulsion system shall be protected against short circuit.

17.6 MEASURING INSTRUMENTS AND ALARM

17.6.1 The control boards/panels are to be fitted with the following measuring instruments providing monitoring of the system parameters affecting the operation of the electrical propulsion plant:

1. ammeter in main current circuit;
2. voltmeter in main current circuit;
3. ammeter in excitation circuit for systems with adjustable excitation;
4. voltmeter in excitation circuit for systems with adjustable excitation;
5. tachometer for motors of electric propulsion plants or propulsion shafts;
6. indicator "power generating plant is ready for operation of electrical propulsion plant";
7. indicator "power generating plant is not ready for operation of electrical propulsion plant";
8. indicator "control from central control station";
.9 indicator "control from wheelhouse";
.10 indicator "local control station";
.11 indication of generators energizing the electrical propulsion plant.

In the AC system the following devices shall be arranged in addition to the above:
.12 frequency meter;
.13 synchronizer for connecting the generators to parallel operation;
.14 wattmeter;
.15 indicator "limitation of electrical propulsion plant power" (receives data from frequency converter).

17.6.2 The electrical propulsion plant system shall be equipped with an insulance monitoring device. In the main current circuits the following is to be provided: insulance permanent monitoring, light and sound alarm activated in the event of insulance decrease.

17.6.3 Every control station is to be fitted with an indication of voltage availability in the control circuits.

17.6.4 If the control panel/board is fitted with measuring devices which use oil, steam or water, then measures shall be taken to prevent ingress of the above substances to the alive parts in the event of damage of such devices or their pipes.

17.7 ELECTRICAL PROPULSION PLANT CONTROL

17.7.1 When the control from the board or panel of the plant is performed using electric or hydraulic drive then the stop of the drive shall not be accompanied by the shut down of the plant, and every post of the board shall be ready for manual control.

17.7.2 If the ship is fitted with two or more remote control stations, each control station shall be fitted with an alarm indicating the station being which station is used for control. Apart from that the control stations shall be designed in such a way as to send the orders only from the control station in service.

17.7.3 The control station switch is to be fitted with an interlocking device preventing commutation from one control station to another without de-excitation of the propulsion plant. The commutation is to be carried out by setting the handle of the control station in service into "Stop" position. Regardless of the position of the control handle at the control station to be put into service the activation of the electric propulsion motor is to be carried out only through "Stop" position.

17.7.4 The control stations of electric propulsion plants shall meet the requirements of I.5, Part IV, of the Rules.

17.7.5 The control system of electric propulsion plant is to have an interlocking preventing actuation of the plant when the bar ring gear is also actuated.

17.7.6 When the generators of the power systems of electric propulsion plant operate in parallel, an automated control system of the power generating plant is to be provided.

17.7.7 In case of overload at the busbars of the main switchboard (frequency reduction, current and/or power overload) the power supplied to the electric propulsion plant shall be automatically limited in order to avoid deenergization of the busbars.

17.7.8 If the protection system shuts down one of the generators operating in parallel, then the automated control system of the power generating plant is to automatically reduce the power of electric propulsion plant in order to protect the remaining generators from the overload and ensure their operation. This requirement shall be applicable for the automatic switches at the busbars of the main switchboard.

17.7.9 If the parallel operation of the generators is not envisaged and the frequency converters of the electric propulsion motors are interconnected via DC link, it is required to provide leveling of currents of the frequency converters rectifiers in order to provide balanced load of the generators.

17.7.10 A failure of automatic functions of the electric propulsion plant control system shall lead to activation of the alarm warning system.
17.7.11 At least two control stations (remote and local) independent from each other are to be provided for the electric propulsion plant.

17.7.12 In case of damage, failure or loss of power in the control system at the remote control station of electric propulsion plant a control of the electric propulsion plant converters from the local control station shall be provided.

17.8 ELECTRICAL PROPULSION PLANTS WITH SEMICONDUCTOR CONVERTERS

17.8.1 The capacity of power sources and consumers connected to the busbars of electrical propulsion plant shall be selected with due regard of expected distortions on the busbars as well as additional distortions caused by the dissimetry of the main and high harmonics in the transient operating conditions of electric propulsion motor.

17.8.2 The main generators, semiconductor converters of electric propulsion motor and the accessories of main current circuits shall withstand the current overloads of at least 250% within 2 seconds. The converters shall withstand at least 150% of the rated current from electric propulsion motor during 1 minute.

17.8.3 The capacity of electric propulsion motors shall be selected with due regard of expected voltage distortions at the outlet of semiconductor converter.

17.8.4 The main generators and the electric propulsion motors are to ensure the specified technical characteristics according to ship’s purpose at voltage and current distortions caused by the operation of semiconductor converters.

17.8.5 The overload capability of the main generators and the electric propulsion motors shall meet the requirements of the onboard operating conditions. Measures shall be taken to compensate the decrease of the overload capability caused by induction of high voltage harmonics during operation of semiconductor converters.

17.8.6 The power filter capacitors used in semiconductor converters to improve the quality of electric power shall be fitted with discharging devices.

17.8.7 The consumers sensitive to the harmonicity of supply voltage shall be fed from separate sources or fitted with local suppression devices of high harmonics down to technically reasonable level regardless of the permissible value of the non-linear distortion factor.

17.8.8 The current ripple factor $K_n$ of electric propulsion motors of AC/DC plants, when fed by rectified current, shall be determined as follows:

$$K_n = \sum_{v=2}^{n} \frac{I_{v}}{I_{dn}},$$  \hspace{1cm} (17.8.8)

where $n$ — harmonic number,

$I_{dn}$ — constant component of rectified current,

$I_{v}$ — effective current of $v$th harmonic component.

The current ripple factor for electric propulsion motors designed for operation from DC generators shall not exceed 2%.

17.8.9 The dynamic slowdown current shall not exceed 200% of the rated current.

17.8.10 The semiconductor converters shall meet the requirements of 6.9, Part VI, of the Rules.

17.8.11 At least two semiconductor converters are to be provided for the electric propulsion plant. These semiconductor converters shall be fully independent and installed separately.

17.8.12 Each converter is to have a separate control system.

17.8.13 Two galvanic isolated speed sensors are to be provided for each control system. For the electric propulsion plants with power less than 500 kVA in the systems with a frequency converter it is allowed to monitor the speed using data received from frequency converter.

17.8.14 The converters are to have overload capability that provides the appropriate
torque, capacity and reactive power (for AC systems) required during starting, maneuvering and emergency shut down conditions.

The converters' protection shall not be activated in case of short-term overloads and changes (drops) of rotation frequency.

17.8.15 Malfunctions of the converters' cooling system shall not lead to the shut down of all converters of the ship's electric propulsion plant.

17.8.16 The feedbacks of the converter are to control (limit) the current in such a way that none of the components is damaged even when the converter is connected to the motor with locked rotor or its terminals are short-circuit.

17.8.17 In the "frequency converter – AC electric motor" systems the converter is to provide the following types of protection:
- .1 overheat protection of frequency converter;
- .2 short-circuit protection between the output phases;
- .3 power supply phase failure;
- .4 protection from current overload between the output phases and the hull;
- .5 overvoltage protection in DC link;
- .6 protection from power supply over(under-)voltage;
- .7 motor phase failure.

17.9 ELECTRIC CLUTCHES

17.9.1 The electromagnetic and electroinduction clutches are covered by all the requirements of the previous sections as well as the requirements for electrical machinery as far as practicable.

17.9.2 The design of electric clutches shall allow their dismantling without disassembling the drive motor or the reduction gear.

17.9.3 The design and arrangement of electric clutches shall allow free access for maintenance, replacement of brushes and measuring of air clearance without dismantling the clutches.

17.9.4 The drive motor bearings or the driven gear bearings shall be designed in such a way as to prevent the ingress of lubricating oil inside the clutch.

17.9.5 The clutch connection system shall be designed in such a way as to avoid transmission of excitation to the clutch during start or reverse of the main engine.

17.9.6 When a number of driving motors are in operation for one common transmission, the excitation system of electric clutches shall have an interlocking device preventing simultaneous actuation of driving motors rotating in opposite directions.

17.9.7 The excitation windings of electric clutches are to be protected against overvoltage.

17.9.8 The excitation circuit of electric clutches shall be fitted with:
- .1 two-polar circuit breaker;
- .2 magnetic field damper;
- .3 protection device against short-circuit current.

17.10 DESIGN OF ELECTRIC PROPULSION PLANT

17.10.1 The electric propulsion plants are to be designed for the ship's operating conditions specified in 3.1.1.

The electric propulsion plant shall be so designed that a failure of a component of power part or control system does not cause the shut down of the electric propulsion motors. The capacity required for operation of electric propulsion plant shall be restored within 30 seconds after loss of power.

17.10.2 The electric propulsion plant consists of the following components:
- .1 main generators of electrical propulsion plant – at least two;
- .2 main distribution switchboard split in two parts with an intersectional circuit breaker;
- .3 power transformers for converting the voltage of main generators into the voltage of semiconductor converters (if specified by the design of electric propulsion plant) – one transformer for each converter;
- .4 electric propulsion motor powered by its semiconductor converter;
- .5 control system.
17.10.3 The electric propulsion plants with one electric propulsion motor shall meet the following additional requirements:

1. Synchronous and asynchronous motors are to have two systems of stator windings capable to disconnect independently from their semiconductor frequency converter. Two frequency converters shall be provided – one for each stator winding system. Each semiconductor frequency converter is to be designed for at least 50% of the rated power of electric propulsion plant.

2. DC motors are to be of double-armature (double-commutator) type. Each armature winding is to be designed for at least 50% of the rated power of electric propulsion plant and is to be fed by its independent converter.

17.10.4 Braking or locking devices shall be provided for the propulsion shaft.

In the "frequency converter – AC electric motor" systems it is allowed to apply dynamic braking provided that it will not cause overheating of motor windings.

17.10.5 The alarm warning signal is to be provided at each operating control station. This signal is to warn of a malfunction in the system of electric propulsion plant.

17.11 ELECTROMAGNETIC COMPATIBILITY OF ELECTRIC PROPULSION PLANTS

17.11.1 The electric propulsion plant is to operate without failures and malfunctions under the influence of electromagnetic interference and is to meet the requirements specified in Appendix 15 of RTSC.

17.11.2 If harmonic distortions exceed 10% during operation of electric propulsion plant, then appropriate filtration and interference-free performance of connected consumers is to be provided.

18 SPARE PARTS AND SUPPLY ITEMS

18.1 SPARE PARTS

18.1.1 The nomenclature and number of spare parts for the electrical equipment are specified in the delivery specifications according to the technical documentation.

18.1.2 The spare parts shall be designed in such a way that their use should not require any additional processing or adjustment.

18.1.3 The spare parts shall be located in accessible places, fastened and marked.

18.2 SUPPLY ITEMS

18.2.1 Every ship fitted with electrical power sources of more than 3 kW capacity shall be equipped with portable voltammeter, ohmmeter or combined instrument for measuring current strength, voltage and resistance, with high-resistance ohmmeter and load nippers in case of AC current use.
PROTECTION LEVELS OF ELECTRICAL EQUIPMENT

1 In accordance with GOST 14254 the designation of protection level of electrical equipment shall include the following:
   conventional sign IP;
   digital designation of protection level for attending personnel against touching the moving parts of the equipment and against ingress of solid foreign objects inside the casing (Table A1.1-1);
   digital designation of protection level against ingress of water inside the casing (Table A1.1-2).

2 If a protection level is not required for the product, then "X" sign is put in the conventional sign instead of the designation of protection level which is not required and is not tested.

7 | Protection at submergence. Water shall not penetrate inside under the pressure and test time conditions agreed by the customer and manufacturer
8 | Protection at unlimited long-time submergence. The pressurized water shall not penetrate inside the casing under the pressure conditions agreed by the customer and manufacturer

**APPENDIX 2**

**CLASSIFICATION OF EXPLOSIVE MIXTURES**

1. In accordance with GOST R IEC 60079-0, when designating the protection level the explosive gas-air and vapour-air mixtures are classified as in Table A2.1 with regard to the size of maximal experimental safe clearance (MESC).

2. Explosive gas-air and vapour-air mixtures are subdivided into six groups depending on their self-ignition temperature as specified in Table A2.2.

3. The explosion-proof electrical equipment may have the explosion protection types specified in Table A2.3.

CABLE TEST FOR FLAME RETARDANCE

1 The tests are carried out in order to check the flame retardance of insulated cable or wire.

2 The test specimens are cable or wire sections (600±25) mm long. Prior to the test the specimens shall be kept at (23±5) °C temperature and (50±20) % humidity for at least 16 hours. If the cable or wire is coated with paint or varnish, the specimen shall be kept at (60±2) °C temperature during 4 hours before the test.

3 The test chamber is a metal box (450±25) mm long, (300±25) mm width and (1200±25) mm height without the front side. The test chamber floor shall be protected with a layer of mineral insulation. The test chamber shall be arranged in a space free from draughts and fitted with toxic gas (generated during combustion) disposal systems.

4 Prior to the test the burner shall be mounted on a horizontal surface in such a way that the flame is directed strictly upwards. The overall length of the flame is to be 125 mm and the length of internal blue-colored part – 44 mm. The work of the burner is to be checked by inserting a copper wire with (0.710±0.025) mm diameter and at least 100 mm length at right angle to the flame at a distance exceeding the end of internal blue-colored part of the flame by 10 mm and in such a way that the wire end is located above the edge of burner’s nozzle. The temperature of the flame is to provide melting of the copper wire within the time limits from 4 to 6 seconds.

5 The specimen shall be fastened using copper wire to two horizontal supports (Fig. A3.5-1) in such a way that the distance between the lower edge of the upper support and the upper edge of the lower support is (550±5) mm. The lower end of the specimen shall be approximately 550 mm apart from the chamber floor. The burner shall be located in such a way that the tip of the internal blue-colored cone of the flame touches the surface of the specimen at a distance approximately 75 mm higher than the lower clutch.

Fig. A3.5-1. Arrangement of a specimen in the test chamber:
1 — metal chamber; 2 — support bar and fastening of copper wire; 3 — specimen; 
A — distance between chamber floor and specimen's lower end (approx. 50 mm).
The angle between the axis of burner's nozzle and the specimen vertical axis shall be 45° (Fig. A3.5-2). The internal blue-coloured part of the flame is to be at a distance of 10 mm apart from the specimen.

Fig. A3.5-2. Application of burner's flame to the specimen:
1 — lower edge of upper support; 2 — specimen

6 The time, during which the specimen is permanently exposed to the flame, shall be as specified in Table A3.6. In the end of the test the burner shall be removed and its flame shall be extinguished.

7 After the burning stops the specimen shall be carefully wiped with a cloth.

If the specimen's surface has no damages, the presence of soot on its surface after wiping is allowed. Softening or deformation of non-metal material shall not be taken into account. The distance between lower edge of the upper support and the beginning of specimen's charred part shall be measured with accuracy of 1 mm.

The beginning of the charred part shall be defined as follows. The cable surface is pressed with a sharp object, e.g. knife blade. The place where the elastic surface of the specimen changes to a brittle one is determined as the beginning of the charred part.

8 It is considered that the cable or wire has passed the test when the specimen has not caught fire or when the specimen stops burning after the test flame is removed and the traces of fire did not reach the upper end of the specimen.

When the flame spreads downwards up to the point located at a distance more than 540 mm from the lower edge of the upper support, it is considered that the cable or wire has not passed the test.

If the specimen has not passed the test, two more tests are to be carried out. If the results of these two tests are satisfactory, then it is considered that the cable or wire has passed the test.
Part VII

RADIO COMMUNICATION EQUIPMENT
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 This Part of the Rules covers technical requirements to radio communication equipment for inland and river–sea navigation ships as well as requirements to components and parameters of this equipment.

1.1.2 This part of the Rules applies to products, ships being designed and ships in construction in accordance with 1.5, Part 0 of the Rules, unless otherwise provided, the ships and products in service are covered by the requirements of the Rules according to which they were built (manufactured).

1.2 TERMS AND DEFINITIONS

1.2.1 The following terms are used in this Part of the Rules:

1. Emergency position-indicating radio beacon (EPIRB) means a mobile service station, the emissions of which are intended to facilitate search and rescue operations;

2. Start-up time means a period of time necessary for radio equipment to become operational as measured from the moment of energizing the equipment;

3. Inner road within harbour water area means a section of port water area within the established boundaries sheltered from waves by natural coastline or external breakwater structures for ships berthing;

4. Main VHF radio telephone station means a station for transmission and receipt of distress alerts, navigation warnings, meteorological forecasts, medical, urgent and other messages as may be required for navigation safety;

5. Global Maritime Distress and Safety System (GMDSS) means an international radio communication system developed by the International Maritime Organization (IMO), requirements to which are brought to amendments 1988–1989 to Chapter IV “Radio Communication” of the International Convention for the Safety of Life at Sea, 1974 and to this Part of the Rules;

6. Length of the ship means length of a ship at design waterline;

7. GMDSS identities mean maritime mobile services identity, the ship’s call sign, INMARSAT identities and serial number identity which may be transmitted by the ship’s equipment and used to identify the ship;

8. INMARSAT means an organization established by the Convention on the International Maritime Satellite Organization adopted on 3 September 1976; since 9 December 1994 it is an International Mobile Satellite Organization;

9. Maritime safety information means navigational and meteorological warnings, meteorological forecasts and other urgent safety-related messages broadcast to ships;

10. Convention means the International Convention for the Safety of Life at Sea, 1974, as amended;

11. COSPAS-SARSAT means an international system for search and rescue of ships and aircraft in distress using near-polar orbiting satellite system;

12. Sea area Al means within the radio-telephone coverage of a VHF coast station which provides continuous digital selective call (DSC) alerting;
1.3 Sea area A2 means an area other than sea area A1 within the radio-telephone coverage of an MF coast station, which provides continuous digital selective call (DSC) alerting;
1.4 Sea area A3 means an area other than sea areas A1 and A2 within the coverage of INMARSAT geostationary satellite system, which provides continuous distress alerting;
1.5 Sea area A4 means an area other than sea areas A1, A2 and A3;
1.6 NAVTEX means an international automated alerting system; its stations broadcast, in coordinated manner, every four hours some maritime safety information (navigation warnings, meteorological warnings, information on search and rescue operations as well as other information affecting navigation safety within range of these stations); its automatically receive the said information at 518 kHz by means of narrow-band direct-printing (NBDP) telegraphy in English;
1.7 Continuous watch means an uninterrupted radio watch except for short intervals when the ship radio capability is impaired or blocked by its own communications or when the radio equipment is under periodical maintenance, repair or checks;
1.8 Man-portable radio station means a radio station designed for radiotelephone communication between a life-saving appliance (LSA) and the ship, support of mooring and specific operations, transmission of emergency commands from the wheelhouse; it has its own power source and adapted for operation when carried;
1.9 MF/HF radio station means a radio station operating within the medium and short wave bands;
1.10 Mobile earth station means an earth station in the mobile satellite service intended to be used underway or at rest at unspecified points;
1.11 Interferences mean the effect of unwanted energy due to one or a combination of emissions, radiations, or inductions upon receipt in a radio communication system, manifested by any performance degradation, misinterpretation or loss of information, which could otherwise be avoided in the absence of such unwanted energy;
1.22 Portable radio station means a man-portable radio station with weight not exceeding 1 kg;
1.23 Radio equipment means technical facilities designed for communication and broadcasting;
1.24 General radio communication means service and public correspondence traffic, other than distress, urgency and safety messages, conducted by radio;
1.25 Enhanced group calling (EGC) means a service for broadcasting distress, safety and urgency messages via INMARSAT mobile satellite communications system;
1.26 Radio Regulations means a document being an appendix or considered as an appendix to the latest effective revision of the International Telecommunication Convention;
1.27 Standby power source means a storage battery independent of power installation and ship's electric system, which is designed for supplying radio communication equipment in case of malfunction of ship's main and emergency electric power sources;
1.28 Security alert system means a system which generates and transmits a hidden signal or message on security breach or that a ship is under threat of unauthorized intrusion to an authorized organization;
1.29 Rescue unit means an object (ship, helicopter, etc.) manned with trained personnel and equipped with arrangements for search and rescue operations;
1.30 Ship earth station means a mobile earth station in the maritime mobile satellite service installed on board the ship;
1.31 Narrow-band direct-printing (NBDP) telegraphy means communication technique using automated telegraphy equipment, which complies with the relevant recommendations of the International Telecommunication Union (ITU);
1.32 Two-way VHF radiotelephone apparatus means a VHF apparatus designed for communication between
buoyant life-saving appliances (LSA) and a ship as well as between buoyant life-saving appliances and a rescue unit;

33 Digital selective calling (DSC) means a way of communication complying with recommendations of the International Radio Consultative Committee and using digital codes; this allows a radio station to establish communication and transmit information to another station or a group of stations;

34 Operational VHF radio-telephone station means a radio station designed for transmission and receipt of service messages.

1.3 GENERAL REQUIREMENTS TO RADIO EQUIPMENT

1.3.1 Every self-propelled river–sea navigation ship in service shall be fitted with radio equipment able to provide the following:

.1 transmission of ship-to-shore distress alerts by at least two separate and independent means, each using a different radio communication service;

.2 receipt of shore-to-ship distress alerts;

.3 transmission and receipt of ship-to-ship distress alerts;

.4 transmission and receipt of search and rescue coordinating communications;

.5 transmission and receipt of safety information when in voyage;

.6 transmission and receipt of on-scene communications;

.7 transmission and receipt of position finding;

.8 transmission and receipt of signals for position finding;

.9 transmission and receipt of shore-based communication systems and networks;

.10 transmission and receipt of wheelhouse-to-wheelhouse messages.

With respect to those operations, provisions shall be made to prevent making false distress signals.

1.3.2 Every self-propelled inland navigation ship shall be fitted with radio equipment able to provide the following:

.1 transmission of shore-to-ship distress alerts;

.2 receipt of shore-to-ship distress alerts;

.3 transmission and receipt of ship-to-ship distress alerts;

.4 transmission and receipt of safety information when in voyage;

.5 transmission and receipt of navigation and other ship data in alert systems, navigation conditions compliance control systems and navigation safety systems, if these data are to be transmitted by ships navigating within the coverage area of such systems.

1.3.3 Serviceability of radio equipment on board river–sea navigation ships shall be provided as follows:

.1 for ships fitted with radio equipment in accordance with 2.2.1 and navigating within sea areas A1 or A1+A2, serviceability of radio equipment is to be provided by one of the following methods:

- redundancy of equipment (see Table 2.2.1);
- shore-based maintenance and repair;
- afloat maintenance and repair by the ship radio officer having the radio operator's first or second class certificate;
- or combination of these methods.

For ships fitted with radio equipment in accordance with 2.2.3 and navigating within sea areas A1 or A1+A2, serviceability of radio equipment is to be provided by means of shore-based maintenance and repair;

.2 For ships fitted with radio equipment in accordance with 2.2.1 and 2.2.3 and navigating within sea areas A1+A2+A3 as well as A1+A2+A3+A4, serviceability of radio equipment is to be provided by two following methods:

- redundancy of equipment (see Table 2.2.1);
- shore-based maintenance and repair;
- afloat maintenance and repair by the ship radio officer having the radio operator's first or second class certificate;

.3 provision shall be made for necessary tools, spare parts and measuring (test) equipment on board each ship for maintenance and
repair of radio equipment regardless of its maintenance and repair methods;

.4 on board each ship engaged on voyages within sea areas A1+A2+A3 or A1+A2+A3+A4 there shall be always kept descriptions, operating manuals for each type of radio equipment, as well as provision shall be made for necessary tools, spare parts and measuring (test) equipment for maintenance of radio equipment;

.5 for ships engaged on voyages within sea areas A1 or A1+A2, the scope of technical documentations, tools, instruments, spare parts and measuring (test) equipment is to be stated by the manufacturer in technical documentation for the equipment;

.6 where serviceability of radio equipment is provided by combination of methods, one of which being shore-based maintenance and repair, an agreement on shore-based maintenance with equipment manufacturer or an enterprise authorized by the manufacturer shall be available on board the ship, or a written declaration/plan indicating the method of shore-based maintenance shall be submitted. Provision shall be made for maintenance and repair of radio equipment in sea areas where such ships navigate.

1.3.4 Radio equipment may be replaced with that of the same type without the need in approval by the River Register if such a replacement does not cause change in cable rerouting/replacement or equipment relocation.

1.3.5 Radio equipment not covered in Table 2.1.1, 2.2.1 and 2.2.3 may be installed on board ships as additional equipment provided that:

.1 the requirements with respect to electromagnetic compatibility, electrical safety, permissible heating of cases and absence of harmful radiations as stipulated by these Rules are complied with;

.2 the requirements of Part VI of these Rules with respect to its connection to the ship’s power mains are complied with;

.3 results of reliability checks for equipment fasteners designed for its safe operation under heel, trim and roll conditions according to 6.1.2 are satisfactory;

.4 results of checks of arrangement and installation for compliance with requirements of 4.1, 4.5, 4.10, 5.4 and 5.5 and checks of access for repair and maintenance of equipment installed in accordance with 2.1.1, 2.2.1 and 2.2.3 are satisfactory;

.5 documentation on its installation agreed upon with the River Register is available.
2 RADIO EQUIPMENT

2.1 RADIO EQUIPMENT FOR SHIPS OF M, O, P AND I CLASSES

2.1.1 Each self-propelled ship, with regard to how communication for safe navigation within the ship navigation area is arranged, in order to comply with requirements stated in 1.3.2, shall be fitted with radio equipment according to Table 2.1.1.

<table>

1 No radio equipment is needed on board ships engaged on voyages within continuous coverage of shore-based VHF radiotelephone station systems, port water area, road, as well as engaged on voyages as part of a convoy or on operations as part of a group of ships, provided that such a convoy or a group of ship includes ships equipped with complete set of radio equipment required for navigation within respective area and the permanent radio communication by means of VHF radiotelephone stations is maintained with these ships.

2 Satellite EPIRB of COSPAS-SARSAT system may be fitted instead of MF/HF radio installation or ship earth station, provided that voyage, navigation and meteorological information is received by means of other equipment on board the ship.

3 For ships of P and I class less than 25 m long installation of a portable/man-portable MF/HF radiotelephone station supplied from ship's mains and connected to the external stationary antenna may be sufficient. Such a radiotelephone station may not replace the radiotelephone station given in 4 Table or may not be such a station.

4 Required only for passenger ships and ships with a length of 25 m and above or ships with main engines power of 367 kW and above.

5 Required only for passenger ships with a length of 25 m and above.

6 Frequency range of a portable/man-portable VHF radiotelephone station may be 300.025 to 300.225, 336.02 to 336.225 MHz.

7 Required for passenger ships only.

8 Where only main VHF radiotelephone station is installed on board the ship, its frequency range shall be 300.025 to 300.500, 336.025 to 336.500 MHz.

9 For passenger ships: of O class: when the crew consists of 2 persons — 2 sets, when the crew consists of 3 and more persons – 3 sets; of P class: when the crew consists of more than 1 person — 2 sets, of I class — 1 set.

The ships in service shall be fitted with radio stations according to the requirements by the time of ordinary survey of the ship after 01.01.2017 but not later than 19.07.2021.

10 Not required for ships engaged on voyages within port water area or road.
2.1.2 Non-self-propelled ships manned with crew or specific personnel shall be equipped with radio equipment according to Table 2.1.1 as ships of Í class. In addition to Note 3 of Table 2.1.1 it is permitted to equip the ship (irrespective of ship's length) with a portable (mobile) VHF radiotelephone station instead of main VHF radiotelephone station provided that the ship's mains is not available onboard the ship. In this case when it is not possible to charge the accumulator batteries onboard the ship, a set of accumulator batteries is to be available onboard the ship. The total capacity of the batteries shall ensure the operation of the radio station during the whole time of crew or special personnel presence onboard the ship expected that the radio station is to operate continuously during 24 h: at least 1 h for transmission and 24 h for receipt. Where satellite EPIRB of COSPAS-SARSAT system is installed instead of MF/HF radiotelephone on board non-self-propelled ships, it is permitted not to have other means of reception of voyage, navigation and meteorological information.

Non-self-propelled ships in service are to be fitted with radio equipment according to the requirements of the present paragraph by the time of ordinary survey of the ship starting from 01.01.2017 but not later than 19.07.2021.

2.1.3 Inland navigation ships, which navigate within maritime traffic areas, shall have a VHF radiotelephone station with maritime mobile service frequencies. This station shall be permanently supplied from the ship's electric power source throughout the period when the ship is within the maritime traffic area.

2.1.4 Ships shall be provided with operating documents for radio equipment.

2.2 RADIO EQUIPMENT FOR SHIPS OF M-III, M-IIP AND O-IIP CLASSES

2.2.1 In order to comply with requirements stated in 1.3.1, each passenger ship and each ship of gross tonnage of 300 and above engaged on international voyages shall be fitted with radio equipment according to Table 2.2.1.

Note: see 2.2.2 with number corresponding to footnote number.

2.2.2 When using Table 2.2.1, the following shall be considered:

.1 if a ship is engaged on voyages within sea area A1, in addition to radio equipment mentioned in Table 2.2.1 for this area, it shall be fitted with a second independent distress alerting arrangement: this may be either the second VHF DSC radio installation without special receiver for continuous DSC watch on channel 70, or VHF EPIRB, or MF DSC radio installation (if the ship is engaged on voyages within sea area covered by shore-based MF DSC radio stations), or HF DSC radio installation, or INMARSAT ship earth station, or satellite EPIRB of the COSPAS-SARSAT system. If the ship is engaged on voyages within sea areas A1+2 or A1+2+A3, in addition to radio equipment mentioned in Table 2.2.1 for these sea areas, either additional INMARSAT ship earth station, or satellite EPIRB of the COSPAS-SARSAT system, or HF DSC radio installation (unless installed as a main one specified in Table 2.2.1 for sea areas A1/A2/A3) may be used as a second independent distress alerting arrangement. If the ship is engaged on voyages within sea areas A1+2+A3+A4, a satellite EPIRB of the COSPAS-SARSAT system may be used as a second independent distress alerting arrangement. Where serviceability of equipment on board the ships is provided by redundancy, the second independent distress alerting arrangement may be omitted provided that it is available in the redundant equipment;

.2 combined radio installation or radio installation as a separate device may be used;

.3 continuous listening watch may be used on VHF channel 16;

.4 mentioned equipment is not required if the MF/HF radio installation is available;

.5 where radio telephone station does not provide for transmission and receipt of general radio messages at operating frequencies at 1605 to 4000 kHz, provision shall be made for a separate radio installation or MF/HF radio installation for transmission and receipt of general radio messages by means of radiotelephony or direct-printing telegraphy, or INMARSAT ship earth station;

.6 mentioned equipment is not required if the INMARSAT ship earth station is available;

.7 where MF/HF radio installation does not provide for transmission and reception of general radio messages at operating frequencies of 1605 to 4000 kHz and 4000 to 27500 kHz, provision shall be made for a separate radio installation for transmission and reception of general radio messages by means of radiotelephony or direct-printing telegraphy;
.8 mentioned receiver is mandatory if the ship is engaged on voyages within any area covered by NAVTEX;
.9 mentioned equipment is allowed as part of INMARSAT ship earth station;
.10 the receiver is mandatory if the ship is engaged on voyages within any area covered by INMARSAT geostationary satellites and not covered by NAVTEX;
.11 the mentioned receiver may be installed instead of EGC receiver on ships engaged on voyages exclusively within the area where maritime safety information is broadcast by means of HF direct-printing telegraphy;
.12 one of satellite EPIRBs of COSPAS-SARSAT system shall be of free floating type;
.13 a single EPIRB may be installed if the distress alerting is provided from the usual steering position by means of at least two separate and independent arrangements using different types of communication corresponding to a ship navigation area;
.14 equipment configuration shall comply with requirements in 2.1.1;
.15 VHF EPIRB may be provided instead of EPIRB of COSPAS-SARSAT system on board ships engaged on voyages exclusively within sea areas A1;
.16 ship’s radar transponder or ship’s AIS transmitter may be one of LSA radar transponders or LSA AIS transmitters;
.17 for non-passenger ships of gross tonnage less than 500, two sets of two-way VHF radiotelephone apparatus and one LSA radar transponder or LSA AIS transmitter are sufficient;
.18 where serviceability of equipment is provided by redundancy, the second set of such equipment shall be fitted. All the redundant equipment shall be connected to separate antennas, to main, emergency and standby electric power sources, and be readily available;
.19 depending on sea navigation area, INMARSAT ship earth station may be installed instead of redundant MF radiotelephone;
.20 redundant set of INMARSAT ship earth station is not required if MF/HF radio installation is installed as a redundant arrangement;
.21 for ships engaged on occasional voyages in the sea area A4 and equipped with MF/HF radio installation, the redundant MF/HF radio installation may be replaced with INMARSAT ship earth station;
.22 ship engaged on voyages within sea areas A1+A2 and equipped with INMARSAT ship earth station shall be fitted with receiver for DSC watch at frequency of 2187.5 kHz;
.23 each passenger ship, at the position from which the ship is normally steered, shall be fitted with local two-way radio communication arrangement using aircraft frequencies 121.5 MHz and 123.1 MHz for the purposes of search and rescue operations;
.24 two sets are recommended, one set being man-portable;
.25 to be available on board passenger (including high-speed) ships and cargo (including high-speed) ships of gross tonnage of 500 and above engaged on international voyages;
.26 if the ship’s crew consists of one person — 1 set, if the crew of a passenger ship or a ship carrying dangerous goods consists of 3 or more persons — 3 sets.

2.2.3 Every ship not engaged on international voyages and every ship with gross tonnage less than 300 engaged on international voyages shall be fitted with the following radio equipment:
.1 for inland waterways according to Table 2.2.1;
.2 for voyages within sea area A1:
VHF DSC radio installation;
free floating satellite EPIRB of COSPAS-SARSAT system;
ship’s radar transponder or AIS transmitter;
LSA two-way VHF radiotelephone apparatus, two sets;
command public address device;
.3 ships engaged on voyages within sea areas A1+A2 shall be fitted, in addition to mentioned in 2.2.3.2, with the following radio equipment:
MF or MF/HF DSC radio installation;
NAVTEX receiver. Ships intended for permanent operation outside the coverage area of NAVTEX shall be fitted with EGC receiver or direct-printing telegraphy HF receiver for receipt of maritime safety information if the ship is engaged on voyages exclusively within an area where maritime safety information is broadcast by means of HF direct-printing telegraphy;

when the ship is engaged on voyages within sea areas A1+A2+A3 or A1+A2+A3+A4, the following shall be installed, in addition to radio equipment mentioned in 2.2.3.2:

MF/HF DSC radio installation;

INMARSAT-C ship earth station with EGC receiver and GLONASS/GPS receiver;

NAVTEX receiver with regard to its application as stated in 2.2.3.3.

Radio equipment of ships fitted under this paragraph shall be compliant with requirements of 2.2.2.2, 2.2.2.3, 2.2.2.6, 2.2.2.18 to 2.2.2.20, 2.2.2.26.

2.2.4 Every ship intended for navigation inside the port water area shall be fitted with radio equipment for sea area A1 in accordance with 2.2.3 except for free floating satellite EPIRB of COSPAS-SARSAT system.

2.2.5 Non-self-propelled manned ships intended to be towed/pushed at sea shall be fitted with radio equipment for sea area A1 according to 2.2.3.2 except for command public address device.

2.2.6 For oil tankers, oil skimming vessels, gas carriers and chemical tankers, transmitter power at the carrier frequency shall not exceed 500 W in the antenna. The peak power of transmitter shall not exceed 1000 W.

Portable/man-portable VHF radiotelephone stations on these ships shall have an explosion group stated in Table A2.3 Appendix 2 Part VI of these Rules and comply with requirements of 6.1.32.

2.2.7 In addition to mentioned in 2.1.1, 2.2.1 and 2.2.3, the ships shall be provided with equipment used in alert systems, navigation conditions compliance control systems and navigation safety systems, if such an equipment is mandatory for ships (or group of ships) operated within coverage areas of these systems.

2.2.8 In order to comply with requirements of 2.2.1 and 2.2.3 with respect to distress alerting by at least two separate and independent radio arrangements, refer to Table 2.2.8.

3 POWER SOURCES

3.1 POWER SOURCES FOR RADIO EQUIPMENT FOR SHIPS OF M, O, P AND J CLASSES

3.1.1 The main power for radio equipment required by the present Part of these Rules shall be provided from ship’s power plant.

3.1.2 Main VHF radiotelephone station, MF/HF radio station and ship earth station of mobile satellite service shall be supplied from ship’s emergency power source, in addition to main power from the ship’s mains.

3.2 POWER SOURCES FOR RADIO EQUIPMENT FOR SHIPS OF M-CII, M-IIP AND O-IIP CLASSES

3.2.1 Radio equipment shall be supplied according to Table 3.2.1.

### 3.2.2 Standby power sources for radio stations shall not be used for supplying power to other consumers except for emergency lights of radio room.

### 3.2.3 Standby power sources shall provide for concurrent operation of VHF radio installation and, depending on sea areas, for which the ship is equipped, either MF radio installation, or MF/HF radio installation, or INMARSAT ship earth station for at least 1 hour.

Concurrent powering of MF and HF radio installations from standby sources is not required.

For ships engaged on voyages exclusively within port water area, the standby power source shall ensure concurrent operation of radio equipment for at least 1 hour.

### 3.2.4 If data are to be entered continuously from ship navigation or other equipment in order to provide for proper operation of radio installation, provision shall be made for continuous input of such information in case of failure in the main or standby ship electric power source.

Provision shall be made for visual and audible alarm on changeover to standby source in the wheelhouse.

### 3.2.5 For calculation of capacity of standby power source, the averaged discharge current shall be determined as a sum of three values:
.1 0.5 of current consumption in transmission mode;
.2 current consumption in reception mode;
.3 current for powering of additional consumers.

In order to consider possible decrease in capacity of standby power source during its operation, the calculated capacity shall be increased by 40%.

3.2.6 Provision shall be made for automatic charging device for a standby power source. This charging device shall ensure its recharging within max. 10 hours to the required minimum level.

3.2.7 Automatic charging device shall be provided with activation visual alarm.

Provision shall be made for audible and visual alarm in the wheelhouse to indicate when charging voltage or current are beyond the limits specified in technical documentation of storage battery manufacturer for automatic charging conditions. Provision shall be made for only manual acknowledgment and deactivation of audible alarm. The alarm shall be capable of being automatically reset after the normal charging conditions have been restored. Alarm failure shall not interrupt storage battery charging or discharging.

3.2.8 Automatic charging device shall be readily available within at least 5 s after activation or power interruption is restored.

3.2.9 Automatic charging device shall be designed so as to be protected against damage in case of broken or disconnected cables as well as short-circuit of storage battery terminals. Where this protection is provided by electronic means, it shall be capable of being reset after remedy of open circuit or short-circuit fault.

3.2.10 The rated current of charging device shall be determined in the equipment manufacturer's technical documentation as a sum of following values:
.1 0.1 of current consumption in transmission mode;
.2 current consumption in reception mode;
.3 current for powering additional consumers;
.4 rated storage battery charging current.
4 ARRANGEMENT OF RADIO EQUIPMENT AND INSTALLATION OF CABLE NETWORK

4.1 GENERAL REQUIREMENTS

4.1.1 Radio equipment of each radio installation shall:

.1 be so arranged that no harmful interference of mechanical, electrical or other origin affects its proper use;

.2 be so arranged as to ensure electromagnetic compatibility and avoid harmful interaction of radio installation with other equipment and systems;

.3 be arranged so that to ensure safety and operating conditions as established by technical documentation;

.4 be protected against water, temperature variations and other environmental conditions that may affect serviceability of radio installation;

.5 be provided with lighting independent of main and emergency electric power sources and purposed for illuminating radio installation controls;

.6 be spaced so that not to be closer than the distance between radio installation and compass as specified in the manufacturer's technical documentation.

All radio equipment of ships of М-СП, М-ПР, О-ПР, М and О classes, which is mandatory under the present Part of these Rules (including emergency and standby power sources), shall be arranged so that to ensure its serviceability in case of flooding up to the bulkhead deck level.

4.1.2 Provision shall be made for applying Convention-compliant symbols where two-way VHF radiotelephone apparatus and LSA AIS transmitter, each ERIPB or radar transponder are installed, stored and arranged.

4.1.3 Depending on radio equipment components and arrangement of communication on board ships, provision shall be made for special-purpose spaces for radio equipment and its power sources, namely radio room, radio equipment room, power equipment room and battery room.

4.1.4 Radio equipment may be installed in the wheelhouse provided that its operation does not cause change in magnetic compass readings, produce noise with sound pressure level not exceeding 60 dB (A) or impede maintenance of other equipment. In such a case requirements of 4.2.2.1, 4.2.11, 4.2.14.2, 4.2.16, 4.2.17, 4.3.2, 4.3.3, 4.3.5.2 to 4.3.5.7, 4.3.8, 4.3.9 and 4.3.11 shall be complied with.

4.1.5 For arrangement of storage batteries and converters, requirements of 2.8, 8.5 to 8.7 Part VI of these Rules shall be complied with.

4.1.6 Metal or metal-lined bulkheads, ceilings and decks of ship's spaces where radio equipment is installed shall be connected to each other and to the hull and ensure continuity of screening. For non-metal ships, screening lining shall have electrical connection with the rubbing strip or otherwise grounded.

4.1.7 All radio equipment shall be installed so that to be accessible for maintenance and repair. Radio equipment shall be properly secured to prevent displacement at maximum permissible operating heel and trim as well as in case of dramatic shocks and shaking.

4.1.8 For arrangement of radar transponders on board inland navigation ships, refer to requirements of 4.9.2.
4.2 RADIO ROOM

4.2.1 Radio room shall be located in a space adjacent to the wheelhouse (see 1.2.1.25 Part III of these Rules).

4.2.2 Radio room shall be arranged so that:
 .1 to ensure leading out antennas when they are as far as possible from the metal parts of the ship;
 .2 to be as far as possible from devices and spaces with high noise level, heat sources (see 4.2.4).

4.2.3 Radio room shall be located and arranged so that it is not used as a passage to spaces not related to radio equipment or as a cabin for permanent accommodation. Radio operator’s/GMDSS radio officer’s cabin shall be located in a space adjacent to the radio room (see 1.2.1.25 Part III of these Rules).

4.2.4 Bulkheads, ceilings and doors of the radio room shall be provided with acoustic and thermal insulation made of non-combustible materials.

4.2.5 Radio room deck shall be provided with electric insulating covering.

4.2.6 Radio room doors shall be arranged so that to provide a short cut for exit to an open deck. The doors shall be sized and arranged so to provide access for maintenance and repair of radio equipment. The door shall be at least 600 mm wide. Radio room doors leading to the open deck shall be designed to open outwards. The radio room shall be accessible from the interior spaces of the ship.

4.2.7 The radio room shall be provided with heating and air conditioning systems to maintain air temperature within 18 °C to 23 °C. Steam heating is not allowed in the radio room.

4.2.8 The radio room shall be provided with ventilation.

4.2.9 The radio room shall be provided with natural and artificial lighting. Emergency lighting of the radio room shall provide for illumination of at least 50 lx of clock face and front panels of the radio equipment. Luminous lamps are not allowed.

4.2.10 Transit electric cables or wires or transit pipelines are not allowed to be laid through radio room.

4.2.11 Provision shall be made for at least two socket outlets with indication of their purpose in the radio room: one outlet shall be connected to the ship’s main lighting mains, the other to the emergency lighting mains.

4.2.12 The voice two-way communication shall be provided between the radio room and wheelhouse.

4.2.13 Where PABX is provided, provision shall be made for telephones connected to PABX in the radio room and radio operator’s/GMDSS radio officer’s cabin.

4.2.14 The following shall be installed in the radio room:
 .1 radio operator’s/GMDSS radio officer’s desk;
 .2 marine clock with the second hand;
 .3 lamp of general group of calls.

4.2.15 Radio operator’s/GMDSS radio officer’s desk shall be installed so that during operation the operator is faced toward the ship’s bow and to provide for natural lighting of the free desk surface from the front and left side.

4.2.16 The desk top shall be sized so that after radio equipment is fitted, the surface of the desk near the radio operator’s/GMDSS radio officer’s workstation remains free to allow him keeping records by handwriting or keyboard typing. The desk top shall be 750 mm above the deck.

4.2.17 The face of clock installed in the radio room shall be at least 125 mm in diameter with clock hands (hour, minute and second) concentric.

The clock time error per 24 hours under conditions specified in 4.2.7 shall not exceed 30 s.

4.2.18 Clock shall be installed in front of radio operator/GMDSS radio officer when at his workstation.
4.3 ARRANGEMENT OF RADIO EQUIPMENT IN THE RADIO ROOM

4.3.1 Radio equipment and supporting auxiliary equipment shall be arranged in the radio room.

4.3.2 Storage batteries and equipment not related to radio communication are not allowed in the radio room except for those specified in 4.1.5.

4.3.3 No resistors of charging devices, which dissipate more than 500 W during storage battery charging, or resistors with cases heating above 60 °C are allowed in the radio room.

4.3.4 Radio equipment in the radio room shall be arranged so that radio operator/GMDSS radio officer while sitting at his workstation could be able to do the following:
   .1 activate and deactivate radio equipment;
   .2 use receiver and transmitter controls;
   .3 listen to received messages with recording by handwriting or keyboard typing;
   .4 keep transmission using a radiotelephone;
   .5 observe instrument readings and position of radio equipment controls;
   .6 observe clock readings;
   .7 use a voice communication system;
   .8 when radio equipment is controlled from the workstation, its controls shall not be more than 750 mm away from the shoulder of the radio operator/GMDSS radio officer.

4.3.5 When radio equipment is arranged, the following is to be ensured:
   .1 proper illumination of desk free surface near radio operator's workstation and equipment controls;
   .2 as minimum as possible length of antenna radio cables from entries to transmitters or to their matching units, duly confirmed by drawings and calculations;
   .3 possibility to switch antennas;
   .4 as minimum as possible length of cables connecting separate parts of radio equipment, duly confirmed by drawings and calculations;
   .5 possibility for pulling-out frames and opening equipment doors. In any position of frames and doors, distances to each other, bulkheads and near standing equipment shall be at least 30 mm;
   .6 access to output terminals of equipment and groundings;
   .7 safety of people according to requirements of technical documentation for radio equipment.

4.3.6 Remote control consoles as well as starting and control devices of transmitters shall be arranged in accordance with requirements of 4.3.4.8.

4.3.7 Distance between separate radio equipment units as well as between radio equipment and bulkheads shall be at least 30 mm.

4.3.8 Non-combustible gaskets installed between resistors of charging devices and bulkheads shall be at least 20 mm away from bulkheads to ensure free circulation of air.

4.3.9 All passages in the radio room shall be at least 600 mm wide.

4.3.10 Equipment shall be fastened to bulkheads with shackles, brackets or bolts welded to them. Equipment having weight less than 15 kg may be secured directly to the bulkhead plating using wood screws.

4.3.11 Spare parts for radio equipment shall be kept in the radio room and secured at the designated places.

Spare parts lockers may be arranged in the radio equipment room or power equipment room.

4.3.12 In the radio room, provision shall be made for placing a board with instructions on activation of radio equipment so that alert and distress signals could be transmitted on air by untrained personnel.

4.4 RADIO EQUIPMENT ROOM

4.4.1 Radio equipment room (designed for remotely controlled radio equipment) with respect to its layout on board the ship, design,
heating, ventilation as well as main and emergency electric lighting shall comply with requirements imposed on the radio room. Natural lighting is not required in the radio equipment room.

4.4.2 In the radio equipment room, provision shall be made for a table for repair work with drawers for store spare parts, tools, supplies and documentation, as well as chair or arm-chair.

4.4.3 Above the table, provision shall be made for a single wall-mounted lamp and at least two socket outlets with indication of their purpose: one outlet shall be connected to the ship’s main lighting mains, the other to the portable lighting mains.

4.4.4 Radio equipment shall be arranged in the radio equipment room so that to be accessible for inspection, maintenance and dismounting in case of replacement.

4.5 ARRANGEMENT OF RADIO EQUIPMENT IN WHEELHOUSE

4.5.1 Radio equipment installed in accordance with 4.1.3 in the wheelhouse shall be arranged so that to be accessible for inspection, maintenance and dismounting in case of replacement. Where radio equipment is installed, provision shall be made for clock complying with requirements of 4.2.17, 4.2.18 as well as main and emergency electric lighting.

4.5.2 Main controls of VHF radiotelephone shall be arranged so that to be accessible and the operator is faced to the ship’s bow when using them.

4.5.3 In order to comply with the requirements for arrangement of radio equipment, in the wheelhouse of every river – sea navigation ship, in addition to 4.1.4, 4.5.1 and 4.5.2, provision shall be made for a place for control and operation of GMDSS equipment as well as for internal communication during ship navigation – radio workstation or a separate space for radio equipment (see 4.1.3) with remote controls located in the wheelhouse.

4.5.4 The radio workstation mentioned in 4.5.3 shall be arranged in the aft of the wheelhouse to allow officer on watch a full view of the navigation conditions while operating radio equipment.

4.5.5 Where radio workstation mentioned in 4.5.3 is separated from the remaining part of the wheelhouse by a bulkhead, this bulkhead shall be made of glass or be fitted with windows.

4.5.6 There shall be no lockable door between the radio workstation mentioned in 4.5.3 and remaining part of the wheelhouse. To avoid dazzling effect of light sources at night, provision shall be made for a curtain at the radio workstation.

4.5.7 At the radio workstation mentioned in 4.5.3, provision shall be made for a table, a clock in accordance with requirements of 4.2.17, a working chair with deck fixing arrangement, as well as main lighting and lighting from a standby power source.

4.5.8 Controls of radiotelephone channels as well as those for generation and transmission of distress and safety alerts, when the VHF radio installation operates in the DSC and radiotelephone mode, shall be located in the forward part of the wheelhouse.

Provision shall be made for arrangements for radio communication from bridge wings. In order to comply with this requirement, man-portable VHF radio equipment may be used.

4.5.9 For river – sea navigation ship, a stationary two-way VHF radiotelephone apparatus for aircraft communication shall be arranged in the wheelhouse.

4.5.10 In the wheelhouse of the river – sea navigation ship provision shall be made for placing operating instructions on using DSC, as well as instructions on handling radio installations in emergency situations and for using these instructions when handling radio installations. In addition, GMDSS Operating Guidance for Masters of Ships in Distress Situations developed by International Maritime Organization (IMO) and procedures for
cancellation of false distress alerts shall be placed.

4.5.11 For river–sea navigation ship, provision shall be made for MF radio installation, MF/HF radio installation, INMARSAT ship earth station as well as VHF, MF and MF/HF radio installations and INMARSAT ship earth station intended for redundancy in the radio workstation mentioned in 4.5.3.

4.5.12 In the wheelhouse provision shall be made for placing information on call sign, ship station identity and other codes used during operation of radio equipment and for using this information when handling radio installations.

4.5.13 NAVTEX receivers, INMARSAT EGC receivers and HF NBDP receivers for receipt of maritime safety information shall be arranged in the radio workstation mentioned in 4.5.3.

4.5.14 For passenger river–sea navigation ships the following requirements are to be additionally complied with:

1. a distress alert panel shall be fitted in the radio workstation mentioned in 4.5.3. This panel shall contain either a single button, which is pressed to give a distress alert using all radio installations installed on board the ship, or a single button for each radio installation. The panel shall allow for displaying indication that a button/buttons was/were activated. Provision shall be made for arrangements to prevent accidental pressing of button/buttons. Where EPIRB is used as a second distress alerting arrangement and is incapable of being activated remotely, provision shall be made for the additional EPIRB in the radio post;

2. information on ship's position shall be continuously and automatically transmitted to all corresponding radio equipment to be used for initial distress alerting when the button/buttons on the distress alerting panel is/are pressed;

3. distress alert receipt alarm panel shall be fitted in the radio workstation mentioned in 4.5.3. This panel shall be provided with visual and audible distress alert receipt warn-}

ings with indication of a radio service through which these alerts were received.

4.5.15 Radio equipment installed for redundancy on board ships engaged on voyages within sea areas A1+ A2+A3 and A1+A2+A3+A4 is not required to be connected to the distress alerting panel, if this equipment can transmit distress alert and is arranged in the radio post.

4.5.16 A satellite EPIRB intended to be used as a second independent distress alerting arrangement and not capable of being activated remotely shall be arranged in the radio workstation so that to be accessible for distress alerting, be released manually and transferred to any lifeboat or liferaft.

4.6 POWER EQUIPMENT ROOM

4.6.1 Power equipment room where converters for radio equipment are arranged shall be located at the radio room deck level or above in such a place to provide for minimum length of cable routes to the radio room as confirmed by drawings and calculations.

4.6.2 Power equipment room shall be of adequate size for convenient arrangement of equipment. Clear height of the power equipment room shall not be less than 2 m. Deck of the power equipment room shall be covered with electric insulating material.

4.6.3 The power equipment room shall be provided with ventilation, heating and electric heating complying with requirements of 10.12 Part IV and 9 to 10 Part VI of these Rules.

4.6.4 Electric devices in the power equipment room shall be at least 100 mm above the deck subject to requirements of 2.8 Part VI of these Rules.

4.7 BATTERY ROOM

4.7.1 Battery room or cabinet where storage batteries supplying radio equipment are arranged shall be located at the radio room deck level or above in such a place to provide for minimum length of cable routes to the radio room as confirmed by drawings and
calculations. The battery room shall have an exit to the open deck.

4.7.2 Design, lighting, heating and ventilation of battery room as well as arrangement of storage batteries shall comply with requirements of 2.8, 8.5 to 8.7, 10.1 to 10.6 Part VI and 10.12 Part IV of these Rules.

4.8 ARRANGEMENT OF PUBLIC ADDRESS AND BROADCASTING EQUIPMENT

4.8.1 Main microphone station of duplex or simplex public address device shall be installed in the wheelhouse.

4.8.2 Megaphone control devices (one-way public address device for communication with neighbouring ships or shore) shall be installed in the wheelhouse. Megaphone shall be arranged above the wheelhouse where it is capable of turning for acoustic propagation in any direction.

4.8.3 The public address device shall provide communication of the wheelhouse with central control station, main engine local control station, bow and stern anchoring and mooring control stations, steering gear actuator local control station, propulsion motor local control station.

4.8.4 On board passenger ships equipped with public address and broadcasting device in accordance with 2.1.1, 2.2.1 and 2.2.3, there shall be at least three main broadcasting lines:
   1. a deck line designed for connection of loudspeakers installed on open decks;
   2. a service line designed for connection of loudspeakers installed in service and accommodation spaces for the crew (see 1.2.1.26 Part III of these Rules);
   3. a passenger line designed for connection of loudspeakers installed in passenger spaces and in corridors and at platforms adjacent to these spaces.

4.8.5 For passenger ship provision shall be made for public address microphone station to transmit service orders through broadcasting lines, which is installed in the room intended for watchkeeping when in port. If there is no room for watchkeeping, this equipment shall be installed at the embarkation and disembarkation area.

4.8.6 Where main public address microphone station and broadcasting device’s units are structurally integrated, such a device is to be installed in the wheelhouse. For radio broadcasting, a tape recorder and record players installed outside the wheelhouse may be connected to the public address device integral with broadcasting device.

4.8.7 Loudspeakers fitted in accommodation and service spaces shall be provided with volume controls. Plug adapters are not allowed.

4.8.8 A short-circuit in one or more loudspeakers of broadcasting line shall not cause transmission of messages through other broadcasting channels to be interrupted.

4.8.9 A command public address device on board each river–sea navigation ship shall have at least three main broadcasting lines. Each of these lines shall have at least two loops of flame retardant cable, which are separated over the entire length and connected to two separate and independent amplifiers.

4.8.10 Minimum sound pressure level while transmitting emergency messages with the ship underway under normal conditions shall be as follows:
   1. at least 75 dB (A) in interior rooms;
   2. at least 80 dB (A) on open decks.

4.8.11 The command public address device shall be designed to prevent electric and acoustic feedback or other interferences.

4.9 ARRANGEMENT OF EPIRBs, RADAR TRANSPONDERS, AIS TRANSMITTERS, VHF APPARATUSES

4.9.1 A free floating satellite EPIRB and a VHF EPIRB intended to be arranged on board ship shall be fitted on open deck to prevent their displacement under extreme operating conditions and to be capable of floating free if the ship sinks. They shall be
accessible for manual release and distress alerting as well as for transfer to any lifeboat or liferaft.

4.9.2 Radar transponders and ship’s LSA AIS transmitters shall be installed in areas to be capable of being transferred to any lifeboat or liferaft, or there shall be a single radar transponder or AIS transmitter at each lifeboat or liferaft.

For ships having at least two radar transponders or AIS transmitters and equipped with free-fall lifeboats, there shall be one radar transponder or AIS transmitted in such a lifeboat, and the other shall be arranged to be capable of being used on board the ship and transferred to any other lifeboat or liferaft.

4.9.3 A two-way VHF radiotelephone apparatus shall be kept in the wheelhouse or in other space not locked during voyage, if the equipment is capable of being transferred to any other lifeboat or liferaft from this space. The apparatus shall be arranged at the radio post.

4.9.4 The stationary two-way VHF radiotelephone apparatus of a lifeboat shall be arranged according to requirements of Part V of these Rules so that not to impede its performance when the lifeboat is flooded up to upper thwart level.

4.9.5 Where storage batteries are provided as a external electric power source of the stationary two-way VHF radiotelephone apparatus of life-saving appliances, they shall be arranged in lockers complying with requirements of 8.5 Part VI of these Rules and protected to IP68.

4.9.6 Illumination of the front panel of the stationary two-way VHF radiotelephone apparatus of the lifeboat shall be at least 50 lx. Electric lighting of this panel shall be powered from storage batteries mentioned in 4.9.5.

4.9.7 Provision shall be made for charging storage batteries mentioned on 4.9.5 in the lifeboat, as well as from the ship's electric power source. The flexible cable for connection of storage batteries to the charging device from the ship's electric power source shall provide for release of this connection without any tool when emergency lifeboat launching is required.

4.10 CABLE NETWORK INSTALLATION

4.10.1 Installation of radio equipment cable network and measures to protect radio signal reception against interference produced by electric devices shall be performed according to requirements of 2.6, 2.7, 12 Part VI of these Rules as amended by this Chapter.

4.10.2 Power cables laid into radio room for powering radio equipment from the ship's power plant shall not be used for powering loads not related to radio equipment. At the switchboard in the radio room provision shall be made for connection of radio equipment installed in accordance with 2.1.1 for inland navigation ships, and in accordance with 2.2.1 and 2.2.3 for river–sea navigation ships.

4.10.3 In the radio room provision shall be made for a device capable of continuously monitoring of ship's mains voltage.

4.10.4 If there is no radio room on board the ship, the radio equipment switchboard may be installed in the radio room subject to requirements of 4.10.2.

4.10.5 Where cables enter the apparatus, their shieldings shall be connected to the equipment case.

4.10.6 Insulation resistance of any laid cable disconnected from radio equipment at both ends shall be at least 20 MΩ regardless of its length.

4.10.7 All cable network related to radio arrangements and public address and broadcasting equipment shall be made with cables having a continuous shielding.
5 ANTENNA ASSEMBLIES AND GROUNDING

5.1 GENERAL REQUIREMENTS

5.1.1 Antennas of any type suitable for continuous most effective use of radio equipment regardless of ship course may be installed on board ships. Antennas shall be resistant to mechanical and climatic factors under ship operating conditions (see 6 to 13 Appendix 15 to RTSC).

5.1.2 Ship antennas installed on board inland navigation ships shall withstand wind speed of up to 29 m/s and up to 60 m/s for river–sea navigation ships. Ship speed and other factors are not taken into account to this end.

5.1.3 For beam antennas, a flexible strand made of copper or a copper-based alloy shall be used. For calculation of minimum diameter of beam antenna strand required to comply with requirement of 5.1.2, bending deflection shall be taken to be equal to 6% of antenna length between suspension points.

5.1.4 Each antenna beam shall be made of a one piece of an antenna strand. If the antenna design does not allow for making a downlead and beam from a one piece of a strand, they shall be connected by splicing or by means of connections providing for their electrical contact.

5.1.5 To ensure proper performance of the beam antenna, basic load from the downlead shall not be applied directly to the downlead tail area.

5.1.6 Beam antenna downlead near the entry shall be fastened to a stay equipped with insulators and be connected to the entry by means of copper or brass cap. Cap shall be connected to the downlead by soldering or cold press-fitting.

5.1.7 The device intended for suspension of the beam antenna shall be capable of its lowering and hoisting as well as tension control from the deck (superstructure top, wheelhouse top).

5.1.8 When fitting multi-beam antennas, provision shall be made for hoisting and lowering each beam separately. Beams shall be at least 700 mm apart from each other.

5.1.9 Flexible halyards shall be used for hoisting and lowering beam antennas. For ships carrying flammable cargoes the halyards shall be attached in an explosion safe area and be made of non-combustible materials. Steel ropes used for this purpose shall be electrically connected to the hull.

5.1.10 Antenna insulators rated for working voltages fed from radio installation shall be used for insulation of antennas.

5.1.11 Insulation resistance of antennas relative to hull shall be at least 10 MΩ and in case of increased humidity at least 1 M.

5.1.12 Transmitting antennas shall be designed to allow for operation of any connected radio transmitter at maximum emitted power and input voltages.

5.1.13 Receiving and transmitting antennas shall be arranged so that to protect receivers against interference when transmitters are operating with maximum power.

5.1.14 Antenna wires and downleads shall not be less than 1 m from pipes, masts or other metallic parts of the ship. Antennas
shall be installed so that not to be in contact with metallic structures of the ship under any operating conditions. Distance between antenna insulator chains and pipes shall be at least 2 m.

5.1.15 Self-supporting antennas above the superstructure shall be designed to be folded or lowered to the superstructure level.

5.1.16 Beam antennas secured on the folding masts shall be designed not to be lowered before folding the mast and subsequently hoisted after restoring the mast.

5.1.17 For oil tankers and equivalent ships, insulators shall be fitted into steel mast rigging (shrouds, jackstays, ropes for hawser and horn, etc.) so that to be maximum 6 m apart, and the distance between the deck and lower insulator is at least 3 m and not more than 4 m. In order to reduce power losses during operation of radio transmitters, rigging shall be divided by insulators for all ships.

5.1.18 Antennas of broadcasting and television receivers shall be located as far as possible from all service antennas to the extent allowed by the ship design.

5.1.19 In L-type and T-type beam antennas provision shall be made for arrangements to prevent breakage in case of tension, for example, a runner with mechanical safety arrangement in antenna halyards.

Breaking force of the mechanical safety arrangement shall be max. 0.3 of that of the antenna strand. Safety arrangement shall be as such to release antenna tension and prevent its contact with superstructures, rigging and hull.

5.1.20 While radio stations are controlled remotely, provision shall be made for arrangements for automatic grounding of antennas when the equipment is switched off. Antenna grounding device may be controlled remotely from the radio station control console.

5.1.21 Provision shall be made for transmitting and receiving antennas on board each ship equipped with MF/HF radio station, if radio station transmitter and receiver are provided for separate antennas. For folding masts, additional antennas not extending beyond the ship shall be provided.

5.1.22 Provision shall be made for a common antenna for all broadcasting receivers. Radio communication and navigation antennas are not allowed to be used as antennas for broadcasting receivers.

5.1.23 To ensure operation of radio equipment mentioned in Tables 2.1.1, 2.2.1 and 2.2.3, on board each ship provision shall be made for necessary antennas for operation of the following equipment:

- VHF radiotelephone stations;
- VHF receiver for DSC watch;
- MF radiotelephone station;
- MF receiver for DSC watch;
- MF/HF receiver for radiotelephone and telephony and NBDP receiver; and
- INMARSAT ship earth station and EG C receiver antenna;
- INMARSAT ship earth station and EGC receiver antenna;
- MF/HF receiver for DSC watch and telephony and NBDP MF/HF radio receiver;
- NAVTEX receiver and HF NBDP receiver for receipt of maritime safety information.

5.2 ANTENNAS OF INMARSAT SHIP EARTH STATION

5.2.1 Antenna of INMARSAT ship earth station shall:

- be arranged so that to ensure continuous tracking of satellite;
- be arranged in the upper part of the radar antenna mast or at the designated mast;
- be arranged so that to be accessible for maintenance;
- be arranged in a plane other than that of radar antenna.

5.2.2 For directional antennas of INMARSAT ship earth station provision shall be made for exclusion of shadow angles above 6° caused by ship structures within a radius of 10 m from antenna.

For nondirectional antennas provision shall be made for exclusion of shadow angles above
2° caused by ship structures within a radius of 1 m from antenna.

5.2.3 When installing the antenna of INMARSAT ship earth station, the following safe distances to other antennas and magnetic compass shall be provided:
.1 more than 5 m to HF antenna;
.2 more than 4 m to VHF antenna;
.3 more than 3 m to magnetic compass.

5.2.4 Antenna of INMARSAT earth ship station shall be installed to exclude shadow angles degrading radio equipment performance forward and aft of the ship up to –5° and starboard and portside up to –15°.

5.2.5 Where two antennas of INMARSAT earth ship station are installed, they shall be at least 1 m apart in the vertical plane.

5.3 ANTENNA OF VHF RADIOTELEPHONE STATION

5.3.1 Antenna of VHF radiotelephone station shall have a vertical polarization.

5.3.2 Antenna of VHF radiotelephone station shall be arranged as high as possible according to the ship design but not higher than air terminal. This antenna shall ensure unobstructed propagation of electromagnetic field.

5.4 ANTENNA CABLE LEADS AND LAYING INSIDE SPACES

5.4.1 Cables of radio transmitting antennas shall be laid into ship interior spaces through specific leads with insulators rated for operating voltage except for cases when antenna routing inside the space is made with radio frequency cable using radio frequency couplings.

5.4.2 Lead of transmitting antenna shall be designed to provide for its connection and disconnection without any tool.

5.4.3 Leads of transmitting antennas shall be installed in areas providing a short cut for cable laying to radio transmitters inside, to be confirmed by drawings and calculations. Where the lead and antenna connected to it are installed in the area intended for passage of people, they shall have fencing within 1800 mm preventing contact with them. Where lead columns are installed, provision shall be made for condensate drainage from internal cavities of the structure.

5.4.4 In order to avoid power losses, fencing made of electric insulating materials shall be used. Where metallic fences are used, they shall be grounded to the hull.

5.4.5 Radio frequency paths of MF/HF radio transmitters shall be made of radio frequency cable.

If the radio equipment design provides for unshielded cables/conductors from transmitter to antenna (or a switching or matching unit), these cables/conductors located in the radio room or wheelhouse shall be shielded. Cables/conductors located in the screened room other than radio room or wheelhouse are not required to be shielded.

5.4.6 The switching gear of transmitting antenna shall be circuitted and designed so that to prevent electric connection of antenna loop of transmitter with that of receiver or other transmitter.

5.4.7 Cables of receiving and transmitting antennas shall be of radio frequency type and ensure continuity of coverings.

Antenna switching devices, switches, lightning arrestors and other devices connected to these cables shall be of shielded type. Cables shall not cause signal attenuation above 3 dB.

5.4.8 Radio frequency cables of receiving and transmitting antennas shall be lead out to the open deck and connected to antennas by means of a waterproof or tight contact device, which provides for electric connection and access for checking its condition.

5.4.9 For each antenna not intended for continuous operation in working position, provision shall be made for a switching device inside the room allowing the antenna to be set to working, isolate and grounded positions.

5.4.10 Each receiving antenna shall be provided with protection device in order to pro-
tect the receiver input against atmospheric discharges. Where a matching system is used between receiving antenna and radio frequency cable, an atmospheric discharge protection devices shall be connected upstream of matching system input (from the antenna side).

5.4.11 Remote control of antenna switching process shall provide for manual switching of antenna.

5.5 GROUNDING

5.5.1 Working / high frequency grounding intended for operation of radio transmitters installed in the radio room shall be made in the form of a copper bus laid in a short cut from antenna switching device to metal bulkhead or deck electrically connected to the hull, with branches to transmitter grounding clamps. The length of the bus coming from transmitter to bulkhead or deck connection point shall be max. 1500 mm.

5.5.2 Working grounding of receivers installed in the radio room shall be made with a copper bus or flexible bronze/copper strand wit cross section at least 6 mm², laid in a short cut (as confirmed by drawings and calculations) from the receiver to the main grounding bus of transmitters or directly to the metal bulkhead electrically connected to the hull.

5.5.3 Working grounding of radio navigation, public address and broadcasting equipment and other radio equipment outside the radio room shall be made in accordance with requirements of the present Part of the Rules imposed on working grounding of receivers or transmitted installed in the radio room.

5.5.4 For non-metal ships, a common working grounding for the whole radio equipment shall be made in the form of a tinned copper or brass plate with area of at least 0.5 m² and at least 4 mm thick connected to the hull external surface below the lightest draught line.

5.5.5 Metal cases of radio equipment shall be electrically connected to the hull. Grounding wire shall be max. 150 mm long.

5.5.6 Protective grounding of lower ends of mast standing rigging shall be made with a strand of the main rope or by means of flexible metal conductors. Conductors shall have soldered lugs to be fastened to the hull with two screws or by welding. The hull connection areas shall be painted.

5.5.7 Total resistance of all electric connections of any grounding shall not exceed 0.02 Ω.

5.5.8 Grounding devices of radio equipment shall not be used as lightning conductors.
6 REQUIREMENTS TO RADIO EQUIPMENT

6.1 GENERAL REQUIREMENTS

6.1.1 Radio equipment shall be designed for operation in accordance with 6.1.2 and be able to withstand mechanical and climatic tests defined by national standards.

6.1.2 Radio equipment shall remain operable at heel of up to 22.5° and trim of up to 10° (with those heel and trim occurring simultaneously), as well as at roll of up to 22.5° with rolling period of 7 to 9 s and pitch of up to 10° from vertical line.

Radio equipment shall also remain operable when exposed to vibration, humidity and temperatures with parameters and values stated in 2.2.2, 2.2.3 and 2.2.5 Part VI of these Rules.

Radio equipment shall be designed to be connected to the ship's power mains. Radio equipment whose power voltage differs from that of the ship's mains shall be fitted with appropriate devices, which enable its connection to the ship's mains. Radio equipment shall remain operable under ship's power source voltage variations in accordance with 6.1.30.

Protection degree of the equipment shall not be less than stated in Table 2.3.6 Part VI of these Rules depending on its location.

Portable/man-portable radio equipment shall be designed to be resistant when exposed to sea water, oil and solar radiation (see 12, 13, 15 and 16 Appendix 15 RTSC).

6.1.3 The equipment shall be designed so that its main units may be replaced without need in additional calibration or set-up and installed so that to be accessible for inspection, maintenance and repair.

6.1.4 The equipment shall have a protection against overcurrent, overvoltage, and short-term accidental power source reverse polarity.

6.1.5 All current-carrying parts of radio equipment except for antenna leads and grounding conductors shall be accessible after opening only. Then, neither conductor of radio equipment shall be under voltage above 50 V relative to other conductors or to the earth. Capacitors in the high voltage circuits shall be capable of being self-discharged.

6.1.6 Radio equipment shall be circuited and designed to be functionally tested when opened. Provision shall be made for protection against electric shock (see 2.1.11 Part VI of these Rules).

6.1.7 Provision shall be made for clamps for grounding at all cases of radio equipment.

6.1.8 Metal parts on the external side of the radio equipment shall be electrically connected to its case.

6.1.9 Cables shall be connected to radio equipment in such a way as to maintain continuity of shielding. Provision shall be made for securing the cable on the equipment case.

6.1.10 Twist locks, thumbscrew dog or latches, which are capable of being opened or unscrewed without any tool, shall be used for fastening hinged or extended frames, removable panels and doors to the radio equipment case.

6.1.11 To avoid falling out loose hinged or extended frames of radio equipment because

---

1 GOST 16019, GOST R IEC 60945.
of ship roll or heel, provision shall be made for bidirectional safety stops.

6.1.12 Controls and indications of any radio equipment shall be located at front panel of the equipment case.

Controls shall be as such to prevent their accidental activation and deactivation and change of settings of radio equipment.

6.1.13 All controls shall provide for setting up of radio equipment. Provision shall be made to prevent access to controls not required during operation (except for those required for control of radio equipment in emergency situations).

The function and operation of radio equipment controls shall be marked with appropriate symbols and/or inscriptions contained in technical documentation for equipment.

6.1.14 The ON, START, SCALE UP, etc. positions of radio equipment controls shall correspond to handles set to the upper position, pushed off or to the right, knobs turned clockwise and upper or right-hand buttons pressed. The OFF, STOP, SCALE DOWN, etc. positions of radio equipment controls shall correspond to handles set to the lower position, pulled or to the left, knobs turned counterclockwise and lower or left-hand buttons pressed.

6.1.15 Graduation of main scales, inscriptions, notations as well as positions of indicators and controls on radio equipment shall be clearly visible at a distance of 700 mm.

6.1.16 Provision shall be made for lighting on equipment itself to enable distinguishing controls and taking indicator readings and to reduce intensity of light emitted by the equipment.

6.1.17 Internal wires as well as structural parts of radio equipment shall be connected to exclude spontaneous disconnection under vibration, roll or heel conditions (see 6, 8 Appendix 15 RTSC).

6.1.18 Internal wiring of radio equipment shall be made with multicoloured wires for designation of different circuits.

6.1.19 There shall be a spare wire in each flexible hose which connects individual parts of radio equipment. In addition, provision shall be made for a spare wire per ten wires in the hose.

6.1.20 Internal components of radio equipment shall be marked consistent with schematic circuit diagram and wiring diagram. Function of output terminals shall be specified on the case of radio equipment; for power circuits, voltage and polarity shall be specified.

6.1.21 Controls of radio equipment shall be protected against mechanical damages should the radio equipment be put with its front panel facing down to the supporting surface.

6.1.22 Fasteners of removable and hinged panels and frames of radio equipment shall be designed as such to be integral with its panels and frames.

6.1.23 Plug-in connections used in radio equipment shall be designed to prevent their improper connection and fitting into wrong sockets.

6.1.24 Voltage between contacts of microphones and head telephone sets shall not exceed 55 V, voltage relative to earth shall not exceed 30 V.

6.1.25 Radio equipment shall be circuited and designed to prevent damages caused by improper action sequence with controls or by reverse polarity of power source.

6.1.26 In radio equipment and remote control consoles provision shall be made for arrangements indicating faults or critical mode in essential circuits of radio equipment as well as on energization and high voltage supply.

6.1.27 Grounding (connection to case) of ship's mains and storage batteries through radio equipment circuit is not allowed.

6.1.28 Insulation resistance of radio equipment power circuits shall comply with requirements of 1 Appendix 5 RTSC).

6.1.29 Temperature of radio equipment cases during operation shall not exceed 60° C.
6.1.30 Radio equipment shall be operable in the event of change in ship’s mains power in accordance with 2.2.1 Part VI of these Rules.

If radio equipment is supplied with power from multiple electric power sources, provision shall be made for switches for automatic changeover from one power source to the other. These arrangements are not required to be included into equipment if they are provided as part of the ship’s power system.

6.1.31 Radio equipment power circuits shall be provided with replaceable fuse links or circuit-breakers. Fuses shall be designed to prevent any contact with their current-carrying parts while replacing fuse links. Time required for access to fuses shall not exceed 5 s.

6.1.32 Only explosion-proof portable/movable VHF radiotelephone stations of a certified safe type not less than “explosion-proof electric equipment” are allowed for operation in explosive spaces and areas on board oil tankers and equivalent ships. Radio stations of the basic type may be operated outside the explosive area.

6.1.33 Visual alarm of radio equipment located in the wheelhouse shall correspond to requirements of 6.1.16 Part VI of these Rules.

6.1.34 Radio equipment intended for distress alerting shall be designed so to prevent unintentional distress alerting.

Controls for radio equipment emergency operation shall be closed with a cover. Switches located on the emergency panel shall be distinctly coloured.

6.1.35 Radio equipment intended for distress alerting shall be as such to provide for preparation and making of distress and safety alert from the ship steering position.

6.1.36 In radio equipment intended for distress alerting, any distress alert shall result in actuation of visual and audible alarms indicating that the radio equipment transmits distress alert signal until its operation is stopped manually.

6.1.37 Radio equipment intended for distress alerting shall include built-in automatic data input arrangements for updating ship position and the date and time of fix.

For equipment having no built-in positioning devices, provision shall be made for a device for interfacing with an external electronic positioning system.

Radio equipment shall have arrangements for manual input of ship position and the date and time of fix.

Provision shall be made for audible and visual alarms, which actuate when no information is received from electronic positioning device or, in case of manual input, when these data were not updated for last 4 hours. Any ship position information not updated for more than 23.5 hours shall be deleted from memory.

Position information in INMARSAT ship earth station not updated more than 24 hours shall be highlighted with colour or otherwise.

6.1.38 In radio installations intended for distress alerting, distress alert shall be given by two independent actions (raising protective cap or cover is considered as the first action, pressing the distress alerting button is considered as the second action) using the only specially designated button isolated from controls used for equipment operation (functional buttons, keyboard keys). This button shall not be used for purposes other than distress alerting.

This button shall be red, marked with DISTRESS inscription and protected against unintentional activation.

If an opaque cover or cap are used to protect the distress alerting button from unintentional activation, it shall also have DISTRESS inscription. Distress alert button shall be closed with spring-loaded cover or cap fastened to equipment (for example, with hinges). The distress alerting shall not require removal of seals or breaking the cover/cap.

Activation of distress alert button shall be accompanied by audible and visual alarm.

The distress alert button shall be held pressed at least for 3 s, while the intermittent audible and visual signals shall start immediately. Within 3 seconds of holding the button, distress alert transmission shall start and in-
termittent audible and visual signals shall turn steady. Provision shall be made for interruption of repeated transmission of distress alert. Such an action shall not interrupt distress alert or distress alert during its transmission but shall prevent its repeated transmission.

6.1.39 In radio installations intended for distress alerting, provision shall be made for audible and visual alarm actuating upon receipt of distress call or urgency call or call having a distress category. The alarm shall be of non-disabled type and be capable of being acknowledged manually.

6.1.40 A minimum safe distance from magnetic compasses for installation of equipment unit shall be specified in operating documentation or on each unit.

6.1.41 All marine VHF, MF and HF transmitters shall be designed for continuous operation for at least 6 hours with duty cycle (total emission duration to total pause duration ratio) of 2:1.

6.1.42 With respect to electromagnetic compatibility, radio equipment shall comply with requirements of 2.7 Part VI of these Rules.

6.1.43 Radio equipment shall be designed to have arrangements for its fixing in place and keep serviceable at heel, trim and roll in accordance with requirements of 6.1.2.

6.2 TECHNICAL REQUIREMENTS TO RADIO COMMUNICATION MEANS

6.2.1 Radio communication means shall receive and transmit safety-related messages and meet the following requirements:

1. activation shall be performed by a single action;
2. starting time of tuned transmitter shall not exceed 5 s;
3. frequency retuning within the same subrange shall be performed within max. 15 s;
4. failure in automatic frequency tuning device shall not exclude manual frequency adjustment;
5. changeover from one type of radiation to the other shall be performed by a single action.

6.2.2 Transmitter remote control console designed to be located outside the radio room shall be provided with controls to enable radio transmission without controls located on the transmitter itself.

6.2.3 Radio communication means shall be designed to detect and remedy faults and to meet the following requirements:

1. internal elements shall be clearly visible with the case opened;
2. internal elements shall be arranged so that to be repaired and replaced;
3. metallic shields as well as covers and doors of shielded assemblies inside the case shall be capable of being opened without tools.

6.2.4 Radio transmitter permissible frequency deviations, RF bandwidth and out-band radiation spectra shall comply with standards approved by decision of the State Commission for Radio Frequencies.

6.2.5 For class H3E and J3E emissions, the upper side band shall be used.

6.2.6 For class J3E emissions, the carrier suppression shall be at least 40 dB less than peak power of transmitter. For class H3E emissions, the full carrier shall be emitted with carrier suppression 6±2 dB less than peak power.

6.2.7 Levels of carrier spurious amplitude and frequency modulation shall comply with requirements of national standards.

6.2.8 In case of class H3E and J3E emissions, unwanted emission power supplied to the transmitting antenna at any discrete frequency during operation of transmitter at the full peak power shall comply with requirements stated in Table 6.2.8.

1 Regulations 17-13, 18-13, 19-13.
2 GOST 12252, GOST 22580, GOST 22579, GOST 26897.
6 Requirements to Radio Equipment

### Table 6.2.8

<table>
<thead>
<tr>
<th>Spacing Δ between unwanted emission frequency and assigned frequency* (kHz)</th>

<tr>
<td>over 7.5</td>
<td>43 and unwanted emission power is not to exceed 50 mW</td>
</tr>
</tbody>
</table>

* Assigned frequency in a single-band channel shall be 1400 Hz higher than the carrier.

#### 6.2.9
Acoustic frequency band of transmitters designed for emissions classes H3E and J3E shall be from 350 to 2700 Hz with permissible amplitude variation of max. 6 dB.

#### 6.2.10
Modulation depth of transmitters for emission class H3E shall be at least 80%. Modulation depth caused by foreign voltage sources shall not exceed 5%.

Modulation of transmitters for emissions class J3E shall be so that intermodulation components do not exceed values stipulated by national standards.

#### 6.2.11
All transmitters with rated power above 20 W shall be provided with an indicator allowing for continuous monitoring of antenna current during transmission. Failure in the indicator shall not result in open circuit fault of antenna loop.

#### 6.2.12
The transmitter shall be tuned to any frequency required by the present part of the Rules with the frequency well locked.

#### 6.2.13
Antenna break or short-circuit to case as well as feed of powerful HF signal shall not cause damages degrading the performance of transmitter.

#### 6.2.14
Intermediate frequency shall not cause interference in the secured call and distress international frequency bands.

#### 6.2.15
In this Section, the following classification is adopted for receiver bands by high/intermediate frequency measured at a level of 6 dB:

- **Wide band**: ±3000 Hz
- **Medium band**: ±1500 Hz
- **Narrow band**: ±600 Hz
- **Very narrow band**: ±100 Hz
- **Single-band**: ±350 to ±2700 Hz

#### 6.2.16
Receiver’s LF path band shall be, except for cases specified in technical documentation, at least 300 to 2700 Hz for output voltage irregularity of 6 dB within the band above 1000 Hz.

#### 6.2.17
The receiver power circuits shall be provided with devices to protect against interference produced by ship’s electric equipment.

#### 6.2.18
Input circuits of receivers shall be protected against voltages induced by operating ship transmitters.

#### 6.2.19
Receivers shall be designed so that to connect an RF cable to the antenna clamp with continuity of shielding maintained.

#### 6.2.20
All ship receivers shall be designed for continuous 24-hour operation.

#### 6.2.21
The following shall be included into radiotelephone station:

- .1 transmitter/receiver with antenna;
- .2 integral or remote control console/consoles with microtelephone handset and integral or remote loudspeaker.

#### 6.2.22
Man-portable VHF radiotelephone station with rechargeable power source shall be provided with arrangement for its charging from ship’s mains.

### 6.3 MF/HF RADIO INSTALLATION

#### Ships of M, O, P and J classes

#### 6.3.1
Operating parameters of transmitter shall comply with those stated in Table 6.3.1.

#### 6.3.2
Where radio installation is provided with an integral or a separate automatic radiotelephone alerting device, the latter shall comply with requirements of 6.3.7 to 6.3.12.

#### 6.3.3
The transmitter shall be complete or shall have an integral dummy antenna.

#### 6.3.4
Basic operating parameters of receiver shall comply with those stated in Table 6.3.4.

### 6.3.6 The receiver shall be rated for connection of head telephone sets and loudspeakers with power of at least 0.5 W.

### 6.3.7 Automatic radiotelephone alerting device shall enable the MF/HF radiotelephone to automatically transmit the signals specified in 6.3.8 and 6.3.9.

### 6.3.8 Radiotelephone alert signal given by automatic alerting device shall consist of dual-tone acoustic frequency sine-wave oscillations being transmitted alternatively and continuously within max. 1 min and min. 30 s. Frequency of one tone shall be equal to (2200±33) Hz, frequency of the other tone to (1300±19.5) Hz.

Each tone duration shall be equal to (250±10) ms. Interval between the tones shall be max. 4 ms. Stronger tone to weaker tone amplitude ratio shall be within 1 to 1.2.

### 6.3.9 Automatic transmission of radiotelephone alert signals shall be cyclic with intervals between two subsequent cycles approximately equal to a single cycle. Automatic alerting device shall be capable of transmitting alert signals until disabled.

### 6.3.10 Automatic alerting device shall be started by a single action. Starting duration shall not exceed 5 s.

### 6.3.11 Automatic alerting device shall come complete with instruction on its activation and monitoring.

### 6.3.12 Automatic alerting device shall be designed so that to make its inadvertent activation impossible. Provision shall be made for disabling of automatic alerting device any time to transmit a distress message.

### Ships of M-CII, M-IIP and O-IIP classes

### 6.3.13 Radio installation shall provide for the following categories of alerts using radiotelephony and DSC for:

- .1 distress, urgency and safety alerting;
- .2 transmission of information related to ship operation;
- .3 transmission of other information.
6.3.14 Radio installation shall provide communication when operated in the radio-telephone and NBDP mode for:
   .1 distress, urgency and safety alerting;
   .2 transmission of information related to ship operation;
   .3 transmission of other information.

6.3.15 Where radio installation is intended only for distress alerting, as well as communication in distress and for safety, requirements of 6.3.13.2, 6.3.13.3, 6.3.14.2 and 6.3.14.3 may be omitted.

6.3.16 Radio installation shall comprise the following:
   .1 equipment stated in 6.2.21;
   .2 integral or remote narrow band direct-printing device;
   .3 integral or remote DSC device;
   .4 receiver for continuous DSC watch at frequencies of 2187.5, 8414.5 kHz and at least one of distress and safety frequencies in DSC system: 4207.5, 6312, 12577 or 16804.5 kHz. The receiver shall enable one of these distress and safety frequencies in DSC system to be selected.

6.3.17 The transmitter shall be capable of operating within frequency band of 1.605 to 27.5 MHz. The number of operating frequencies shall not be less than 18: for radio telephony: 2182, 4125, 6215, 8291, 12290 and 16420 kHz; for NBDP: 2174.5, 4177.5, 6268, 8376.5, 12520 and 16695 kHz; for DSC: 2187.5, 4207.5, 6312, 8414.5, 12577 and 16804.5 kHz.

6.3.18 The transmitter shall provide the following emission classes: J3E, H3E and J2B or F1B.

   For transmitters produced after 1 July 2002, emission class H3E is not required.

6.3.19 Radio installation shall be provided with arrangements to automatically prevent overmodulation.

6.3.20 During normal modulation, peak envelope power for emission class J3E or H3E or mean transmitter power for emission class J2B or F1B shall be as follows:
   - at least 60 W for any frequency within the operating band;
   - max. 400 W for MF band;
   - max. 1500 W for HF band.

6.3.21 If mean output power of transmitter exceeds 400 W, when the transmitter is switched to MF frequencies, this power shall be automatically reduced down to 400 W or less.

6.3.22 Radio installation shall be capable of operating at frequencies of 2182 kHz and 2187.5 kHz within one minute after activation.

6.3.23 The receiver shall be capable of discrete tuning within the band of 1.605 to 27.5 MHz. A receiver tuned to fixed frequencies (at least 18) may be used:
   - for radio telephony: 2182, 4125, 6215, 8291, 12290 and 16420 kHz;
   - for NBDP: 2174.5, 4177.5, 6268, 8376.5, 12520 and 16695 kHz;
   - for DSC: 2187.5, 4207.5, 6312, 8414.5, 12577 and 16804.5 kHz.

6.3.24 The receiver shall be capable of receiving upper side band with emission classes J3E, H3E, J2B and F1B.

6.3.25 After warming up, receiver frequency shall remain within ±10 Hz of the tuned/set frequency.

6.3.26 The receiver sensitivity for class J3E and F1B emissions shall not be less than 6 µV when signal-to-noise ratio at receiver output is 20 dB. For NBDP and DSC, error index per character of max. 10^-2 shall be obtained for signal-to-noise ratio of 12 dB.

6.3.27 The receiver shall provide power of at least 2 W to the loudspeaker and at least 1 mW to microphone handset.

6.3.28 Where DSC and NBDP devices are not integral, in radio installation provision shall be made for inputs/outputs for transmission/reception of DSC and NBDP signals.

6.3.29 Adjacent-channel selectivity of the receiver shall be at least 60 dB for interference offset by ±6 kHz.

   Side channel selectivity shall be at least 80 dB.
Intermodulation selectivity relative to 1 µV shall be at least 70 dB.

Nonlinear distortion factor shall not exceed 7%.

6.3.30 Provision shall be made for signal automatic gain control.

6.3.31 DSC shall be capable of decoding and encoding, composing and verifying DSC formats.

6.3.32 If received messages are not immediately printed, storage memory shall be as such to store at least 20 received distress messages in the DSC device memory. The messages shall be stored in the memory until they are read and shall be deleted in 48 h after receiving.

6.3.33 Where a receiver with scanner for continuous watch on multiple DSC distress channels is used, all selected channels shall be scanned within 2 s, and watch time on each channel shall provide for detection of a sequence of dots preceding each DSC. Scanning is stopped only as soon as dots transmitted at 100 Baud are detected.

6.3.34 The narrow band direct-printing device shall be capable of operating in circular and selective call modes on single-frequency distress channels intended for NBDP.

6.3.35 The narrow band direct-printing device shall comprise the following:

1. arrangements for decoding and encoding messages;
2. arrangements for composing and verification of messages to be transmitted;
3. arrangements for recording received messages.

6.3.36 Self-identification data shall be stored in the NBDP device. Provision shall be made for protection against data tampering.

6.3.37 Radio installation shall be capable of being controlled from built-in or remote control console/ consoles.

Where two remote control consoles are provided, a priority shall be given to the console located at the place where the ship is controlled.

6.3.38 The radio installation control system shall be capable of:

1. activation of DSC distress call. DSC distress call activation shall have a priority over any other operations;
2. acknowledgment of received DSC distress call;
3. relaying DSC distress call;
4. switchover to frequencies of 2182 and 2187.5 kHz. These frequencies shall be marked on tuners and controls;
5. autoselect of emission class (J3E/H3E) when switching to frequency of 2182 kHz;
6. autoselect of emission class (J2B/F1B) when switching to distress and safety frequencies of DCS and NBDP devices specified in 6.3.17 and 6.3.23;
7. emission classes shall be switched using not more than one control;
8. provision shall be made for independent tuning of receiver and transmitter frequencies. The tuning process shall not impede usage of transceivers.

6.3.39 Transceiver controls shall operate so as not to cause side and outband emissions.

6.3.40 Provision shall be made for indication of entered and received DSC formats. The data displays shall be sized to fit at least 160 characters in at least two rows.

6.3.41 It shall be possible to test audible and visual alarm.

6.3.42 Provision shall be made for indication of transmission and reception frequencies.

6.3.43 Manually tuned radio installation shall be provided with devices to enable its fine adjustment.

6.3.44 Self-identification data shall be stored in the DSC device memory and shall be displayed for verification purposes. These data shall be unchangeable without special-purpose tool.

6.3.45 Provision shall be made for regular verification of DSC device without emitting signals.
6.3.46 Where radio installation is to be preheated for normal operation, power shall be supplied to preheating circuits when radio installation is de-energized.

Preheating circuit switch shall be properly marked. It shall be protected against accidental deactivation.

Operating temperature shall be reached within 30 min after power on.

6.3.47 Where a delay in power supply to any part of the transmitter after its activation is required, this delay shall actuate automatically.

6.4 VHF RADIO TELEPHONE STATION

6.4.1 VHF radiotelephone station mentioned in 2.1.1 shall be compatible with VHF radio communication system for inland waterborne transport and meet requirements of the national standard1.

6.4.2 VHF radiotelephone station shall be capable of radio communicating within the bands specified in Table 2.1.1 using emission class G3E (F3). Frequency grid pitch shall be equal to 25 kHz.

6.4.3 The main VHF radiotelephone station shall have at least three channels including distress, safety and call channel (300.2 MHz, channel 5). Operating radio station shall be capable of operating at any channels within bands stated in Table 2.1.1 and providing operating modes in accordance with communication arrangement.

6.4.4 Maximum frequency deviation corresponding to 100 % modulation depth shall be as close as possible to ±5 kHz, but shall not in any case exceed ±5 kHz.

6.4.5 Frequency response of transmitter modulator shall have precorrection (rise towards high frequencies) of 6 dB per octave with subsequent backward correction in receiver.

6.4.6 Acoustic frequency band shall not exceed 3000 Hz.

6.4.7 Transmitter's radiated power shall be max. 25 W. It shall be possible to reduce the power down to 1 W. Radiated power of portable/man-portable VHF radiotelephone station shall be max. 2 W.

6.4.8 Mean power of any side radiation caused by modulation products on any channel shall not exceed 10 µW, and mean power of any side radiation at any discrete frequency shall not exceed 2.5 µW.

6.4.9 Receiver sensitivity at signal-to-noise ratio of 12 dB shall be at least 1.0 µV.

6.4.10 Radio station receiver output shall be rated for loudspeaker with power of at least 0.5 W and microtelephone handset (or manipulator). The loudspeaker shall be incorporated into radio station case.

6.4.11 The receiver's high/intermediate frequency band at 6 dB shall ensure reception of a signal with maximum frequency deviation of 5 kHz.

6.4.12 Nonlinear distortion factor of receiver shall be max. 7 %.

6.4.13 Two-signal selectivity of receiver shall be such as the attenuation of signal received ±25 kHz off the resonance frequency shall be at least ±75 dB.

6.4.14 Adjacent and side channel selectivity of the receiver shall be at least 70 dB.

6.4.15 Radio station shall be capable of being switched to the 300.2 MHz channel (channel 5) by a single action.

6.4.16 Switchover from simplex to duplex operation and vice versa shall be automatic with switching to the selected channel.

6.4.17 Channels shall be displayed or indicated according to enumeration established by authorized state executive authority of the Russian Federation.

6.4.18 On the 300.2 MHz (channel 5) channel provision shall be made for minimum power of 50 µW on the loudspeaker, when volume control is set to the zero position.

1 GOST 12252.
6.4.19 VHF radiotelephone station shall have a noise suppressor capable of being disabled and fitted with an adjuster.

6.4.20 VHF radiotelephone station may come complete with arrangements allowing for radio communication directly from bridge wings.

6.4.21 Relative instability of transmitter frequency shall be not worse than 7\( \times 10^{-6} \), for portable/man-portable station not worse than 10\( \times 10^{-6} \).

6.4.22 VHF radiotelephone station shall be designed to be powered from the main and emergency power sources meeting requirements of 3.1.2.

6.4.23 The loudspeaker shall be capable of being disabled automatically during duplex operation/radiation.

6.4.24 Transmitter bandwidth at minus 30 dB at frequency grid pitch of 25 kHz shall be max. 18.8 kHz.

6.4.25 Transmitter side emission shall be max. 2.5 \( \mu \)W.

6.5 PUBLIC ADDRESS AND BROADCASTING DEVICE

6.5.1 Public address device shall provide for duplex or simplex communication of wheelhouse with main control stations (see 4.8.3), as well as allow orders be transmitted to service spaces, passenger compartments and to open decks through broadcasting arrangements of broadcasting device.

6.5.2 At least three lines shall be connected to the public address device.

6.5.3 The public address device shall have the main microphone station in the wheelhouse and microphone stations near public address communication subscribers.

6.5.4 Public address stations within spaces with noise level above 90 dB (A) shall be provided with additional visual alarm.

6.5.5 On board ships of M and O classes, provision shall be made for one-way public address devices for communication with nearby ships and shore. On ships of 300 gross tonnage or less, public address system on the upper deck may be used instead of one-way public address device.

6.5.6 Public address device shall be able to:

.1 broadcasting communication with at least three microphone stations;

.2 broadcasting through at least three broadcasting lines to all accommodation spaces (see 1.2.1.22 Part III of these Rules) and open decks;

.3 broadcasting from radio receiver, tape recorder, record player, as well as from local and remote microphones;

.4 transmission of orders throughout all broadcasting lines, concurrently or separately, from microphone stations of public address system, as well as from local and remote microphones. Broadcasting shall be capable of being disabled automatically when local or remote microphones are enabled from microphone stations of public address system;

.5 monitoring of transmission quality in each broadcasting line;

.6 transmission of orders through broadcasting lines with volume controls of loudspeakers set to minimum or to the OFF position.

6.5.7 In order to transmit orders through broadcasting arrangements, all control operations (activation, switching broadcasting lines, reset of programs and activation of forced broadcasting) shall be performed remotely from microphone stations of the public address device.

6.5.8 Provision shall be made for a visual alarm when broadcasting lines are connected to equipment of the public address microphone post for transmission of orders.

6.6 COMMAND PUBLIC ADDRESS DEVICE

6.6.1 The command public address device shall be capable of interrupting, from the wheelhouse, any signal transmitted from the other microphone station or broadcasting or audio recording.
Provision shall be also made for automatic interruption of broadcasting or audio recording upon activation of ship’s general alarm system.

6.6.2 The command public address device shall be protected against unauthorized use.

6.7 MF RADIO INSTALLATION

6.7.1 MF radio installation required in 2.2.1 and 2.2.3 shall comply with requirements of 6.3.13, 6.3.18, 6.3.19, 6.3.21, 6.3.22, 6.3.24 to 6.3.27, 6.3.29 to 6.3.32, 6.3.37, 6.3.39 to 6.3.47.

6.7.2 MF radio installation required in 2.2.1 shall be capable of radio communicating in the radiotelephone mode for:

.1 distress, urgency and safety alerting;
.2 transmission of information related to ship operation;
.3 transmission of other information.

6.7.3 Where radio installation is intended only for distress alerting and distress and safety communicating, requirements of 6.3.13.2, 6.3.13.3, 6.7.2.2 and 6.7.2.3 do not apply.

6.7.4 Radio installation shall include:

.1 transmitter/receiver with antenna;
.2 integral or remote control console/consoles with microtelephone handset and integral or remote loudspeaker;
.3 integral or remote DSC device;
.4 receiver for continuous watch at frequency of 2187.5 kHz (DSC).

6.7.5 The transmitter shall be capable of operating within the band of 1605 to 4000 kHz. The number of operating frequencies shall not be less than two: 2182 and 2187.5 kHz.

6.7.6 For normal modulation, peak envelope power for class J2B or F1B emissions shall be at least 60 W.

6.7.7 The transmitter shall come complete with a standard dummy antenna: $C = 300 \text{ pF}$, $R = 4 \Omega$.

6.7.8 The transmitter shall be capable of discrete tuning within the band of 1605 to 4000 kHz. The receiver tuned to fixed frequencies (at least two, 2182 and 2187.5 kHz) may be used.

6.7.9 If the DSC device is not integral, provision shall be made for a separate output for digital selective calling signals.

6.7.10 The radio installation control system shall ensure the following:

.1 activation of DSC distress call. DSC distress call shall be activated to provide its priority over other functions of the radio installation control system;
.2 manual relaying DSC distress call;
.3 switchover to frequencies of 2182 and 2187.5 kHz. These frequencies shall be marked on tuners and controls;
.4 autoselect of emission class (J3E/H3E) when switching to frequency of 2182 kHz;
.5 autoselect of emission class (J2B/F1B) when switching to frequency of 2187.5 kHz.

6.7.11 Emission classes shall be switched using no more than one control.

6.7.12 Provision shall be made for independent tuning of receiver and transmitter frequencies. The tuning process shall not impede usage of transceivers.

6.8 VHF RADIO INSTALLATION

6.8.1 VHF radio installation required in 2.2.1 shall be capable of producing the following categories of alerts using radio telephony and NBDP:

.1 distress, urgency and safety alerting;
.2 transmission of information related to ship operation;
.3 transmission of other information.

6.8.2 VHF radio installation required in 2.2.1 shall enable radio communication when operating in the radiotelephone mode for:

.1 distress, urgency and safety alerting;
.2 transmission of information related to ship operation;
.3 transmission of other information.

6.8.3 Radio installation shall include:

.1 transmitter/receiver with antenna;
.2 integral or remote control console/consoles;
.3 microphone with RX/TX push-button switch, which may be combined with a telephone in the telephone handset;
.4 integrated or remote loudspeaker;
.5 integrated or separate DSC device;
.6 DSC watch receiver capable of continuous watching on channel 70.

Additional receivers may be fitted in the radio installation.

6.8.4 The DSC device shall be capable of operating on channel 70 and shall consist of:
arrangements for decoding and encoding DSC messages;
arrangements for composing DSC message;
arrangements for verification of prepared message prior to transmission;
arrangements for displaying data in the received call.

The DSC device shall meet the following requirements:
.1 if received messages are not immediately printed, storage memory shall be as such to store at least 20 received distress messages in the DSC device memory. The messages shall be stored in the memory until they are read and shall be deleted in 48 h after receiving;
.2 DSC distress call activation shall have a priority over any other operations;
.3 Self-identification data shall be stored in the DSC device memory and shall be displayed for verification purposes. These data shall be unchangeable without special-purpose tool;
.4 provision shall be made for periodical verifying the DSC device without emitting signals;
.5 with modulated DSC signal of 1 µV at input of receiver connected to DSC device, the DSC device shall decode the message with maximum permissible error index of $10^{-2}$ (at output).

6.8.5 Radiotelephone station included into VHF radio installation shall meet the following requirements:
.1 radio station shall be designed for operation at maritime mobile service frequencies within band of 156 to 174 MHz using class G3E (radiotelephone channels) and G2B (DSC channel 70) emissions. Frequency spacing shall be equal to 25 kHz;
.2 radio station shall operate:
within band of 156.3 to 156.875 MHz on simplex channels;
within band of 156.025 to 157.425 MHz for transmission and within band of 160.625 to 162.025 MHz for reception on duplex channels;
.3 radio station shall have at least five channels including channel 70 (156.525 MHz), channel 6 (156.3 MHz), channel 13 (156.65 MHz), channel 16 (156.8 MHz);
.4 maximum frequency deviation corresponding to modulation depth of 100% shall not exceed ±5 kHz;
.5 frequency modulation shall have a pre-correction of 6 dB per octave with subsequent backward correction in receiver;
.6 acoustic frequency band shall not exceed 3000 Hz;
.7 radio station shall send signals to antenna with vertical polarization. Radiations shall be nondirectional in the horizontal plane;
.8 the rated power of transmitter shall be min. 6 W and max. 25 W. The transmitter shall have a device for reducing power from 1 to 0.1 W except for channel 70 (156.525 MHz);
.9 the mean power of any side emission caused by modulation products in any other channel of the International maritime mobile service shall not exceed 10 µW while mean power of any other side emission at any discrete frequency within the band of International maritime mobile service shall not exceed 2.5 µW;
.10 sensitivity of receiver at signal-to-noise ratio of 20 dB shall be at least 2 µV;
.11 radio station receiver output shall be rated for loudspeaker with power of at least 0.5 W and microtelephone handset. Provision shall be made for disabling loudspeaker without affecting output acoustic power of handset;
12 the loudspeaker shall be disabled automatically during duplex operation/emission. Provision shall be made to prevent electric and acoustic feedback in the handset;

13 switchover from one channel to another shall be made within 5 s. Switchover from transmission to reception and vice versa shall not exceed 0.3 s;

14 receiver shall be provided with a manual volume control, which allows for varying output power;

15 on channel 16 (156.8 MHz), provision shall be made for a device providing a minimum power of 59 mW on loudspeaker when volume control is set to zero;

16 provision shall be made for a noise suppressor capable of being disabled on the front panel of radio station;

17 provision shall be made for a two-position switch to enable the whole VHF radio installation with visual indication on its activation;

18 provision shall be made for a visual indication on carrier frequency transmission;

19 radio station shall be able to display the number of channel, which it is tuned to. Information on the channel number shall be visible in all lighting conditions. Control console shall have channel 16 indicated;

20 radio station may come complete with arrangements allowing for radio communication directly from bridge wings;

21 radio station shall not emit signals when channels are being switched over;

22 the TC/RX control shall be operated so as not to cause any side or outband emissions;

23 provision shall be made for devices allowing for changeover to reception mode from transmission mode using RX/TX switch. Devices with no manual control may be provided for operating on duplex channels;

24 the receiver's high/intermediate frequency band at 6 dB shall provide for reception of a signal with maximum frequency deviation of ±5 kHz;

25 receiver's nonlinear distortion factor shall be max. 7 %;

26 adjacent channel selectivity shall be at least 75 dB;

27 intermodulation selectivity shall be at least 70 dB;

28 where there is no scanning mode, provision shall be made for a device for switching the radio station back to channel 16 (156.8 MHz) when microtelephone handset is fitted to its standard place;

29 switchover from simplex to duplex operation and vice versa shall be automatic when appropriate channels are transited to;

30 receiver's output power shall be suppressed in the transmission mode during simplex operation;

31 radiotelephone station provided with multichannel watch/scanning device shall meet the following requirements:

  provision shall be made for a two-channel monitoring with automatic scanning priority and additional channels;

  where selection of priority channel is not provided, channel 16 (156.8 MHz) shall be considered as priority channel;

  numbers of both scanned channels shall be marked;

  transmission shall not be possible in the scanning mode;

  upon deactivation of scanning device, transmitter and receiver shall automatically switchover to the selected additional channel;

  provision shall be made for a manual switchover to the priority channel with one control only.

  Scanning characteristics shall meet the following requirements:

  priority channel shall be scanned with the rate of at least once every two seconds;

  if the signal is received on a priority channel, receiver shall remain on this channel during the whole length of the signal;

  if the signal is received on an additional channel, the priority channel shall continue to be scanned so that receipt on an additional channel is not interrupted for more than 150 ms;

  if the signal fails to be received on a priority channel and the signal is received on an
additional channel, the time of stay on an additional channel shall be at least 850 ms; provision shall be made for indication of a channel where the signal is received.

6.9 ENHANCED GROUP CALLING RECEIVER

6.9.1 Enhanced group calling (EGC) receiver shall provide for continuous receipt of the following message types:
- messages to all ships;
- messages via INMARSAT system;
- messages to a group of ships;
- individual messages;
- geographically addressed messages.

6.9.2 The EGC receiver shall be provided with arrangements for a fixed tuning to any of 20 reception channels with numbers stored in the EGC receiver memory. Four channels out of them are assigned permanently:

<table>
<thead>
<tr>
<th>Frequency (MHz)</th>
<th>Channel number</th>
</tr>
</thead>
<tbody>
<tr>
<td>1537.10</td>
<td>10840</td>
</tr>
<tr>
<td>1537.70</td>
<td>11080</td>
</tr>
<tr>
<td>1537.72</td>
<td>11088</td>
</tr>
<tr>
<td>1541.45</td>
<td>12580</td>
</tr>
</tbody>
</table>

6.9.3 Sensitivity of EGC receiver shall be at least 23.0 dB/kW.

6.9.4 The equipment shall be capable of printing the received information. The received EGC messages shall be stored in memory, with indication that the message has been received, for subsequent printing, except for messages mentioned in 6.9.8 and 6.9.11 to be printed immediately after receipt.

6.9.5 The EGC receiver shall be designed as a single unit or be combined with other devices. Components of other devices such as antenna, low-noise amplifier and ship earth station frequency converter may be used as a component of the receiver.

6.9.6 The EGC receiver shall be provided with arrangement for manual input of the following:
- ship position data, NAVAREA code (where the ship navigates) for receipt of area group calls;
- individual identifier (ID) and group identifier (ENID);
- automatic input of ship coordinates from navigation equipment and their automatic conversion into geographic area may be provided.

6.9.7 The EGC receiver shall have a separately supplied memory device to store data on selected types of received messages, ship coordinates, NAVAREAs, geographic areas and receiver identifier within at least 6 months.

6.9.8 The EGC receiver shall be provided with audible and visual alarm on receipt of distress and urgency category messages. Provision shall be made for an adequate visibility of the received message indication from the ship steering position. The audible alarm shall be designed to be of non-disabled type. Upon actuation, the alarm shall be capable of being reset to the monitoring status manually from received message displaying and/or printing position.

6.9.9 The EGC receiver shall be provided with indication on incorrect tuning to the EGC carrier frequency or on lack of synchronization.

6.9.10 Received messages shall be printed out regardless of errors during reception. The printer shall print a low line mark if a character is received corrupted.

6.9.11 The operator shall have control over printing or non-printing of service groups, except for codes of the following messages, which shall be always printed upon reception by the EGC receiver:
- navigational and meteorological warnings and forecasts;
- information on search and rescue of ships in distress;
- shore-to-ship distress alerts sent by shore-based radio stations to a definite or indefinite geographic area where the ship is voyaging.

6.9.12 The equipment shall not print the message repeatedly if this message was received without errors.
6.9.13 The printer shall be capable of reproducing all characters of the International Telegraph Code (ITC-5), printing at least 40 characters in a row, and hyphenating automatically when a word can not fully fit into a current row. Upon completion of printout, line feed shall be made five times.

6.9.14 Switchover between different ship’s power sources to the EGC receiver or any power supply interruption within 60 s shall not require repeated manual setting the equipment to the operating mode or lead to loss of received messages stored in memory.

6.9.15 In addition to requirements stated in the present part of these Rules, the EGC receiver shall meet technical requirements of the International Mobile Satellite Organization and be type approved by INMARSAT.

6.9.16 Provisions shall be made to exclude antenna shadow angles degrading EGC receiver performance forward and aft of the ship up to –5° and starboard and portside up to –15° in the horizon plane.

For nondirectional antennas, provisions shall be made for exclusion of shadow angles above 2° in the horizontal plane caused by ship structures within a radius of 1 m from antenna.

6.9.17 Where a stabilized directional antenna is used, provisions shall be made to exclude shadow angles in accordance with 5.2.2 and 6.9.16.

6.10 NAVTEX RECEIVER

6.10.1 NAVTEX receiver shall comprise two radio receivers, signal processing unit and one of the following devices:

1. built-in printer;
2. displaying unit with connector for interfacing with the printer and non-volatile memory for received messages;
3. non-volatile memory for received messages connected to other navigation systems.

6.10.2 NAVTEX receiver shall receive information on service areas and types of messages excluded from reception by operator and/or a data displaying unit shall be readily available at all times.

6.10.3 The equipment shall come complete with one receiver operating at 518 kHz of the NAVTEX International Service and the second receiver capable of operating concurrently with the first one at least at two other NAVTEX frequencies. The receiver operating at 518 kHz shall have priority in respect of output of the received information to displaying unit or printer. The printing or displaying messages received by one of receivers shall not impede the progress of information reception by both receivers.

6.10.4 Sensitivity of the receiver shall be so that error index per character shall be lower than 4 % for a source with electromotive force of 2 µV and active resistance of 50 Ω.

6.10.5 Each NAVTEX receiver shall have a non-volatile memory to store at least 200 messages of 500 characters each in average (printed and non-printed). Provision shall be made to preclude from deletion of any saved message. When the memory is full, provision shall be made for automatic deletion of the oldest messages to record the new messages.

6.10.6 For NAVTEX receiver provision shall be made for saving of marked messages in the non-volatile memory. These messages shall take up max. 25 % of the non-volatile memory and shall not be overwritten by new messages. Provision shall be made for removing a permanent storage mark from the messages, which may be then subsequently overwritten by newly received messages as the memory is getting full.

6.10.7 NAVTEX receiver shall be capable of storing of at least 200 identifiers of messages for each receiver.

Upon expiry of the storage period between 60° and 72nd hours, message identifier shall be automatically erased from the memory. If the number of received messages exceeds the equipment memory, the earliest identifiers of received messages shall be deleted automatically.

NAVTEX receiver shall store only identifiers of messages, which were received cor-
The messages with error index per character lower than 4 % are considered as received correctly.

6.10.8 Information on service areas and types of messages stored in memory of equipment shall be kept within 6 hours after power breakdown.

6.10.9 For receipt of search and rescue messages, alarm in the normal ship steering position shall actuate. This alarm shall be reset only manually.

6.10.10 The displaying unit and/or printer shall be capable of displaying and/or printing of at least 32 characters in a row.

6.10.11 Where the displaying unit is provided in NAVTEX receiver, it shall meet the following requirements:

1 indication of new received messages shall be displayed until acknowledged or within 24 hours after receipt;
2 text of the new received messages shall be displayed;
3 the displaying unit shall be capable of displaying of at least 16 rows of text;
4 the displaying unit’s readings shall be readable from the distance as stated in 6.1.15;
5 where there is no printer, the displaying unit shall be arranged at the ship steering position.

6.10.12 If automatic line feed entails division of a word, this shall be indicated in the displayed/printed text.

6.10.13 While displaying received messages by means of the displaying unit, provision shall be made for automatic display of message end with a line-feed character added automatically or any other way of delineation. Upon printing the received message, the printer or a unit interfaced with it shall automatically insert line-feed characters.

6.10.14 Equipment of NAVTEX receiver shall be capable of displaying/printing asterisk if the character is received corrupted.

6.10.15 If the printer is not integral, provision shall be made for selection of the following information to be printed:

1 all messages as they are received;
2 all messages stored in the non-volatile memory;
3 all messages received at definite frequencies, areas or having definite codes;
4 all messages displayed on a displaying unit;
5 messages selected from those appearing on the display.

The NAVTEX receiver shall be provided with an interfacing unit for connection with the printer.

6.10.16 The equipment shall be fitted with performance test arrangements for radio receiver, data displaying unit, printer and non-volatile storage memory.

6.10.17 NAVTEX receiver shall come complete with interfacing unit for interfacing with other radio and navigation equipment and transmission of received data to this equipment.

6.10.18 All interfaces with other navigation and radio equipment shall comply with national standards.

6.11 HF NBDP RECEIVER FOR RECEPTION OF MARITIME SAFETY INFORMATION

6.11.1 HF NBDP receiver for reception of maritime safety information (the receiver, here below in the chapter) shall comprise a radio receiver, signal processing unit, printer and automatic and manual frequency tuning controls.

6.11.2 The receiver shall be capable of operating at frequencies of 4210, 6314, 8416.5, 12579, 16806.5, 19680.5, 22376, 26100.5 kHz. The receiver may be operated at additional frequencies provided for international and national NAVTEX services (518, 490 and 4209.5 kHz).

6.11.3 Provision shall be made for performance testing of receiver, signal processing

unit, printer and arrangements for automatic frequency retuning if the latter are provided in the receiver.

6.11.4 The equipment shall be capable of storing at least 255 message identifiers. Upon expiry of the storage period between 60th and 72nd hours, message identifier shall be automatically erased from the memory. If a number of received messages exceeds the memory size, the earliest message identifiers shall be deleted automatically.

6.11.5 Provision shall be made for audible and visual alarm at the steering position for displaying search and rescue messages. This alarm shall be deactivated only manually.

6.11.6 Information on service areas and types of messages stored in memory of equipment shall be kept within 6 hours after power breakdown.

6.11.7 Sensitivity of the receiver shall be so that error index per character does not exceed $10^{-2}$ for a source with electromotive force of 6 $\mu$V.

6.11.8 Provision shall be made for monitoring over printing or non-printing service groups of messages, navigational and meteorological warnings, search and rescue information and individual specific warnings, which are transmitted by a shore-based radio station in the ship navigation area.

6.11.9 Provision shall be made for receipt of information on service areas and types of messages excluded from reception.

6.11.10 Only identifiers of correctly received messages shall be stored in the receiver. The message is considered as received correctly if the error index per character is lower than 4 %.

6.11.11 Printer shall be capable of printing of at least 32 characters in a row.

6.11.12 Signal processing device and printer shall provide for line feed if this word can not be fully fitted within a row.

The printer shall automatically perform line feed upon completion of message printing.

6.11.13 The equipment shall print an asterisk if the character is received corrupted.

6.11.14 If the equipment includes arrangements for automatic frequency retuning, provision shall be made for a universal coordinated time clock with accuracy of $\pm 1$ s to be connected to the reprogrammable storage memory containing a frequency sequence and transmission schedules for all radio stations engaged in transmission of maritime safety information to HF receiver by means of NBDP.

6.12 INMARSAT SHIP EARTH STATION

6.12.1 The ship earth station shall receive and transmit data for:

1. distress, urgency, safety and general alerting;
2. coordination of actions during search and rescue operations;
3. transmission of information on navigation safety.

6.12.2 The ship earth station shall not have external controls, which may allow for changing its identification number.

6.12.3 Provision shall be made to give a distress alert in the telephony mode or in the data transmission mode from the ship steering position and from any position provided by the ship design for purposes of distress alerting. In addition to that, where a specific room for radio communication is provided, arrangements for distress alerting shall be provided in that room. Distress alerting arrangements shall comply with 6.1.38.

Unless other distress, urgency and safety alert receivers or signal relaying arrangements are provided and the existing level of telephone or printer signals is not adequate for receipt of such messages, the ship earth station shall be capable of giving of audible and visual alarm.

6.12.4 The changeover between ship’s power sources or any power supply interruption within 60 s shall not require manual resetting of the ship earth station to the operating mode or result in deletion of received messages from the ship earth station memory.
6.12.5 If the ship earth station includes the enhanced group calling device, its specifications shall meet the requirements to the enhanced group calling equipment (6.9).

6.12.6 The ship earth station shall have a self-test system and provide for automatic activation of audible and/or visual alarm in case of:
- loss of antenna tracking to satellite;
- malfunction of radio station;
- no power supply or activation of a standby source.

6.12.7 The ship earth station shall be capable of testing the distress alerting function without actually transmitting the alerts.

6.12.8 In addition to requirements mentioned in the present part of these Rules, the ship earth station shall meet technical requirements of INMARSAT and be type approved by INMARSAT.

6.13 GENERAL REQUIREMENTS TO EPIRBs

6.13.1 In addition to requirements of 6.1, VHF EPIRBs and satellite EPIRBs of COSPAS-SARSAT system shall meet the requirements of the present Section.

6.13.2 EPIRB shall be capable of being activated automatically after free floating.

6.13.3 EPIRB shall:
- be capable of being activated by an untrained person and have a weight of max. 20 kg;
- be fitted with arrangements preventing its accidental activation;
- be designed so that its electric parts are of waterproof type to the depth of 10 m for at least 5 minutes;
- be able to withstand temperature changes up to 45° C when immersed. The EPIRB shall remain serviceable when exposed to water, condensation or moisture;
- be capable of being activated and deactivated manually;
- be fitted with arrangements indicating the signals emission;
- be capable of floating in vertical position and have a positive stability;
- be able to withstand drop in water from height of 20 m without sustaining any damage;
- be yellow/orange and have a reflective surface coating or stripes;
- be provided with a buoyant line suitable for use as a towing hawser, which shall be stowed to exclude its entanglement during free floating of EPIRB;
- be provided with a lamp with luminosity of 0.75 Cd capable of being automatically switched on in the dark for a short period to indicate the EPIRB position;
- be designed to be resistant when exposed to sea water, oil and solar radiation (see 12, 13, 15 and 16 Appendix 15 RTSC).

6.13.4 The EPIRB shall be designed to be serviceable under the following ambient conditions:
- temperature of –20 to +55° C;
- icing;
- relative wind speed up to 50 m/s;
- after storage at temperature of –30 to +70° C.

6.13.5 EPIRB shall be capable of being manually activated locally. Provision shall be made for a remote activation from the wheelhouse when the EPIRB is installed in the float-free mounting.

6.13.6 The EPIRB shall be externally marked with the following:
- manufacturer data;
- radio equipment number or codename assigned for type approval testing;
- serial number of radio equipment;
- year of manufacturer;
- kind of current and voltage of power supply;
- brief operating instructions in English and Russian;
- expiry date of storage battery shelf life;
- identification number (for satellite EPIRB of COSPAS-SARSAT system);
- safe distance from magnetic compass;
- date of the next due shore-based maintenance.
6.13.7 EPIRB shall be designed to be serviceable within at least one year without maintenance.

6.13.8 The shelf life of the storage battery used as an EPIRB power source shall be at least two years. The storage battery is subject to replacement if at the time of survey of the ship radio equipment its remaining shelf life is less than 12 months. The storage battery shall be marked with date of manufacture and maximum shelf life.

6.13.9 In order to test the performance of EPIRB with dummy antenna, provision may be made for connection of external power source.

6.13.10 EPIRB shall be designed to be released and floating free when submerged to a depth of 4 m or more at any heel or trim angle.

6.13.11 The satellite EPIRB shall not be automatically activated after it has been manually removed from the release gear.

6.13.12 If the satellite EPIRB is to be activated manually, distress alerting shall be performed by two independent actions (see 6.1.38) using a dedicated switch only.

Such a distress alerting switch shall be duly marked and protected against its unauthorized activation.

6.13.13 Satellite EPIRB shall be tested and have a document certifying that its serviceability has been tested following a procedure established by an authorized state executive authority of the Russian Federation.

6.14 Satellite EPIRB of COSPAS-SARSAT System

6.14.1 Satellite EPIRB shall transmit a distress alert to near-polar orbiting satellites and homing signals by means of integral beacon.

6.14.2 Provision shall be made for testing of EPIRB without using the satellite system.

6.14.3 The power source shall have a capacity sufficient for operation of the satellite EPIRB for at least 48 hours.

6.14.4 Distress alert signal shall be transmitted by the satellite EPIRB at an assigned band frequency of 406 MHz.

6.14.5 The satellite EPIRB shall have non-volatile memory to store the invariable part of a distress message.

6.14.6 Six figures of the ship station identifier shall form part of all EPIRB messages.

6.14.7 The satellite EPIRB shall have a frequency of 121.5 MHz for homing.

6.14.8 The type of satellite EPIRB of COSPAS-SARSAT system shall be approved by COSPAS-SARSAT.

6.15 VHF EPIRB

6.15.1 VHF EPIRB shall transmit a distress alert. VHF EPIRB and radar transponder operating at frequency of 9 GHz may be structurally combined in a single unit. Radar transponder shall comply with requirements to LSA radar transponders (see 6.16).

6.15.2 VHF EPIRB shall be of automatic free floating type and capable of being tested on board with no distress alert actually emitted.

6.15.3 The power source shall have a capacity sufficient for operation of VHF EPIRB for at least 48 hours.

6.15.4 VHF EPIRB shall meet the following requirements:

1. distress alert signals in DSC system shall be transmitted at a frequency of 156.525 MHz using a class G2B emission;

2. relative frequency stability shall not exceed \(10^{-6}\);

3. bandwidth shall be at least 16 kHz;

4. output power shall be at least 100 mW;

5. for transmission and reception, antenna with horizontal and circular polarization shall be used;

6. frequency modulation with preemphasis of 6 dB per octave (phase modulation) with subcarrier frequency modulation shall be used;
.7 a subcarrier frequency of 1700 Hz with modulation frequencies of 1300 and 2100 Hz shall be used;
.8 deviation of frequency of 1300 and 2100 Hz shall be within ±10 Hz;
.9 modulation rate shall be 1200 Baud;
.10 modulation index shall be (2.0±10)%.

6.15.5 DSC format and sequence of message transmission shall comply with Radio Regulations (see 1.2.1.26).

6.16 SHIP’S AND LIFE-SAVING APPLIANCE’S RADAR TRANSPONDER

6.16.1 Radar transponder shall enable positioning of the ship in distress by transmitting signals displayed at radar screen as a series of equally spaced points.

6.16.2 Radar transponder shall comply with requirements of 6.13.3.1 to 6.13.3.4, 6.13.3.8 to 6.13.3.10, 6.13.3.12 as well as:
.1 be fitted with audible and visual arrangements for performance testing and arrangements to warn the personnel in distress that the radar transponder is being activated by radar;
.2 be capable of being activated and deactivated manually. Provision may be made for its automatic activation. Where the test using radar at frequency of 9 GHz is performed on board the ship, operation of the radar transponder shall be restricted to a few seconds to avoid interference with other shipborne or airborne radars and to avoid energy consumption of power sources;
.3 have a readiness mode indication;
.4 have a positive buoyancy unless it is incorporated into a floating life-saving appliance;
.5 have an external surface safe for the floating life-saving appliance.

6.16.3 Radar transponder shall be designed to remain serviceable at temperature of –20 to +55° C. It shall remain serviceable after storage at temperature of –30 to +65° C.

6.16.4 The transponder antenna shall be installed so that to be at least 1 m above the water level. In order to comply with this requirement, a pole or other similar device shall be kept in the lifeboat or life raft pocket, as well as illustrated installation instructions for radar transponder.

6.16.5 For transmission and reception, antenna with horizontal polarization shall be used.

6.16.6 Radar transponder shall receive and transmit signals at a distance of at least 5 nautical miles (9.26 km) when interrogated by radar with antenna mounted at a height of 15 m. The radar transponder shall also receive and transmit signals at a distance of at least 30 nautical miles when interrogated by an airborne radar with pulse power of at least 10 kW installed on board an aircraft flying at a height of 1000 m.

6.16.7 The radar transponder shall be marked as provided in 6.13.6 (except for 6.13.6.5) with regard to 6.13.8, as well as with name and call sign of the ship.

6.17 FREE FLOATING EMERGENCY RADIO EQUIPMENT RELEASE AND ACTIVATION ARRANGEMENTS

6.17.1 Free floating emergency radio equipment release and activation arrangements shall enable automatic release from the ship in distress and automatic activation.

6.17.2 Free floating emergency radio equipment release and activation arrangement shall:
.1 be capable of actuating the release mechanism at a depth of 4 m or more at any heel and trim of the ship;
.2 remain serviceable at temperatures from –30 to +65° C;
.3 be made of corrosion-resistant materials compatible with each other in terms of contact corrosion to prevent from damage or malfunction of the radio equipment mounted in. Galvanizing or other forms of metallic coating on parts of the release unit is not permitted;
.4 be designed to prevent release of the radio equipment when seas wash over the unit;
.5 be designed to be resistant when exposed to sea water, oil and solar radiation (see
12, 13, 15 and 16 Appendix 15 RTSC) and shall not be exposed to the above media at its location on board the ship;

.6 remain operable when exposed to shocks and vibrations with parameters stipulated in 2.2.5 Part VI of these Rules;

.7 where the ship navigates within areas of possible icing, be designed to prevent from ice formation in such a way that can prevent radio equipment release;

.8 be arranged so that to make impossible entrapment of the emergency radio equipment by structures of the ship in distress;

.9 have instructions on the hull on manual release of the radio equipment.

6.17.3 For radio equipment, which requires an external power source and/or data input source, the connection shall so designed to enable free release and activation of radio equipment.

6.17.4 Provision shall be made for service-ability tests of free floating emergency radio equipment release and activation arrangements without radio equipment activation.

6.17.5 Provision shall be made for manual release of free floating emergency radio equipment from the release gear.

6.17.6 Free floating emergency radio equipment release and activation device shall be externally marked with the due date of the next inspection or replacement.

6.18 TWO-WAY VHF RADIOTELEPHONE APPARATUS OF LIFE-SAVING APPLIANCES

6.18.1 Two-way VHF radiotelephone apparatus (hereinafter, the apparatus) is purposed for on-scene communication between floating life-saving appliances, between floating life-saving appliances and ship, as well as between floating life-saving appliances and rescue unit (see 1.2.1.29). Portable/man-portable apparatus for radio communication on board the ship may be used if capable of operating at frequencies other than those stated in Tables 2.1.1 and 6.18.4.

6.18.2 Portable/man-portable apparatus shall be designed as a single/one piece unit including:

.1 transmitter, receiver, antenna and power source;

.2 control unit with reception / transmission push-button switch;

.3 microphone and loudspeaker.

6.18.3 Portable/man-portable apparatus shall be designed as to:

.1 be activated by a person with no special training;

.2 be activated by a person wearing gloves;

.3 be activated by one hand (except for selection of a channel);

.4 remain serviceable in case of falling down onto a hard surface from height of 1 m;

.5 remain watertight at a depth of 1 m for at least 5 minutes;

.6 remain serviceable after temperature change up to 45° C due to immersion in water;

.7 be resistant to sea water, oil and solar radiation (see 12, 13, 15 and 16 Appendix 15 RTSC);

.8 have no sharp corners or other casing components able to damage the floating life-saving appliance;

.9 be able to be fastened to clothes and to have a belt to be suspended to a wrist or neck;

.10 be resistant to damage or malfunction in case of falling into water (see 17 Appendix 15 RTSC).

Man-portable/portable apparatus shall have yellow or orange colour or have a yellow/orange marking stripe around the case.

6.18.4 The apparatus shall operate at frequency of 156.8 MHz (channel 16) and at least on one additional channel of the maritime mobile service.

6.18.5 Simplex radiotelephone channels shall be used in apparatus.

6.18.6 The apparatus shall have a class G3E emission.
6.18.7 The apparatus shall be provided with a two-position switch with visual indication on its activation.

6.18.8 The receiver shall be provided with the volume control.

6.18.9 Provision shall be made for a noise suppression unit (damper) and channel switch.

6.18.10 Provision shall be made to switch channels and display information on a selected channel.

6.18.11 Provision shall be made for adequate visibility of selectable channel 16 in any lighting conditions.

6.18.12 The apparatus shall be capable of being set into operating state for max. 5 s after activation.

6.18.13 Output power of transmitter shall be minimum 0.25 W and maximum 2 W. If output power of transmitter exceeds 1 W, provision shall be made for a device reducing power down to 1 W or less. When the apparatus is used for internal communication, output power of transmitter shall not exceed 1 W.

6.18.14 Sensitivity of receiver for signal-to-noise ratio of 12 dB shall be at least 0.5 µV.

6.18.15 The antenna shall have vertical polarization and circular pattern in the horizontal plane. The antenna fault shall not result in damage of apparatus.

6.18.16 Signal power at the loudspeaker output shall be as such to provide its audibility at ambient noise level of 70 dB (A).

6.18.17 The apparatus shall remain serviceable at temperature of −20 to +55° C and after storage at temperature of −30 to +70° C.

6.18.18 Power source shall be incorporated into the apparatus. External power supply devices may be provided for the apparatus.

6.18.19 Where the power source is to be replaced/recharged during operation, the apparatus shall be provided with additional/backup primary battery to be used in case of distress. This battery shall be fitted with a non-removable seal (nonrecoverable enclosure) to indicate that the battery was not used.

Where the electric power source is not to be replaced during operation, the apparatus shall be provided with primary battery. Such an apparatus shall be fitted with a non-removable seal to indicate that the battery was not used.

The primary battery shall have a capacity sufficient for operation for at least 8 hours at the highest output power with duty cycle of 1:9. Duty cycle is defined as cycle comprising transmission for 6 s, reception above receiver’s threshold level for 6 s, and reception below receiver's threshold level for 48 s. Service life of primary battery shall be at least two years. The batteries shall be coloured or marked in accordance with 6.18.3.10 if designated as non-replaceable in operation.

The batteries not to be used in distress shall be coloured and marked any way other than that of 6.18.3.10.

A brief operating instruction and expiry date of service life of primary battery, name and call sign of the ship shall be available externally on the apparatus.

6.19 MAN-PORTABLE TWO-WAY VHF RADIO TELEPHONE APPARATUS FOR AIRCRAFT COMMUNICATION

6.19.1 Man-portable two-way VHF radiotelephone apparatus for aircraft communication (hereinafter, the apparatus) shall provide on-scene communication between the ship and aircraft.

6.19.2 The apparatus shall include:

.1 integral transmitter/receiver including antenna and power source;

.2 integral control unit with reception/transmission push-button switch;

.3 microphone and loudspeaker.

6.19.3 The apparatus shall:

.1 be activated by a person with no special training;

.2 withstand fall down onto a hard surface from height of 1 m;
.3 be capable of operating at ambient noise level of at least 90 dB (A);

.4 have a colour other than that of man-portable two-way VHF radiotelephone apparatus of life-saving appliances (see 6.18.3.10);

.5 provide amplitude modulation and operation at frequencies of 121.5 MHz and 123.1 MHz;

.6 have a two-position switch fitted with visual alarm on its activation;

.7 be provided with manual volume control for a receiver to vary output acoustic power;

.8 be capable of switching frequencies and visibly indicating the selected channel number in any lighting conditions;

.9 be ready for operation not more than in 5 s after activation.

6.19.4 Open circuit fault or short-circuit of antenna shall not result in damage of apparatus.

6.19.5 Carrier frequency power shall be minimum 50 mW and maximum 1.5 W.

6.19.6 Signal output power shall be adequate for listening at ambient noise level of at least 90 dB (A).

6.19.7 In the transmission mode, output acoustic signal of the receiver shall be suppressed.

6.19.8 The apparatus shall be powered by integral primary battery, which may be replaced during operation. In addition, the apparatus may be powered from an external electric power source.

6.19.9 Shelf life of primary battery shall be at least two years.

6.19.10 In addition to requirements of 6.16.7, the apparatus shall be externally marked with the following:

.1 “For emergency communication with aircraft only” inscription;

.2 name and call sign of the ship.

6.20 STATIONARY TWO-WAY VHF RADIOTELEPHONE APPARATUS FOR AIRCRAFT COMMUNICATION

6.20.1 Stationary two-way VHF radiotelephone apparatus for aircraft communication (hereinafter, the apparatus) shall provide on-scene communication between the ship and air rescue unit/units (see 1.2.1.29).

6.20.2 The apparatus shall include:

.1 transmitter and receiver;

.2 antenna mounted on the equipment or individually;

.3 microphone with reception/transmission push-button switch and loudspeaker.

6.20.3 The apparatus shall:

.1 be activated by a person with no special training;

.2 be capable of operating at ambient noise level of at least 90 dB (A);

.3 provide amplitude modulation and operation at frequencies of 121.5 MHz and 123.1 MHz;

.4 have a two-position switch fitted with visual alarm on its activation;

.5 be provided with manual volume control for the receiver to vary output acoustic power;

.6 be capable of switching frequencies and visibly indicating the selected channel number in any lighting conditions;

.7 be ready for operation not more than in 5 s after activation.

6.20.4 Open circuit fault or short-circuit of antenna shall not result in damage of apparatus.

6.20.5 Carrier frequency power shall be minimum 50 mW and maximum 1.5 W.

6.20.6 Signal output power shall be adequate for listening at ambient noise level of at least 90 dB (A).

6.20.7 In the transmission mode, output acoustic signal of the receiver shall be suppressed.

6.20.8 The apparatus shall be powered from the ship’s main electric power source. In
addition, provision shall be made for powering from an emergency electric power source.

6.20.9 Integral primary battery, which may be replaced during operation, may be used instead of electric power source stated in 6.20.8.

6.20.10 Shelf life of primary battery shall be at least two years.

6.20.11 In addition to requirements of 6.13.6, the apparatus shall be externally marked with the following:

.1 "For emergency communication with aircraft only" inscription;
.2 expiry date of service life of primary battery;
.3 name and call sign of the ship.

6.21 GMDSS INTEGRATED RADIO COMMUNICATION SYSTEM

6.21.1 Integrated radio communication system is a system where individual radio communication aids and installations are used as sensors, i.e. have no own control panels, and provide output data and receive commands from points referred to as the radio workstations.

These points are referred to as the GMDSS radio workstations if they are capable of controlling and monitoring all the onboard equipment and installations of GMDSS and for general radio communication.

6.21.2 Integrated radio communication system shall meet applicable functional requirements of GMDSS (see 1.3.1) as well as all functional requirements for each individual radio communication aid. No functional requirements to individual radio communication aids shall impede compliance with any other functional requirements to other radio communication aids integrated into the radio communication system.

6.21.3 All functional requirements to equipment of the integrated radio communication system shall comply with operating requirements stipulated by the present Part of these Rules to individual equipment included into the integrated radio communication system.

6.21.4 Failure in one type of radio equipment included into the integrated radio communication system shall not affect more than one sensor of radio communication aids or more than one radio workstation.

6.21.5 The integrated radio communication system shall:

.1 include at least two radio workstations each linked with sensors of GMDSS radio communication aids via local area network or hardwired communication system;
.2 include at least two printers;
.3 have means for automatic update of ship position and time in addition to manual data input;
.4 have an electric power source preventing the accidental deactivation of any part of the integrated radio communication system;
.5 have GMDSS fault detection means with alarm activation;
.6 be protected against computer viruses.

6.21.6 GMDSS radio workstations shall:

.1 have an identical user interface and identical access to each sensor function;
.2 operated independently;
.3 provide for simultaneous operation of at least two sensors of radio communication aids;
.4 transmit distress alerts made only by a button specially designated for each sensor of radio communication means; this button shall not be used for any other purpose. The appearance of this button shall differ from others, and the button shall be protected against inadvertent activation; distress alert shall be made by two independent actions (see 6.1.38) with activation of alarm notifying on activation of alert signal. Each distress alert button shall not be electrically linked to the local area network or hard wired communication system of the integrated radio communication system. Provision shall be made to interrupt or make a distress alert at all times (see 6.1.38).
6.21.7 VHF radio installation may be included/integrated in the integrated radio communication system only subject to requirement of 4.5.8.

6.21.8 Additional radio workstations intended for general radio communication only shall not have access to distress alert functions and shall not impede transmission of a distress alert. The radio communication aids from GMDSS radio workstations shall have a priority over other additional radio workstations.

6.21.9 Additional sensors not required for GMDSS radio communication aids shall not impede or degrade performance of distress alert and alert signal functions.

6.22 SECURITY ALERT SYSTEM

6.22.1 Security alert system shall be provided on board ships for transmission of the ship-to-shore alert on security condition in order to notify an organization authorized by the state executive authority of the Russian Federation that the ship security is under threat or is breached. Security alert system shall include at least two actuation positions, one located in the wheelhouse and the other according to the ship security plan. Provision shall be made for a continuous alert from these positions until it is deactivated and/or reset. The system shall provide for a hidden transmission of the signal for alerting the authorized organization on shore. The signal transmission mode shall not be accompanied by alarm on board the ship and shall not make an alert to other ships.

6.22.2 Functions of the security alert system may be performed using GMDSS radio installations and other systems intended for general radio communication or system specially designed for this purpose.

6.22.3 The security alert system shall be protected against inadvertent activation. Activation of security alert system shall not require preliminary removal of any seals or opening covers.

6.22.4 The actuation of the security alert system shall entail activation of the radio communication system so that the transmission of alert does not require any tuning of the radio communication system (tuning channels, selection of operating modes or menu). The operation of security alert system activation controls shall not result in actuation of alarm on board the ship.

6.22.5 Operation of the security alert system shall prevent degrading functional characteristics of GMDSS radio installations required by the present part of these Rules.

6.22.6 An alert generated by the security alert system control shall contain a unique code/identifier to indicate that the alert is made not in accordance with GMDSS distress procedures. The signal shall contain an identifier of the ship and current ship position and the date and time of fix.

6.22.7 In the security alert system, provision shall be made for serviceability testing without actually transmitting any alert signal.

6.23 SHIP’S AND LIFE-SAVING APPLIANCE’S AUTOMATIC IDENTIFICATION SYSTEM TRANSMITTER

6.23.1 Automatic identification system (AIS) transmitter for search and rescue shall transmit messages with coordinates, static information and safety-related information for ship in distress.

6.23.2 The format of transmitted messages shall be compatible with the AIS equipment, be recognized and displayed on receivers within the AIS transmitter coverage range. The transmitted messages shall differ from those of AIS equipment.

6.23.3 The AIS transmitter shall:
   .1 be activated by a person with no special training;
   .2 be fitted with arrangements preventing its accidental activation;
   .3 be provided with visual and/or audible indication of operation;
   .4 be capable of being activated and deactivated manually. Automatic activation ar-
rangements may be used along with manual activation;

.5 be able to withstand drop in water from height of 20 m without sustaining any damage;
.6 be watertight to a depth of 10 m for at least 5 minutes;
.7 remain watertight and serviceable under temperature variation by 45° C during immersion;
.8 have a positive buoyancy unless it is a component of a floating life-saving appliance and be provided with a buoyant line if the AIS transmitter has a positive buoyancy;
.9 be designed to be resistant when exposed to sea water, oil and solar radiation (see 12, 13, 15 and 16 Appendix 15 RTSC);
.10 be coloured in yellow/orange;
.11 have an external surface safe for the floating life-saving appliance;
.12 have a device for hoisting AIS transmitter antenna at a height of at least 1 m above sea level. This device shall be accompanied with illustrated instructions on antenna deployment;
.13 have a transmitted message repetition interval not exceeding 1 minute;
.14 be equipped with integral coordinate unit to transmit current position in each message;
.15 provide for functional test of transmitter using the set parameters and their initial values.

6.23.4 The AIS transmitter shall have a primary battery capacity sufficient for operation for at least 96 hours at temperature of –20 to +55° C and serviceability testing the radio equipment.

The AIS transmitter shall have its unique identification number to ensure integrity of data transmission line within VHF band.

6.23.5 The AIS transmitter shall be designed to be operable under ambient temperature of –20 to +55° C and to sustain no damage when stored at temperature of –30 to +70° C.

6.23.6 The AIS transmitter shall be capable of being detected at a distance of at least 5 nautical miles (9.26 km).

6.23.7 The AIS transmitter shall continue transmitting message even if position and time data from the position fix system are lost or corrupted.

6.23.8 The AIS transmitter shall begin transmitting message within 1 minute after activation.

6.23.9 The shelf life of the primary battery shall be at least two years, and it shall be replaced if at the time of survey of the ship radio equipment its remaining shelf life is less than 12 months.

6.23.10 The AIS transmitter shall be externally marked with the following:
.1 manufacturer data;
.2 navigation equipment type number or codename assigned for type approval testing;
.3 serial number of navigation equipment;
.4 year of manufacturer;
.5 operating instructions;
.6 name and call sign of the ship;
.7 expiry date of service life of primary battery.

6.24 STATIONARY TWO-WAY VHF RADIO TELEPHONE APPARATUS FOR LIFE-SAVING APPLIANCES

6.24.1 Stationary two-way VHF radiotelephone apparatus for life-saving appliances (hereinafter, the apparatus) shall provide for on-scene communication between floating life-saving appliances, between floating life-saving appliances and ship, and between floating life-saving appliances and rescue unit.

6.24.2 The apparatus shall include:
.1 transmitter and receiver;
.2 antenna mounted on the apparatus (or provision shall be made for its separate installation);
.3 microphone with reception / transmission push-button switch and loudspeaker.

6.24.3 The apparatus shall:
.1 be activated by a person with no special training;
.2 be activated by a person wearing gloves;
.3 withstand exposure to shocks and vibrations with parameters stipulated in 2.2.5 Part VI of these Rules;
.4 be watertight to a depth of 1 m for at least 5 minutes;
.5 remain watertight under temperature variation by 45°C during immersion;
.6 be designed to be resistant when exposed to sea water, oil and solar radiation (see 12, 13, 15 and 16 Appendix 15 RTSC);
.7 have an external surface safe for the floating life-saving appliance;
.8 be capable of operating at ambient noise level of at least 70 dB (A);
.9 be designed to install on the floating life-saving appliances without special-purpose tool or fixtures;
.10 comply with requirements of 6.18.4 to 6.18.19.

6.24.4 In the transmission mode, output signal of the receiver shall be muted.

6.24.5 Where a microphone is provided in the apparatus, the receiver volume control shall not affect the output microphone power.

6.24.6 The apparatus shall be externally marked with the following:
.1 operating instructions;
.2 numbers of channels;
.3 name and call sign of the ship;
.4 expiry date of service life of primary battery.
Part VIII

NAVIGATIONAL EQUIPMENT
1 GENERAL REQUIREMENTS

1.1 SCOPE OF APPLICATION

1.1.1 The present Part of the Rules contains the norms of the navigational equipment for the inland and river-sea self-propelled ships and technical requirements for it.

1.1.2 The requirements of this Part of the Rules apply to ships under design and construction, as well as ships in service constructed on or after 1 July 2002.

Ships in service constructed before 1 July 2002 shall comply with the requirements of those Rules, according to which they were constructed, unless otherwise is specified in the later editions of the Rules and in the statements of amendments and changes, as well as with requirements of 1.3.9 to 1.3.13.

1.1.3 The requirements of this Part of the Rules are mandatory for the ships engaged on coastal navigation. Requirements of the international conventions and agreements, which the Russian Federation acceded to, are mandatory for the ships engaged on international navigation.

1.2 TERMS AND DEFINITIONS

1.2.1 The following terms are used in this Part of the Rules:

1 Automatic identification system (AIS) means a system that provides continuous automatic exchange of static and dynamic (navigational) information between ships, as well as between ships and shore-based stations, for the purpose of navigational safety;

2 Night vision equipment means an electronic system that provides safe navigation during the hours of darkness through assisting in detection of above-water objects, which may pose hazard for navigation;

3 Display base means a scope of information of a system electronic navigational chart, which cannot be removed from screen. This information is continuously displayed on the screen in any navigation areas. This information is not sufficient for navigational safety;

4 Image redrawing time in an electronic navigational chart and information display system means a time from the start of redrawing to completion of redrawing;

5 Image refreshment time in an electronic navigational chart and information display system means a time from operator's action to completion of respective redrawing;

6 Global navigation satellite system (GNSS) means a system designed to find coordinates and velocities of objects and position fix time relative to Universal Time Coordinated (UTC);

7 Depth means a vertical distance from the water surface to ground;

8 Display means an electronic mean for displaying information in the alphabetical, numerical or graphical form;

9 Acquisition means selection of a target (targets) for radar tracking;

10 Visibility zone means a horizontal angle, within which observation of environment is possible from the workstation in the wheelhouse;

11 Integrated navigational system (INS) means a combination of the ship's navigational equipment for cooperative
processing and displaying information received from these means, as well as for automatically testing integrity/reliability of the navigational information;

.12 **Time division multiple access (TDMA)** means a way of information transmission in multiple-access communication systems with specified time of message transmission for each station;

.13 **Observation** means one of the main functions of the navigator to be carried out by sight and hearing, as well as using ship equipment, to assess navigational situation and risk of collision;

.14 **Navigational equipment** means ship equipment installed on board the ship for solving navigational tasks;

.15 **Data carrier** means a device designed for data storage and reading with the use of respective equipment;

.16 **Generalized display** means a combined displaying information from two or more navigational devices or systems;

.17 **Waypoint** means a point on the specified path of the ship, whose designation and coordinates were entered in control software of GNSS, Inland ECDIS/ECDIS or ECS receiver;

.18 **Radio module** means a module (an AIS component) for reception and transmission of information on the VHF communication channel;

.19 **Raster navigational chart** means a facsimile copy of the paper chart or a collection of charts, prepared and distributed by an authorized hydrographic service;

.20 **Voyage data recorder (VDR)** means a device designed for collection, recording and storage of voyage data including: data coding and recording equipment; interfaces to data sensors; data carrier in protective container; main and integral standby power sources;

.21 **Backup officer** means a ship operator who is to be called whenever ship operator keeping underway watch needs assistance;

.22 **Wheelhouse** means a space accommodating the main ship steering station where observation over environment, ship steering, and control of ship equipment and systems are carried out;

.23 **Sea watch alarm system** means equipment for monitoring psychophysical state of the navigator on underway watch in the wheelhouse;

.24 **Electronic Chart Display and Information System for Inland Navigation (Inland ECDIS)** means a navigational information system, which, together with the respective backup equipment, displays information from system electronic navigational chart and ship position received from navigational equipment, for route planning and ship steering. Inland ECDIS includes its software, operating system and computer hardware, as well as interface and backup equipment;

.25 **System electronic navigational chart (SENC)** means a database obtained by transformation of an electronic navigational chart to include corrections and other information as may be entered by the navigator. This database is used in the Inland ECDIS/ECDIS to generate the chart image on the display to provide navigational safety;

.26 **EPA** means electronic plotting aid;

.27 **ATA** means automatic tracking aid;

.28 **ARPA** means automatic radar plotting aid;

.29 **Standard display** means SENC information, which shall be represented at first display of the chart in the Inland ECDIS/ECDIS and enable route planning or ship steering by the navigator depending on the information level;

.30 **Remote heading transmission device** mean an electronic device that receives ship heading from the sensor and transmits it to other navigational equipment;

.31 **Navigation bridge** means a wheelhouse deck including open or closed areas on the sides (bridge wings) where the local control stations may be located;

.32 **Log and/or echo sounder trunk** means a dedicated watertight space in the ship hull below the waterline with a watertight enclosure;

.33 **Electronic chart display and information system (ECDIS)** means a system combining information from
the system electronic navigational chart (SENC) with ship position data received from the navigational sensors, for preliminary and in-route plotting and displaying other navigational information;

34 Electronic navigational chart (ENC) means a database standardized in contents, structure and format and generated for use in the Inland ECDIS/ECDIS by authorities received from the state hydrographic service. ENC shall include all the mapping information as may be required for navigational safety and enable entering additional data normally included in the pilot charts, atlases and other navigation guidelines.

35 Electronic Chart Display System (ECDS) means a system designed for working with official navigation charts of inland waterways in order to monitor the ship movement and information support of navigation.

1.3 NAVIGATIONAL EQUIPMENT COMPOSITION

General requirements

1.3.1 Navigational equipment installed on board ships including ships in service, above the norms specified in 1.3 in order to enhance navigational safety shall comply with the requirements in 6.1 Part VII of the Rules, 2, 3 of this Part, and shall be surveyed by the River Register.

Requirements to I, II, III and IV class ships

1.3.2 To determine the navigational equipment and outfit, the ships are divided into three groups:

I — ships of 300 gross tonnage or more;
II — ships 25 m long or more with 300 gross tonnage or less;
III — ships less than 25 m long.

Gross tonnage and length of a tugboat designed for pushing or alongside towing shall be taken equal to gross tonnage and length of whole convoy.

1.3.3 Ship navigational equipment composition shall be taken according to the norms specified in Table 1.3.3 depending the navigation basin category and ship category.

1.3.4 It is allowed not to install the speed and travelled distance indicators, gyrocompasses, autopilots and directional stabilizers, echo sounders and rate-of-turn indicators, as well as other navigational equipment not specified in Table 1.3.3.

1.3.5 It is allowed to install fixed navigational equipment with combined functions (radar + echo sounder + electronic chart system) with technical characteristics not below those specified for the ships of M-III, M-IIIP and O-IIIP classes on board ships with maximum 12 persons (including the crew members) and ships with length of less than 25 m, except for the passenger ships and ships carrying hazardous cargoes.

1.3.6 All the self-propelled inland ships operated in the areas with active cardinal system of the navigational equipment of the International Association of Lighthouse Authorities shall be fitted with a heading finding and displaying device.

Requirements to M-III, M-IIIP and O-IIIP class ships

1.3.7 Self-propelled ships shall be fitted with navigational equipment according to Table 1.3.7.

1.3.8 It is allowed not to install an automatic radar plotting aids (ARPA), rate-of-turn indicators, automatic heading and course keeping systems, devices for measuring and indicating speed and travelled distance over ground in forward and transverse directions.

1.3.9 Ships built before 1 July 2002, not later than the first annual survey carried out after 1 July 2002, shall be fitted with a GNSS receiver or a radio navigation system receiver suitable for continuous usage in the ship operation areas.

1.3.10 All passenger and cargo ships of gross tonnage of 3000 and more engaged on international voyages and constructed after 1 July 2002 shall be fitted with a voyage data recorder.

1. In case of remote transmission of readings, including through optical line, from the standard (master) magnetic compass to the main steering station, it is allowed not to install a steering (secondary) magnetic compass.

2. Ships of M class and of length less than 20 m and ships of O class not fitted with a steering (secondary) magnetic compass shall be fitted with a boat magnetic compass with the card diameter of not less than 75 mm.

3. On the ships on board of which installation of a magnetic compass is not provided, the boat magnetic compass card diameter shall be sufficient to be read at a distance of not less than 70 cm.

4. Only passenger ships and ships carrying dangerous cargoes, irrespective of gross tonnage.

\textsuperscript{1} Applies to passenger ships irrespective of their dimensions.

\textsuperscript{2} Or some other mean irrespective of any power source and suitable for finding the heading and transmitting it to the main steering station and other equipment.

\textsuperscript{3} Not required if the ship is fitted with a gyrocompass providing able to transmit heading to the equipment referred to in 5, 7, 10 and 11 of this Table.

\textsuperscript{4} Heading shall be transmitted to the equipment referred to in 5, 7, 10 and 11 of this Table. Heading shall be visually indicated at the emergency station, if any, by a gyrocompass repeater.

\textsuperscript{5} Minimum effective diameter of the radar indicator image display shall be 180 mm for the ships of gross tonnage of less than 500, and 250 mm for the ships of gross tonnage of 500 and more.

\textsuperscript{6} EPA and ATA are not required if Automatic Radar Plotting Aids (ARPA) is installed.

\textsuperscript{7} Passenger ships and ships carrying vital and dangerous cargoes irrespective of their dimensions.

\textsuperscript{8} Not required on the ships not engaged on international voyages, if updated paper navigational charts are available for preliminary and in-route plotting throughout the voyage.

\textsuperscript{9} Not required in cargo ships of gross tonnage of 500 and less not engaged on international voyages.

\textsuperscript{10} Passenger ships engaged on international voyages shall be fitted with a voyage data recorder irrespective of their dimensions.

\textsuperscript{11} May be omitted on the ships of gross tonnage of less than 1600 constructed before 1 July 2002.

\textsuperscript{12} May be omitted.

Cargo ships of gross tonnage of 3000 and more engaged on international voyages and constructed before 1 July 2002 may be fitted with a simplified voyage data recorder (S-VDR).

1.3.11 The following ships engaged on international voyages shall be fitted with the electronic chart display and information system (ECDIS):

.1 passenger ships of gross tonnage of 500 and more;

.2 cargo ships of gross tonnage of 3000 and more.

1.3.12 Cargo ships of gross tonnage of 150 and more and passenger ships irrespective of their dimensions constructed on 1 July 2002 or after this date shall be fitted with a sea watch alarm system.

Cargo ships of gross tonnage of 150 and more and passenger ships irrespective of their dimensions constructed before 1 July 2002 shall be fitted with a sea watch alarm system within the following time frames:

.1 passenger ships – not later than the first survey after 1 January 2016;

.2 cargo ships of gross tonnage of 3000 and more — not later than the first survey after 1 January 2016;

.3 cargo ships of gross tonnage of 500 and more and less than 3000 — not later than the first survey after 1 January 2017;

.4 cargo ships of gross tonnage of 150 and more and less than 500 — not later than the first survey after 1 January 2018.
1.3.13 Passenger ships including high-speed passenger craft irrespective of their dimensions and cargo ships including high-speed cargo craft of gross tonnage of 300 and more engaged on international voyages shall be fitted with a ship identification and long-range tracking system (hereinafter referred to as the System).

It is allowed not install the System on the ships fitted with the automatic identification system equipment and designed for navigation solely within the sea area A1, irrespective of their date of construction.

For the definition of the sea areas A1, A2, A3 and A4, see 1.2.1.12 to 1.2.1.15 Part VII of the Rules.

1.3.14 ECDS designed for working with official navigation charts of inland waterways does not supersede Inland ECDIS/ECDIS and paper navigation maps. ECDS shall comply with the requirements in 1.1.2 Part VI of the Rules.

When using ECDS on mobile hardware (notebook, tablet), the later shall comply with the requirements in 1.1.2.2 Part VI of the Rules.
2 LOCATION OF NAVIGATIONAL EQUIPMENT

2.1 GENERAL REQUIREMENTS

2.1.1 Navigational equipment shall be installed in such a way as to enable its operation according to the requirements of technical documentation and access for maintenance, repair and survey.

2.1.2 The main devices of the navigational equipment shall be installed in dry spaces. Maintenance of equipment and taking readings at the devices shall be provided. Power and auxiliary equipment shall be installed in the power equipment room or in enclosure of a dry space not preventing operation or maintenance of other equipment.

2.1.3 Navigational equipment and its cable network shall be located so that not to cause inadmissible (exceeding 0.5°) change in readings of magnetic compasses installed on board the ship.

The power equipment room with navigational equipment converters shall be located in a space adjacent to the wheelhouse (spaces sharing bulkheads and deck plating) or in the radio equipment room, if any. The power equipment room shall be located so that acoustic noise from the operating units is not heard in the wheelhouse.

2.1.4 The space (trunk) designed for log or echo sounder vibrators shall comply with the following requirements:

a. the trunk shall be watertight;

b. the trunk dimensions shall be sufficient for maintenance of the installed equipment by one person;

c. a sliding door or a manhole sized to at least 400 × 600 mm with a watertight cover shall be provided for access into the trunk;

d. a ladder shall be provided for descending into the trunk;

e. a socket outlet for a 12 V portable lamp and the main lighting switch shall be placed at the entrance to the trunk;

f. a cock shall be installed at the outside on the upper part of the trunk;

g. when devices to be installed in the trunk require cutouts in the bottom, strength of the bottom plating shall not be compromised.

2.2 RADAR LOCATION

2.2.1 Radar's main indicator (a device to display radar and additional navigational information) shall be installed in the wheelhouse at the navigator's workstation. Images shall be displayed under all the light conditions which may occur in ship operation.

Additional indicator (if any) shall be installed so that to provide radar information to the workstation where plotting operations are carried out.

If the radar control panel is a separate device, then functioning of the radar controls shall be provided from all the workstations fitted with radar and additional navigational information displaying equipment.

The radar indicator shall be so located that to allow the navigator to observe navigational conditions on the indicator and steer the ship from the steering station.

2.2.2 The transceiver and other radar equipment may be installed in the wheelhouse, if power flow density of RF radiation, mechanical noise level and electric radio interference level do not exceed the norms set
by the sanitary regulations\textsuperscript{1} and 2.7 Part VI of the Rules. If the said norms are exceeded, the equipment shall be installed in a dedicated screened room.

2.2.3 The navigator shall be provided with information on the radar pattern and the shadow sectors.

2.2.4 If a second radar is provided, its indicator shall be also installed in the wheelhouse. This way, the main radar indicator shall be installed closer to the starboard and the second radar indicator closer to the portside.

2.2.5 The radar antenna shall be installed on a dedicated mast/pedestal to provide maximum target detection range and the required horizon view in 360°.

The antenna placement height shall also provide target detection at short range, also in noise conditions caused by water surface oscillations and by re-reflection related to radio wave propagation.

The antenna shall be placed high enough so that the power flow density of RF radiation on the manned open decks does not exceed the permissible level set by the sanitary regulations\textsuperscript{2}.

2.2.6 In the direction from the antenna right ahead, the length of the shaded water surface shall not exceed two lengths of the ship or 250 m, whichever is less, irrespective of draught, trim or type of carried cargo.

No shadow sectors shall take place from the right ahead to 22.5° abaft the beam at each side.

Any two shadow sectors separated by an angle of 3° or less shall be considered as one shadow sector.

No individual shadow sectors exceeding 5° shall take place in the remaining horizon arc. The sum of the shadow sectors shall not exceed 20°.

2.2.7 Antennas of two ship radars shall be located so that the shadow sectors are minimized and the radars do not cause interference to each other during simultaneous operation.

2.2.8 When two radar antennas are within 3 m from each other, they shall be separated in vertical plane by not less than 1 m.

2.2.9 The radar antenna location shall be selected so to minimize electromagnetic radiation reflections from any ship structures or deck cargo.

2.2.10 The radar antenna shall be installed at a distance specified by the manufacturer from RF radiation sources and other radio transmitting/receiving antennas.

2.2.11 If radar antenna is installed on a dedicated mast, the platform for its maintenance and repair shall have a minimum area of 1 m\textsuperscript{2}, appropriate (see 2.2.5) height, and rails that do not obstruct antenna rotation. The mast structure, with the antenna and platform taken into account, shall be designed for operating conditions with vibration and impacts regulated in 2.2.5 Part VI of the Rules.

2.2.12 Radar antenna lower edge shall be at least 500 mm higher than any rail of the platform.

2.2.13 If antenna is located in any accessible place, it shall be installed at a height of at least 1800 mm above the deck, ladder or other place where men may present. That deck and other possibly manned places shall not lay in the radar scanning sector with electromagnetic radiation flow density exceeding the norm set by the sanitary regulations\textsuperscript{3}.

2.2.14 Antenna mounting accessories and radar antenna itself shall be located so that to meet the requirements to safe distance to the magnetic compass as specified in the technical documentation for the antenna.

2.2.15 Anyway, antenna shall be placed / installed in such a way that to enable inspection and repair of its any part.

\textsuperscript{1} SanPiN 2.1.8/2.2.4.1358-03, SanPiN 2.5.2-703-98.

\textsuperscript{2} SanPiN 2.1.8/2.2.4.1383-03.

\textsuperscript{3} SanPiN 2.1.8/2.2.4.1383-03.
2.2.16 The rigging insulators dividing the guys into uneven sections 2 to 6 m long shall be installed in all the guys of the mast carrying the radar antenna. If the guys cannot be insulated, they shall be electrically connected to the hull.

2.2.17 When installing the radar, all the shielded cables shall be laid according to the radar manufacturer's technical documentation and with respect to requirements in 12, Part VI of the Rules.

2.2.18 Type and length of cables shall be determined by the radar manufacturer to minimize the signal attenuation.

2.2.19 In order to reduce electromagnetic noise effects, all the cables between the radar antenna and other devices shall be laid along the straight paths, with due respect to cable laid to other equipment.

Cables shall be crossed at the right angle.

2.2.20 Cables shall be laid at not closed than 0.5 m from high voltage sources.

2.2.21 In order to avoid moisture penetration into the cables, all the junctions located on the open deck shall be at least IP56.

2.2.22 Cables and microwave transmission lines shall be laid with respected minimum inner bending radius as set forth in 12.4.17 Part VI of the Rules.

2.2.23 Cables and microwave transmission lines shall be laid in separate cable ducts in accordance with radar manufacturer's technical documentation.

2.3 MAGNETIC COMPASS LOCATION

2.3.1 Magnetic compass shall be placed and installed so that its vertical plane passing through the lubber line does not deviate from the centre plane or a plane parallel thereto by more than 0.2°.

2.3.2 In order to avoid noise that may distort the readings, magnetic compass shall be placed away from magnetic and electromagnetic field sources at a distance not less than specified in the compass and equipment manufacturer's technical documentation.

2.3.3 The steering (secondary) magnetic compass shall be placed in the wheelhouse so that its readings could be taken from the steering position and access to the compensation device could be provided.

2.3.4 The standard (master) magnetic compass shall be installed on the bridge, in a place where visual bearings could be taken to objects within the sector of not less than 230° (115° to each side from the right ahead direction). The compass shall be accessible from all the sides.

2.3.5 Any equipment apart from those initially designed to be placed nearby those compasses may be installed only upon agreement with the River Register.

2.3.6 Two-way communication shall be provided between the places or rooms with the standard (master) and steering (secondary) magnetic compasses and the main and emergency (if any) steering stations.

2.3.7 When data from the standard (master) magnetic compass shall be transmitted through optical line, the following requirement shall be met:

periscope screen shall be located at the navigator's eye level and at a distance not more than 1.2 m from him;

the periscope mast shall not generate dead areas for the navigator.

2.4 GYROCOMPASS LOCATION

2.4.1 Gyrocompass main device, converter and power switchboard shall be installed in a dedicated room (gyrocompass room) located at the level of one of the actual waterlines at such a distance from the midship section centre line plane that requirements in 3.4.1 and 3.4.2 are met. The small-size main device of the gyrocompass combined with the control panel may be located in the wheelhouse or in the chartroom.

2.4.2 No equipment unrelated to the navigational equipment may be installed in the gyrocompass room.

2.4.3 The gyrocompass room, shall have, except for the main electric lighting, emer-
2 Location of Navigational Equipment

2.4 Location of Navigational Equipment

2.4.1 The gyrocompass room shall have a two-way communication with the wheelhouse.

2.4.2 The gyrocompass room ventilation shall prevent air flow influence on the gyrocompass's sensitive element.

2.4.3 Access to the gyrocompass main device shall be provided from all the sides for inspection and repair.

2.4.4 The gyrocompass main device as well as repeaters (designed for visual direction finding) shall be installed so that the straight line passing through 0° and 180° on azimuth dial is parallel to the centreline plane within 0.2°.

2.4.5 The repeater for visual direction finding shall be installed in the wheelhouse so that direction finding is enabled within the relative bearing of at least 115° to each side. It is allowed to install one repeater on each bridge wing instead of single repeater in the wheelhouse. Those repeaters shall be so arranged to enable direction finding in any direction within the relative bearing of 180° to each side.

2.4.6 The steering repeaters shall be located in the places where ship is steered. They shall be located so that navigator could easily read and use them.

2.4.7 The power units and their control equipment shall be installed in the power equipment room (if any) or in the same room with the main device in such a way then to enable measurements of the power unit revolution frequency and maintenance of bearings. The power unit remote control station shall be located in the room with the gyrocompass main device or in the wheelhouse/chartroom.

2.4.8 It is allowed to use the same repeaters when a gyrocompass and a magnetic compass with remote electrical transmission of the readings are provided. In this case, a display panel with inscription “Repeaters are showing data from the magnetic compass” and “Repeaters are showing data from the gyrocompass” shall be installed in the wheelhouse to get switched over depending on the compass type.

2.4.9 Water cooled gyrocompasses not suitable for operation with cooling water temperature exceeding 30 °C shall receive water for cooling from a dedicated cooler installed on board the ship.

2.5 AUTOPILOT AND DIRECTIONAL STABILIZER LOCATION

2.5.1 The autopilot or directional stabilizer control console shall be installed near the manual steering station to enable their maintenance and switching between automatic to manual control.

2.5.2 The control console combining automatic and manual control shall be installed in the wheelhouse in the centreline plane or at a distance compliant with requirements in 3.6.

2.6 ECHO SOUNDER LOCATION

2.6.1 A depth indicator shall be installed in the wheelhouse and an echograph in the wheelhouse or chartroom. Those devices shall be located in places accessible for maintenance and repair. It is allowed to install only the depth indicators in the wheelhouse.

2.6.2 The echo sounder sensors shall be installed under the ship bottom at a distance of 0.2 to 0.75 of the ship length from the bow as measured along the minimum operating draught waterline, and at such a distance from the sides and ends that prevents their exposure at roll and air bubble ingress.

2.6.3 No ultrasonic emitters of other devices operating simultaneously with the echo sounder as well as any hull projections, inlets or discharges or other structures interfering with the echo sounder shall be located near the echo sounder sensor.

2.6.4 Measures shall be taken to prevent progress of contact corrosion on the hull as a result of sensor installation.
2.6.5 The echo sounder sensors shall be installed so that their radiating and receiving surfaces are parallel to the horizontal plane and are at the same level when the ship has no heel and trim. This requirement applies to portable sensors too.

2.6.6 The echo sounder sensors installed in bottom openings shall be located so that their surfaces are flush with external shell plating. Where it is impossible to install sensors in the horizontal position because of hull curvature, the fore-to-aft fairings shall be used.

2.6.7 Where echo sounder sensors are to be installed in a dedicated tank without any cutout in the bottom, the tank shall be filled with water.

2.6.8 The echo sounder sensors may be located in special spaces named moonpools. The structure of the moonpool cover shall prevent sparking.

2.6.9 The radiating surface of echo sounder sensor shall never be painted or subjected to mechanical stresses (impacts, friction, etc.).

2.6.10 In order to eliminate electromagnetic interferences, the "sensor - receiver - amplifier" line shall be laid at least 1 m away from the "sensor - transmitter" line (when the echo sounder does not utilize a combined sensor) and at least 0.5 m away from other electrical devices and parallel cables. Both lines shall be shielded.

2.6.11 High voltage relay box shall be installed in a dry place accessible for maintenance and repair and shall be protected against dust and mechanical stresses according to Appendix 1, Part VI of the Rules. It shall not be located in the holds carrying coal, cotton or other inflammable cargoes.

2.6.12 When echo sounder sensors are placed in cofferdams of cargo and fuel tanks, in the double bottom compartments and ventilated tunnels under cargo compartments of the oil tankers, they shall be located in a dedicated water-and-gastight enclosure, which is a hull structure. The cables shall be laid according to the requirements in 2.10, Part VI of the Rules.

The sensors installed in the said spaces shall have a maintenance-free design.

2.6.13 Local and global strength of the hull shall be provided when installing the sensors in the hull.

2.6.14 Dedicated tanks for echo sounder sensors shall be tested for tightness after installation on board the ship according to Appendix 10 of RTSC.

2.6.15 Access shall be provided from the ship interior spaces for inspection of the cable boxes and for sensor resistance measurements.

2.6.16 The echo sounder power equipment (converter, transformers, etc.) shall be installed in the power equipment room or in a dedicated enclosure in the ship interior heated spaces.

2.7 LOG LOCATION

2.7.1 The primary speed transducers shall be installed in the ship bottom, in the place of intersection of the base plane and centreline plane so that the transducers are not exposed during roll at minimum draught and the water flow lines are parallel to each other and to the centreline plane.

2.7.2 Transducers fixed in bottom openings shall be secured in the welded pads. The welded pad securing method shall not weaken the hull.

2.7.3 The speed and travelled distance indicators shall be installed at the navigator's workstation. The speed indicator shall be installed in the wheelhouse (on the ship steering station) and at the main engine control station, if any.

2.7.4 No projections or system inlets or discharges that can affect parallel water flow lines around the hull shall be present aforesaid the log's underwater receiver.

2.7.5 Transducers may be installed in retractable bottom arrangements or fixed. Their longitudinal axes shall be parallel to the centreline plane within 1°.
2.7.6 Retractable bottom arrangements of the primary transducers shall be located in a moonpool complying with the requirements in 2.1.4.

2.7.7 If generalized TV-type displays of navigational information are provided in the wheelhouse, it is allowed not to install separate speed and travelled distance repeaters, except for the speed repeaters installed at the ship steering station.

2.8 LOCATION OF THE ANTENNAS AND RECEIVERS OF THE RADIO NAVIGATION SYSTEMS AND GLONASS, GPS, GLONASS/GPS, GALILEO SYSTEMS

2.8.1 The radio navigation system receivers shall be installed in the place of navigational plotting so that ship position could be visible from the navigator’s workstation.

2.8.2 The radio navigation system receiver antennas shall not be installed below the large-sized metal ship structures and shall be at least 3 m away from any transmitting antennas.

If the ship dimensions do not allow to locate GLONASS/GPS antenna more than 3 m away from any transmitting antennas, then the distance between these antennas shall not be less than 1 m horizontally and 0.7 m vertically.

2.8.3 Antennas shall not be installed at the mast tops, in the places subject to vibration, under the ship deck structures and rigging, as well as near the heat or smoke sources.

2.8.4 The GNSS receiver antenna place shall be selected to enable tracking of satellite constellation. This place shall be at least 1 m above the horizontal surfaces of the ship structures.

2.8.5 The GNSS receiver antenna shall not be located in the main beam of the radar emitting pattern. The distance between antennas shall not be less than that specified in the technical documentation for the equipment.

2.9 RATE-OF-TURN INDICATOR LOCATION

2.9.1 The main device of the rate-of-turn indicator shall be installed on a hard foundation in the power equipment room or radio equipment room adjacent to the wheelhouse; it shall be placed in the centreline plane and be oriented along this plane. The upper surface of the foundation shall be parallel to the base/horizontal plane. Vibration and temperature differences shall not be present in the place of installation.

2.9.2 The main device may be placed in the wheelhouse if magnetic fields produced by this equipment do not distort magnetic compass readings by more than ±0.5° and the acoustic noise level does not exceed the norms set by the sanitary regulations.

2.9.3 The rate-of-turn indicator devices shall be located in the wheelhouse so that navigator could easily read them and could have an access to their controls.

2.9.4 The rate-of-turn indicator repeaters shall be installed at the steering station so that they could be read simultaneously with observing navigational conditions ahead, as well as above radar indicator, at the bridge wings and at the top bridge wings, if ship steering is provided from these places.

2.10 LOCATION OF THE ELECTRONIC CHART DISPLAY AND INFORMATION SYSTEM FOR INLAND NAVIGATION (INLAND ECDIS)

2.10.1 Inland ECDIS shall be installed in the wheelhouse at the ship steering station so that to provide access to the information displays, system controls and radar, as well as observation over environment, for safe navigation under any operating conditions.

2.10.2 Making changes in the in-route plotting from a remote indicator (if any) shall not be possible.

1 SanPiN 2.5.2-703-98.
2.11 SHIP PATH CONTROL SYSTEM LOCATION

2.11.1 The control console of the ship track control system supporting the manual steering system shall be connected to the manual steering station by mechanical or electrical link.

2.11.2 The combined automatic and manual control console shall be installed in the wheelhouse in the centreline plane to enable its maintenance and switching between the automatic and manual steering.

2.11.3 Remote control stations of the system shall be installed on the bridge wings or in other places specified by the ship design.

2.12 AUTOMATIC IDENTIFICATION SYSTEM LOCATION

2.12.1 AIS equipment shall be installed in the wheelhouse so that to enable use of its controls and indicator along with simultaneous observation of radar indicators, Inland ECDIS/ECDIS and environment.

2.12.2 Individual units included in AIS and not requiring operational control may be installed in a room adjacent to the wheelhouse.

2.12.3 The output contacts of the device actuating in case of a failure in the AIS equipment shall be connected to an audible alarm device or to the ship warning alarm system.

2.12.4 AIS antennas shall be installed at a height sufficient for effective signal emission and reception at all the operating frequencies, and with no obstacles shall be around the horizon on the way of the electromagnetic field propagation.

2.12.5 The AIS UHF antenna shall be located so that the no conductive ship structures or powerful energy transmitters (radar or radio communication antennas) are located less than 2 m away from it. When placing the antenna at the same level with other antennas, they shall be at least 5 m away from each other. If the ship dimensions do not allow to locate the antennas at a distance more than 5 m, the distance between these antennas shall be not less than that specified in the technical documentation of the equipment manufacturer.

2.12.6 Coaxial and power cables shall be laid in separate pipes placed at least 10 cm from each other or in double steel plaiting which provides screening continuity. The cables shall be crossed at the right angle.

2.12.7 Antenna of AIS GNSS signal receiver shall be installed in a place where satellite signals can be received.

2.12.8 The coaxial cable between the antenna and AIS main unit shall be laid together with coaxial and power cables of any other purpose. The distance between such cables shall be at least 1 m.

2.13 VOYAGE DATA RECORDER LOCATION

2.13.1 VDR equipment shall be located in the wheelhouse or in an adjacent dry heated room.

2.13.2 A dedicated protective container with an end data carrier with recorded information shall be installed on the open part of the uppermost deck, e.g. on the open parts of the bridge wings, on the wheelhouse roof, in a place where it can float free in case of a collision or transport accident.

2.13.3 A fixed data carrier shall be located in a dedicated fixed protective container rigidly securing to the open deck.

2.14 EXTERNAL AUDIO SIGNAL RECEPTION EQUIPMENT LOCATION

2.14.1 The receiving microphones of the equipment shall be installed in the places with minimum acoustic noise from the ship's noise sources.

2.14.2 The external audio signal reception equipment indicator shall be installed in a place where it is visible from the ship steering station.

2.14.3 The equipment loudspeakers shall be located so that the broadcast external signals are audible from any place of the wheelhouse.
2.15 RADAR REFLECTOR LOCATION

2.15.1 The radar reflector shall be secured on board the ship using a rigid support or by suspending it on rigging.

2.15.2 The radar reflector shall be installed at a height at least 4 m above water. Preferred orientation of the reflector shall be marked on it.

2.16 INTEGRATED NAVIGATIONAL SYSTEM LOCATION

2.16.1 Integrated navigational system shall be installed in the wheelhouse so that navigator could operate the system's equipment and simultaneously observe the navigational conditions.
3 REQUIREMENTS TO NAVIGATIONAL EQUIPMENT

3.1 GENERAL REQUIREMENTS

3.1.1 Navigational equipment shall comply with requirements in 2.2 to 2.7, 4.5.1, Part VI and 6.1, Part VII of the Rules.

3.1.2 Navigational equipment shall remain serviceable under any operating conditions of the ship.

3.1.3 All the navigational equipment shall be designed for continuous 24-hour operation. Operating temperature shall be:
   0 to 45 °C for the main gyrocompass devices
   −4 to +40 °C for the speed log primary transducers and echo sounder vibrators submerged in water

3.1.4 All the navigational equipment and devices shall have the following degrees of protection:
   IP22 for equipment installed in closed dry service spaces;
   IP56 for equipment installed on the open decks and in cargo holds;
   IP68 for equipment installed in the double bottom spaces.
   For equipment installed in the closed dry service spaces at a distance more than 1 m from the doors and windows facing the open deck, IP21 protection is allowed.

3.1.5 The structure of the navigational equipment shall enable its maintenance and repair in the marine conditions by replacement of its main units without need in any special adjustment.

3.1.6 If the navigational equipment unit is connected to one or several units of other navigational equipment, the operating parameters of each equipment shall not change comparing to independent operation of such equipment.
   In case of data exchange loss, the navigational equipment shall continue performing other functions.

3.1.7 Operational controls of navigational equipment shall be located at a distance of not more than 700 mm from the leading edge of the navigational equipment. Their location shall prevent necessity of crossing or changing navigator's hands when simultaneously operating two controls.

3.1.8 Emergency functions shall be indicated on the navigational equipment front panel.

3.1.9 If digital keyboard for entering digital information from 0 to 9 is provided, the keys with figures shall be arranged according to recommendations of the Consultative Committee for International Telegraphy & Telephones (4 rows with 3 keys in each row).
   If alphanumeric keyboard is provided, the keys with figures from 0 to 9 shall be arranged according to provisions of the standards1.

3.1.10 Controls shall be grouped according to the functional features, and their unintended use shall be prevented by appropriate arrangement on the front panel.

3.1.11 Operating a control shall not cause distortion of the related indicator's reading when observation over this indicator is required during adjustment of the navigational equipment.

---

3.1.12 The controls, whose unintended use may cause shutdown or damage of the navigational equipment or alarm actuation, shall be provided with protection against unauthorized access.

3.1.13 Design possibility of removing controls with additional functions or devices of the navigational equipment (not included in the installed navigational equipment set) or interlocking such controls in position shall be provided.

3.1.14 The device readings and inscriptions on the operational controls shall be readable at least from 1 m away. All other information shall be readable from at least 2 m away.

The instrument scales shall enable the use of the observed readings without applying any correction factor.

3.1.15 The navigational equipment arrangement and structure shall prevent damage of this equipment or a harm to people as a result of using the controls in a sequence not specified in the technical documentation for the equipment.

3.1.16 The navigational equipment shall have a design preventing erroneous human actions as follows:

1. All the actions which may cause irreversible processes in the navigational equipment shall require confirmation before applying;

2. In case of detecting erroneous human actions, the navigational equipment shall display a feedback with enabling the “cancel and/or restore” menu;

3. The navigational equipment shall display information on receiving signals from other systems or sources;

4. The navigational equipment shall have a recover function to set the specified equipment to the default state by navigator’s single action.

3.1.17 The image display devices shall display brief overview on the function being carried out. Information not complying with the task being carried out or additional text or graphics shall not be displayed. The following requirements are imposed on information display:

1. Menus shall be grouped by functional tasks;

2. Elements displayed simultaneously shall be grouped according to the sequence of their use. The navigator shall be provided with information on the sequence of actions when shifting from one part of menu to another;

3. A system device shall display entered data. All the information required by the navigator to perform necessary actions shall be available on the active display device;

4. Any operation mode when performing the actions shall be identified by the display device(s). The display device screen shall display each stage of work; there shall be provided the possibility to return to the menu initial state before commencement of this stage by navigator’s single action;

5. When performing the actions, feedback shall be enabled to return to the menu initial state. Feedback synchronization shall comply with the requirements of the actions being performed. If response to an action is delayed, information on such a delay shall be displayed on the display device;

6. The terminology of the water transport used in the Russian Federation shall be used to display information on the navigational equipment displays;

7. In case of quick help available, it shall be provided in the form of appendix to the task being carried out and shall be called by a sequence of actions as programmed.

3.1.18 The navigational equipment arrangement and design shall not prevent its functional testing with opened case using special-purpose tools. Protection against electric shock shall be provided in the circuits with voltage above 50 V. Warning inscriptions shall be made on the external and internal parts of the navigational equipment and its protective casings. The navigational equipment design shall enable opening its case only after switching off any voltage above 50 V.

3.1.19 Grounding clamps shall be provided on all the cases of the navigational equipment. The grounding clamps shall be provided on
the cases of the radar transceivers in a number sufficient to ground RF voltages.

The opening doors, retractable units and hinged panels accommodating instruments and/or other components shall be grounded with a flexible link.

3.1.20 Threaded connections shall be fitted with means against self-unfastening. Metal parts located on the external side of the navigational equipment case shall be electrically connected to the case.

3.1.21 The inscriptions describing the technical parameters and other data of the navigational equipment shall be applied on the equipment in a place where they are well readable.

3.1.22 The design of the plug-in connections in the navigational equipment shall prevent improper connection of plugs and sockets. The projecting pins of detached plug-in connections shall be deenergized.

3.1.23 The design of the navigational equipment shall prevent heating of the control knobs by internal heat to temperature exceeding the ambient temperature by more than 15 °C.

3.1.24 Light alarm on energizing and supplying voltage more than 50 V shall be provided in the navigational equipment.

3.1.25 Indication of the current operation mode shall be provided in the navigational equipment normally capable of operating in several operation modes.

3.1.26 Audible and/or visual alarm on operational fault shall be provided in the navigational equipment.

The said alarm shall also actuate when the navigational equipment reaches critical operation conditions able to result in loss of functionality.

If the alarm is displayed on a multicolour display device, the emergency alarm shall remain visible if one of the constituent colours is not available.

The level of the acoustic noise generated by the audible alarm at a distance of 1 m from its source shall be within 75 dB(A) to 85 dB(A).

The level of the acoustic noise generated by the navigational equipment during operation (when audible alarm is off) shall not exceed 60 dB(A) at a distance of 1 m from any part of the navigational equipment.

The types of alarm and alarmed faults or critical conditions shall be agreed with the River Register.

3.1.27 Adjustable highlight shall be provided for the navigational equipment or in the room where it is installed, enabling to distinguish the controls and to read indicators at all times.

Signal lamps or other visual inspection means shall be located in the navigational equipment or control consoles.

Transparent protective coatings on the navigational equipment shall not cause reflections which may impair reading information.

3.1.28 The colours of the signal lamps depending on the type of alarm shall comply with the requirements of Table 6.1.16, Part VI of the Rules.

3.1.29 Intensity of lighting, brightness of the signal, indicating and highlight lamps of the navigational equipment shall be adjusted to minimum level down to blackout, except for highlight of the warning alarm indicators and reset and switch on/off indicators, which shall be on and well visible under all the light conditions in the wheelhouse.

3.1.30 If a voice messaging is provided in the navigational equipment, it shall be a mean additional to indicators and warning alarm required in this Chapter.

Voice messaging loss shall not degrade serviceability of the provided indication and alarm systems.

The voice messages shall be articulated with the use of the terminology of the water transport used in the Russian Federation and shall be well audible in all the places within the wheelhouse where the navigator may be present during ship steering.

Means for testing and adjustment of voice message level, including means for voice message volume adjustment, shall be provided.
The voice message volume level shall not exceed the warning alarm volume level. Change of the voice message volume level shall require navigator’s approval.

The voice messages shall be interrupted when the related indication or warning alarm signals are acknowledged.

3.1.31 The operational software used in the navigational equipment shall comply with the requirements in 11.15.8, 11.15.13, 11.15.14 and 11.15.16, Part IV of the Rules, as well as with the following requirements:

.1 Data used during operation of the navigational equipment and stored in the system (database) shall be protected so that the modifications/changes in part of the data made by the navigator do not lead to loss of integrity or safety of the other part of the database;

.2 Default values shall be displayed at each restoration of the navigational equipment functionality;

.3 The core information display and update devices provided in the navigational equipment, as well as safety functions, shall not degrade the navigational equipment functionality in any operation mode;

.4 If the information submitted for processing is determined as invalid, alarm in the navigational equipment shall be generated;

.5 Means shall be provided in the navigational equipment for automatically testing, in the specified time intervals, functionality of the software and safety of the used data (as specified in the technical documentation for the navigational equipment), as well as for actuation of independent alarm in case of a stable fault when the system is not under automatic testing;

.6 Functional keys for accelerated access to selected actions shall be provided in the software user interface integrated in the navigational equipment;

.7 Technical documentation used for developing and testing the software integrated in the navigational equipment shall include description of the methodology used for improvement of software and model programs.

Such software and model programs shall comply with the following requirements:

Complex software shall have a structure that enables functional testing of the individual modules or groups of functionally interconnected modules. Safety functions shall have priority over other functions including control functions.

The software maintenance and update structure shall be developed so that functional testing of the equipment as well as detected errors and failures is provided;

.8 Maintenance and update of the navigational equipment software shall be possible on board the ship. Upon completion of maintenance, the software shall require no additional settings or adjustments.

Name and version of each separate program included in the navigational equipment software system shall be identified or displayed, upon command, on the navigational equipment display device.

If software is identified only with the use of the navigational equipment display device, the respective information shall be included in the ship technical documentation.

All the changes in the software made in the course of maintenance shall be also included in this documentation;

.9 The software developer shall submit a document confirming that the navigational equipment software is developed and tested according to the technical documentation and requirements specified in 3.1.31.8 (flowcharts, algorithm of data check and respective diagrams are available).

3.1.32 The navigational equipment shall remain serviceable when interrupting power supply for up to 60 s. No software failure or loss of data stored in RAM shall occur.

If power supply of the navigational equipment is provided from more than one power source, means shall be provided to switch between the sources. These means may be not a part of the navigational equipment.

3.1.33 Means shall be provided to protect the navigational equipment against current surges and overvoltages, and, for 5 minutes,
against power source wrong polarity or wrong phase order.

3.1.34 Insulation resistance of the navigational equipment power circuits measured between the conductors and equipment case as well as between the transformer windings shall be, depending on the test conditions, at least:
   - under normal climatic conditions, 20 MΩ;
   - at (55±3) °C and RH < 20 %, 5 MΩ;
   - at (40±2) °C and RH = (95±3) %, 2 MΩ.

3.1.35 Image viewing during the daytime shall be provided in the navigational equipment fitted with a CRT indicator.

3.1.36 Navigational equipment installed near the magnetic compass shall be marked with minimum safe distance from the compass. This is a distance, at which influence of any active navigational equipment (or individual unit) is so that deviation of magnetic compass on the upper deck does not exceed 5.4°/\(B_n\) and of magnetic compass in the wheelhouse does not exceed 18°/\(B_n\), where \(B_n\) is the horizontal component of the earth magnetic field strength (\(\mu\)T) at the compass location spot.

3.1.37 Interface with other radio- and navigational equipment as well as with the integrated navigational system shall be provided in the navigational equipment.

   Interface formats of the shipborne radio- and navigational equipment corresponding to the national and international standards shall be used for the digital information exchange\(^1\).

3.1.38 All the navigational equipment shall be displayed and submitted to the navigator in the decoded and processed form.

3.1.39 The electric intensity level of the noise radiated by the navigational equipment installed on board the ship shall not exceed the values specified in 2.7, Part VI of the Rules.

3.1.40 The navigational equipment designed so that fault diagnostics and further repair are possible down to the element base level, shall have a set of electrical and wiring diagrams as well as a list of components of this equipment.

   The operating documentation of the navigational equipment consisting of separate modules not suitable for repair on board shall contain a methodology for finding and replacing the faulty module.

   Besides, the documentation shall contain information enabling to check equipment performance against performance specifications set by the Rules, considering influence of such a test on other navigational equipment installed in the wheelhouse.

3.1.41 The navigational equipment shall be marked with the following information:
   - information on the manufacturer;
   - navigation equipment type number or codename assigned for type approval testing;
   - serial number of navigational equipment;
   - year of manufacture;
   - kind of current and voltage of power supply;
   - safe distance of the navigational equipment installation from the magnetic compass;
   - protection degree (IP) of the equipment protection enclosure.

3.1.42 The navigational equipment spare parts shall be stored in the conditions that exclude their damage and enable their transfer and identification as belonging to a specific type of equipment.

3.1.43 The radio navigation system receivers shall comply with the requirements in 6.1, Part VII of the Rules and shall provide:
   - accuracy of the ship position finding depending on the used system or radio navigation systems;
   - interfacing with the navigational equipment and integrated navigational system;
   - functional testing with the help of a built-in testing system;

Requirements to Navigational Equipment 803

4 receiver input protection according to 5.4.10, Part VII of the Rules;
5 a 5 minute protection of the receiver against damage in case of short-circuit failure or ground failure of antenna, any input or output connection of the receiver, and any input or output of the receiving equipment;
6 performance under noise conditions;
7 use of compound (multi-channel) receivers handling signals of ground radio navigation systems and signals of the global navigation satellite systems with WAAS (Wide Area Augmentation System), EGNOS (European Geostationary Navigation Overlay Service) and MSAS (Multifunctional Satellite Augmentation System); SBAS (Space Base Augmentation System), as well as regional augmentation systems like Starfix, SkyFix and Eurofix/Skorpion.

3.1.44 IF receivers handling signals of ground radio navigation systems or compound (multi-channel) receivers able to handle signals of, among others, ground radio navigation systems are to be installed on board the ship, they shall comply with the requirements of this Part of the Rules.

3.2 REQUIREMENTS TO RADAR

3.2.1 A radar station (hereinafter referred to as the radar) for the ships of J1, P, O and M classes shall comply with the requirements in 3.2.2 to 3.2.23. Ships of O-P1P, M-P1P and M-C1P classes of gross tonnage of 300 and more, as well as on all the passenger ships of O-P1P, M-P1P and M-C1P classes shall be fitted, in addition to the radar required for navigation in inland waters, with an additional radar complying with the requirements in 3.2.24 to 3.2.82. It is allowed to use one radar for the ships of gross tonnage up to 3000, if it complies with the requirements in 2.1, 2.2, 3.1 and 3.2.2 to 3.2.82.

3.2.2 The radar shall provide detection and display of the ships, buoys, other surface objects and obstacles, as well as of coastline and navigational marks relative to the own ship by continuous scanning round the horizon in the relative and/or true motion modes.

3.2.3 When there are no radio interferences, rain and fog, and when wave height is below 1 meter, the radar indicator shall display various objects at distances as show in Table 3.2.3 provided that the radar antenna is 10 m above the water surface. All the objects shall remain visible in case of roll and pitch of ±10°.

<table>

* On ships of gross tonnage less than 1600 antennas with resolution of maximum 3.0° is allowed.

3.2.5 Image orientation on the radar indicator shall be switchable between "heading up" and "true north up".

3.2.6 The controls required for the radar functioning according to the requirements of this Chapter shall be provided at the radar indicator.
Arrangement, functioning method, place, arrangement with respect to each other, and dimensions of the controls shall comply with the requirements in 3.1.8 to 3.1.16. Unauthorized switch of the scale range from miles to kilometres and back shall be prevented. Inscriptions shall be made in Russian or with generally accepted symbols according to the River Register Guidelines P.028-2009 "Guidelines on Abbreviations and Symbols Used in Radio Communication and Navigation".

3.2.7 Measures shall be taken to suppress rain and wave reflections.

3.2.8 The radar startup time shall not exceed 1 minute. The radar shall be fully operational within 4 minutes after switching on. The standby mode shall be provided so that the radar could be set to the operation mode within 15 s.

3.2.9 The effective display diameter of the radar indicator without magnifier shall be at least 180 mm for the ships of gross tonnage of 300 to 1600 and at least 250 mm for the ships of gross tonnage of more than 1600. For the ships engaged on international voyages on Danube - Rhine inland waterway system, the radar screen diameter shall be at least 270 mm irrespective of the ship gross tonnage.

3.2.10 For the ships operating on inland waterways, the indicator shall have the following set of range scales: 0.5, 1.6, 2, 3.2, 4, 8, 16 and 32 km. Each scale shall have minimum 2 and maximum 6 fixed range rings. It is allowed to provide additional scales calibrated in kilometres or miles. Switching between kilometres and miles shall be provided.

3.2.11 Variable range mark with numerical readout in kilometres or miles shall be provided on the radar indicator. Range measuring accuracy with on-screen variable range mark shall not exceed 10 m on the 0.5 to 2.0 km range scales and 1.0 % of the scale rating for the next scales.

3.2.12 Brightness control for fixed and variable range marks shall be provided. Fixed range rings and variable range mark shall have thickness of less than 1 % of the effective display diameter and not exceeding 1 mm.

3.2.13 The radar indicator shall be fitted with an electronic (digital) or mechanical bearing finder to take bearings to detected objects, and the following requirements shall be also met:

Digital readout of the directions obtained with the help of electronic direction finder shall be displayed with at least four figures including one decimal place. Place for indication of this readout is not to be used to display other data. Notation of the measured value (relative bearing or true bearing) shall be displayed.

Azimuth scale shall be displayed along the perimeter of the effective display diameter. It is allowed to use linear or nonlinear azimuth scale.

Azimuth scale shall be marked every 5°, and the 5° and 10° marks shall be different. The figure marks shall be provided at least every 30°.

Measurement of the direction relative to the heading line (i.e. relative bearing) and relative to the true meridian (true bearing) shall be provided.

3.2.14 Own ship motion shall be displayed with an electronic heading mark on the display. Error of this mark shall not exceed 0.5°. The heading mark line width shall not exceed 0.5°.

3.2.15 Provision shall be made to temporarily disable the heading line image by the use of a switch with automatic reset to the enabled position.

3.2.16 An input shall be provided for the radar azimuth stabilization signal from the gyrocompass.

3.2.17 The radar antenna rotation speed shall be at least 18 min⁻¹. The antenna shall be in operation condition at relative wind velocity of 50 m/s.

The radar antenna rotation speed for the high-speed craft shall be at least 40 min⁻¹. The antenna shall be in operation condition at relative wind velocity of 70 m/s.
3.2.18 Shifting the origin to any point on the screen at a distance of not less than half of its radius shall be provided.

3.2.19 Means shall be provided to detect radar performance degradation relative to the calibrated value taken at the time of radar installation, as well as to readjust the radar when there are not targets.

3.2.20 The radar shall have an integrated performance testing system.

3.2.21 Radar antenna shall radiate high-frequency energy only when the radar is operating as intended. During repair or maintenance, an interlocking device shall be used to provide safety.

3.2.22 The own ship mark on the radar operating in the true motion mode shall be shifted both manually and automatically when the own ship mark is approaching 0.5 of the display radius. An alarm device shall be provided to warn that the ship mark has approached to 0.5 of the display radius.

3.2.23 In radars designed for operation in the true motion mode, the own ship speed may be entered from a speed meter and/or manually along with drift correction.

3.2.24 The radar on ships of О-ПР, М-ПР and М-СП classes shall provide support collision avoiding and navigational safety by detecting and displaying positions of other ships, surface objects and obstacles, navigation marks and coastline.

To reach the said goals, the radar shall provide:
- displaying radar video signals;
- indicating positions and motion data of the tracked targets;
- indicating own ship coordinates as received from the positioning equipment and brought to the reference coordinate system and fixed common reference point of own ship;
- displaying information on the targets as received from the AIS equipment;
- displaying electronic navigational chart data for monitoring own ship position.

3.2.25 The radar shall comply with the requirements of Table 3.2.25 irrespective of the type of ship where it is installed, used frequency band and type of display device.

3.2.26 The radar shall be capable of operating in the following frequency bands:
- X band — 9.2 to 9.5 GHz (wave length of 3 cm) for high resolution and good sensitivity with no clutter
- S band — 2.9 to 3.1 GHz (wave length of 10 cm) for sure detection and tracking with presence of interferences (rain, fog, sea clutter)

The frequency band in use shall be indicated.

3.2.27 The radar shall be functional under passive radio interference noise and shall be capable of measuring:
- range with error not exceeding 30 m or 1% of the maximum range of the range scale in use, whichever is greater;
- bearing with error not exceeding 1°.

3.2.28 The radar capability to detect target at least 8 times out of 10 scans (antenna revolutions) with probability of false detection not exceeding $10^{-4}$ shall be verified during its operation in the X and S bands under the following conditions:
- no clutter;
- antenna height of 15 m above sea level.
The minimum detection ranges for various targets in clutter-free conditions are specified in Table 3.2.28.

The minimum target detection ranges shall be achieved with the use of a regular antenna with the smallest aperture.

3.2.29 With own ship zero speed, no clutter, sea state of up to 2, and radar antenna height of 15 m above sea level, the navigational buoy specified in Table 3.2.28, shall be detectable at a horizontal distance to the antenna not exceeding 40 m. This target shall be displayed to the distance equal to one nautical mile without change of the adjustment control position, except for the range scale selector.

In case of several antennas, range corrections shall be automatically applied for each antenna.

3.2.30 The radar shall feature consistent target detection performance on all the working range scales under passive interferences.

The radar shall have means to enhance the visibility of targets under passive interferences at close ranges.

Technical documentation shall contain information on possible deterioration of detection performance (comparing to the values of the parameters specified in Table 3.2.28) for the following conditions:

- light rain (up to 4 mm/h) and heavy rain (up to 16 mm/h);
- sea state of 2 and 5;
- a combination of the said conditions.

Possible degradation in performance due to a long transmission line, actual antenna height or any other factors shall be stated in the technical documentation.

3.2.31 Means shall be provided in the radar design for the adequate suppression of unwanted echoes including clutter caused by sea, rain and other precipitations, clouds, sandstorms, as well as and interferences from other radars.

Manual or automatic anti-clutter functions shall be provided. A combination of automatic and manual anti-clutter functions is permitted.

A gain control function shall be provided to set smoothly the system gain and signal threshold level.

There shall be indication of the gain and all anti-clutter settings.

</table>

1 Radar cross-section of radar reflector shall be 7.5 m\(^2\) for the X band and 0.5 m\(^2\) for the S band.
2 Radar cross-section of radar reflector shall be 10 m\(^2\) for the X band and 1 m\(^2\) for the S band.
3 Radar cross-section of navigation buoy shall be 5 m\(^2\) for the X band and 0.5 m\(^2\) for the S band. For the channel buoys with radar cross-section of 1.0 m\(^2\) (for X band) and 0.1 m\(^2\) (for S band) at a height of 1 m, detection range shall be 2.0 and 1.0 nautical miles respectively.
4 Radar cross-section of a 10 m long small-size ship shall be: 2.5 m\(^2\) for the X band and 1.4 m\(^2\) for the S band.
5 Radar reflectors are considered as point targets, ships as complex targets, and shore line as distributed targets (average height of rocky shore line is specified, but dependent on profile).
6 It is allowed to change the detection range depending on various factors like atmospheric conditions, target speed and aspect, target hull material and design.
3.2.32 Means shall be available to enhance target presentation on the display. The radar image shall continuously update with a delay of less than 100 ms. The radar signal processing principle and target displaying capabilities/limitations shall be specified in the technical documentation.

3.2.33 The radar of the X band (3 cm) shall be capable of detecting radar beacons and shipborne/LSA transponders operating in the relevant frequency band.

It shall be possible to disable those signal processing functions, including polarization modes, which may prevent radar transponders from being detected.

The signal processing mode shall be displayed on the radar screen.

3.2.34 Range and direction resolution shall be determined using the range scale of 1.5 NM or less, at calm water and at distances of 50 to 100 % of the rating of the selected range scale.

In so doing, the following requirements shall be met:

Two point targets on the same bearing line shall be displayed separately if they are 40 m or more apart;

Two point targets at the same distance from own ship shall be displayed separately if they are 2.5° apart.

3.2.35 The target detection performance shall not deteriorate when roll and/or pitch amplitudes do not exceed ±10°.

3.2.36 Means shall be available to monitor performance of the radar.

Capability of monitoring performance of the radar shall be retained when there are no targets.

The radar shall be adjusted with automatic adjustment means or manually. Means shall be available to determine a significant drop in radar performance relative to a calibrated standard established at the time of installation.

3.2.37 The radar shall be fully operational (operation mode) within 4 minutes after switching on.

The radar operation mode without transmission of electromagnetic energy (standby mode) shall be provided. The radar shall be fully operational within 5 s from the standby condition.

3.2.38 The results of all the radar measurements (target ranges, variable range marks, target bearings, cursor position and tracking data) shall be brought to a fixed common reference point of own ship.

When several radar antennas are installed on board the ship, correction of the antenna offset relative to the fixed common reference point of own ship shall be automatically applied.

Offset of any sensor submitting data to the radar shall be also applied automatically.

Own ship’s scaled outline shall be available on lower range scales. Position of the fixed common reference point and the active radar antenna shall be shown within this outline.

The image on the radar display shall be centred relative to the fixed common reference point of the ship, which all the radar bearings shall be measured from.

Range shall be measured in nautical miles. The results of measurements may be indicated in meters on lower range scales. Unambiguous indication of the measured ranges shall be provided.

All the radar targets shall be displayed on the radar display on the linear range scale. Display delays at change of the target position are prohibited.

3.2.39 The radar shall be capable of operating in the following range scales: 0.25; 0.5; 0.75; 1.5; 3; 6; 12 and 24 nautical miles. Additional range scales, including large-sized metric scales may be used.

The selected range scale shall be continuously displayed on the radar indicator.

3.2.40 The radar indicator shall display the fixed range rings regularly spaced from each other and from the origin. The distance between the fixed range rings shall be continuously displayed on the radar indicator.

Position of the fixed range rings shall be provided with error not exceeding 1 % of the
selected range scale or 30 m, whichever is greater.

3.2.41 At least two variable range marks with numerical readout shall be provided in the radar indicator.

The variable range mark shall enable measuring the range to an object with maximum error of 1% of the range scale in use or 30 m, whichever is the greater.

3.2.42 An azimuth scale designed to read bearings relative to the fixed common reference point of own ship shall be displayed on the smaller edge of the display space periphery.

The azimuth scale shall be numbered at least every 30° and shall have division marks every 5° and 10°. Divisions in 1° shall be displayed if they are provided by the technical documentation for the radar.

3.2.43 Own ship heading shall be displayed on the radar screen with an electronic heading line mark, which shall start from the fixed common reference point of own ship and reach the azimuth scale of the screen. The electronic heading line mark shall be displayed with error no exceeding 0.1°. When there are several radar antennas, corrections for radar antenna offset from the fixed common reference point of own ship shall be applied automatically for each antenna.

Provision shall be made to temporarily disable the heading line mark by the use of a switch with automatic reset to the enabled position. This function may be combined with disabling other graphics.

3.2.44 At least two electronic bearing lines (hereinafter referred to as the EBL) shall be provided in the radar indicator to measure bearing to any point object within 1° using the azimuth scale.

The EBL shall be capable of measuring radar heading angles and bearings. The bearing reference, relative to which measurements are taken, shall be indicated on the radar indicator.

It shall be possible to offset the EBL origin from the fixed common reference point of own ship to any point of the operational display area and to reset it EBL back to the fixed reference point by a single action.

It shall be possible to fix the EBL origin at any point of the display or to make the EBL origin moving with the speed of own ship.

EBL shall be capable of being smoothly guided on a selected object with measurement accuracy according to 3.2.11.

Each EBL shall have a numerical readout device with resolution sufficient to maintain measurement accuracy (see 3.2.13).

3.2.45 Displaying at least four independent parallel index lines shall be provided with possibility of truncating and/or disabling each of them. Besides, change in direction of and distance between those lines shall be possible.

3.2.46 There shall be means to measure distances and bearings of any point relative to any other point on the operational display area.

3.2.47 An electronic cursor shall be provided to mark any point on the screen. The cursor shall provide continuous readout of range and bearing of the point under cursor with respect to the fixed common reference point.

The cursor shall enable selection of targets, making or removal of graphical information, and selection of radar operation modes, functions, parameters and control menus outside the operational display area.

Means shall be provided to easily locate the cursor position on the display.

Cursor’s direction and distance measurement accuracy shall meet the relevant accuracy requirements for variable range mark and EBL.

3.2.48 The own ship’s heading shall be provided by a gyrocompass or an equivalent sensor, whose characteristics meet the requirements for the sensor type approved by the River Register.

Accuracy of the radar image orientation relative to true north shall not exceed 0.5° at any rate of turn the ship may likely experience.

Information on heading shall be displayed in numerical form with resolution similar to radar to gyrocompass interfacing precision.
The heading data shall be determined relative to the fixed common reference point of the ship.

3.2.49 The radar shall display information in the true motion mode having regard to motion parameters of own ship. Own ship mark on the display shall be automatically updated according to the following features:
- mark position on the indicator screen;
- time;
- or both of them.

Own ship mark position shall be updated for each antenna revolution.

The north up and heading up radar image orientation shall be provided. Type of the actual orientation and radar image mode shall be continuously displayed on the radar indicator.

3.2.50 Manual off-centring to any point on the screen within 0.5 of the radius from the centre of the radar display space shall be provided.

On selection of off-centred display, the selected antenna position shall be capable of being located to any point on the display within 0.75 of the radius from the centre of the operational display area.

Automatic offsetting own ship mark for maximum coverage area ahead of the ship shall be provided in the true motion mode.

Means shall be provided for presetting the origin position.

3.2.51 Two radar image stabilization modes shall be provided in the radar: relative to ground and relative to water.

The stabilization mode and active data sensors enabling implementation of the selected mode shall be displayed on the radar screen. The speed sensor shall comply with the requirements of the River Register to the respective stabilization mode.

3.2.52 Display of the target trails (afterglow) with variable (depending on extrapolation time) length of vectors shall be provided with indication of extrapolation time and display mode.

Selection of the target afterglow display mode shall be provided in the true or relative motion.

The trails shall be distinguishable from targets.

Either scaled trails or past positions or both shall be displayed within 2 revolutions of the radar antenna under the following changes:
- reduction or increase of range scale;
- change of the scan centre position;
- change of the display mode from true to relative motion and back.

3.2.53 The targets shall be displayed according to the established symbols specified in the River Register Guidelines P.028-2009.

The target information may be provided by the radar tracking function and/or by the target information from AIS equipment.

The number of the displayed targets shall comply with the requirements in Table 3.2.25.

If the number of the displayed targets approaches the limit value specified in this table, warning alarm shall automatically actuate.

Radar and AIS target data processing and display formats shall be compatible.

3.2.54 Data on the radar targets shall be received from the radar transceiver. The primary target data shall be filtered with anti-jamming means. Target acquisition for tracking may be manual or automatic.

Calculations related to target tracking shall be based on measurements of their position relative to own ship and their motion parameters. Other information sources may be also used to improve the tracking performance.

Target tracking shall be provided on range scales of 3, 6 and 12 nautical miles. Target tracking range shall be at least 12 nautical miles.

The radar shall be capable of tracking targets at their relative speeds equivalent to those of sea-going ships and river-sea navigation ships, including high-speed craft.

3.2.55 In addition to the requirements for processing and presentation of AIS targets, radar target data presentation shall be provided for the number of radar targets according to Table 3.2.25.
If the limit number of the targets is about to be exceeded, a warning alarm shall be activated. When the limit number of processable targets is exceeded, the radar performance shall not degrade.

3.2.56 Manual and automatic acquisition of radar targets shall be provided in the number specified in Table 3.2.25. Means to define the boundaries of the auto-acquisition zone shall be provided.

3.2.57 When a target is acquired, the radar shall present the trend of the target motion within one minute and the prediction of the target motion for next 3 minutes.

The radar tracking system shall automatically update data for all the tracked targets and shall keep tracking radar target distinguishable on the indicator screen for five of 10 sequential antenna revolutions.

The tracking system shall calculate smoothed vectors of target motion and detect the target manoeuvre commencement.

Cancelling tracking one or all the targets shall be provided.

Maximum possible accuracy of the target motion parameters shall be provided if the target moves smoothly and accuracy performance of the data sensors complies with requirements.

For ships capable of making up to 30 kn inclusively, the tracking facility shall present target relative motion trend after 1 minute of steady tracking and target motion parameters with accuracy specified in Table 3.2.57 after 3 minutes of steady tracking.

Significant accuracy deterioration is allowed:
- shortly after acquisition;
- during own ship manoeuvring;
- during target manoeuvring;
- failure in tracking and change of sensor accuracy.

Target range and bearing measuring accuracy shall not exceed:
- range — 50 m (or 1 % of the target range);
- direction — 2°.

For ships with speeds of 30 to 70 knots inclusive (high-speed craft) the above accuracy shall be provided at a target relative speed up to 140 knots inclusive.

Provision shall be made to stabilize the displayed image with respect to ground based on the fixed point target tracking.

3.2.58 Target data provided by the automatic identification system (AIS) are filtered for parameters to be defined by the navigator. AIS targets may be sleeping or activated. Activated targets shall be considered as similar to radar targets.

The total number of displayed AIS targets shall comply with the values given in Table 3.2.25. When the number of targets approaches the limit value, warning alarm shall automatically actuate.

3.2.59 To avoid data overflow on the display, provision shall be made for selecting data on sleeping AIS targets basing on the following criteria: target range, time and distance to the point of closest approach ($D_{CPA}$ and $T_{CPA}$), AIS target class (A, B), etc.

It shall not be possible to remove any AIS target from the display.

3.2.60 The means shall be provided to activate the sleeping AIS targets and to deactivate the earlier activated targets.

<table>

</table>

* Whichever is greater.
** See 3.2.59.
Where the radar provides for the zones of AIS target automatic activation, these zones shall coincide with the zones of radar target acquisition for tracking. In addition to the beginning of activation the AIS targets when they entered in an established zone, sleeping AIS target may be automatically activated basing on preset criteria (target range, time and distance of closest approach, AIS target class (A or B)).

3.2.61 AIS target information shall be displayed on the radar as specified in Table 3.2.61.

3.2.62 The symbols for graphic presentation of AIS targets on radar displays shall comply with symbols as specified in the River Register Guidelines P.028-2009.

AIS targets shall be displayed as sleeping by default.

The heading and speed of a tracked radar target or AIS target shall be indicated by a predicted vector of adjustable length. Permanent indication of vector time and stabilization shall be provided.

The fixed common reference point of own ship shall be used for presentation of radar targets and AIS targets on the radar display.

To present activated AIS targets on close range from the own ship, means to present the scaled outline of an activated AIS target shall be provided.

It shall be possible to display the past track of activated AIS targets.

3.2.63 It shall be possible to select any tracked radar or AIS targets for alphanumeric display of this target data. The selected target shall be displayed on the radar by means of the symbol as given in the River Register Guidelines P.028-2009. If several targets data are requested, their identities and their sources (radar or AIS) shall be displayed.

The target message shall include:
- data source (radar or AIS);
- target range;
- target bearing;
- target course over ground;
- target speed over ground;
- distance $D_{CPA}$ and time $T_{CPA}$.

In addition, AIS target heading and rate of turn may be displayed.

For each selected tracked AIS target the following data shall be presented: target identification, navigational status (underway, at anchor, etc.) and position.

 Provision shall be made for displaying other additional data on the navigator's request.

If the received AIS information is incomplete, the missing information shall be indicated as “MISSING” in the target data field.

The data on selected target shall be displayed and continually updated until another target is selected for data display or until the window is closed.

Means shall be provided to present own ship data on the navigator’s request.

<table>

</tbody>
</table>

3.2.64 It shall be possible to select any tracked radar or AIS targets for alphanumeric display of this target data. The selected target shall be displayed on the radar by means of the symbol as given in the River Register Guidelines P.028-2009. If several targets data are requested, their identities and their sources (radar or AIS) shall be displayed.

The target message shall include:
- data source (radar or AIS);
- target range;
- target bearing;
- target course over ground;
- target speed over ground;
- distance $D_{CPA}$ and time $T_{CPA}$.

In addition, AIS target heading and rate of turn may be displayed.

For each selected tracked AIS target the following data shall be presented: target identification, navigational status (underway, at anchor, etc.) and position.

 Provision shall be made for displaying other additional data on the navigator's request.

If the received AIS information is incomplete, the missing information shall be indicated as “MISSING” in the target data field.

The data on selected target shall be displayed and continually updated until another target is selected for data display or until the window is closed.

Means shall be provided to present own ship data on the navigator’s request.
3.2.64 All warning alarms shall be displayed together with indication of their reason.
If calculated values $D_{CPA}$ and $T_{CPA}$ of a tracked radar target or activated AIS target are less than their specified limits, the following shall be provided:
- warning alarm activation based on these criteria;
- indication of targets related to activated alarm.
The preset $D_{CPA}/T_{CPA}$ limits specified for radar targets and AIS targets shall be identical. Alarm functionality shall be applied for all AIS targets.
Alarm functionality may also be applied to sleeping AIS targets, on the navigator’s request.
In case of detecting targets, which were not earlier detected, within the target acquisition and activation zone, these targets shall be identified and a warning shall be generated.
In case of a lost target being tracked, an alarm shall be given. If the target tracked is cancelled by a pre-determined range or other pre-set parameter, an alarm shall not be given. The last position of the lost target or target whose tracking is cancelled shall be indicated on the radar display.
It shall be possible to enable or disable the lost target alarm function for both radar targets and AIS targets. A clear indication shall be given if the target is lost and if the lost target alarm is disabled.
The last position of the lost AIS target shall be clearly indicated on the radar display.
The indication of the lost target shall disappear if the AIS signal is received again, or after the lost target alarm has been acknowledged. Means of recovering limited historical data from previous AIS reports on lost targets shall be provided.
3.2.65 It shall not be possible to have one physical target presented as 2 independent targets (radar target and AIS target).
If the association criteria are fulfilled such that the radar and AIS targets are considered as one physical target, then as a default condition, such target shall be displayed by the activated AIS target symbol and alphanumeric AIS target data.
The navigator shall have the option to change the default condition to display data and shall be permitted to select target data source (radar or AIS).
If the AIS and radar information become sufficiently different, the AIS and radar information shall be considered as two distinct physical targets: one activated AIS target and one tracked radar target shall be displayed. No warning alarm shall be raised.
3.2.66 On ships of 10000 gross tonnage and more the radar system shall be capable of simulating the manoeuvre, namely, shall provide a possibility of simulating the approach situations during the manoeuvre with due regard for own ship’s dynamic characteristics.
This operation mode of the radar shall be clearly identified.
The trial manoeuvre requirements are as follows:
- Own ship heading and speed shall be variable.
- A simulated manoeuvre time and countdown time shall be provided.
- Target tracking and indication of the actual target data.
- Trial manoeuvre shall be applied to all tracked radar targets and all activated AIS targets.
3.2.67 It shall be possible to manually display sketch maps of the navigation area, various navigation lines, own ship courses and geographical position.
It shall be possible to remove this data from the display by navigator’s single action.
The sketch maps may consist of lines, symbols and reference points, which shall comply with the specified requirements.
The displayed additional information shall not degrade the radar information. It shall be retained when the equipment is switched off and restored when a relevant equipment module is replaced.
3.2.68 The radar system may provide the means to display the electronic navigational
chart (ENC) to provide real-time navigation conditions monitoring.

The displayed ENC shall comply with the format set out in national standards and requirements of the International Hydrographic Organization (IHO).¹

It shall be possible to display information derived from ENC updates.

It shall be possible to display ENC by levels or categories of information, but not by individual chart symbols.

ENC shall be displayed in the same datum as the AIS and be referenced to the fixed common reference point of own ship. Scale and orientation of ENC and radar indication shall be identical.

It shall be possible to remove the ENC from display by navigator's single action.

The radar data display shall have priority over all other displayed data. Chart information shall be displayed such that radar information is not obscured or degraded and shall not clearly differ from other data.

Any malfunction of displayed ENC shall not affect the operation of the radar/AIS system.

### 3.2.69 Alarms and indications shall comply with requirements given in 3.1.17.

Alarm shall be provided to alert of “picture freeze”. Failure of any sensor interfaced to the radar, such as gyro compass, log, antenna position sensor, video signal, synchronizing signal, shall be alarmed.

In case of the radar failure, provision shall be made for transfer to available standby means or arrangements shall be made to continue the radar operation with some system functionality limitations.

### 3.2.70 When multiple radars operate jointly, the system shall safeguard against single point system failure.

When an integrated multiple radar system includes components of the same purpose, provision shall be made for switching between them.

The mode used to receive and process the radar information as well as the operational data on system status shall be indicated at each radar position.

#### 3.2.71 The radar system shall be capable of being switched “on” or “off” at the main system radar display or at an additional control position.

The radar control functions may be implemented as an individual control panel or with a programmed access (e.g. on-screen menu) or a combination of these.

The main control functions are as follows:
- radar standby/run;
- range scale selection;
- gain control;
- manual tuning function (if appropriate);
- suppression of rain clutter;
- suppression of sea clutter;
- AIS signal processing on/off;
- alarm acknowledge;
- marker control;
- electronic bearing line control;
- variable range marks control;
- display brightness control;
- radar target acquisition.

The primary functions, in addition to the main system radar display, may be operated at the remote control position.

#### 3.2.72 The radar design shall be so that to provide automatic performance testing and failure diagnosis.

The radar system shall include means to record the total operating hours for equipment and its components with a limited life.

Radar maintenance requirements shall be listed in the technical documentation.

#### 3.2.73 Provision shall be made to switch off automatically high-frequency radiation within the pre-set sectors.

These sectors shall be clearly indicated.

#### 3.2.74 The radar antenna shall be designed to operate reliably in wind speeds likely to be encountered on the class of ship on which it is installed.

Antenna lateral lobes shall comply with the requirements given in 2.7, Part VI of the Rules.

The radar rotation shall be such as to provide information update rate as appropriate for the ship where it is installed, as stated in 2.3.17.

Means shall be provided to stop antenna rotation and electromagnetic radiation.

3.2.75 The radar documents shall contain recommendations on the radar installation.

Measures shall be taken to avoid shadow sectors from right ahead up to relative bearings of 22.5° abaft the beam on each side.

The antenna shall be so located that the ship structures and deck cargo do not reflect electromagnetic radiation.

The antenna shall be located at such a height that to provide target detection at close range in adverse conditions of sea clutter.

The radar display shall be installed so that not to interfere visual observation of the situation ahead and to avoid display glare from light sources in the wheelhouse.

3.2.76 The radar system shall be capable of receiving the required information in NMEA format from:

- gyro compass or heading data transmitter;
- devices measuring speed and travelled distance;
- electronic position-fixing means;
- AIS equipment;
- other devices generating the same data and approved by the River Register.

3.2.77 Means shall be provided in the radar system to preclude the use of invalid data. The data validity shall be identified on the radar display.

The radar shall provide checking the integrity of data from external sensors.

The latency of checking and processing the input data shall not exceed 10 ms.

3.2.78 It shall be possible to provide radar information in standard format to other ship’s systems.

The radar system shall provide radar image output from the display to the voyage data recorder.

At least one isolated normally closed contact shall be provided for indicating general failure of the radar.

The radar shall have a bi-directional interface to the joint systems to facilitate communication so that alarms indicating failure of the radar can be transferred and audible alarms can be remotely muted.

3.2.79 In the event of failure in receiving input data necessary for operation of the radar, there shall be an appropriate indication. In the event of failure of heading indicator, the radar shall be able to continue operation in an "unstabilized heading up" mode.

The stabilization mode shall be changed automatically within 1 min after a failure of the heading indicator.

If automatic anti-clutter sea processing could prevent from detection of targets in the absence of azimuth stabilization, this processing mode shall be disabled automatically within 1 min.

An indication shall be given on the radar display when only relative bearing measurement mode is used.

In the event of failure of the device measuring speed through water, means for manual speed input shall be provided.

In the event of failure of devices measuring speed and travelled distance over ground, the equipment shall be switched to the speed through water sensor.

In the event of failure of electronic position fixing means, ENC shall be displayed if only at least a single reference point with known position is used or if ship position is manually entered.

In the event of failure of radar signal emission and reception equipment, the radar display shall continue to indicate AIS targets.

In the event of failure of AIS input information, the radar display shall indicate the radar video and target database.

In the event of failure of information from other ship’s systems interfaced to the radar, the radar shall keep operating as a standalone system.

3.2.80 The radar design shall include the target simulation function.

3.2.81 The technical documentation package to be supplied by the radar manufacturer
shall comprise the Radar operating manual in Russian, which shall contain the following information:

- recommended control/adjustment settings for different weather conditions and the station operating conditions;
- radar performance characteristics;
- failure procedures and contingency operation procedures;
- limitations of the display and tracking process and accuracy, including any delays in processing and presentation of information;
- using own ship heading and speed over ground/course over ground information for collision avoidance;
- conditions and limitations of target association and separate target presentation;
- criteria of selection for automatic acquisition of AIS targets and cancellation of activation;
- methods and limitations of displaying AIS targets;
- principles underlying the trial manoeuvre technology, including simulation of own ship’s manoeuvring characteristics, if provided
- list of alarms and indications;
- equipment installation and arrangement requirements;
- range and bearing measurement accuracies;
- special radar tuning and operator’s actions, e.g. for detection of SARTs;
- the value of the fixed common reference point of own ship in the information processing and presentation process.

3.2.82 Ship technical documentation shall contain description of radar, including factors affecting its characteristics.

Criteria of target selection and the accepted method of association and separate presentation of AIS and radar targets shall be specified.

Equipment installation and arrangement requirements, as well as factors, which may affect its characteristics, shall be listed in the technical documentation.

Abbreviations used for presentation of operating modes and other information on the radar display shall comply with abbreviations specified in the Russian River Register Guidelines R.028-2009.

3.3 REQUIREMENTS TO MAGNETIC COMPASS

3.3.1 Voltage of the compass main lighting shall not exceed 24 V.

3.3.2 The magnetic compass shall indicate the heading with accuracy:
- underway on calm water 1°
- at motion in any direction with angles of heel up to 22.5° and period of 6–15 sec.
- 5°

3.3.3 The card of the master and steering compasses shall allow for readout with up to 0.5° accuracy. The card scaling factor shall not exceed 1°.

3.3.4 The magnetic compass shall include a damping mechanism to provide the card stability under the ship’s vibrations and a device to maintain normal position of the compass bowl vertical axis.

3.3.5 The gimbaled compass bowl shall maintain its horizontal position when the binnacle is tilting up to 45° in any direction. The card shall remain free when the bowl is tilting in any direction to an angle no less than:
- for gimbaled compasses 10°
- for gimballess compasses 30°

3.3.6 The magnetic compass shall include a device for semicircular, quadrant, heeling and latitude correction. This device shall correct the compass deviation with an accuracy not exceeding 0.2°.

3.3.7 The magnetic compass design shall provide such deviation correction that residual deviation values do not exceed ±3° for the master compass and ±5° for the steering compass.

3.3.8 The magnetic compass shall have a binnacle and electric lighting of the card to make the card divisions visible. In addition to the basic lighting, provision shall be made for emergency lighting and for brightness adjustment function.

3.3.9 The height of binnacle of the master compass shall be such as the compass bowl
glass plane, including the supporting pad, is at a height not less than 1300 mm from the deck.

3.3.10 The master magnetic compass shall be fitted with a locator to take bearings to objects and celestial bodies visible from the ship with a readout accuracy of 0.25°. The locators of a new design shall provide direct taking bearings.

3.3.11 It shall be possible to read correctly the steering compass card at a distance not less than 1.4 m both in natural and artificial light. It is allowed to use magnifying devices.

3.3.12 The electric remote reading magnetic compass shall comply with the requirements given in 3.3.2 – 3.3.10 and shall provide heading to repeaters for indication.

3.3.13 The magnetic system of the master magnetic compass or magnetic sensing units may be used as a sensing element of the electric remote reading compass.

3.3.14 If the magnetic system of the master magnetic compass is used for remote reading, the device used for electric reading transmission to repeaters shall ensure no interferences for location, for heading and bearing readout from the compass card, and for deviation correction.

3.3.15 The sensing element shall include a deviation correction device in accordance with the requirements given in 3.3.6 and 3.3.7. The sensor and the whole electric remote reading system of the magnetic compass shall remain operable under the following ship motion conditions:

1. turning motion at the rate up to 6°/s;
2. yawing with period of 10 to 20 sec. and the greatest deviation from set heading of ±5°.

3.3.16 The difference between the readings of repeaters and the sensing element of the remote reading magnetic compass shall not exceed 1°.

3.3.17 Disabling remote signal transmission or particular repeaters failure shall not affect reading accuracy of the master compass and remaining repeaters.

3.3.18 Provision shall be made for audible alarm to signal a failure of follow-up system in the electric remote reading magnetic compass. The audible alarm shall be energized by a separate circuit.

3.3.19 The package of electric remote reading magnetic compass shall include the annunciator with inscriptions "Repeaters are showing data from the magnetic compass" or "Repeaters are showing data from the gyro-compass".

3.3.20 The optic remote reading magnetic compass shall be designed to display a directly reflected image of the card scale sector with visible graduations on the arc not less than 30°, and the lubber line fixed in the compass bowl casing. The device shall be provided to receive the card scale image from fore and aft sides of the periscope.

3.3.21 The periscope of the optic remote reading magnetic compass's optic path shall be so long as the installation of the compass on the pad, considering the periscope mast passing through the deck, shall allow for the screen location at the helmsman's eye level. Provision shall be made for the screen moving to 100–150 mm up and down from the middle position.

3.3.22 The screen shall be fitted with arrangement to protect it from bright sunlight or any other light, which can glare the card screen image. The screen image shall be visible day and night.

3.3.23 The design of the optic path and the screen shall provide that the image of the card scale sector remains clear during visual taking bearings, and when the compass helmet is closed.

3.3.24 It shall be possible to adjust and lock the screen position.

3.3.25 The optic path shall have at least IP56 protection degree. Measures shall be taken to prevent sweating on the path and
moisture condensation inside it, as well as to provide access to the optics for cleaning.

3.3.26 The boat magnetic compass shall comply with the following requirements:

1. The compass scaling factor shall be 1°, 2° and shall not exceed 5° subject to the card diameter;

2. The compass card shall be fitted with lighting;

3. Provision shall be made for the compass securing arrangement and a storage case;

4. The card diameter shall allow for readout.

3.4 REQUIREMENTS TO GYROCOMPASS

3.4.1 At latitudes up to 60° the gyrocompass mounted on a horizontal and fixed base shall comply with the following requirements:

1. The gyrocompass settling time shall not exceed 6 h;

2. A steady reading accuracy on any heading shall be limited to \( \pm 0.75 \times \sec Lat \), where \( Lat \) = geographic latitude, degrees; the root mean square of differences between particular heading readings and the average heading value shall be less than \( \pm 0.25 \times \sec Lat \);

3. A turn-on reading consistency shall be within \( \pm 0.25 \times \sec Lat \);

4. The compass follow-up rate shall be not less than 6°/sec.

3.4.2 The onboard gyrocompass operating at latitudes up to 60° shall comply with the following requirements:

1. The gyrocompass settling time shall not exceed 6 h under conditions of harmonic rolling and pitching up to 5° with a period of 6 to 15 sec at a maximum acceleration of 0.22 m/sec²;

2. The master compass reading accuracy shall be within \( \pm 1 \times \sec Lat \) under operating conditions subject to modification of the ship’s power mains and variation of magnetic fields on board the ship;

3. Reading accuracy related to quick change of the ship’s speed shall not exceed 2°;

4. Reading accuracy related to a quick 180 degree change of the ship’s heading at a speed up to 36 km/h shall not exceed 3°;

5. Residual error of readings after correction of effects related to speed, heading and latitude, where applicable, at a constant speed up to 36 km/h shall not exceed \( \pm 0.25 \times \sec Lat \);

6. Reading accuracy related to rolling up to 20°, pitching up to 10° and the ship’s yawing up to 5° with a period of 6 to 15 sec with maximum horizontal acceleration not exceeding 1 m/sec² shall not exceed \( \pm 1 \times \sec Lat \);

7. Differences between readings of repeaters and the master gyrocompass shall not exceed 0.5°.

3.4.3 The gyrocompass shall be completed with a heading recorder and a device to correct the compass readings to the ship’s speed and latitude of fix.

3.4.4 The gyrocompass follow-up system shall be designed so as to provide simultaneous operation of own repeaters and heading recorder, as well as repeaters of other navigation equipment.

3.4.5 The heading recorder shall provide timed heading record with an accuracy of 1 %.

3.4.6 The design of repeater cards, locators, lighting and other arrangements shall allow for heading and bearing readout in accordance with the requirements stated in 3.3.2, 3.3.3, 3.3.8 – 3.3.10.

3.4.7 Device for remote transmission of the true heading at latitudes up to 70°, provided that the used sensing element (heading sensor) remains operable under the ship’s operating conditions (including high-speed operation), shall comply with the following requirements:

True heading data shall be transmitted and displayed with an accuracy not exceeding 0.2°;

Static accuracy defined at the ship’s constant speed and direction shall be less than 1.0°;
Dynamic accuracy defined at rolling and pitching, vibration and variation of the ship’s speed shall not exceed 1.5°. If dynamic accuracy range exceeds 0.5°, its oscillation frequency shall be less than 0.033 Hz (with a period not exceeding 30 sec);

Error due to the ship’s heading change shall not exceed:

- 0.5° at heading change rate up to 10°/sec;
- 1.5° at heading change rate from 10 to 20°/sec;

Controls and regulators allowing for changing the true heading data, transmitted by the device, shall be protected from unintended interference;

Provision shall be made for indicating the manual correction input in data transmitted by the device;

Visual and (or) audible alarm shall be provided for warning the device failure and power supply interruption.

3.5 REMOTE HEADING TRANSMITTING DEVICE

3.5.1 The О-ПП, М-ПП and М-СП class ships of gross tonnage from 300 to 500 not fitted with a gyrocompass complying with the international requirements or with a dedicated device for finding and transmission of magnetic heading, shall be fitted with transmitting heading devices to support operation of other navigational equipment.

3.5.2 The remote heading transmitting device shall have performance characteristics conforming to the requirements given in 3.5.4 at least from 70°N to 70°S, if this range is not limited by the selected sensing element (heading sensor).

3.5.3 The remote heading transmitting device shall comply with the operation requirements both for conventional displacement ships and high-speed ships.

3.5.4 Under operating conditions given in the requirements to the heading sensors, the remote heading transmitting device operating together with the relevant sensing element shall provide the following accuracy:

- Heading data shall be converted with an accuracy not exceeding ±0.2°;
- The static error measured at permanent speed and direction of the ship shall not exceed ±1.0°;
- The dynamic error measured under the conditions of vibration, roll, pitch or change of speed shall not exceed ±1.5°. If the amplitude of the dynamic error exceeds ±0.5°, the dynamic error frequency shall not exceed 0.033 Hz (with a period of not exceeding 30 sec).

3.5.5 An alarm shall be provided to indicate a malfunctions of the heading transmitting device or a failure of the power supply.

3.6 REQUIREMENTS TO AUTOPILOT AND DIRECTIONAL STABILIZER

3.6.1 The autopilot and directional stabilizer shall provide that the ship maintains a selected heading with an accuracy not exceeding 1° at a speed ensuring normal ship’s manoeuvrability. Maximum deviation from the set heading shall not exceed ±1° at sea state up to 3, and ±3° at sea state up to 5.

3.6.2 Provision shall be made for automatic ship heading keeping with minimum number of rudder shifts.

3.6.3 Provision shall be made for unintentional power interruption light and audible alarm.

3.6.4 Audible alarm shall be provided to indicate the set heading deviation by ±3°, an alarm response tolerance shall not exceed 1°. In case of adverse weather conditions it shall be possible to shift the alarm threshold value by 6 to 9°.

3.6.5 The circuit and design of autopilot and directional stabilizer shall allow for changing over to manual control of steering gear from any control station in case of any damage of the automatic control system.

3.6.6 Changeover from one type of control to another shall be made by a single action within not exceeding 3 sec.
3.6.7 The autopilot and directional stabilizer control console shall be installed on the manual steering control station to provide their maintenance and switch from automatic to manual control.

3.6.8 The control console combining automatic and manual control shall be installed in the wheelhouse in the centreline plane.

3.6.9 The remote control stations shall be installed on the bridge wings or in other places used for switching to the ship steering from the remote control station.

3.7 REQUIREMENTS TO ECHO SOUNDER

3.7.1 The echo sounder shall be capable of measuring soundings under the ship’s bottom starting from 0.5 m.

3.7.2 The echo sounder shall have:
- shallow-water scale;
- deep-water scale with maximum depth not less than 50 m.

3.7.3 Sounding accuracy shall be not less than:
- 10 cm at depths up to 5 m;
- 2 % of measured depth at depths more than 5 m.

3.7.4 Sounding and sea bottom recording shall be continuous. Soundings shall be presented in two modes:
- graphic data to represent a seabed profile of the ship run with time mark discreteness not exceeding 5 min;
- numeric data to represent an instantaneous depth with values divisible by 0.1 m.

3.7.5 The priority shall be given to the graphical presentation of soundings to represent an instantaneous depth and its visual recording. The displayed record of soundings shall be visible within not less than 15 min.

3.7.6 The echo sounder indications may be recorded on paper tape or other media. Provision shall be made for recording the soundings with time marks for previous 12 h, and for all recorded data retrieval on shore.

3.7.7 The echo sounder shall provide audible and light depth control alarm. Manual setting of depth shall be gradual within the range from 0.5 to 5.0 m or on intermittent basis.

Provision shall be made for making ship draught corrections and sound-in-water speed corrections without stopping the ship or opening the device housing.

3.7.8 The echo sounder shall be switched on by a single action. The echo sounder startup time shall not exceed 30 sec, measuring scales switching shall be simultaneous for graphic and numeric data.

The echo sounder may include one or several emitters. Provision shall be made for indicating the used emitters.

3.7.9 The echo sounder shall be able to operate continuously. Its design shall include audible and light alarm warning on failures affecting displayed data validity.

3.7.10 If the ship design allows for the echo sounder operation as a part of complex navigation systems, the interface with these systems shall be provided by means of standard digital outputs.

3.7.11 It is allowed to operate echo sounders, whose performance characteristics differ from those given in 3.7.1 – 3.7.10 and in 3.7.12 – 3.7.15, for М-СП, М-ПР and О-ПР class ships outside inland waterways.

3.7.12 The echo sounder shall be capable of measuring soundings under the ship’s bottom starting with 1.0 m.

3.7.13 The echo sounder shall have:
- shallow-water scale covering 0.1 of depth range (1 to 20 m);
- deep-water scale with maximum depth not less than 200 m.

3.7.14 Sounding accuracy shall be not less than:
- 50 cm at depths up to 20 m;
- 2.5% of measured depth at depths more than 20 m.

The echo sounder performances shall not degrade at the ship rolling up to ±10° and
pitching up to ±5°. According to technical documentation, some omissions in readings are permissible when the ship is rolling more than 10° and (or) pitching more than 5°, or when the sea bed has rocky or steeply sloping character (over 15°).

3.7.15 The scale of graphic depth displaying shall be not less than:
- 1 m = 5 mm — on the shallow-water scale;
- 1 m = 0.5 mm — on the deep-water scale.

The displayed record of soundings shall be visible within not less than 15 min.

3.8 REQUIREMENTS TO LOG

3.8.1 The log shall continuously record the distance covered by the ship at any speed and continuously display the ship's speed data.

The log transmitting the ship speed data to a radar plotting aid (EPA, ATA, ARPA) and/or to the ship track control system shall be able to measure longitudinal speed through water.

3.8.2 Initial sensitivity of the log shall not exceed 0.2 km/h. The log shall measure the ship’s speed through water with an accuracy not exceeding 2% of actual ship speed or ±0.4 km/h, whichever is greater.

3.8.3 The speed indicators shall be of self-synchronous type. Differences between the ship speed indications from the master device and from repeaters shall not exceed 1.5% of upper limit of speed measured by the log. Differences between indications of travelled distance from repeaters and those from the master device shall not exceed 0.02 km, those between repeaters 0.04 km. The log shall have a sufficient number (not less than number of ship steering stations) of speed and travelled distance repeaters for safe navigation.

3.8.4 The log shall be completed with adjusting arrangements to allow for removing unacceptable errors in their readings after the log is installed on board the ship.

3.8.5 Speed data may be presented both in analog and digital form. Reading increment of the digital indicator shall not exceed 0.1 km/h, that of the analogous indicator with normal scale 0.5 km/h, that of analogous indicator with coarse scale 5 km/h.

3.8.6 Data on covered distance shall be presented in numerical form. The indicator shall cover the range from 0 to at least 9999.9 km with increment not exceeding 0.1 km, it shall have a resetting unit. Scales of the master device and repeaters shall be fitted with adjustable electric highlighting allowing for data readout day and night.

3.8.7 The log shall comply with the following requirements:

.1 Underwater retractable units of the log shall allow for their extending to operating position and retracting inside the hull by a single operator;

.2 The method of attaching the log units to the ship hull, their afloat replacement and possible damage of any part of underwater equipment shall not result in affecting the structural integrity of the ship hull or ingress of water inside it;

.3 If a retractable unit weighs more than 16 kg, its retraction inside the hull shall be provided by means of mechanical arrangements (winches, tackles, hoist blocks) or an arrangement for remote lifting and lowering an underwater part of the log, and control of such arrangement shall be from the wheelhouse. Lifting time shall not exceed 2 min.

An arrangement shall be provided for remote lifting and lowering an underwater unit of the log with control from the wheelhouse. In this case, provision shall be made for relevant limit switches to restraint lifting and lowering of the underwater unit in the retractable bottom arrangement, as well as for the bottom arrangement tightening, and light indication in the wheelhouse to indicate up and down positions of the underwater unit and closed position of the bottom arrangement, if so prescribed by technical documents and if applicable to the log design;

.4 The log shall be completed with a sufficient number of speed and travelled distance repeaters complying with the requirements given in 3.8.3. It is allowed to use speed and
travelled distance repeaters integrated into a single housing.

3.8.8 The log capable of measuring ship’s speed over ground and though the water shall be fitted with an operational switch and an operating mode indicator. The two-component log capable of measuring longitudinal and lateral speeds shall be provided with indication of operating mode and measured parameter.

3.8.9 The primary transducers of the log shall not cause interference for the operation of other ship navigation equipment.

3.9 REQUIREMENTS TO GNSS
GLONASS/GPS RECEIVER

3.9.1 The combined GLONASS and GPS receiver designed for navigation-purpose use on the ships with speed not exceeding 130 km/h (70 knots), shall include at least the following:

.1 antenna to receive GLONASS/GPS signals;
.2 combined GLONASS/GPS receiver and processor;
.3 means to calculate position (latitude, longitude);
.4 controls and interfaces;
.5 position display unit.

3.9.2 GLONASS/ GPS receiver shall provide:

.1 receiving and processing the signals provided by the Standard Positioning Service (SPS) with selective availability and GLONASS ranging code on, as well as calculating the ship’s position latitude and longitude in WGS-84 datum in degrees, minutes, thousandths of a minute and position fix time with regard to Universal Time Coordinated (UTC). Provision shall be made for converting WGS-84 coordinates to PZ-90 coordinates or coordinates of a datum provided in the used navigational chart

The receiver display unit shall indicate the coordinates conversion mode and datum used for displaying the ship’s position, if such function is prescribed by the technical documentation;

.2 operating on GPS L1 frequency signal and C/A code, and GLONASS L1 frequency signal and C code;
.3 the static mode precision such that ship’s antenna position is calculated with accuracy within 35 m for 95 % probability without a differential subsystem and within 10 m for 95 % probability with a differential subsystem and horizontal dilution of precision equal to 4 or positional dilution of precision equal to 6;
.4 the dynamic mode precision such that ship’s position is calculated with accuracy within 35 m for 95 % probability without a differential subsystem and within 10 m for 95 % probability with a differential subsystem and with horizontal dilution of precision equal to 4 or positional dilution of precision equal to 6 subject to sea state and navigation conditions;
.5 the opportunity to select automatically relevant satellites transmitting signals for calculating the ship’s position with an appropriate accuracy and data updating discreteness;
.6 searching and processing the satellite signals at variation of their input carrier frequency level from –130 dBm to –120 dBm. After the signals search being completed, the receiver shall keep working with carrier frequency signals level decreased to –133 dBm;
.7 the opportunity to receive the first measurements of coordinates with an appropriate accuracy within 30 min, if no actual database (almanac) is stored in the receiver memory;
.8 the opportunity to receive coordinates measurements with an appropriate accuracy within 5 min, if the actual database is stored in the receiver memory;
.9 re-searching the signals and calculating the fixed coordinates with an appropriate accuracy within 5 min, in the case, when emission of all GLONASS/GPS signals is interrupted for a period at least 24 h, but without power supply interruption;
.10 re-searching the signals and calculating the fixed coordinates with an appropriate accuracy within 2 min in case of power supply interruptions for up to 60 sec;
.11 re-searching a particular satellite signal and using it for calculating the fixed coordinates within 10 sec after signal locking for up to 30 sec;

.12 calculating the fixed coordinates and new data output to the display unit and interface for marine radio navigational aids with discreteness not exceeding 1 sec;

.13 the minimum resolution of displayed coordinates (latitude, longitude) up to 0.001 min;

.14 calculating, displaying and output to the interface the following: course over ground (COG), speed over ground (SOG) and UTC. The said output data shall have a time mark linked to the ship's position data.

The requirements to the accuracy of the course over ground and speed over ground shall be not less than operational requirements imposed on heading indicators (see 3.3.2) and speed and travelled distance meters (see 3.8);

.15 the opportunity to receive and to process correction signals provided by differential subsystem (DGLONASS/DGPS) complying with recommendations of the International Telecommunications Union (ITU) and national standard1.

3.9.3 The receiver shall provide indication when calculated position does not comply with the operational requirements given in 3.9.2.

3.9.4 The receiver shall provide indication within 5 sec when:

.1 The horizontal dilution of precision exceeds a stated limit value;

.2 New position is calculated within a time period exceeding 1 sec.

In the above cases until normal operation of the receiver is restored, the display unit shall indicate time and position of the last reliable position fix with visual indication of a reason, due to which position fix (calculation) was interrupted.

3.9.5 The receiver shall be provided with alarm warning on failure of position calculation.

3.9.6 The receiver shall provide for indication of differential operating mode, in case of:

.1 receiving the differential correction signals;

.2 including the differential corrections in the displayed ship's position.

3.9.7 The receiver shall provide indication about loss of use (integrity) and critical condition of the differential mode, as well as displaying the differential mode message on the display unit.

3.9.8 The equipment receiving signals from sea beacons transmitting differential corrections provided by GLONASS and GPS global positioning systems, which is designed for navigation-purpose use on the ships with speed not exceeding 130 km/h (70 knots) shall include at least the following:

.1 antenna to receive correction signals from DGLONASS and DGPS sea beacons;

.2 receiver of correction signals from DGLONASS and DGPS sea beacons, and processor;

.3 receiver control and data output interfaces.

3.9.9 The receiving equipment shall provide the following:

.1 receiving and processing the correction signals from DGLONASS and DGPS sea beacons within frequency band of 283.5 to 325 kHz;

.2 availability of means for automatic and manual station selection;

.3 data availability with delay not exceeding 100 ms after the signal receiving;

.4 receiving and processing a signal within not less than 45 sec under atmospheric noise conditions;

.5 availability of nondirectional antenna in the horizontal plane.

3.10 REQUIREMENTS TO GPS RECEIVER

3.10.1 GPS receiver designed for navigation-purpose use on the ships with speed not exceeding 130 km/h (70 knots) shall include at least the following:

.1 antenna to receive GPS signals; 
.2 GPS receiver and processor; 
.3 means to calculate position (latitude, longitude); 
.4 controls and interfaces; 
.5 position display unit and other outputs, if necessary.

3.10.2 GPS receiver shall provide the following:

.1 receiving and processing the signals provided by the Standard Positioning Service (SPS) with selective availability on, as well as for calculating the ship's position latitude and longitude in the World Geodetic System 1984 (WGS-84) datum in degrees, minutes, thousandths of a minute and position fix time with regard to Universal Time Coordinated (UTC). Provision shall be made for converting WGS-84 coordinates to coordinates of the datum in the used navigational chart. If such provision is prescribed by technical documentation, the receiver display unit shall indicate the coordinates conversion mode and the datum used to calculate the ship's position;

.2 operating on L1 (1575.42 MHz) frequency signal and C/A (Coarse/Acquisition) code. It is allowed to operate also on L2 (1227.6 MHz) signal with use of high-precision code P (Precise);

.3 the static mode precision, at which the ship's antenna position is calculated with accuracy within 100 m for 95% probability and with horizontal dilution of precision (HDOP) equal to 4 or positional dilution of precision (PDOP) equal to 6;

.4 the dynamic mode precision, at which the ship's position is calculated with accuracy within 100 m for 95% probability without a differential subsystem and horizontal dilution of precision equal to 4 or positional dilution of precision equal to 6 subject to sea state and navigation conditions;

.5 the opportunity to select automatically relevant satellites transmitting signals for calculating the ship's position with an appropriate accuracy and data updating discreteness;

.6 searching and processing the satellite signals at variation of their input carrier frequency level from –130 dBm to –120 dBm. After the signals search being completed, the receiver shall keep working with carrier frequency signals level decreased to –133 dBm;

.7 the opportunity to receive the first measurements of coordinates with an appropriate accuracy within 30 min, if no actual database (almanac) is stored in the receiver memory;

.8 the opportunity to receive the first coordinate measurement with an appropriate accuracy within 5 min, if the actual database is stored in the receiver memory;

.9 re-searching the signals and calculating the fixed coordinates with an appropriate accuracy within 5 min in the case of signals reception interruption for a period at least 24 h, but without power supply interruption;

.10 re-searching the signals and calculating the fixed coordinates with an appropriate accuracy within 2 min in case of power supply interruptions for up to 60 sec;

.11 calculating the fixed coordinates and new data output to the display unit and interface for marine radio navigational aids with discreteness not exceeding 1 sec;

.12 the minimum resolution of displayed coordinates (latitude, longitude) up to 0.001 min;

.13 calculating, displaying and output to the interface the following: course over ground (COG), speed over ground (SOG) and Universal Time Coordinated (UTC). The said output data shall have a time mark linked to the ship's position data.

The requirements to the accuracy of the course over ground and speed over ground shall be not less than operational requirements imposed on heading indicators and speed and travelled distance meters (see 3.9.2.14);

.14 the opportunity to receive and to process correction signals provided by GPS differential subsystem (DGPS) complying with recommendations of the International Telecommunications Union (ITU) and an appropriate standard of the Radio Technical Commission for Maritime Services (RTCM). If GPS receiver is fitted with a unit for receiving and processing the correction signals from differential subsystem, the precision in
static and dynamic modes shall be not less than 10 m for 95% probability (see 3.10.2.3 and 3.10.2.4).

3.10.3 The receiver shall provide indication when calculated position does not comply with the operational requirements given in 3.10.2.

3.10.4 The receiver shall provide indication within 5 sec when:
- the horizontal dilution of precision exceeds a stated limit value;
- new position is calculated within a time period exceeding 1 sec.

In the above cases until normal operation of the receiver is restored, the display unit shall indicate time and position of the last reliable position fix with visual indication of a reason, due to which position fix (calculation) was interrupted.

3.10.5 The receiver shall be provided with alarm warning on failure of position calculation.

3.10.6 The receiver shall provide indication of differential operating mode, in case of:
- receiving the differential correction signals;
- including the differential corrections in the displayed ship’s position.

3.10.7 The receiver shall provide indication about loss of use (integrity) and critical condition of the differential mode, as well as displaying the differential mode message on the display unit.

3.11 REQUIREMENTS TO GLONASS RECEIVER

3.11.1 GLONASS receiver designed for navigation-purpose use on the ships with speed not exceeding 130 km/h (70 knots), shall include at least the following:
- antenna to receive GLONASS signals;
- GLONASS receiver and processor;
- means to calculate position (latitude, longitude);
- controls and interfaces;
- position display unit.

3.11.2 GLONASS receiver shall provide the following:
- receiving and processing the signals provided by GLONASS Standard Positioning Service, and calculating the ship’s position latitude and longitude in PZ-90 (“Parameters of the Earth 1990”) datum with the position presentation in degrees, minutes, thousandths of a minute and position fix time with regard to Universal Time Coordinated (UTC). Provision shall be made for converting WGS-84 coordinates to PZ-90 coordinates or coordinates of a datum provided in the used navigational chart. If such means are available, the receiver display unit shall indicate the coordinates conversion mode and the datum used for displaying the ship’s position;
- operating under the Standard Positioning Service mode on L1 and C code frequencies;
- the static mode precision, at which the ship’s antenna position is calculated with accuracy within 45 m for 95% probability and with horizontal dilution of precision (HDOP) equal to 4 or positional dilution of precision (PDOP) equal to 6;
- the dynamic mode precision, at which the ship’s antenna position is calculated with accuracy within 45 m for 95% probability and with horizontal dilution of precision (HDOP) equal to 4 or positional dilution of precision (PDOP) equal to 6 subject to sea state and navigational conditions;
- the opportunity to select automatically signals transmitted by a relevant satellite for calculating the ship’s position with an appropriate accuracy and data updating discreteness;
- searching and processing the satellite signals at variation of their input carrier frequency level from –130 dBm to –120 dBm. After the signals search being completed, the receiver shall keep working with carrier frequency signals level decreased to –133 dBm;
- the opportunity to receive the first measurements of coordinates with an appropriate accuracy within 30 min, if no actual database (almanac) is stored in the receiver memory;
8. the opportunity to receive the first coordinate measurement with an appropriate accuracy within 5 min, if the actual database is stored in the receiver memory;
9. re-searching the signals and calculating the fixed coordinates with an appropriate accuracy within 5 min, in the case, when emission of GLONASS signals is interrupted for a period at least 24 h, but without power supply interruption;
10. re-searching the signals and calculating the fixed coordinates with an appropriate accuracy within 2 min in case of power supply interruptions for up to 60 sec;
11. calculating the fixed coordinates and new data output to the display unit and interface for marine radio navigational aids with discreteness not exceeding 1 sec;
12. the minimum resolution of displayed coordinates (latitude, longitude) up to 0.001 min;
13. calculating, displaying and output to the interface the following: course over ground (COG), speed over ground (SOG) and UTC. The said output data shall have a time mark linked to the ship's position data.

The requirements to the accuracy of the course over ground and speed over ground shall be not less than operational requirements imposed on heading indicators and speed and travelled distance meters (see 3.9.2.14);
14. the opportunity to receive and to process correction signals provided by GLONASS differential subsystem (DGLONASS).

If GLONASS receiver is fitted with a unit for receiving and processing the correction signals from a differential subsystem, the precision in static and dynamic modes shall be not less than 10 m for 95% probability (see 3.11.2.3 and 3.11.2.4).

3.11.3 The receiver shall provide indication when calculated position does not comply with the operational requirements given in 3.11.2.

3.11.4 The receiver shall provide indication within 5 sec when:
1. the horizontal dilution of precision exceeds a stated limit value;
2. new position is calculated within a time period exceeding 1 sec.

In the above cases until normal operation of the receiver is restored, the display unit shall indicate time and position of the last reliable position fix with visual indication of a reason, due to which position fix (calculation) was interrupted.

3.11.5 The receiver shall be provided with alarm warning on failure of position calculation.

3.11.6 The receiver shall provide indication of differential operating mode, in case of:
1. receiving the differential correction signals;
2. including the differential corrections in the displayed ship's position.

3.11.7 The receiver shall provide indication about loss of use (integrity) and critical condition of the differential mode, as well as displaying the differential mode message on the display unit.

3.12 REQUIREMENTS TO GALILEO RECEIVER

3.12.1 European GALILEO satellite navigation system receiver designed for navigation-purpose use on the ships with speed not exceeding 130 km/h (70 knots), shall include at least the following:
1. antenna to receive GALILEO signals;
2. GALILEO receiver and processor;
3. means to calculate position (latitude, longitude);
4. controls and interfaces;
5. position display unit.

If GALILEO receiver is a part of the integrated navigation system approved by the River Register, this system shall comply with the requirements given in 3.12.1.3 – 3.12.1.5, and additional means may be not needed.

3.12.2 GALILEO receiver shall provide the following:
1. receiving and processing the signals of measuring the position, speed and time on L1 frequency within the band of 1559 to 1591 MHz for a single-channel receiver, which shall generate sky-wave corrections; or
on L1 and E5a frequencies within the band of 1164 to 1215 MHz and 1559 to 1591 MHz, or on L1 and E5b frequencies within the band of 1164 to 1215 MHz and 1559 to 1591 MHz for a two-channel receiver, which shall provide dual-frequency processing of signals for generating sky-wave corrections.

GALILEO signals may be received and processed on three frequencies: L1, E5a and E5b;

1. calculating the ship's position latitude and longitude in WGS-84 datum with displaying the position in degrees, minutes, thousandths of a minute and position fix time with regard to UTC;
2. the static mode precision, at which the ship's antenna position is calculated with an accuracy within 15 m for 95% probability in the horizontal plane and 35 m for 95% probability in the vertical plane for single-channel receivers operating on L1 frequency; and within 10 m for 95% probability in the horizontal plane and 10 m for 95% probability in the vertical plane for two-channel receivers operating on L1 and E5a frequencies or on L1 and E5b frequencies at positional dilution of precision not exceeding 3.5;
3. the dynamic mode precision, at which the ship's position is calculated with the static mode precision subject to operational conditions;
4. the minimum resolution of displayed coordinates (latitude, longitude) up to 0.001 min;
5. time measuring accuracy within 50 ns from UTC;
6. the opportunity to select automatically relevant satellites transmitting signals for calculating the ship's position with an appropriate accuracy and data updating discreteness;
7. searching and processing the satellite signals at variation of their input carrier frequency level from –128 dBm to –118 dBm.

After the signals search being completed, the receiver shall keep working with signal level decreased to –131 dBm;
8. the opportunity to receive the first measurements of coordinates, speed and time with an appropriate accuracy within 5 min, if no actual database (almanac) is stored in the receiver memory;
9. the opportunity to receive the first measurements of coordinates, speed and time with an appropriate accuracy within 1 min, if the actual database is stored in the receiver memory;
10. the opportunity to re-search signals and to calculate fixed coordinates, speed and time with an appropriate accuracy within 1 min in case of signals reception interruption for a period at least up to 60 sec;
11. calculating the fixed coordinates and new data output to the display unit and interface for marine radio navigational aids with discreteness not exceeding 1 sec, and for high-speed craft not exceeding 0.5 sec;
12. calculating, displaying and output to the interface the following: course over ground (COG), speed over ground (SOG) and UTC with time mark referred to the ship's position.

The requirements to the accuracy of the course over ground and speed over ground shall be not less than operational requirements imposed on heading indicators and speed and travelled distance meters and shall be met under different dynamic conditions of the ship operation (see 3.9.2.14).

3.12.3 In addition GALILEO receiver shall have:
1. output for receiver failure indication;
2. bidirectional interface to allow communications when transmitting receiver alarm to an external system in such a way, that audible alarms can be acknowledged from that external systems;
3. means to process correction signals from GALILEO differential subsystem (DGALILEO), and indicating the reception of DGALILEO signals and their including in calculation of the ship's position.

3.12.4 The receiver shall provide indication about loss of GALILEO system use, when its technical characteristics are beyond the limits imposed by the requirements on conventional navigation in open sea, coastal water, near ports and inland water ways.
3.12.5 GALILEO receiver shall at least:

.1 provide indication, within 5 sec, in case of position calculation failure or, if new position is calculated within a period exceeding 1 sec. In the above cases until normal operation of the receiver is restored, the display unit shall indicate time and position of the last reliable observation with visual indication of a reason, due to which position fix was interrupted;

.2 use the receiver autonomous integrity monitoring (RAIM) to ensure integrity of technical characteristics complying with the implemented task.

3.12.6 In receivers processing the signals from the Safety of Life Service (SOL), integrity monitoring and notification algorithms shall be based on combination of GALILEO integrity message and the receiver autonomous integrity monitoring.

The receiver shall supply alarm within 10 sec from start of the event, if error threshold in the horizontal plane is exceeded by 25 m within more than 3 sec.

Event detection probability shall be over 99.999% for a three hour period (integrity risk not exceeding $10^{-5}/3$ h).

3.13 REQUIREMENTS TO RATE-OF-TURN INDICATOR

3.13.1 The rate-of-turn indicator shall comply with the requirements given in 1.3.1 and shall indicate rate and direction (starboard or port) of ship turning.

3.13.2 The rate-of-turn indicator may be a separate device or a part of other equipment or may receive data therefrom.

3.13.3 The rate-of-turn indicator shall not result in performance degradation of other equipment, to which it is connected, whether it is switched on or off.

3.13.4 Indicators and controls shall have highlighting with smooth adjustment of light brightness and allowance for its switching off at minimum brightness level position.

3.13.5 Provision shall be made for use of the rate-of-turn indicator both under automatic and manual control of the ship's motion.

3.13.6 If the rate-of-turn indicator goes outside the range of specified measuring accuracy, the warning alarm shall automatically switch on.

3.13.7 Provision shall be made for the external signalling connector to output signals in the following case:

.1 the rate-of-turn indicator is off;

.2 the rate-of-turn indicator fails;

.3 activating alarm warning on accuracy degradation exceeding admissible limits.

3.13.8 With regard to the Earth rotation influence, the indicated rate of turn shall not differ from the actual ship's rate of turn by more than 0.5°/min. +5% of the measured value.

3.13.9 The rate-of-turn indicator shall remain serviceable during the ship yawing in waves.

The indicator readings shall not differ from the mean actual rate of turn by more than 0.5°/min. at the ship rolling with an amplitude of ±5° and a period of 25 sec, and at the ship pitching with an amplitude of ±1° and a period of 20 sec.

3.13.10 The rate-of-turn indicator shall be ready for operation within 4 min from its activation. Provision shall be made for indication of its activation.

3.13.11 Rate of turn shall be displayed by means of a dial analog indicator with the top position of zero. It is allowed to use dials with alphanumerical characters. In any case the direction of turn shall be indicated.

3.13.12 The ship's turn to port shall be indicated to the left of the zero point, turn to starboard – to the right of the zero point. If actual rate of turn exceeds the dial limits, it shall be displayed on the indicator.

3.13.13 The dial size to every direction from zero shall be not less than 120 mm. The system shall have such sensibility that variation of rate of turn by 1°/min. corresponds to not less than a 4 mm interval on the dial.
3.13.14 Provision shall be made for a linear scale with a measuring range not less than ±30°/min. This scale shall have a factor of 1°/min. to each direction from zero and numerical characters every 10°/min. Each mark of 10°/min. shall be much longer than the mark of 5°/min., which in turn shall be longer than the mark of 1°/min. Marks and digits shall be red or white on black background. It is allowed to use extra linear scales.

3.13.15 Provision shall be made for adjustable damping of rate-of-turn indicator allowing for time constant variation range from 0 to 10 sec.

3.13.16 The rate-of-turn indicator units shall be supplied from the main and emergency power sources.

3.14 REQUIREMENTS TO PRESENTATION OF NAVIGATION-RELATED INFORMATION ON SHIPBORNE NAVIGATION DISPLAYS

3.14.1 If the display is multifunctional, provision shall be made for clear indication of its operating mode and primary function (radar, Inland ECDIS, ECDIS).

3.14.2 If an electronic navigation chart and radar image of environmental conditions are displayed together, both images shall use a fixed common reference point and match in scale, projection and orientation. Any mismatch shall be indicated.

3.14.3 The following range scales shall be provided on the display: 0.25, 0.5, 0.75, 1.5, 3, 6, 12 and 24 nm. Other range scales may also be provided. Actual range scale shall be indicated.

3.14.4 When range rings are displayed, the scale of each ring shall be indicated.

3.14.5 Only navigational information shall be permanently displayed in the range of the operational display area. Information windows, menus and other auxiliary information may be displayed only as a provisional measure for a period set by the navigator.

3.14.6 Radar display, tracked radar targets and Automatic Identification System (AIS) targets shall not be substantially degraded, masked or obscured by other presented information.

3.14.7 It shall be possible to temporarily suppress all graphic information from the display, retaining only radar image and target trails for a period set by the navigator.

3.14.8 The brightness of radar echoes and associated graphic symbols for tracked radar targets shall be variable.

It shall be possible to control the brightness of all displayed information. Brightness of graphics and alphanumeric data shall be controlled separately.

The brightness of the lubber line shall not be variable to complete extinction.

3.14.9 If the radar indicates vector chart data, it shall be possible to select separately elements of standard electronic navigation chart basing on categories or levels but not by individual chart symbols. The chart information shall be displayed complying with the operational requirements to the Inland ECDIS/ECDIS and the requirements of this Chapter.

3.14.10 When the electronic navigational chart is displayed on the radar presentation, its status, the source of updating and source of information shall be permanently indicated. Here, the radar information shall have priority.

3.14.11 The ENC graphic may be presented on the radar display, but it shall not substantially degrade, mask or obscure the radar image, tracked radar targets and AIS targets.

3.14.12 The electronic navigational chart and all updates to it shall be presented on the ECDIS display without any degradation of their information content.

3.14.13 Chart information shall not be substantially degraded, masked or obscured by other presented information.
3.14.14 It shall be possible to temporarily suppress all supplemental information from the display, retaining only ENC related information contained in the base of the display unit of the Inland ECDIS/ECDIS for a period set by the navigator.

3.14.15 It shall be possible to select a safe depth contour from the contour database provided by the electronic navigational chart. This selected safety depth contour shall be highlighted on the display.

3.14.16 It shall be possible to select a safety depth from the spot soundings presented on the chart. Soundings equal to or less than the safety depth shall be highlighted.

3.14.17 An indication shall be provided if the information is displayed at a larger scale than that contained in the ENC, or if own ship’s position is covered by an ENC of a larger scale than that provided by the display.

3.14.18 Overscaled areas displayed on the Inland ECDIS/ECDIS shall be identified.

3.14.19 Radar and target information displayed on the Inland ECDIS/ECDIS shall not substantially degrade, mask or obscure the chart information. Radar and target information shall be presented in accordance with the radar operational requirements and the requirements of this chapter.

3.14.20 Radar and target information shall be clearly distinguishable from the chart information. It shall be possible to remove this information by navigator’s single action.

3.14.21 Information from additional sources may be displayed on ECDIS but shall not substantially degrade, mask or obscure the chart information.

3.14.22 Additional information shall be distinguishable from the chart information. It shall be possible to remove this information by navigator’s single action.

3.14.23 It shall be possible to present information in any form at the navigator’s option. In this case it shall be possible for the navigator to present a composite radar and chart display with entering own ship’s data.

3.14.24 The form of information presentation shall comply with the requirements to radar (see 3.2) or chart information\(^1\). Presentation exceptions are referred to the sizes of presented area, as well as to windows and incuts of images of particular water area sections.

3.14.25 It shall be possible to adjust the contrast and brightness of the display as applied to the lighting conditions in the wheelhouse.

3.14.26 Provision shall be made for protecting the display from electromagnetic field effect at its location with regard to the requirements given in 2.7 Part VI of the Rules.

3.14.27 The operational display area of the chart presentation for in-route plotting shall be at least 270 × 270 mm.

3.14.28 The operational display area of the radar presentation shall be at least a circle of diameter of:

- 180 mm for ships with gross tonnage less than 500;
- 250 mm for the ships of gross tonnage more than 500 and high-speed craft of gross tonnage less than 10000;
- 320 mm for ships with gross tonnage more than 10000.

3.14.29 Displays intended for navigation information presentation shall be multicoloured, except where monochrome displays are permitted by the Rules.

3.14.30 Multicoloured displays including multifunction displays shall provide not less than 64 colours. Displays of logs, echo sounders and GNSS receivers may provide for presentation in less number of colours.

3.14.31 Displays mounted in the wheelhouse shall provide a minimum resolution of 1280 × 1024. For displays of particular devices, such as log, echo sounder and GNSS

---

receivers, it is permitted to use the displays with less resolution.

3.14.32 The display shall support the reading of information simultaneously by at least two navigators, from standing and sitting positions under all lighting conditions in the wheelhouse.

3.14.33 The presentation of navigation information shall be consistent with respect to the equipment purpose prescribed by its technical documentation and to the place of display installation at the steering station according to 2 of this Part of the Rules.

3.14.34 Information and functions of controls shall be grouped according to purpose and approved technical documentation. To outline the priority information, sizes and colour of the image as well as its arrangement on the display shall be used.

3.14.35 The presentation of navigation information shall combine particularly the following data: a parameter, its measurement unit, information purpose and source, validity and integrity of displayed information.

3.14.36 The presentation of information shall be separated into an operational display area (e.g. chart, radar) and one (or more) user dialogue areas (e.g. menus, information data, control functions).

3.14.37 The presentation of alphanumeric data, text, symbols or other graphical information (e.g. radar image) shall support readability from typical user positions under all ambient light conditions likely to be experienced in the wheelhouse, and with due consideration to the night vision of the officer on watch.

3.14.38 Alphanumeric data and text shall not be presented using italic font. The font size shall be appropriate for the viewing distance from operating workstations in the wheelhouse.

3.14.39 Text shall be presented with no distortions.

3.14.40 In case of using a single display for information from navigation systems and equipment, alarms and indications presentation shall be consistent with regard to presentation of time, reason and source of alarm, as well as to current alarm state (e.g. acknowledged, unacknowledged).

3.14.41 The colours of alphanumeric characters, text, symbols and graphical information presented on the displays shall be contrast against the background under all lighting conditions in the wheelhouse.

3.14.42 It shall be possible to adjust the contrast, colour and brightness of the display as applied to the lighting conditions in the wheelhouse day, night and at twilight. At night information shall be presented on a dark matt background with highlight.

3.14.43 The background colour and contrast shall not affect colour and legibility of the displayed information.

Symbols used for presentation of chart information shall comply with symbols stated by International Hydrographic Organization (IHO).

3.14.45 Information may be coded using image colours. In such cases, the colour of different groups shall differ from each other.

3.14.46 The red colour shall be used for coding of alarm and emergency related information.

3.14.47 Colour coding shall be used in combination with changing in size, form and orientation of symbols.

3.14.48 For unacknowledged alarms information shall be displayed with flashing symbols.

3.14.49 The source, validity and, where possible, the integrity (completeness index) shall be indicated for each type of information. Invalid information shall be appropriately marked.

3.14.50 When colour coding is used, incomplete information shall be qualitatively marked by using yellow, and invalid information shall be qualitatively marked by using red.

3.14.51 Means shall be provided to immediately make the navigator aware of a presentation failure.

3.14.52 The operational status of displayed information shall comply with the requirements specified in Table 3.14.52.

3.14.53 Emergency and accident alarms, as well as event sequence shall be indicated in the alarm list. It shall be possible to set the priority of alarms received from multiple sources. Alarms that have been acknowledged shall be deleted from the list of alarms, but may be retained in an alarm history list.

3.14.54 When a single display is used to present information from multiple navigation systems and equipment, provision shall be made for consistent indication of the time of alarm occurrence, the cause of the alarm, the source of the alarm and the status of the alarm (e.g. acknowledged, not acknowledged) on the display.

3.14.55 Provision shall be made for presentation of own ship position data by means of a scaled conventional symbol or an unscaled symbol specified in the River Register Guidelines P.028-2009. The size of conventional symbol shall be consistent with the scale of navigational chart or be equal to 6 mm, whichever is greater.

3.14.56 The heading line or its displacement vector, shall originate at the position of the fixed common reference point of own ship.

3.14.57 The presentation of chart information published by a duly authorized organization (state hydrographic services or other authorized organizations) shall comply with the relevant national standards and IHO requirements.

3.14.58 Presentation of additional chart information shall comply with 3.14.57. There shall be a clear indication when the presentation is not in accordance with these requirements.

3.14.60 When data derived from different scale charts appear on the display, the boundary of such data shall be indicated.

3.14.61 The radar image shall be displayed using a basic colour (set by the manufacturer) to provide contrast image. Radar target echoes shall be visible on the electronic navigational

---

1 GOST R IEC 61174:2001 (IEC 61174:2001),
GOST R IEC 62376:2010 (IEC 62376:2010),
chart background. The strength of echoes may differ by tones of the same basic colour. Provision shall be made for changing the basic colour according to the lighting conditions in the wheelhouse.

3.14.62 Target trails shall be distinguishable from true targets and clearly visible under all lighting conditions in the wheelhouse.

3.14.63 Target information may be provided by radar tracking and/or by reported target information from the AIS.

3.14.64 Tracking radar targets and AIS targets shall be carried out in compliance with the requirement to radars as specified in these Rules. The presentation of tracked radar and AIS targets shall comply with the requirements of this Chapter.

3.14.65 Interface protocols and format of radar and AIS target data shall comply with national and international standards.

3.14.66 There shall be an indication when the tracked and processed radar and/or AIS target capacity is about to be exceeded.

3.14.67 There shall be alarm signal when the tracked and processed radar and/or AIS target capacity has been exceeded.

3.14.68 Provision shall be made for specifying criteria to activate/filter the sleeping AIS targets. These criteria may be as follows: target range, time and distance to the point of closest approach \((D_{CPA} \text{ et } T_{CPA})\), class of AIS target \((A, B)\), etc.

3.14.69 If sleeping AIS targets are processed using such a filtering, constant indication shall be provided (see 3.14.68). The navigator shall be allowed to set target filtering criteria.

3.14.70 It shall be possible to remove individual AIS targets from the display.

3.14.71 If zones for the automatic activation of AIS targets are provided for the radar, they shall be the same as for automatic radar target acquisition, if available. Any defined zones shall be presented graphically on the display.

3.14.72 Sleeping AIS targets shall be automatically activated when navigating defined parameters (e.g. target range, CPA/TCPA or AIS equipment class).

3.14.73 AIS information shall be graphically presented either as activated or as sleeping targets. Target symbols shall comply with the symbols prescribed by the River Register Guidelines P.028-2009.

3.14.74 Course over ground and speed of tracked radar targets or AIS targets shall be indicated by vectors, which clearly shows the predicted motion. These vectors shall refer to the same time intervals for all the targets regardless of their source.

3.14.75 The presentation of vector symbols shall be consistent irrespective of the source of information. The vector presentation mode shall permanently indicate: operating mode (true / relative motion), stabilization mode (over ground / through water), time interval corresponding to vector length.

3.14.76 The orientation of the AIS target symbol shall indicate its heading. If the heading information is not received, the orientation of the AIS symbol shall be aligned to the course.

When the rate of turn and/or the turning direction are reported from the AIS, the manoeuvre of an activated AIS target shall be displayed.

3.14.77 A fixed common reference point shall be used for the referencing tracked radar/AIS targets and other information on the same display.

3.14.78 On large scale/low range displays, means to present a scaled outline of an activated AIS target shall be provided.

3.14.79 It shall be possible to display the past track of activated AIS targets.

3.14.80 A target selected for the display of its alphanumeric information shall be identi-
3.14.81 When data are presented on the display, provision shall be made for indication of the target status (AIS, radar, combined).

3.14.82 For each tracked radar target selected by the navigator the following data shall be presented in alphanumeric form: source (sources) of data, calculated range of target, calculated bearing of target, predicted target range and time to the closest point of approach, true heading of target, true speed of target. Additional target information shall be provided on request of the navigator.

3.14.83 For each selected AIS target, the following data shall be presented in alphanumeric form: source of data, ship’s identification, position and its quality, calculated range of target, calculated bearing of target, predicted target range to the closest point of approach, course over ground, speed over ground, operational state, target heading and rate of turn. Additional target information shall be provided on request of the navigator.

3.14.84 If the received AIS information is incomplete, the source of the missing data shall be indicated in the target data field.

3.14.85 Target data shall be continually displayed and updated, until another target is selected for data display or until the target data window is closed.

3.14.86 Means shall be provided to present own ship AIS data on request of the navigator.

3.14.87 The alphanumeric displayed data shall not obscure graphically presented information.

3.14.88 A clear indication of the status of the alarms and of the alarm criteria shall be given.

3.14.89 If CPA/TCPA is less than that determined by the navigator, provision shall be made for indication of dangerous radar target or AIS target. In such a case, the target shall be marked by symbol “Dangerous target”.

3.14.90 If the navigator has defined a radar target acquisition zone / AIS target activation zone, the targets entering this zone and the zone itself shall be indicated with the relevant symbol prescribed by the River Register Guidelines P.028-2009, and an alarm shall be given.

3.14.91 If an AIS target has been lost, its last position shall be clearly marked with a special symbol “Lost target”. The lost target alarm shall be given. If the tracking the previously lost target is resumed, that symbol shall be automatically replaced with a normal one. Acknowledgment of alarm shall cause removal of “Lost target” symbol from the display. There shall be a clear indication whether the lost target alarm function for AIS targets is enabled or disabled.

3.14.92 Two target symbols for the same physical target shall never be presented on the display. If data on the tracked radar targets and activated AIS targets are same, the activated AIS target symbol and alphanumeric data of this target shall be automatically displayed.

The navigator shall have an opportunity to change conditions of radar and AIS information association and to choose target presentation as from radar station data or from AIS reports.

3.14.93 If the tracked radar target and the activated AIS target are identified as two distinct targets (data do not match), such targets shall be displayed by different symbols. No alarm shall be activated.

3.14.94 The operational status of AIS information shall be presented in compliance with the requirements specified in Table 3.14.94.

3.14.95 A trial manoeuvre simulation shall be clearly identified by the relevant symbol positioned astern of own ship within the operational display area of the screen as prescribed by the River Register Guidelines P.028-2009.

3.15 REQUIREMENTS TO THE ELECTRONIC CHART DISPLAY AND INFORMATION SYSTEM FOR INLAND NAVIGATION (INLAND ECDIS)

3.15.1 Inland ECDIS shall be capable of displaying all chart information prepared by an authorized organization in order to enhance navigational safety and to solve navigation tasks.

3.15.2 Inland ECDIS shall automatically generate alarms and indications related to displayed data or equipment failures as specified in Table 3.15.2.

3.15.3 For ships with gross tonnage of 1000 and more and for ships engaged on international voyages regardless of their gross tonnage, the size of the chart presented for voyage monitoring shall be not less than $270 \times 270$ mm, for ships with gross tonnage less than 1000, not less than $180 \times 180$ mm.

3.15.4 The display of Inland ECDIS shall provide the following:

1. number of colours — not less than 64;
2. resolution — not less than $1280 \times 1024$;
3. readout distance — not less than 1 m.

3.15.5 The following measurement units shall be adopted in the Inland ECDIS:

1. position — latitude and longitude in degrees, minutes, and tenths, hundredths and thousandths of a minute and/or in degrees and tenths and thousandths of a degree;
2. depth — meters and tenths of a meter;
3. height— meters and tenths of a meter;
4. range — nautical miles and tenths, hundredths and thousandths of a nautical mile and/or kilometres and tenths, hundredths and thousandths of a kilometre, or meters;
3.15.6 Information displayed on the screen shall be visible by at least two observers both by day and by night. It shall be possible to control brightness. Inland ECDIS shall provide at least two colour sets to display the chart and additional information by day and by night. Colour switching and brightness control shall not result in exit from the operation mode.

3.15.7 Whatever mode is selected, Inland ECDIS shall continuously display the following information:

- indicator of ship’s position fixing methods;
- current time and date;
- number of displayed ENC or number of volume and sheet;
- incoming ship’s position coordinates and correction indicator;
- ship’s course and speed over ground coming from a positioning system;
- heading;
- speed;
- depth;
- current scale;
- latest update date.

3.15.8 Inland ECDIS shall provide continuous direct-to-scale chart display with filling all operational display area with data from the available ENC database at any ship’s speed with screen redrawing time of 5 s max.

3.15.9 Inland ECDIS shall display all the SENC information.

3.15.10 SENC information available for display during route planning and ship voyage monitoring shall be divided into the following categories: display base, standard display, and other information.

3.15.11 The display base chart data shall include the following:

- shore line;
- dangerous depth contour for own ship, which shall be determined by the navigator;
- indication of isolated underwater dangers with depth values that are less than depth of dangerous depth contour;
- indication of isolated dangers, including bridges, antenna cables, etc. located within the safe depth area defined by the dangerous depth contour. Buoys and beacons also belong to such dangers whether they are used as aids to navigation or not;
- traffic regulation systems (crossing, a route segment where passing and overtaking of convoys and bulky ships are prohibited, one-way route segment, controlled route segment, etc.);
- units of measurement of height and depth;
- scale, orientation, and presentation mode.

3.15.12 Inland ECDIS shall present the standard display on the navigator’s request by his/her single action. When a chart is displayed for the first time, Inland ECDIS shall provide the standard display in the largest scale available in SENC for a navigation area. The standard display chart data shall include:

- display base;
- area of depths, including a tidal line;
- indication of fixed and floating aids to navigation;
- boundaries of fairways, traffic lanes, etc.;
- visual and radar references;
- roads;
- chart scale boundaries;
- indication of caution symbol.

3.15.13 Other information which shall be displayed on the navigator’s request:

- depth marks;
- submarine cables and pipelines;
- ferry routes;
- details of all isolated dangers;
- details of aids to navigation;
- contents of cautions;
- ENC publication date;
- geodetic datum;
- magnetic variation;
3.15.14 It shall be possible for the navigator to select a dangerous depth contour from among depth contours available in SENC. Inland ECDIS shall highlight the dangerous depth contour over other depth contours on the screen.

3.15.15 It shall be possible for the navigator to select a dangerous depth. Whenever depth marks are selected for display, Inland ECDIS shall highlight depth marks which are equal to or less than the dangerous depth set by the navigator.

3.15.16 ENC information and all update data shall be displayed on the screen with no distortions. It shall be possible to check loading of ENC data and update information into the SENC database.

3.15.17 Manual update data and data entered by the navigator shall be distinguishable from other displayed information.

3.15.18 Radar and other navigational data shall not degrade SENC information contents and shall be distinguishable from it.

3.15.19 If manual input of data referred to a datum other than the ENC datum is needed (manual update, user’s objects), Inland ECDIS shall save entered coordinates and datum attribute, but it shall display them in the chart datum.

3.15.20 The displayed radar information shall meet the following requirements:

- The radar picture and the chart picture shall have the same scale and orientation;
- The radar picture and the position received from a position fixing means shall both be adjusted automatically for antenna offset from the ship steering position (radar and respective receiver antennas);
- It shall be possible to manually match the radar picture to the chart picture;
- It shall be possible to delete the radar picture by navigator’s single action;

3.15.21 Possibility of “north up” and “heading up” orientation of SENC picture shall be provided. Other display modes are permitted.

3.15.22 Inland ECDIS shall provide the following chart and overlaid object display modes:

- “True motion” when the ship’s symbol moves against non-moving chart background within the current screen area;
- “Relative motion” when the ship’s symbol is kept within the centre of the screen or an assigned point of the screen area, and the chart with overlaid information moves synchronously with the ship motion.

The “north up” and “heading up” chart orientation shall be possible for each mode.

3.15.23 Switching to the next screen area display and preparation of this picture shall take place automatically: within the screen redraw cycle in the relative motion mode or when the ship’s symbol approaches the screen edge at a distance set by the navigator in the true motion mode.

3.15.24 It shall be possible to manually replace the chart being used and change the own ship’s position relative to the screen edge.

3.15.25 Inland ECDIS shall be capable of displaying ENC in scales complying with standard navigational chart scales from 1:500 to 1:200,000,000.

3.15.26 It shall be possible to increase and decrease the standard scales. Here, present and initial scales shall be indicated.

3.15.27 Inland ECDIS shall provide indication when:

- Information is displayed in a scale exceeding two-fold ENC scale;
- The ship’s position is covered by ENC data in a scale larger than the display scale.
ENC data and update representation shall conform to the national standard requirements to colours, signs and symbols and shall be distinguishable from the following displayed navigational elements and parameters used in Inland ECDIS:

1. own ship symbol: past track with time stamps according to the primary navigation means; past track with time stamps according to auxiliary navigation means;
2. true vector of heading and speed (over ground);
3. variable range mark and/or electronic bearing line;
4. cursor;
5. “Event” symbol: dead reckoned time and position; estimated time and place;
6. position coordinates and time;
7. danger highlighting;
8. clearing line;
9. reference point;
10. travelled distance;
11. planned heading and speed;
12. planned position with date and time;
13. boundaries of visibility of lights;
14. position and time of turn;
15. left and right edges of navigable pass.

SENC information displayed in the original ENC scale shall use sizes of symbols, figures and letters specified by the national standard mentioned in the footnote to 3.14.24.

Inland ECDIS shall allow the navigator to select whether the own ship is displayed in a scale of currently used chart or as a symbol.

In Inland ECDIS shall use the official ENC of the latest edition with all issued updates created by the authorized agency and complying with the national (international) standard requirements.

It shall be possible to prevent from making changes to ENC contents.

ENC updates shall be stored separately from ENC.

Inland ECDIS shall enable automatic and manual input of SENC update data. By whatever means updates are transmitted to Inland ECDIS, its input procedure shall not affect the chart display process.

Inland ECDIS shall record all update data, including time of inputting them into SENC.

Inland ECDIS shall allow the navigator to display updates to read their contents and to ensure that they have been entered into SENC.

It shall be possible for the navigator to plan a route and monitor the ship motion.

It shall be possible to carry out the preliminary plotting, including straight and curved route segments displayed in the present display scale.

It shall be possible to change the planned route, for example, by:

1. adding waypoints and reference points;
2. deleting waypoints and reference points;
3. changing position of waypoints and reference points;
4. changing sequence of waypoints and reference points.

It shall be possible to plan a reserve route together with the primary one. The route selected by the navigator shall be distinguishable from all other routes.

If the navigator plots a route through the dangerous depth contour, Inland ECDIS shall provide an appropriate indication.

If the navigator plots a route through the boundary of a prohibited area of navigation or a geographical area, in which special conditions of navigation exist as defined in 3.15.43, Inland ECDIS shall provide an appropriate indication.

Areas for which special conditions of navigation exist:

---

.1 area of cables;
.2 area of aerial crossings;
.3 area of pipelines;
.4 area of anchorage;
.5 area where anchorage is prohibited;
.6 deepened area (split);
.7 restricted navigation area;
.8 caution area;
.9 prohibited fishing area;
.10 fishing area;
.11 prohibited passage and overtaking area.

3.15.44 It shall be possible for the navigator to set a limit for possible deviation of the ship from the planned route, which, when reached, shall automatically activate the deviation signal.

3.15.45 When the ship motion is monitored, the chart shall display the selected transit route and the ship’s position.

3.15.46 When the ship motion is monitored, it shall be possible to display any segment of inland waterway which does not show the ship’s position (for example, during analysis of a forthcoming transit route segment, transit route planning, etc.). If it takes place on the screen of the display, which is used for monitoring the ship motion, automatic monitoring functions (for example, current ship’s position fixing, signal generation and indication) shall not be interrupted. It shall be possible to switch to the current ship’s position display mode by navigator’s single action.

3.15.47 Inland ECDIS shall generate a warning signal or indication to inform that in a definite time set by the navigator the ship will cross the dangerous depth contour, boundary of prohibited navigation area, geographical area in which special conditions of navigation exist as defined in 3.15.43, or will reach the navigator-specified distance to the specified limitations.

3.15.48 If the ship deviation from the planned route exceeds the tolerance set by the navigator, a warning signal with indication of deviation side shall be generated.

3.15.49 The displayed ship’s position shall be derived from continuous position fixing performed by a system whose accuracy is consistent with the safe navigation requirements. If the ship design allows for a second independent position fix system, Inland ECDIS shall be capable of identifying discrepancies in position finding between the two sources.

3.15.50 Inland ECDIS shall provide indication if input from any connected positioning system is lost.

3.15.51 Inland ECDIS shall generate a warning to inform that the ship will, after a definite time or distance set by the navigator, reach a reference point on the planned route.

3.15.52 The coordinates received by the navigation equipment and ENC coordinates shall be presented in the same geodetic datum. If this requirement is not met, Inland ECDIS shall generate a warning signal.

3.15.53 It shall be possible to display a reserve route in addition to the selected route. The selected route shall be distinguishable from the other routes. While navigating, the navigator shall be enabled of changing the selected transit route or switching to the reserve route.

3.15.54 It shall be possible to display:
.1 time stamps on ship track line applied manually or automatically at interval of 1 to 120 minutes as specified by the navigator;
.2 appropriate number of points, bearing lines, variable and fixed range rings and other symbols required for navigating purposes and specified in 3.15.28.

3.15.55 It shall be possible to input geographical coordinates of any point and display them on demand. It shall be possible to select any point (mapped objects, symbols or ship’s position) on the display screen and read its geographical coordinates on the navigator’s request.

3.15.56 It shall be possible to manually correct the ship’s position. Manual correction data shall be displayed alphanumerically on the screen and maintained until altered by the operator and automatically recorded in Inland ECDIS.
3.15.57 When the ship crosses the navigable pass edge, Inland ECDIS shall generate a warning signal.

3.15.58 When generating all signals and indications about crossing a safety depth contour and entry into a prohibited area, as well as signals and indications listed in 3.15.2, Inland ECDIS shall use the navigation area charts of the largest scale available in SENC.

3.15.59 Inland ECDIS shall store and be capable of replaying the information specified in this para and required to reconstruct the travelled route and verify the official database used for last 12 hours of navigation. The following information shall be recorded at interval of 10 sec maximum:
- 1. past track of own ship: time, position coordinates, heading and speed;
- 2. information on official data used: ENC source, edition number, publication date, cell name and update history.

3.15.60 Inland ECDIS shall also record past track along all transit route with time stamps at interval of 4 h max. Possibility of tampering the recorded information shall be excluded.

3.15.61 Accuracy of calculations made by Inland ECDIS shall not depend on characteristics of navigational data sensors and shall match SENC accuracy.

3.15.62 When displayed, ENC data proportionality in latitude/longitude shall not change. Inland ECDIS shall be fitted with means for vertical and horizontal image adjustment. The residual error of display in this case shall not exceed 3 % of the screen diagonal size.

3.15.63 The accuracy of reading coordinates shall be not be worse than the electronic chart display resolution.

3.15.64 Inland ECDIS shall not degrade technical characteristics of any navigation equipment and radio equipment used as sensors. Connection of equipment shall not affect performance characteristics of Inland ECDIS specified in this Chapter.

3.15.65 Inland ECDIS shall be interfaced with navigation equipment so as to provide continuous ship positioning, generation of heading and speed, and input of radar information and information of ship’s rate-of-turn indicator.

3.15.66 If Inland ECDIS fails, the corrected set of paper charts shall be used to provide safety of navigation.

3.15.67 Inland ECDIS shall provide possibility of automatic connection to the emergency power source if the normal power source fails or is disconnected.

3.16 REQUIREMENTS TO ELECTRONIC CHART DISPLAY AND INFORMATION SYSTEM

3.16.1 These performance requirements for the Electronic Chart Display and Information System (ECDIS) shall apply to all ECDIS equipment to be installed on all ships of Ì-ÌÑÈ, Ì-ÌÎ and Î-ÌÎ class, which are covered by these Rules, when it is used both at the dedicated standalone workstation and at the multifunction workstation as a part of the integrated navigational system.

3.16.2 The performance requirements shall apply to ECDIS operation mode, ECDIS operating in the Raster Cart Display System (RCDS) mode and ECDIS redundancy means.

3.16.3 The chart data structure, format, encryption and presentation shall comply with the national standard and IHO requirements1.

3.16.4 In addition to the requirements of this Chapter, ECDIS shall comply with 3.14 and the applicable requirements of 6.1 Part VII of the Rules.

3.16.5 To provide effective safety of navigation, ECDIS shall be capable of displaying all SENC chart information issued and distributed in the name of the Government of the Russian Federation by the government authorized hydrographic offices.

---

3.16.6 ECDIS shall provide possibility of updating the electronic navigational charts.

3.16.7 ECDIS shall provide all actions to be carried out for preliminary and in-route plotting with the ship position displayed.

The ship position shall be displayed continuously.

3.16.8 The ECDIS display may also be used to display the radar, radar tracked target and AIS information and other appropriate data layers to support in-route plotting.

3.16.9 ECDIS shall present the navigational information as the paper chart published by hydrographic offices authorized by the Government of the Russian Federation.

3.16.10 ECDIS shall provide appropriate alarms or indications with respect to the navigational information displayed or equipment malfunctions.

3.16.11 ECDIS may operate in the Raster Chart Display System mode. Here, requirements of 3.16.111 shall be met.

3.16.12 The chart information to be used in ECDIS shall be of the latest edition, as corrected with official updates and issued by the Government of the Russian Federation or by government authorized hydrographic office or other relevant government institution.

3.16.13 The SENC contents shall be adequate and up-to-date for all ship route.

3.16.14 It shall not be possible to tamper the information contents of ENC or SENC transformed from ENC.

3.16.15 Updates shall be stored separately from ENC.

3.16.16 ECDIS shall be capable of receiving official updates to the ENC data. These updates shall be automatically applied to SENC. By whatever means updates are received, the application (entering) procedure shall not interfere with displaying the chart currently in use.

3.16.17 ECDIS shall provide possibility of entering updates to ENC manually with simple means for update verification before this update is finally applied to the data.

Updates entered manually shall differ from ENC information and its official updates and shall not affect display legibility.

3.16.18 ECDIS shall store and display on demand update data (update archive) including time of application of update data to SENC. These update data shall include updates for each ENC until it is superseded by a new edition.

3.16.19 ECDIS shall allow the navigator to display updates in order to review their contents and to ascertain that they have been included in SENC.

3.16.20 ECDIS shall be capable of receiving both non-encrypted ENCs and ENCs encrypted in accordance with the IHO Data Protection Scheme.

3.16.21 ECDIS shall be capable of displaying all SENC information. Any ECDIS shall be capable of receiving and converting an ENC and its updates into a SENC.

ECDIS may also be capable of receiving a SENC resulting from conversion of ENC to SENC ashore in accordance with IHO requirements.

3.16.22 SENC information available for display during preliminary and in-route plotting shall be subdivided into the following three categories:

- display base;
- standard display;
- all other (additional) information.

3.16.23 The display base which is permanently shown on the ECDIS display shall consist of:

- .1 coast line (at high water);
- .2 dangerous depth contour selected by the navigator for own ship;
- .3 isolated underwater dangers of depths less than the dangerous depth contour selected by the navigator for own ship which lie within the safe waters limited by the dangerous depth contour;
- .4 isolated surface dangers which lie within the safe water limited by the dangerous
depth contour, such as fixed structures, overhead communication and power lines, etc;
.5 digital and linear scales and north arrow;
.6 units of depth and height;
.7 display mode.

3.16.24 The initial standard ECDIS display shall consist of:
.1 display base;
.2 tidal line;
.3 buoys, beacons, and other sea aids to navigation and fixed structures;
.4 boundaries of fairways, channels, etc;
.5 visual and radar prominent features;
.6 prohibited and restricted areas of navigation;
.7 chart scale boundaries;
.8 chart warnings;
.9 ship traffic separation schemes and ferry routes;
.10 archipelagic sea lanes.

3.16.25 All additional information which can be displayed the ECDIS display on the request of the navigator includes the following:
.1 individual depth marks;
.2 position of submarine cables and pipelines;
.3 details of all isolated dangers;
.4 details of all aids to navigation;
.5 contents of cautionary notes;
.6 ENC publication date;
.7 most recent chart update number;
.8 magnetic variation;
.9 chart graticule;
.10 object names.

3.16.26 ECDIS shall present the standard display by a single navigator action.

3.16.27 When ECDIS is switched on just after it is switched off or power fails, it shall return to the most recent information display selected manually.

3.16.28 It shall be possible to add or remove information to/from the ECDIS display by navigator’s single action. It shall not be possible to remove information contained in the display base.

3.16.29 For any navigator selected geographical position (e.g. under the cursor) ECDIS shall display on demand the information on the chart objects associated with this position.

3.16.30 It shall be possible to change the display scale in steps, e.g. by changing the chart scale or by changing the range scale in nautical miles.

3.16.31 It shall be possible for the navigator to select a dangerous contour from the depth contours available in SENC. ECDIS shall highlight the dangerous depth contour among other contours on the display, however:
.1 If the navigator does not specify a dangerous depth contour, it shall be set at 30 m by default.

If the dangerous depth contour specified by the navigator or that set at 30 m by default is not available in the SENC database, then the dangerous depth contour displayed by default shall be the nearest and deepest contour;
.2 If the dangerous depth contour in use becomes unsuitable due to a change in source data, the default dangerous depth contour shall be set as per the nearest and deepest contour;
.3 In any of the above cases, the dangerous depth contour indication shall be provided.

3.16.32 It shall be possible for the navigator to select a dangerous depth. ECDIS shall highlight depths equal to or less than the dangerous depth whenever individual depths are selected for display.

3.16.33 ENC and all updates to it shall be displayed without any degradation of their information content.

3.16.34 ECDIS shall provide means to ensure that ENC data and all updates to them have been correctly loaded into SENC database.

3.16.35 ENC data and updates to them shall be clearly distinguishable from other displayed information listed below:
1. own ship:
   - past track with time stamps for primary route;
   - past track with time stamps for secondary route;
2. vector for heading and speed over ground;
3. variable range marker and/or EBL;
4. cursor;
5. event:
   - dead reckoned position with time stamp
   - expected position with time stamp;
6. fixed position with time stamp;
7. position line with time stamp;
8. displaced position line with time stamp:
   - predicted tidal stream or current vector with velocity and time
   - measured tidal stream or current vector with velocity and time;
9. danger which special attention shall be paid to (danger highlight);
10. clearing line (a line passing clear off navigational dangers);
11. planned course and speed to destination point;
12. waypoint;
13. distance along planned course;
14. waypoint with planned date and time of arrival;
15. arc of visibility of lights for defined height of navigator’s eyes;
16. position and time of rudder shifting for manoeuvring.

3.16.36 ECDIS shall provide indication when:
1. the information is displayed in a larger scale than that contained in ENC;
2. own ship position is overlapped by an ENC of a larger scale than that currently provided by the display.

3.16.37 Radar information and/or general-purpose AIS information may be overlaid onto the ECDIS display from systems compliant with the relevant requirements of the Rules. Other navigational information may also be added to the ECDIS display. However, it shall not degrade the displayed SENC information and it shall be clearly distinguishable from the SENC information.

3.16.38 It shall be possible to remove the radar information, AIS information and other navigational information by navigator’s single action.

3.16.39 ECDIS and added navigational information shall use the same datum. If this is not the case, an indication shall be provided.

3.16.40 A radar picture and/or tracked target information may be included in the converted radar information.

3.16.41 If the radar picture is added to the ECDIS display, the radar picture and the chart shall match in scale, projection and orientation.

3.16.42 The radar picture and the position from the position sensor shall be adjusted automatically for antenna offset from the ship steering position.

3.16.43 It shall always be possible to display SENC in the “north up” orientation. Other orientations are permitted (e.g. a “heading up” orientation).

When such orientations are displayed, the orientation shall be altered in steps large enough to avoid blurred display of the chart information.

3.16.44 ECDIS shall provide for the true motion mode (the ship’s symbol moves against non-moving chart background). Other motion modes are permitted.

3.16.45 When the true motion mode is in use, transition to and generation of the next chart picture area shall take place automatically when the own ship’s symbol approaches the ECDIS display edge at a distance specified by the navigator.

3.16.46 It shall be possible to manually change the displayed chart area and the position of own ship relative to the ECDIS display edge.

3.16.47 If the area covered by the ECDIS display includes waters for which no ENC in a scale appropriate for navigation is available,
the areas representing those waters shall have a reference for the navigator to the paper chart or to the RCDS operation mode.

3.16.48 The IHO recommended colours and symbols shall be used to represent SENC information.

3.16.49 The colours and symbols other than those mentioned in 3.16.48, shall comply with the requirements specified in 3.14.

3.16.50 SENC information displayed in a scale specified in the original ENC shall use the specified sizes of symbols, figures and letters recommended by IHO.

3.16.51 ECDIS shall allow the navigator to select whether the own ship is displayed in a scale of currently used chart or as a symbol.

3.16.52 ECDIS shall be capable of displaying information required for:
   .1 preliminary plotting and supplementary navigation tasks;
   .2 in-route plotting.

3.16.53 The effective size of the chart displayed for in-route plotting shall be at least 270 × 270 mm.

3.16.54 The chart display shall be capable of meeting colour and resolution recommendations of IHO.

3.16.55 The method of presentation shall ensure that the displayed information is clearly visible to more than one navigator under light conditions normally experienced in the wheelhouse by day and by night.

3.16.56 If information categories included in the standard display are removed by the navigator, this shall be permanently indicated. The information categories removed from the standard display shall be restored on the navigator’s request.

3.16.57 It shall be possible to carry out preliminary and in-route course plotting.

3.16.58 The largest scale chart data available in SENC for the area given shall always be used by ECDIS for all alarms or indications of crossing the dangerous depth contour and of entering a prohibited area of navigation, as well as for alarms and indications according to Table 3.16.87.

3.16.59 It shall be possible to carry out preliminary plotting including both straight and curved route segments.

3.16.60 It shall be possible to correct preliminary plotting alphanumerically and graphically, including:
   .1 adding waypoints;
   .2 deleting waypoints;
   .3 changing a waypoint position.

3.16.61 It shall be possible to preliminarily plot one or more alternative routes in addition to the primary one. The primary route shall be clearly distinguishable from the other routes.

3.16.62 An indication shall be provided if the navigator plots a course across the own ship’s dangerous depth contour.

3.16.63 An indication shall be given if the navigator plans a route closer than a navigator specified distance from the boundaries of a prohibited area of navigation or a geographic area for which special conditions exist. The indication shall also be given if the navigator plots a course closer than a navigator-specified distance from a point object, such as a fixed or floating aid to navigation or isolated danger.

Special navigation condition areas are the following:
   traffic separation zones;
   inshore navigation zones;
   restricted areas of navigation;
   caution areas;
   offshore production areas;
   areas to be avoided;
   navigator defined areas to be avoided;
   military practice areas;
   seaplane landing areas;
   submarine transit areas;
   anchorage areas;
   marine farms/aquacultures;
   particularly sensitive sea areas.

3.16.64 It shall be possible for the navigator during preliminary plotting to specify a cross track limit of deviation from the planned
route at which an automatic off-track alarm shall be activated.

3.16.65 When in-route plotting is carried out, the selected transit route and the own ship’s position shall appear whenever the chart display covers that area.

3.16.66 When in-route plotting is carried out, it shall be possible to display sea areas that do not cover the ship’s position (e.g. for viewing the areas located ahead to improve preliminary plotting). If this is done on the display used for in-route plotting, the automatic in-route plotting functions (e.g. updating the ship’s position and generating alarms and indications) shall not be interrupted. It shall be possible to return to the area display covering the own ship’s position immediately by navigator’s single action.

3.16.67 ECDIS shall give an alarm if, within the navigator specified time, the own ship will cross the dangerous depth contour.

3.16.68 ECDIS shall give an alarm or indication, as selected by the navigator, if, within the navigator specified time, the own ship will cross the boundary of a prohibited area or of a geographical area for which special conditions exist.

3.16.69 An alarm shall be given when the navigator specified cross track error limit is exceeded.

3.16.70 An indication shall be given, if, continuing on her present course and speed, the own ship will pass closer than the navigator-specified distance from a danger (e.g. obstruction, wreck, or rock) that is shallower than the safe depth contour or from an aid to navigation.

3.16.71 The displayed ship’s position shall be derived from continuous position fixing performed by a system whose accuracy is consistent with the safe navigation requirements. If the ship design allows for a second independent position fix system, ECDIS shall be capable of identifying discrepancies in position finding between the two sources.

3.16.72 ECDIS shall provide an alarm when the input from position, heading or speed sources is lost. ECDIS shall also repeat, but only as indication, any alarm or indication given to it from position, heading or speed sources.

3.16.73 An alarm shall be given by ECDIS when the ship reaches a specified time or distance set by the navigator.

3.16.74 The positioning system and SENC shall use the same geodetic datum. If this is not the case, ECDIS shall give an alarm.

3.16.75 It shall be possible to display the primary route and the secondary routes simultaneously on the chart display. The primary route shall be clearly distinguishable from the other routes. It shall be possible for the navigator to modify the primary route or change it to an alternative route.

3.16.76 It shall be possible to display:

.1 time stamps along the plotted ship’s route that are set manually and automatically at intervals selected between 1 and 120 minutes;

.2 adequate number of points, free movable electronic bearing lines, variable and fixed range markers and other symbols required for navigation purposes and specified in 3.16.35.

3.16.77 It shall be possible to enter the geographical coordinates of any position into the system and then display that position on demand. In addition, it shall be possible to select any point (feature, symbol or position) on the chart display and read its geographical coordinates on demand.

3.16.78 It shall be possible to set the displayed position of the ship manually. This manual setting of coordinates shall be noted alphanumerically on the screen and maintained until altered by the navigator and automatically stored in the memory.

3.16.79 ECDIS shall provide the capability to manually enter and plot obtained bearing and distance lines of position (LOP), and calculate the resulting own ship’s position. It
shall be possible to use the resulting position as an origin for dead reckoning.

3.16.80 When in-route plotting is carried out, ECDIS shall indicate discrepancies between the position received from continuous positioning systems and position obtained by manual position fixing.

3.16.81 ECDIS shall store and be capable of replaying this information required to reconstruct the passed route and verify the official database used during the previous 12 hours of navigation. The following information shall be recorded at maximum intervals of one minute:

1. own ship’s time, position, heading and speed;
2. ENC source by which plotting has been performed, publisher name, publication date, chart tiles displayed, and update list.

In addition, ECDIS shall record the complete track for the entire voyage with the time stamps at intervals not exceeding 4 hours.

It shall not be possible to tamper the recorded information.

3.16.82 ECDIS shall have a capability to protect the recorded data of the previous 12 hours and the track over the entire voyage.

3.16.83 The accuracy of all calculations performed by ECDIS shall be consistent with the SENC accuracy and shall be independent of characteristics of devices which output data to ECDIS.

3.16.84 The accuracy of bearings and ranges drawn on the display or those measured between objects already drawn on the display shall not be less than the display resolution.

3.16.85 ECDIS shall be capable of performing and presenting the results of at least the following calculations:

1. true bearing and distance between two geographical coordinates;
2. geographical coordinates of a position from distance / bearing of a known position;
3. geodetic calculations such as spheroidal distance, rhumb line and great circle.

3.16.86 ECDIS shall be provided with means for automatic or manual onboard tests of its major functions. In case of a failure, the test shall display information to indicate a failed unit (module).

3.16.87 When ECDIS fails or the displayed information is distorted, it shall provide a suitable alarm or indication as required in Table 3.16.87.

3.16.88 ECDIS shall not degrade performance of any equipment being a source of input data. Nor shall connection of optional equipment degrade the performance of ECDIS regarding the requirements of this Chapter.

3.16.89 ECDIS shall be connected to the ship’s position fixing system, to the gyro compass and to the speed and travelled distance measuring device. For the ships not fitted with the gyro compass, ECDIS shall be connected to a remote heading transmitting device.

3.16.90 ECDIS may provide SENC information to external equipment.

3.16.91 ECDIS and all equipment necessary for its normal functioning shall be supplied with electrical power from the main and emergency sources.

3.16.92 Changing from one power supply source to another or any power interruption for a period of up to 45 seconds shall not require the system to be manually restarted.

3.16.93 Adequate redundant means shall be provided to ensure safe navigation in case of ECDIS failure. Such means shall provide the following functions:

1. enabling a safe take-over of ECDIS functions so that ECDIS failure does not lead to a critical situation;
2. providing safe navigation for the remaining part of the voyage after ECDIS failure and providing changeover to the redundant system in critical situation without loss of navigational chart information.

* *Emergency alarm or warning alarm system is provided to warn of an insistent state with sound means or sound and visual means.*

** *Visual indication shall be provided to give information on the system or equipment state.*

3.16.94 The redundant means shall display in graphical (chart) form the relevant information on the hydrographic and geographic environment which is necessary for safe navigation.

3.16.95 The redundant means shall enable the preliminary plotting functions to be performed, including:

1. transferring the planned route originally performed on ECDIS;
2. correcting the planned route manually or transferring it from the plotter.

3.16.96 The redundant means shall enable a takeover of in-route plotting originally performed by ECDIS and provide the following functions:

1. plotting the own ship’s position automatically or manually on the chart;
2. taking courses, distances and bearings from the chart;
3. displaying the planned route;
4. displaying the time stamps on the ship’s track;
5. plotting an adequate number of points, bearing lines, range markers, etc. on the chart.

3.16.97 If the redundant means is an electronic device, it shall be capable of representing on its chart display the information equivalent to the standard display complying with the requirements of this Chapter.

3.16.98 The chart information to be used in the redundant means shall be of the latest edition and as corrected by official updates shall be issued by the Government of the Russian Federation or authorized hydrographic office or other relevant government institution in the name of the Government of the Russian Federation. The chart information shall meet IHO requirements.

It shall not be possible to tamper ENC contents.
The chart or chart data publisher and publication date shall be indicated.

3.16.99 The chart information displayed by the ECDIS redundant means shall be up-to-date for the entire voyage.

3.16.100 If an electronic redundant device is used, it shall provide indication when:
.1 Information is displayed in a larger scale than that contained in the database;
.2 Own ship’s position is overlapped with a chart of a larger scale than that currently used in the system.

3.16.101 If radar and other navigational information is added to the electronic redundant display, all the corresponding performance requirements of this Chapter shall be met.

If an electronic redundant device is used, the display mode and the next screen area display shall be in accordance with 3.16.43 to 3.16.47.

3.16.102 The redundant means shall be able to keep a record of the ship’s actual track, including positions and corresponding time stamps.

3.16.103 The redundant means shall keep operating under all environmental conditions while the ship is in operation.

3.16.104 Accuracy of all calculations shall meet the requirements of 3.16.86 to 3.16.88.

3.16.105 If an electronic device is used in the redundant means, it shall provide a suitable alarm or indication of system malfunction.

3.16.106 If an electronic device is used in the redundant means, it shall be designed in accordance with the ergonomic principles relevant for ECDIS.

3.16.107 If an electronic device is used in the redundant means:
.1 Its colours and symbols shall be in accordance with ECDIS colours and symbols requirements;
.2 Effective size of the chart displayed shall be at least 250 \times 250 \text{ mm} or 250 \text{ mm} in diameter.

3.16.108 If an electronic device is used:
.1 The redundant means power supply shall be separate from ECDIS;
.2 Power sources shall comply with the performance requirements for ECDIS in this Chapter.

3.16.109 If an electronic device is used in the redundant mean, it shall:
.1 be connected to systems providing continuous position fixing capability;
.2 not generate interference and distortions for any equipment providing input data from navigational sensors.

3.16.110 If radar picture overlay on a part of ENC chart information is used as a redundant element, the radar shall comply with the requirements of 3.2.

3.16.111 If ECDIS is used for displaying raster navigation charts, the additional requirements of this Chapter shall be met except for 3.16.20, 3.16.22, 3.16.29 – 3.16.32, 3.16.50, 3.16.54, 3.16.56, 3.16.58, 3.16.62, 3.16.63, 3.16.67, 3.16.68 and 3.16.70:
.1 When operating in RCDS mode, an appropriate set of up-to-date paper charts shall be carried on board and be readily available to the navigator.

This set of charts shall be in scale providing features of topography, depth, navigational dangers, aids to navigation, plotted routes, and determined travel lines in order to provide the navigator with information on general navigation circumstances.

The appropriate set of paper charts shall provide adequate look-ahead capability;
.2 The raster navigational charts (RNC) used in RCDS shall be of the latest edition originated and published by the Government of the Russian Federation or by the government authorized hydrographic office. RNCs not based on the World Geodetic System 1984 (WGS-84) or PZ-90 shall contain additional data, which make it possible to correct fixed position coordinates in order to properly
combine them with data of system RNC (SRNC);

\.3 SRNC contents shall be up-to-date for that part of the intended voyage not covered by ENC;

\.4 It shall not be possible to tamper RNC contents;

\.5 RCDS shall be capable of displaying all SRNC information;

\.6 SRNC information available for display during preliminary plotting and in-route plotting shall be subdivided into two categories:

RCDS standard display consisting of RNC and its updates, including chart scale, chart display scale, geodetic datum, and units of depth and height

any other information such as the navigator's notes;

\.7 It shall be easy to add to or to remove any information additional to RNC data such as navigator's notes and RCDS display notes. It shall not be possible to delete any information from RNC;

\.8 There shall always be an indication for ECDS equipment operating in RCDS mode;

\.9 It shall always be possible to display SRNC in usual “north up” orientation. Other orientations are permitted;

\.10 IHO recommended colours and symbols shall be used to represent SRNC information;

\.11 RCDS shall be capable of displaying the chart notes which are not located on the portion of the chart currently being displayed;

\.12 It shall be possible for the navigator to enter points, lines and areas, which will activate alarm. These features displayed shall not degrade SRNC information and shall be clearly distinguishable from SRNC information;

\.13 While in-route plotting is carried out, it shall be possible to display other areas that do not cover the ship position on the chart display (e.g. for looking ahead). If these actions take place on the display used for in-route plotting, the automatic final plotting as per 3.16.66 shall be continuous. It shall be possible to return to the area display covering the own ship’s position immediately by navigator's single action;

\.14 RCDS shall present only fixed coordinates referenced to WGS-84 or PZ-90 geodetic datum. RCDS shall output a warning if coordinates are not referenced to one of these data. If the displayed RNC cannot be referenced to WGS-84 or PZ-90 geodetic datum, then the respective continuous indication shall be provided;

\.15 RCDS shall allow the navigator to manually match SRNC with the ship position data;

\.16 It shall be possible to activate an alarm when the ship approaches a point, line or boundary of an area selected by the navigator within a specified time or distance;

\.17 RCDS shall be capable of transforming a local chart geodetic datum to WGS-84 geodetic datum and vice versa;

\.18 RCDS shall provide a suitable alarm or indication with regard to represented information or equipment malfunction as required in Table 3.16.111.

Table 3.16.111
3.17 REQUIREMENTS TO SHIP TRACK CONTROL SYSTEM

3.17.1 The ship’s track control system in combination with the sensors providing information on ship’s coordinates, speed, heading and/or rate of turn shall, with steering capabilities taken into account, automatically keep the ship on the planned motion path over ground at different environmental conditions and ship speed from steerable minimum to 50 km/h and at ship’s rate of turn of 10°/s max.

Here, the ship control quality shall not be worse than that of manual control using the standard navigational aids on inland waterways.

3.17.2 Global navigation satellite positioning systems GLONASS/GPS and DGLONASS/DGPS shall be the main system for ship’s position fixing in the ship’s track control system.

3.17.3 The ship’s track control system may be operated in the ship’s heading control mode. In this case, it shall comply with the requirements imposed on the ship’s heading control system.

3.17.4 The ship’s track control system shall provide automatic control of ship motion to the specified waypoint or through the specified sequence of waypoints with the navigator-specified deviation from the track line.

3.17.5 The memory size shall be enough to store the navigation route database containing not less than 1000 waypoints. The database can be implemented either directly in the ship’s track control system memory or programmatically in the GNSS receiving equipment or by means of electronic navigational information and chart system.

3.17.6 The database (route) shall be agreed/approved by the authorized transport authority.

It shall not be possible to change the sequence of waypoints of the given navigation route entered into the system until:

1. planning of a new navigation route is completed and approved; .2 all the conditions of 3.17.9 are met.

3.17.7 The system shall provide possibility of automatic transition from one straight-line route segment to another by turning based on the given turning radius or radius calculated from ship’s rate of turn and linear speed.

3.17.8 The ship’s track control system shall be adjustable (manually or automatically) to ship steering capabilities changing as speed and loading conditions, as well as waterway and weather conditions change.

3.17.9 The system shall enable the navigator of the watch to automatically control the track only if the ship’s position, difference between course over ground and actual heading, and manoeuvring performance of the ship enable safe manoeuvring to the planned motion path.

3.17.10 The ship’s position with reference to the planned motion path shall be continuously monitored by another independent positioning system (device). This monitor may be not a component of the track control system. In case of normal visibility (more than 1 km), the ship’s position can be monitored by visual orientation using the coastal and floating aids to navigation, and in case of limited visibility, by visual orientation using the radar picture.

3.17.11 The system shall enable the navigator on the watch to quickly enter the lateral deviation from the planned track in excess of 200 m to the right and to the left from the ship steering station. The signal of lateral deviation shall be active until the ship returns to the planned track.

3.17.12 When the ship moves along the navigation route, a warning signal shall be provided at least one minute prior to change in heading and at the beginning of turn.

3.17.13 The ship’s track control system shall be fitted with a device which makes it possible for the navigator of the watch to acknowledge the heading change in the turning point. Lack of acknowledgement shall not affect automatic planned track keeping. An alarm shall be given if turning point approach
warning is not acknowledged within 30 s from its output time.

3.17.14 If the actual heading change signal is not acknowledged by the navigator of the watch within 15 seconds after the beginning of turn, an alarm signal shall be given to the watch below navigator to call him urgently to the wheelhouse.

3.17.15 It shall be possible to switch from the ship’s track control mode to the manual control at any rudder position and under any conditions, including the ship track control system failure, using one control and single action in time not exceeding 3 s.

Return to automatic ship’s track control shall take place only if requirement of 3.17.9 is met.

3.17.16 Manual switching from the track control mode to the heading control mode (if such mode is provided for in the technical documentation) shall be possible with one control and single action in time not exceeding 3 s.

The heading control system shall accept actual ship motion parameters at the moment of switching as preset ones.

Reverse change-over to automatic track control shall be possible only if requirement of 3.17.9 is met.

3.17.17 The system control panel shall provide indication of active ship control mode.

3.17.18 A device shall be provided to monitor actual heading value using an independent heading sensor. This monitor may be not a component of the ship track control system.

3.17.19 In case of loss or drop of voltage applied to the track control system which can affect its operational safety, an alarm shall be given.

3.17.20 The ship track control system shall provide:

- warning (with acknowledgement function) in case of no data provided from positioning and rate-of-turn/heading indication systems or failure of these systems;

- alarm if warning of no data from positioning and rate-of-turn/heading indication systems or failure of these systems is not acknowledged by the navigator within 15 s.

It shall not be possible for the system to use information from faulty sensors.

3.17.21 The system shall output an alarm in the following cases:

- deviation from ship track line and rate of turn exceeded preset values;

- ship’s speed through water decreased to a value which does not provide normal steering capabilities.

3.17.22 The track control system shall be capable of calculating a heading between subsequent preset waypoints and radius or rate of turn. In doing so, the system shall consider all limitations determined by the planned track of motion, condition of alarm and warning activation, and other ship control parameters.

3.17.23 The system control panel shall continuously display the following information:

- ship steering mode;

- technical condition of ship’s position, heading, speed and rate of turn sensors;

- course over ground, coordinates, speed, present heading and/or rate of turn and deviation from track line;

- closest and next to it waypoints;

- time and distance to closest waypoint on route;

- calculated heading of the next leg;

- reference designation of preset route.

Information mentioned in 3.17.23.3, 3.17.23.5, 3.17.23.6 and 3.17.23.7 shall be displayed in digital form.

3.17.24 It shall be possible to display the following information on demand:

- list of navigation route waypoints, including their numbers, coordinates, headings and distances between them, and calculated radiiuses of turns or rates of turns;

- preset limitations of ship’s track control mode and other control parameters.
Here, functionally related quantities (preset and actual ones, etc.) shall be displayed together.

3.17.25 All external communications of the track control system with other ship navigational systems shall be implemented in digital form according to the requirements of national and international standards.

3.17.26 All controls and indicators of the ship track control system shall have illumination so as to use the system at any time. Colours for light signalling shall comply with the requirements of 6.1.16 Part VI of the Rules. It shall be possible to control brightness of all indicators.

3.18 REQUIREMENTS TO SHIPBOARD AUTOMATIC IDENTIFICATION SYSTEM EQUIPMENT

3.18.1 The shipboard AIS equipment shall provide data exchange in the following operating modes:

1. mode of continuous independent self-organizing intership exchange of static (ship data) and dynamic (coordinates and motion parameters) information;
2. mode of automatic transfer of static and dynamic information with transfer periodicity assigned by coastal ship traffic control services and at assigned time intervals;
3. mode of automatic transfer of information on ship by request of coastal services and other ships (ship call sign and name, ship coordinates, presence of dangerous cargo, etc.).

3.18.2 The shipboard AIS equipment shall be composed of:

1. communication processor capable of operating in switching mode in short-range radio communication (VHF) and long-range radio communication systems;
2. a device for automatic selection of a frequency channel in the frequency band assigned to the maritime mobile service and operation in the selected channel;
3. at least one TDMA transmitter, two TDMA receivers and one digital selective call receiver (DSC) set up on VHF channel 70 of maritime mobile service;
4. means for data processing from radio-navigation system which enables resolution up to 0.0001 minute in WGS-84 datum;
5. means for automatic input of data from dynamic information sensors;
6. means for manual input, retrieval and display of information (minimum display);
7. means for checking transmitted and received data;
8. means for built-in operability testing;
9. built-in GNSS receiver enabling UTC synchronisation.

3.18.3 The shipboard equipment shall provide:

1. continuous automatic transfer of information to coastal and shipboard AISs;
2. reception and processing of data from coastal services and other ships;
3. transfer of messages in reply to high-priority or safety-related requests with minimum delay prescribed by the technical documentation;
4. transfer of information on ship manoeuvres and coordinates. Data refresh frequency shall comply with 3.18.7 to provide safe ship tracking by coastal services;
5. automatic activation of built-in GNSS receiver in case of failure of main positioning source and output of respective indication of built-in operability check means.

3.18.4 The shipboard AIS equipment shall use the Maritime Mobile Service Identity (MMSI).

3.18.5 The AIS equipment shall operate at VHF frequencies of maritime mobile service (156.025 to 162.025 MHz) with inter-channel frequency separation of 25 kHz and 12.5 kHz. After switched on, the shipboard AIS equipment shall operate by default on two international simplex channels: AIS-1 = 161.975 MHz (channel 2087) and AIS-2 = 162.025 MHz (channel 2088).
It shall be possible for the AIS equipment to change over to other channels by one of three methods:

1. manual changeover;
2. automatic changeover at commands from a coastal station in TDMA format;
3. automatic changeover at commands from a coastal station in DSC format.

3.18.6 The shipboard AIS equipment shall transmit and receive the following information:

1. static information:
   - IMO ship number;
   - ship call signal and name;
   - ship length and breadth;
   - type of ship;
   - location of radio-navigation system receiver antenna (bow or stern and starboard or port with reference to ship’s centreline);

2. dynamic information:
   - ship’s position with indication of measurement accuracy and integrity;
   - universal coordinated time;
   - course over ground;
   - speed over ground;
   - true heading;
   - ship’s rate of turn;
   - ship navigation condition: ship underway, at anchor, etc. by manual input;
   - additional information:
     - heel angle, roll and pitch (if any);
   - voyage information:
     - ship’s draught;
     - presence of dangerous cargo and its type (on request of authorities);
     - port of destination and expected arrival time;
3. safety information.

3.18.7 When operated offline, the shipboard AIS equipment shall provide the following information transfer intervals:

1. for static information, every 6 minutes and on demand;
2. for dynamic information, depending on change in speed and heading according to Table 3.18.7.2;

<table>
<thead>
<tr>

</table>

3. for flight information, every 6 minutes, in case of change of voyage data and on demand;
4. for safety information, when required.

The shipboard AIS equipment shall be capable of processing up to 4500 messages per minute when operated in two channels.

3.18.8 Protection from inadvertent change of received and transmitted information shall be provided.

3.18.9 The shipboard AIS equipment shall be ready for operation in at most 2 minutes after switched on. This requirement does not apply to GNSS receiver warm-up time.

3.18.10 The AIS equipment inactivity time shall be automatically recorded in the non-volatile memory.

3.18.11 Minimum display requirements:

1. The display shall have at least 3 lines of data with 16 characters in each line which shall display at least the ship name, bearing and distance;
2. Bearing and range information shall not be indicated on horizontal displays;
3. The displayed information shall be visually accessible (picture illumination shall be provided);
4. It shall be possible to manually input the voyage messages and safety-related messages;
5. It shall be possible to display alarm information and information from the built-in operability check means and received safety messages and requests from long-range communication means.
3.19 REQUIREMENTS TO VOYAGE DATA RECORDER

3.19.1 The voyage data recorder (VDR) shall continuously and automatically record and store in a safe and retrievable form the information on ship’s position, readings of instruments and systems that characterize condition and operating modes of shipboard equipment, ship motion parameters and ship control commands, her actual state and environment.

3.19.2 The voyage data recorder design shall exclude possibility of intervening in its operation, quantity of data to be recorded, data themselves and already recorded data.

3.19.3 It shall be possible to record any attempts of unauthorized intervention in operation of VDR, validity of its data or data recording.

3.19.4 The method of recording shall make it possible to determine date and time of information recording when it is displayed on the special equipment and shall provide check of information being recorded for validity and activation of alarm in case of detection of an uncorrectable error.

3.19.5 VDR shall be capable of checking its performance characteristics (for example, during annual surveys or after repairs or maintenance of VDR) or any source of signal which shall be recorded in VDR.

Such check may be performed using a device intended for replaying recorded data on condition that all required information has been recorded correctly.

3.19.6 The recorded information medium shall consist of:

.1 a stationary (fixed) recording mean;
.2 a free floating recording mean;
.3 a long-term recording means providing long-term storage of recorded data.

3.19.7 Each recorded information medium shall:

.1 continue recording information during accident/incident;
.2 provide access to recorded information after accident and protection of information from physical or electronic intervention attempts aimed to change or delete data.

3.19.8 The fixed information recording means shall be located in a special fixed protective container designed so as to provide:

.1 rigid attachment to open deck of a ship and possibility of recovering it from a sunk ship manually or by means of underwater vehicle;
.2 protection and retrieval of finally recorded information after any ship incident under the following effects:

mechanical impact (semisine impulse with peak acceleration of 50 g and impact impulse duration of 11 ms);
fall of a rod of 100 mm in diameter and 250 kg in weight from height of 3 m;
low temperature fire (260 °C for 10 h);
high temperature fire (1100 °C for 1 h);
immersion into seawater for 30 days at depth of 3 m;
deep-sea immersion into seawater for 24 h at depth of 6000 m;
.3 storage of recorded information for not less than 2 years on completion of recording;
.4 availability of a sonar beacon working in frequency band of 25 to 50 kHz and providing its underwater detectability during 30 days from its activation time and possibility of applying a visible inscription in English: "VOYAGE DATA RECORDER — DO NOT OPEN — REPORT TO AUTHORITIES";
.5 fluorescent orange colour and reflective marking.

3.19.9 The free floating information recording means shall be located in a special protective container of free floating type and shall comply with the following requirements:

.1 It shall be fitted with attachments to catch and lift it from water;
.2 It shall enable storage of recorded information for not less than 6 months on completion of recording;
.3 It shall be designed so as to comply with requirements imposed to free floating satellite emergency position-indicating radio beacons (see 6.13 – 6.15, Part VII of the Rules);
.4 It shall be fitted with a light indicator and a radio transmitter to transmit signals for initial position finding during 48 h and further transmission of homing signal.

The battery capacity for simultaneous operation of light indicator and radio transmitter shall not be less than 7 days/168 h from time of separation and surfacing of the protective container.

3.19.10 The long-term information recording means shall provide access from the internal space of the ship.

3.19.11 VDR shall record the following information:

.1 date and time with discreteness providing recovery of events sequence. Date and time with reference to UTC shall be received from an external (not mounted on the ship) source, and the built-in VDR clock shall be synchronized with the real dates and times of events. When the external time source is unavailable, the built-in VDR clock shall be used. Recording shall indicate such information source. The method of recording shall be such that time reference of all other recorded information can be retrieved during replay with resolution and continuity enough to recover complete sequence of incidents;

.2 latitude and longitude of ship’s position, and used datum received from radio navigation system receiver with indication of its type and operating mode;

.3 ship’s speed through water and ship’s speed over ground with indication of measurement method and travelled distance from the ship log;

.4 heading indicated by the ship’s heading source;

.5 Voice conversations in the wheelhouse. Microphones shall be placed in the wheelhouse so as to cover all the working posts provided for by the wheelhouse design and to record conversations. Recording shall be such that normal conversational speech provides sufficient intelligibility during normal operation of the ship. This recording requirement shall be met on all working posts in the presence of single audible alarm signal in any place in the wheelhouse or any noise, including noise from faulty equipment, mounting or wind. This shall be obtained by using at least two speech recording channels. Microphones located out of the wheelhouse on the bridge wings shall record conversations via a separate additional channel;

.6 Conversations with other ships, objects and coastal services using VHF radio equipment shall be recorded via an additional separate channel;

.7 radar and auxiliary navigational data displayed on radar indicators mounted on the ship. The method of recording shall provide a capability of replaying the picture in the original recorded form with consideration of possible distortions related to information compression during recording;

.8 if the ship is equipped with an electronic chart display and information system, the voyage data recorder shall record electronic signals of currently used ECDIS display as the main navigation device. The method of recording shall provide a capability of replaying the picture in the original recorded form with consideration of possible distortions related to information compression during recording, and, besides, the source of chart data and its version;

.9 ship under-keel clearance with indication of set measurement scale and operating mode of echo sounder.

The navigational data displayed on the sonar data display (if provided for by the ship design).

The method of recording shall be such as mentioned in 3.19.11.7;

.10 all alarm signals in the wheelhouse;

.11 commands coming to the steering gear and their execution, as well as operating mode of heading or track control system with indication of control station and steering gear power unit(s);

.12 commands coming in the engine room and their execution (position of any engine telegraphs or handles of remote engine/propeller control, including ahead/astern motion indicators and used control station), as well as operating mode of auxiliary thrusters with indication of control station;
..13 condition of sea inlets in the ship’s hull within scope of information coming to the wheelhouse;
..14 condition of watertight and fire doors within scope of information coming to the wheelhouse;
..15 accelerations and strains in the ship’s hull in comparison with data values of which were preset by the navigator on the special equipment (if this equipment and appropriate sensors are available);
..16 wind speed and direction, including their true or relative values;
..17 all the AIS data;
..18 the voyage data recorder shall be connected to the electronic clinometer or, if unavailable, to the appropriate roll sensor having equivalent performance characteristics of measurements. The method of recording shall enable roll representation during display;
..19 data on VDR configuration (information on interface units and connection diagrams).

In addition to the above-stated requirements, the recorded information medium in the delivered VDR shall contain data that determine principle of VDR configuration and sensors which VDR is connected to.

These data shall be actualized and brought to full conformity with data of ship installation. They shall contain information on the sensor manufacturer, type, version number, identification and location, as well as information on the sensor data. Configuration data shall be permanently stored in the recorded information medium of VDR and protected from changes except for changes in VDR configuration made by an authorized person;

..20 If the ship is equipped with an electronic log, its information shall be registered too.

3.19.12 VDR may record other additional information. Here, recording of additional information shall not distort main information or affect its integrity.

3.19.13 VDR shall be capable of recording and storing information for at least previous 12 h of voyage.

3.19.14 Loss of VDR operability shall not affect operation of equipment and information sensors interfaced with VDR.

3.19.15 VDR shall be provided with main and emergency power supply.

If power supply from emergency power source fails, VDR shall continue recording voice conversations in the wheelhouse using its own accumulator batteries (with a charger) for 2 h and then recording of conversations shall be automatically stopped.

3.19.16 To retrieve recorded data and the subsequently display them VDR shall be capable of interfacing with an external portable computer. The interface format shall be compatible at least with one of the international formats, such as Ethernet, USB, Fire Wire or equivalent.

It shall be possible to retrieve recorded data for a selected period.

3.19.17 For each VDR mounted on the ship, a separate copy of software shall be provided in order to enable retrieval of stored data and replay of information on an external computer connected to VDR.

The software shall be compatible with the operating system of the external computer and shall be provided on a portable information storage, such as CD-ROM, DVD, USB storage, etc.

3.19.18 The portable information storage with a copy of software, instructions and any special elements required to connect the external computer to VDR shall be kept in immediate proximity from the main unit of VDR.

3.19.19 If VDR uses nonstandard formats or proprietary manufacturer’s standards for data storage, the software shall be provided directly in VDR or on a portable data storage to convert recorded data to open standard formats.

3.19.20 The technical documentation delivered with VDR shall contain instructions on connection of an external computer to VDR and use of the software.
3.19.21 The technical documentation shall contain information on location of interface unit of long-term information recording means and instructions on interface with it Russian/English language. The VDR documentation shall also contain requirement for the respective information and the abovementioned instructions to be placed near to the interface unit of the long-term information recording means.

3.20 REQUIREMENTS TO SIMPLIFIED VOYAGE DATA RECORDER

3.20.1 The simplified voyage data recorder (S-VDR) shall automatically and continuously record preselected data that characterize readings of navigation devices, operating modes of shipboard equipment, ship control commands and environment. Information shall be stored for 2 years from recording stop time.

3.20.2 The method of recording shall provide a capability of determining data recording date and time when it is displayed on a special device (portable computer).

3.20.3 The recorded information storage shall be located in a special container which can be rigidly attached to the ship hull or be of free floating type.

The container shall comply with the following requirements:

- It shall be capable of continuing information recording during an accident and accessing to recorded data after incident
- It shall protect information from changes and mechanical damages
- It shall have fluorescent orange colour and reflective marking and a device enabling to detect it.

3.20.4 The container rigidly attached to the ship hull shall comply with requirements of 3.19.4, except for impact tests.

3.20.5 The protective container of free floating type shall be:

- fitted with attachments to catch and recover it from water
- designed so as to be capable of surfacing.

3.20.6 The protective container of any type shall comply with requirements of 3.19.5, and the container of free floating type shall also comply with requirements of 3.19.6.

3.20.7 It shall be possible to record the following data:

- date and time with reference to UTC which shall be determined from an external (located out of ship) source or built-in clock with indication of information source with discreteness providing recovery of events sequence during investigation of accident causes;
- position latitude and longitude received from an electronic positioning system with indication of its type and operating mode and datum as well;
- ship’s heading by compass;
- ship’s speed data from the ship log with indication of method of measurement (through water or over ground);
- voice conversations in the wheelhouse and, whenever possible, ship announcements and alarm signals audible in the wheelhouse;
- radio conversations with other ships, objects and coastal services;
- data from AIS;
- all radar and auxiliary navigational data which are displayed at present on the main radar screen. The method of recording shall provide a capability of replaying the picture in the original recorded form with possible distortions related to information compression during recording;
- environment (can be recorded only according to AIS data if the shipboard radar is not interfaced with S-VDR devices);
- other additional information from the ship devices having digital output provided that it does not degrade recording and storage of main data.

3.20.8 S-VDR shall be designed so as to prevent inadvertent intervention in recorded information. Any intervention in operation of VDR shall be recorded in VDR.

3.20.9 The method of information recording shall provide check of validity and completeness of incoming data and alarm
signal when an unrecoverable error is detected.

3.20.10 S-VDR shall record and store information for previous 12 h of voyage until it is completely off.

3.20.11 S-VDR shall operate continuously and automatically. Means shall be available to provide integrity of data recorded during incident with minimum cessation of recording process.

3.20.12 To provide recording of events during accident, S-VDR shall be interfaced with an emergency power supply.

3.20.13 When the shipboard emergency power supply fails, S-VDR shall continue recording voice conversations in the wheelhouse during 2 h using its own standby power supply. After 2 h recording shall be stopped automatically.

3.20.14 Interface of S-VDR with information sensors shall not affect operation of information sensors interfaced with it, including the cases of S-VDR inoperability.

3.20.15 S-VDR shall provide interface with an external portable computer to retrieve the stored data and display the information. The interface format shall be compatible with format such as Ethernet and with USB and Fire Wire as well.

3.20.16 Each S-VDR installation shall be provided with the software, which allows of retrieving the stored data and replay the information on the connected external portable computer.

3.20.17 The S-VDR software shall be compatible with the operating system available in portable general-purpose computers and shall be provided on a portable information storage, such as CD-ROM, DVD, USB storage, etc.

3.20.18 The S-VDR set shall contain instructions on use of software and connection of external portable computer to S-VDR.

3.20.19 The portable storage containing the software, instructions and special parts required to connect the external portable computer shall be included in the equipment set and shall be kept in immediate proximity from the main unit of S-VDR.

3.20.20 If S-VDR uses nonstandard formats or proprietary standards for data storage, the software shall be provided in a portable storage or in S-VDR itself to convert stored data into open standard formats.

3.21 REQUIREMENTS TO RADAR REFLECTOR

3.21.1 The radar reflector (active or passive) shall have the radar cross-section complying with requirements of 3.21.2 to allow detecting it by the shipboard navigating radar operating in 9 GHz band (3 cm wavelength) and 3 GHz band (10 cm wavelength).

3.21.2 When the radar reflector is mounted at height of not less than 4 m above water level, the nominal radar cross-section shall not be less than 7.5 m² in 9 GHz band and 0.5 m² in 3 GHz band.

3.21.3 The nominal minimum radar cross-section shall be provided within total sector of 280° in horizontal plane.

3.21.4 The polar diagram of the radar reflector shall be such that any continuous sector, in which reduction of reflectivity below the nominal minimum level does not exceed 10° (zero area) with required distance of less than 20° between adjacent zero areas.

3.21.5 The radar reflectors capable of meeting the requirement of 3.21.2 at inclination angles of 20° and more to any side from the vertical line shall have the respective marking.

3.21.6 The minimum mounting height recommended by the radar reflector manufacturer (not less than 4 m) and the preferable mounting orientation shall be marked directly on the radar reflector.

3.21.7 The active radar reflectors shall comply with the requirements of International Telecommunication Union (ITU).
3.22 REQUIREMENTS TO INTEGRATED NAVIGATION SYSTEMS

3.22.1 The integrated navigation system (INS) shall comply with the requirements of the national and international standards.

3.23 REQUIREMENTS TO EXTERNAL AUDIO SIGNAL RECEPTION EQUIPMENT

3.23.1 The external audio signal reception equipment shall be installed on ships, on which lookout by hearing is possible only with reception of external audio signals inside the wheelhouse, because of operational conditions or wheelhouse design features.

3.23.2 The external audio signal reception equipment shall:
   - receive external audio signals in frequency band of at least 70 to 700 Hz from all directions;
   - transmit these signals acoustically to the wheelhouse;
   - determine and indicate approximate direction of a source of audio signals.

3.23.3 External audio signals shall be transmitted to the wheelhouse by means of one or several speakers.

3.23.4 When two or more speakers are installed, their acoustic intensity shall be adjusted so that the wheelhouse sound level exceeds noise level on the bridge wings at least by 10 dB(A).

3.23.5 In addition to microphones, amplifiers and speakers, the external audio signal reception equipment shall contain a display to visually display external audio signals and their approximate direction at least 3 s after they are received.

3.24 REQUIREMENTS TO SEA WATCH ALARM SYSTEM

3.24.1 The sea watch alarm system is used to monitor operation of the main steering position and detect incapability of the officer on watch that could result in an accident.

This is provided by transmitting optical and sound signals to draw attention of the officer on watch and then, if he does not react to them, by informing the master or the back-up officer.

3.24.2 Three system operation modes shall be provided for:
   1. "Manual ON" mode for continuous operation when the ship is underway in a voyage;
   2. "Automatic" mode when sea watch alarm system is automatically activated when the vessel is navigating by means of heading or track control system, and changed over to "Manual ON" mode as the heading/track control system is deactivated;
   3. "Manual OFF" mode. Sea watch alarm system can be switched on only by navigator's dedicated actions.

3.24.3 When the system is on, the following sequence of visual (optical) and sound signals shall be observed:
   1. After switched on, the system shall remain dormant for a master-specified period of 3 to 12 min and then it shall activate a light signal;
   2. If the officer on watch does not acknowledge the light signal, i.e. does not reset the system, for 15 sec, the system shall sound a first level audible alarm on the steering station;
   3. If the officer on watch does not reset the system 15 s after the first level audible alarm is initiated, the system shall additionally sound a second level audible alarm in the back-up officer’s and/or Master’s location;
   4. If the officer on watch does not reset the system 90 s after the second level audible alarm is initiated, the system shall sound a third level audible alarm at all navigating personnel locations of the ship;
   5. In vessels other than passenger vessels, the second level audible alarm may sound in all the above locations. If the second level audible alarm is sounded in this way, the third level alarm may be omitted;

In vessels of gross tonnage more than 3000, the delay between the second and third level alarms may be set to a longer value up to 3 min, to allow sufficient time for the back-up officer and/or Master to reach the wheelhouse.

3.24.4 It shall be possible to reset the sea watch alarm system or cancel any alarm signal from the wheelhouse only.

The system reset or alarm signal cancellation shall be possible by operator's single action and shall initiate the next dormant period.

Repeated activation of the reset device shall not prolong the dormant period or change the sequence of light and sound signals.

3.24.5 Means may be provided in the wheelhouse to immediately activate the second and third level audible alarms for emergency call of the back-up officer and/or the Master.

3.24.6 The alarm system shall be capable of achieving the timings with accuracy of 5% or 5 s, whichever is less, under all operational conditions.

3.24.7 If a malfunction of or power supply failure to sea watch alarm system is detected, this should be indicated. Provision shall be made to allow this indication be repeated on the common alarm and communication panel.

3.24.8 Sea watch alarm system shall have the following controls:

.1 means protected from unauthorized access to select the operation mode and the dormant period duration;

.2 a means of activating the “Emergency Call” signal if it is provided in the system;

.3 system reset means which shall be located on the main bridge posts and on its wings.

3.24.9 The system operation mode shall be indicated to the officer on watch.

3.24.10 The visual signal initiated at the end of the dormant period shall be flashing and visible from all positions in the wheelhouse. The colour of the visual signal shall be chosen so as not to impair night vision, and dimming facilities (although not to extinction) shall be incorporated.

3.24.11 The first level audible alarm which sounds on the bridge 15 s after the light signal is initiated shall draw attention of the navigator of the watch. It shall be possible to select its tone or modulation and volume level as well.

3.24.12 The additional second and third level audible alarms which sound sequentially in the locations of the Master, back-up officer and other crew members capable of assisting the officer on watch at the end of the first level audible alarm period shall have sound signal level of not less than 75 dB.

3.24.13 All equipment of the sea watch alarm system shall be tamper-proof so that no member of the crew may interfere with the system operation.

3.24.14 Reset devices shall be designed so as to exclude the possibility of their operation by any means other than activation by the officer on watch. Reset devices shall be illuminated at night and shall be mounted in the wheelhouse.

3.24.15 The sea watch alarm system shall be powered from the ship's main power supply. The malfunction indication means and the Emergency Call facility, if incorporated, shall be powered from a battery.

3.24.16 The sea watch alarm system shall have inputs and outputs for connection of light and audible alarm signals and additional system reset devices.

3.25 REQUIREMENTS TO LONG RANGE IDENTIFICATION AND TRACKING SYSTEM EQUIPMENT

3.25.1 The equipment of the long range identification and tracking system (hereinafter referred to as LRIT) shall automatically transmit the following information:

.1 ship identification number;

.2 ship’s position coordinates (latitude and longitude);
.3 position fixing date and time.

3.25.2 The LRIT equipment shall comply with the performance requirements of this Chapter and the requirements of 6.1 Part VII of the Rules.

3.25.3 The LRIT equipment shall:
.1 provide capability of automatic, without interfering of ship watch personnel, transmission of ship LRIT information to LRIT data centre. LRIT information shall be transmitted at 6 hour intervals;
.2 change over to transmission of LRIT information at an interval shorter than that indicated in 3.25.3.1 by remote control command from LRIT data centre if LRIT data receiver requesting LRIT information has determined LRIT information transmission intervals that differ from 6 hour interval;
.3 provide capability of transmitting LRIT information on receipt of polling commands;
.4 provide capability of direct connection to the shipboard GNSS receiver or the LRIT equipment shall incorporate a receiver capable of finding own ship position based on GNSS signals;
.5 be powered from the main and emergency power sources. If the shipboard radio equipment required in Part VII of the Rules is used as LRIT equipment, it shall be powered according to 3 Part VII of the Rules;
.6 be tested for stability to external mechanical and climatic effects and for electromagnetic compatibility with other shipboard electronic and electrical equipment.

3.25.4 The LRIT equipment shall meet the functional requirements stated in Table 3.25.4.

3.25.5 The LRIT equipment shall transmit LRIT information and enable a remote tuning using a communication system which provides coverage in all areas for which the ship is about to operate.

3.25.6 The LRIT equipment design shall provide capability of periodic operability check without transmitting LRIT information.

### Table 3.25.4

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Requirement and comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shipboard equipment identification number</td>
<td>Ship identification number (MMSI) used in shipboard radio equipment</td>
</tr>
<tr>
<td>Ship position data</td>
<td>Ship position coordinates (latitude and longitude) based on GNSS signals (in WGS-84 datum). Location: the LRIT equipment shall transmit own ship’s position coordinates (latitude and longitude) based on GNSS signals (in WGS-84 datum) without intervention of ship watch personnel. Position reports on polling command(^1): in reply to received polling command, the LRIT equipment shall provide a regular reporting of own ship position without intervention of ship watch personnel whatever the ship’s position is. Planned position reports(^2): it shall be possible to tune the LRIT equipment remotely for transmission of LRIT information at a definite interval: from minimum (15 minutes) to 6 hours. Information shall be transmitted to LRIT data centre without intervention of ship watch personnel whatever the ship’s position is.</td>
</tr>
<tr>
<td>Time stamp</td>
<td>Date and time(^3) of own ship’s position finding based on GNSS signals. In each LRIT information package transmitted the LRIT equipment shall transmit information on time(^3) of own ship’s position finding based on GNSS signals</td>
</tr>
</tbody>
</table>

\(^1\) Position reports on polling command mean transmission of LRIT information either as a result of a polling command or as a result of remote tuning of LRIT equipment for transmission at intervals other than those preset.\n\(^2\) Planned position reports mean transmission of LRIT information at preset time intervals.\n\(^3\) All time data shall be in UTC.
3.25.7 It shall be possible to switch the LRIT equipment off or to stop transmission of LRIT information (with a respective record made in the ship log) in the following cases:

.1 if the international agreements or regional rules provide for protection of navigational data;

.2 in exceptional cases and for time as short as possible if the Master considers that the operating LRIT equipment can endanger the ship safety or reduce her security level.

3.25.8 The LRIT system equipment shall provide possibility of decreasing the LRIT information transmission frequency or stopping the LRIT information transmission temporarily when the ship is docked for repair or refit, located in port or brought out of service for a long time if the Master or the Administration of the flag state made the decision to decrease the LRIT information transmission frequency to a single message a day or to temporarily stop transmitting such information with a respective record made in the ship log.

3.26 REQUIREMENTS FOR ELECTRONIC CHART DISPLAY SYSTEM

3.26.1 ECDS shall display distortionless information from the official navigation map of inland waterways.

3.26.2 The chart dimensions displayed shall be at least 180x180 mm.

3.26.3 The ECDS display shall have a resolution of at least 800x600 pixels and provide information reading at a distance not less than 1 m.
Part IX

REQUIREMENTS FOR SHIPS CARRYING DANGEROUS GOODS
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 This Part of the Rules sets the requirements for ships which carry in their cargo spaces and areas dangerous goods in bulk or in containers.

1.1.2 The requirements of this Part of the Rules apply to design and construction of ships intended to carry dangerous goods and to refit of ships of all classes in use.

1.1.3 If the requirements of this Part of the Rules are not identical to the requirements of the other Parts of the Rules for the same matter, the strictest requirements of the Rules shall apply.

1.1.4 In addition to the requirements of this Part of the Rules, the ships carrying dangerous goods in international voyages shall meet the applicable requirements of the international agreements ratified by the Russian Federation depending on ship design, type of carriage and carried dangerous goods.

1.1.5 Tugboats and/or pushboats which transport non-self-propelled ships with dangerous goods shall meet the applicable requirements of this Part of the Rules that are determined depending on design of non-self-propelled ship, type of carriage and carried dangerous goods.

1.2 TERMS AND DEFINITIONS

1.2.1 Common terms and definitions of the Rules are stated in 2.1 and 2.2 Part 0 of the Rules. The following terms are used in these Rules:

.1 Dangerous goods means substances, materials and products containing such substances and materials with properties which may create a threat to life and health of people, cause damage to the environment, damage or destroy material values during transportation.

This Part of the Rules uses dangerous goods classification set by the International European Agreement concerning the International Carriage of Dangerous Goods on Inland Waterway (ADN).

In view of hazard nature, dangerous goods are divided into the following classes.

Class 1 — explosive substances and articles. Subclasses:

1.1 — substances or articles which have a mass explosion hazard (explosion which affects almost the entire load instantaneously);
1.2 — substances and articles which have a projection hazard but not a mass explosion hazard;
1.3 — substances and articles that have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard;
1.4 — substances and articles which present no significant hazard to people;
1.5 — very insensitive substances which have a mass explosion hazard;
1.6 — extremely insensitive articles which do not have a mass explosion hazard.

Class 2 — compressed gases, liquefied gases, and dissolved gases. Subclasses:

2.1 — flammable dangerous cargoes;
2.2 — non-flammable, non-toxic gases;
2.3 — toxic gases.

Class 3 — flammable liquids. Subclasses:

3.1 — liquids with low vapour flash point (below –18 °C);
3.2 — liquids with medium vapour flash point (from –18 °C to 23 °C, exclusive);
3.3 — liquids with high vapour flash point (from 23 °C to 61 °C).

Note. Vapour flash point shall be measured in closed cup.

Class 4 — flammable solids; substances liable to spontaneous combustion; substances which, in contact with water, emit flammable gases. Subclasses:
4.1 — flammable solids and solids, which are combustible through friction; self-reactive solids and liquids (which are liable to undergo a strongly exothermic decomposition as a result of high temperatures in transport or pollution) and similar; desensitized explosive substances (which may explode if not diluted sufficiently);
4.2 — substances liable to spontaneous combustion;
4.3 — substances which, in contact with water, emit flammable gases.

Class 5 — oxidizing substances and organic peroxides. Subclasses:
5.1 — oxidizing substances which, while in themselves not necessarily combustible, may, generally by yielding oxygen, cause, or contribute to, the combustion of other substances;
5.2 — organic peroxides which may be considered derivatives of hydrogen peroxide, where one or both of the hydrogen atoms have been replaced by organic radicals.

Class 6 — toxic and infectious substances. Subclasses:
6.1 — toxic substances;
6.2 — infectious substances.

Class 7 — radioactive substances.

Class 8 — corrosive substances.

Class 9 — miscellaneous dangerous substances and articles;

Chemically dangerous goods means strong poisonous chemicals and their compounds (acids, alkalis, aldehydes, ethers, hydrocarbons, nitrates, peroxides, and metal compounds) which are toxic and capable, when unpacked and spilled, of causing chemical damages to life forms and environment;

D  a  n  g  e  r  o  u  s  g  o  o  d  s  v  a  p  o  u  r  d  e  s  i  g  n  p  r  e  s  s  u  r  e  \( p_0 \) means the maximum positive pressure at the top of the cargo tank.

Dangerous goods design temperature means the minimum temperature at which dangerous goods may be loaded or transported in the cargo tanks for selection of materials to be used to manufacture the cargo piping and cargo tanks. It shall be specified by the designer (design engineering firm) depending on properties of carried dangerous goods specified in dangerous goods documentation;

Dangerous goods containment system means a structural arrangement for containment of cargo including, where fitted, a primary and secondary barrier, associated insulation and any interbarrier spaces, and adjacent structures if necessary for the support of these elements. If the secondary barrier is a part of the hull structure, it may be a boundary of the hold space;

Secondary barrier means a liquid-resisting structure which is not a part of the hull and which accommodates a cargo tank. The secondary barrier is a component of the dangerous goods containment system designed to afford temporary containment of any envisaged leakage of liquid dangerous goods through the primary barrier and to prevent the lowering of the temperature of the hull structures;

Interbarrier space means a space between a primary and a secondary barrier, whether or not completely or partially occupied by insulation material;

Independent cargo tanks mean tanks the shell of which is not a part of the hull structures and does not contribute to the ship’s hull integrity. Independent cargo tanks are divided into the following types:

Type A is a cargo tank designed using ship-structural analysis procedures recognized by the River Register.

Type B is a cargo tank designed using model tests and analysis methods to determine stress levels, fatigue life and crack propagation characteristics.
Type C is a spherical or cylindrical cargo tank designed in accordance with the requirements of the Rules for pressure vessels;

9 Integral cargo tanks mean tanks which form structural parts of the ship’s hull and contribute together with the hull structures to the general ship strength;

10 High-pressure cargo tank means a cargo tank intended to carry dangerous goods at working positive pressure of at least 0.4 MPa;

11 Internal insulation cargo tank means a tank made of heat insulation materials which are capable of creating appropriate thermostatic conditions for dangerous goods storage and are supported by the structure of the adjacent inner hull or of an independent tank. The inner surface of the insulation is exposed to the dangerous goods;

12 Closed cargo tanks means a cargo tank equipped with a controlled vapour and gas discharge system in which pressure relief valves and vacuum relief valves are installed in free vapour and gas discharge way;

13 Open cargo tanks means a cargo tank equipped with a free-flow vapour and gas discharge system with flame arrester in which free vapour and gas discharge is not impeded, except for friction loss;

14 Gravity cargo tank means an integral or independent tank intended to carry dangerous goods at design positive pressure of 0.07 MPa max;

15 Pressure cargo tank means an independent tank intended to carry dangerous goods at design positive pressure exceeding 0.07 MPa. The pressure tank shall be configured so that pressure tank design procedures agreed by the River Register can be applied;

16 Membrane cargo tank means a cargo tank which consists of a membrane shell supported through insulation by the adjacent hull structures.

The membrane cargo tank is also a tank with non-metallic membranes or membranes incorporated in or connected to the tank insulation;

17 Semi-membrane cargo tank means a cargo tank which consists of a membrane shell, parts of which are supported through insulation by the adjacent hull structures, and deformations are compensated by all shell components connected at radius equal to 5 to 10 values of shell wall thickness;

18 Membrane means a thin-walled shell element used to manufacture the cargo tanks;

19 Cargo tank dome means the cargo tank top protruding over the weather deck or the tank cover when the dangerous goods containment system is located under the deck;

20 Gas-dangerous spaces or areas mean the following spaces or areas:

- spaces in the cargo area which do not ensure that their atmosphere is at all times maintained in a gas-safe condition;
- an enclosed space (see 1.2.1.5 Part III of the Rules) outside the cargo area through which any piping containing liquid or gaseous dangerous products passes, or within which such piping terminates, unless approved arrangements are installed to prevent any escape of dangerous product vapour into the atmosphere of that space;
- a space in which dangerous goods containment system and cargo piping are arranged;
- a hold space where dangerous goods are carried in the dangerous goods containment system reservoirs requiring a secondary barrier and spaces separated from such hold space by a single gas-tight steel boundary;
- a hold space where dangerous goods are carried in the dangerous goods containment system reservoirs not requiring a secondary barrier;
- cargo compressor and cargo pump rooms;
- an open deck area (a deck exposed to the weather) or a semi-enclosed space on the weather deck within 3 m of any cargo tank outlet, gas or vapour outlet, cargo pipe flanges or cargo valves or of entrances and ventilation

The thin-walled shell is a shell for which relation of minimum wall curvature radius to wall thickness exceeds 10 for cylindrical shells and 3.5 for spherical shells.
openings to cargo compressor and cargo pump rooms;

the weather deck over the cargo area and 3 m forward and aft of the cargo area on the weather deck up to a height of 2.4 m above the weather deck;

a zone within 2.4 m of the outer surface of the cargo containment system where such surface is exposed to the weather;

an enclosed or semi-enclosed (see 1.2.1.24 Part III of the Rules) space in which pipes containing liquid or gaseous dangerous goods are located;

a compartment for cargo hoses;

enclosed or semi-enclosed spaces having a direct opening into any gas-dangerous space or area.

A space accommodating gas detection equipment and a space in which exhaling gas is used as fuel are not considered gas-dangerous ones;

.21 Gas-safe spaces mean spaces other than gas-dangerous spaces and those where atmosphere is continuously maintained in fire-safe, explosion-safe and life and health friendly condition;

.22 Machinery spaces — see the definition in 1.2.1.26 Part III of the Rules;

accommodation spaces — see 1.2.1.22 Part III of the Rules;

adjacent spaces — see 1.2.1.25 Part III of the Rules;

machinery spaces — see 2.2.25 Part 0 of the Rules;

explosion-hazardous zone — see 2.1.1.6 Part VI of the Rules;

control stations — see 1.2.1.17 Part IV of the Rules;

.23 Cargo area means an area consisting of cargo areas below and above deck (main and additional parts) (Figs. 1.2.1.23-1 and 1.2.1.23-2), where:

Cargo area (part below deck) is a space between two vertical planes perpendicular to the centre plane of the ship, which comprises cargo tanks, hold spaces, cofferdams, double-hull spaces and double bottoms. These planes normally coincide with the outer transversal cofferdam bulkheads or end transversal hold bulkheads. Their intersection line with the deck is referred to as the deck boundary of the cargo area part below deck.

Cargo area (main part above deck) is a space above deck of 3 m high which is bounded at the sides by the plane located 3 m away of the longitudinal walls of the cargo tanks and fore and aft by planes inclined at 45° to the deck towards the cargo area, starting at the deck boundaries of the cargo area part below deck.

Cargo area (additional part above deck) is a space not included in the main part of the cargo area above deck comprising 1.00 m radius spherical segments centred over the ventilation openings of the cofferdams and service spaces located in the cargo area part below deck and 2.00 m radius spherical segments centred over the ventilation openings of the cargo tanks and pump rooms;

Fig. 1.2.1.23-1. Cargo area:
1 — deck; 2 — cofferdam vent openings; 3 — cargo area above deck additional part; 4 — cargo tank vent openings; 5 — deck boundary of cargo area part above deck; 6 — end cofferdams; 7 — cargo area below deck
Open-type gauge means an instrument used to take measurements through the cargo tank body openings. In doing so, a person taking measurements can be exposed to dangerous goods and/or their vapours.

Partly closed-type gauge means an instrument installed inside the tank and used to take measurements. When this gauge is used, a small quantity of cargo vapours or liquid which is not dangerous to human life and health may be discharged to the open air. As long as the gauge is not used, it shall be closed.

Closed-type gauge means an instrument used to take measurements, which is installed inside the cargo tank and, being a part of the closed system, prevents the cargo tank contents from discharge. Closed-type gauges are also instruments which are not installed inside the tank and prevent the cargo tank contents from discharge (for example, liquid flow meters in piping).

Fire smothering system means a fire extinguishing system based on gas fire extinguishing, but special liquid is applied to a space instead of gas and evaporates to form inert gas heavier than air.

Chemical tanker means a ship designed to carry chemically dangerous goods in bulk. Inland navigation chemical tankers are divided into two types, i.e. C and N. Type C tanker shall be built as a flush decked double hull ship without deck trunk. Type C tanker cargo tanks may be integral (formed by inner walls of double hull) or independent. Chemical tanker type is established depending on carried cargo properties and is specified in col. 3 of Table A1-1 in Appendix 1;

Ships of type 1, 2, 3 are chemical river–sea navigation tankers designed to carry chemically dangerous goods in bulk. Ship type is established depending on carried dangerous goods properties and is specified in col. 3 of Table A2-1 in Appendix 2;

Liquefied gas tanker means a ship designed to carry liquefied gases in bulk. Inland navigation liquefied gas tanker (type G tanker) is designed to carry gases specified in Table A1-1 of Appendix 1 under pressure or under refrigeration. River–sea navigation liquefied gas tankers depending on type of structural fire protection(see 6.8.1) are divided into four types: 1G, 2G, 2PG and 3G; liquefied gas tanker type is established depending on carried dangerous goods properties and is specified in col. 4 of Table A3-1 in Appendix 3.
2 GENERAL REQUIREMENTS

2.1 FIRE WATER MAIN SYSTEM

2.1.1 Ships carrying dangerous goods shall be equipped with the fire water main system meeting the following requirements:

.1 The fire water main system shall be fed from two independent fire pumps. A ballast pump may be used as one of fire pumps, if its capacity and pressure meet the fire pump-requirements specified in Part III of the Rules. Pumps, their drives and electrical equipment shall not be arranged in the same space;

.2 The fire water main system shall supply water under pressure specified in Part III of the Rules by continuously keeping the pressure in the main or by remotely starting the fire pumps from the wheelhouse and from the continuous watch keeping location when the ship is berthed or at anchor, as well as supply water in the main without additional opening of the valves in the pump room. A water pressure indicator shall be installed in the place of pump's remote start;

.3 The fire water main system for И, Ï, Ð and Ë class ships shall be fitted with a water main provided with at least three fire plugs located in the cargo area (a portion of the ship to be protected in accordance with the requirements of the Rules) above the deck and at least four fire plugs fitted with fire hoses with combined nozzles of at least 12 mm in diameter. Any portion of the deck within the protected area shall be simultaneously covered by at least two water jets from different hydrants.

For М-СП, М-ПР and О-ПР class ships carrying cargo in bulk or in containers, the fire water main system shall supply water in amount sufficient to feed four fire monitors with minimum cock pressure of 0.25 MPa to any portion of a void cargo space.

Quantity and location of fire cocks shall be such that at least two of required four water jets can be supplied through fire hoses to any part of void cargo space and all four water jets can be supplied through fire hoses to any part of ro-ro cargo space;

.4 Head and capacity of pumps shall enable simultaneous use of two spray nozzles from any part of the ship, and the water jet shall cover a distance of not less than the hull beam of the ship;

.5 A fire pump or a ballast pump may be available onboard the push-towed barges which do not have their own power installation. It is possible to use the fire water main system of the pushboat with remote start of the own pump from the wheelhouse connected to the fire water main system of the barge with flexible hoses.

2.2 FIRE SMOTHERING SYSTEMS

2.2.1 In addition to the requirements of 2.1.1, the machinery spaces (see 2.2.25 Part 0 of the Rules), as well as the pump room and the spaces accommodating the refrigeration system equipment for the tankers, shall be equipped with a fixed fire extinguishing system meeting the requirements specified in 2.2.2 to 2.4.3.

2.2.2 To provide fire protection in machinery spaces, oiler rooms and pump rooms, only fixed fire extinguishing systems using the following extinguishing agents are permitted:

- CO2 (carbon dioxide),
- HFC-227 ea (heptafluoropropane),
- IG-541 (52% nitrogen, 40% argon, 8% carbon dioxide),
- FK-5-1-12 (dodecafluoro-2-methylpentan-3),
mixture containing 73% ethyl bromide C\textsubscript{2}H\textsubscript{5}Br and 27% dibromotetrafluoroethane C\textsubscript{2}Br\textsubscript{2}F\textsubscript{4} (halon 114\textsubscript{2}) or mixture of C\textsubscript{2}H\textsubscript{5}Br and CO\textsubscript{2} (for fire smothering systems).

2.2.3 In addition to requirements stated in 2.2.2 and 2.3, the fire extinguishing systems using HFC-227\textit{ea} as a fire-extinguishing agent shall meet the following requirements:

1. If several spaces with different volumes are available, each space shall be equipped with its own (separate) fire extinguishing system;

2. Each reservoir with HFC-227\textit{ea} located in the space being protected shall be equipped with an overpressure preventing device. This device shall disperse the reservoir contents in the space being protected if this reservoir is exposed to fire while the fire extinguishing system is not activated;

3. Each reservoir with HFC-227\textit{ea} shall be equipped with a pressure monitor which outputs light and sound alarms to the wheelhouse in case of pressure drop in the gas-carrying medium reservoir. If the wheelhouse is unavailable, these alarms shall be given from the outside of the space being protected;

4. Reservoir filling ratio shall not exceed 1.15 kg/l.

HFC-227\textit{ea} specific volume shall be taken equal to 0.1374 m\textsuperscript{3}/kg;

5. After dispersion, HFC-227\textit{ea} concentration in the space being protected shall be at least 8% and at most 10.5% of the total volume of this space. HFC-227\textit{ea} shall be discharged for 10 s;

6. The fire extinguishing systems shall have no parts of aluminium.

2.2.4 In addition to requirements stated in 2.2.2 and 2.3, the fire extinguishing systems using IG-541 as a fire-extinguishing agent shall meet the following requirements:

1. If several spaces with different volumes are available, each space shall be equipped with its own (separate) fire extinguishing system;

2. Each reservoir with IG-541 located in the space being protected shall be equipped with an overpressure preventing device. This device shall disperse the reservoir contents in the space being protected if this reservoir is exposed to fire while the fire extinguishing system is not activated;

3. Each reservoir with IG-541 shall be equipped with a pressure monitor;

4. Reservoir filling pressure shall not exceed 20 MPa at temperature of +15 °C;

5. After dispersion, IG-541 concentration in the space being protected shall be at least 44% and at most 50% of the total volume of this space. IG-541 shall be discharged for 120 s.

2.2.5 In addition to requirements stated in 2.2.2 and 2.3, the fire extinguishing systems using FK-5-1-12 as a fire-extinguishing agent shall meet the following requirements:

1. If several spaces with different volumes are available, each space shall be equipped with its own (separate) fire extinguishing system;

2. Each reservoir with FK-5-1-12 located in the space being protected shall be equipped with an overpressure preventing device. This device shall disperse the reservoir contents in the space being protected if this reservoir is exposed to fire while the fire extinguishing system is not activated;

3. Reservoir filling ratio shall not exceed 1.15 kg/l.

FK-5-1-12 specific volume shall be taken equal to 0.0719 m\textsuperscript{3}/kg;

4. After dispersion, FK-5-1-12 concentration in the space being protected shall be at least 5.5% and at most 10% of the total volume of this space. FK-5-1-12 shall be discharged for 10 s;

5. Each reservoir with FK-5-1-12 shall be equipped with a pressure monitor, which outputs light and sound alarms to the wheelhouse in case of pressure drop in the fire-extinguishing agent reservoir. If the wheelhouse is unavailable, these alarms shall be given from the outside of the space being protected.

2.3 EQUIPMENT OF PROTECTED SPACES

2.3.1 The forced ventilation system in the space to be protected shall be shut down as
soon as the fire smothering system is activated.

2.3.2 Openings in the space to be protected shall be fitted with quick-closing devices (devices which are closed either automatically under gravity of spring force and quick-closing float or by turning the control). Open and closed positions of these devices shall be indicated.

2.3.3 Air escaping from the pressure-relief valves of the pressurized air tanks installed in the machinery spaces shall be evacuated to the open air.

2.3.4 Overpressure or negative pressure caused by diffusion of extinguishing agent shall not destroy the structural elements of the space to be protected. It shall be possible to safely equalize pressures.

2.3.5 It shall be possible to extract the extinguishing agent from protected spaces. If corresponding suction devices are fitted for this purpose, they shall not operate during fire extinguishing.

2.3.6 The extinguishing agent shall be routed to and distributed in the space to be protected by means of a permanent piping system. Piping installed in the space to be protected and valves and fittings it incorporates shall be made of steel.

The discharge nozzles shall be so arranged as to ensure regular distribution of the extinguishing agent in the space to be protected.

2.3.7 Automatically activated fire extinguishing systems are not permitted. It shall be possible to activate the fire extinguishing system from a suitable position located outside the space to be protected. Opening the extinguishing agent vessel valves and controlling the dispersion valve shall represent two independent operations.

2.3.8 The fire extinguishing system activating devices shall be supplied with power from two energy sources independent of each other. These energy sources shall be located outside the space to be protected. The control system cables located in the space to be protected shall be so designed as to remain capable of operating in the event of a fire for a minimum of 30 minutes.

2.4 ALARM SYSTEMS

2.4.1 The fixed fire extinguishing systems shall be equipped with warning systems (devices) which shall output light and sound signals when the fire extinguishing system is activated. The signals shall be output:

- for self-propelled ship — to pilot room;
- for fire smothering systems — to protected room and in front of its entrance;
- for non-self-propelled ship — to the constant watch post.

2.4.2 The warning system shall be activated automatically with the first activation of the fire extinguishing system. The warning system shall operate within the time until the system starts supplying the extinguishing agent, which shall not be less than 20 s, and shall not be deactivated for this time.

2.4.3 (shall be considered to have lost force.)

2.5 FIRE OUTFIT

2.5.1 The explosion-hazardous areas, spaces and rooms and the weather decks of the liquefied gas tankers and chemical tankers shall be provided with the fire outfit items as prescribed by the Rules, the design and material of which exclude possibility of sparking when these items are used.

For non-self-propelled unmanned liquefied gas tankers and chemical tankers the above requirements for the fire outfit items apply to the fire outfit items installed on open decks of tugboats and pushers which operate together with the specified tankers.

2.5.2 In addition to the fire outfit prescribed by the Rules, the ship shall be provided with the following protective equipment:

- for each member of the crew participating in loading and discharge operations, the protective equipment including: a pair of tight protective goggles and/or facepieces, aprons, a pair of special gloves with oversleeves, an
overall of chemically resistant material, and protective shoes;
a flammable gas detector with the instructions for its use;
a toximeter with the instructions for its use;
two breathing apparatuses.

2.5.3 For pushed convoys or side-by-side formations underway, it shall be sufficient, however, if the pushboat or the vessel propelling the formation is equipped with the protective equipment specified in 2.5.2.
3 SHIPS CARRYING DANGEROUS GOODS IN BULK OR IN CONTAINERS

3.1 CARGO SPACES

3.1.1 The ships carrying dangerous goods in bulk or in containers shall have double sides and double bottom within the cargo spaces. This requirement does not apply to the ships carrying dangerous goods on the deck only.

3.1.2 The cargo spaces of the ships carrying dangerous goods in bulk shall be made of materials that do not react with carried dangerous goods or shall be coated with isolating material that do not react with carried dangerous goods.

3.1.3 The cargo spaces on the ships, except for the ro-ro ships, shall not adjoin the accommodation and service spaces. Exception may apply to the service spaces with low fire hazard which are not parts of the machinery spaces: stores of incombustible material, spares, mechanical and electrical materials.

3.1.4 The bulkheads and the decks, which separate the machinery spaces from the cargo spaces, shall be of type A-60. The bulkheads of type A-0 are allowed if structural or other arrangements have been taken to place dangerous goods at distance of not less than 3 m from these bulkheads.

3.1.5 No heating appliances shall be installed in the holds.

3.1.6 It shall be possible to take air samples in the cargo spaces of the ships carrying dangerous goods, and the ship shall be fitted with equipment which allows of determining concentration of explosion-hazardous gases and vapours or oxygen in the cargo space.

3.1.7 Arrangements shall be made to prevent ingress of contaminated air into spaces with instruments during air sampling from the cargo spaces.

3.1.8 It shall be possible to measure temperature in the cargo spaces at different heights.

3.1.9 The hatch covers of the cargo spaces, which carry dangerous goods, shall be made of steel. The hatch covers shall be designed so as they can move with no impacts to exclude possibility of sparking. It shall be possible to retain the covers in the open position.

3.2 VENTILATION

3.2.1 The ventilation system shall meet the following requirements:

.1 It must be possible to ventilate each hold by means of two mutually independent spark proof (Exi) extraction fans having a capacity of not less than five changes of air per hour based on the volume of the empty hold. The holds may be provided with natural supply ventilation;

.2 The inlet openings of the extraction ducts shall provide air exchange in the hold and no dead air. The inlet openings of the extraction ducts shall be positioned at the opposite ends of the hold at different heights, and the lower opening shall be at least 50 mm clear off the bottom or tank top plating. The requirements of this Subpara do not apply if dangerous goods are carried in bulk;

.3 If dangerous goods are carried in bulk, extraction of vapours and gases shall be possible through the extraction piping;
.4 The ventilation system of a hold shall be arranged so that dangerous gases cannot penetrate into the accommodation and service spaces, wheelhouse and machinery space;

.5 Intake and outlet ventilation openings shall be fitted with flame-arresting fittings. Flow area of these fittings shall be not less than the cross-sectional area of the ventilation pipe.

3.2.2 Doors, hatches, and ventilation openings leading to the machinery and service spaces are not allowed in the fore wall of the superstructure.

3.2.3 The open top ships do not require the fixed ventilation system to be installed. When containerized or packaged dangerous goods are carried in the open holds, these ships shall be provided with portable fans to ventilate the holds, if damage occurred to a container or package, so that concentration of gases evolved from dangerous goods is less than 10% of lower explosive limit or, in case of toxic gases, less than maximum permissible concentration.

3.3 ENGINES AND GAS EXHAUST PIPING

3.3.1 Fuel with vapour flash point 60 °C and below for the main and auxiliary engines and boilers and that with vapour flash point not less than 43 °C for emergency diesel generators shall not be used.

3.3.2 The machinery space inlet ventilation openings and the engine air intakes which do not take air in directly from the machinery spaces shall be located not less than 2.00 m from the cargo area.

3.3.3 Sparking shall not be possible within the cargo area.

3.3.4 The gas exhaust piping of the boilers and main and auxiliary engines shall be equipped with spark extinguishers (spark arresters) and shall be located not less than 2.00 m from the cargo area.

3.4 FUEL TANKS

3.4.1 The double bottom spaces located within the cargo holds may be used as fuel tanks provided that the double bottom space height is not less than 0.6 m.

In this case, piping and openings of these fuel tanks shall not be arranged in the hold.

3.4.2 Height of fuel tank air pipes measured from the deck to the fluid level in the pipe when filled shall not be less than 500 mm.

3.5 DRAINAGE SYSTEM

3.5.1 The drainage systems of the cargo spaces which dangerous goods are carried in shall be independent (not connected with piping or pumps of machinery and other spaces) and shall be located within the cargo area. The spaces accommodating the drain pumps shall be equipped with independent forced exhaust ventilation providing at least 6-fold air exchange per hour and shall be separated from the adjacent spaces with a self-closing door.

3.5.2 The cargo space drain devices shall prevent creation of free water surface.

If this requirement is not met, the fire water main system may be used onboard the ship only the requirements of Part II of the Rules for ship stability with free water surface taken into account are met by results of calculation.

Meeting the requirements of Part II of the Rules for ship stability with free water surface taken into account shall also be verified if peculiarities of dangerous goods require possible fire to be extinguished with water until the cargo space is flooded or if dangerous goods on fire are inclined to dilution.

3.6 FIRE EXTINGUISHING SYSTEM

3.6.1 To cool the enclosed under-deck cargo spaces of the ships intended to carry dangerous goods of class 1, subclasses 1.1 to 1.6, a stationary water spraying system with delivery rate of 5 L/min per square meter of the cargo space area shall be installed or the cargo space shall be flooded with the fire water main system mentioned in 2.1.1. For the cargo spaces of not more than 100 m² in area, fire hoses may be used for those pur-
poses to deliver water with delivery rate specified above.

3.6.2 To disperse fire-extinguishing agent over racks of service spaces where explosive substances are stored, a water sprinkling system may be used. This system shall be fed with water from the fire main. Pumps and power sources to be used shall be located out of the space being protected.

3.6.3 The sprinkling system may be used to flood the explosives stores.

3.6.4 The capacity of pumps serving the drencher shall be at least 24 L/min per square meter of the total area of the protected space.

3.6.5 The cargo spaces shall be equipped with a gas fire extinguishing or fire smothering system. This requirement does not apply to carriage of non-combustible or low inflammability dangerous goods or dangerous goods for which the gas fire extinguishing or fire smothering system is ineffective. Such dangerous goods are listed in Table 3.6.5.

3.6.6 In addition to fire-extinguishers available on the ship the cargo spaces shall be provided with two additional fire-extinguishers with fire-extinguishing agents the type of which is suitable and the quantity of which is enough for localizing inflammations and extinguishing possible fires in the cargo spaces on the ships carrying dangerous goods, but at least 12 kg of dry powder or equivalent quantity of another fire-extinguishing agent.

3.7 FIRE DETECTION SYSTEM

3.7.1 The cargo spaces protected with the water spraying system, aerosol and gas fire extinguishing system and fire smothering system shall be equipped with an automatic fire detection system meeting the requirements of 11.4 Part VI of the Rules.

3.8 ADDITIONAL FIRE SAFETY REQUIREMENTS

3.8.1 Electrical lighting fittings only are allowed outside of the accommodation spaces and wheelhouse.

* Gas fire extinguishing and fire smothering system is not required (low inflammability of goods).
** Gas fire extinguishing or fire smothering systems are ineffective.

### 3.9 ELECTRICAL EQUIPMENT

3.9.1 The electrical equipment installed in the cargo spaces of the ships carrying dangerous goods shall be of the following type of explosion protection:

1. intrinsically safe electrical circuit “i” (Exi)
2. pressurized enclosure “p” (Exp)
3. explosion-proof enclosure “d” (Exd)
4. explosion protected increased safety “e” (Exe).

Nonexplosion-proof lighting fittings and floodlights may be installed in such spaces to illuminate the hold provided that the switchboard of this lighting network has a
removable non-fusible jumper to deenergize the network.

3.9.2 Electrical equipment in the cargo holds shall meet the requirements of 2.10 Part VI of the Rules for group of explosive mixtures of dangerous goods with air T4 and mixture category IIB (see Appendix 2 Part VI of the Rules).

3.9.3 Electrical equipment to be used in the explosion-hazardous zone on the deck shall be of explosion-proof design applicable to category and group of most explosive mixture of dangerous goods vapours with air.

3.9.4 The switches shall exclude possibility of unauthorized (accidental) activation. The sockets in the explosion-hazardous zone shall be designed so that connection and disconnection from the electric circuit can be possible only when they are de-energized. These sockets shall be protected from mechanical damages.

3.9.5 Portable cables can be used:
   .1 for intrinsically safe electric circuits (Exi),
   .2 for connection of navigation lights and gangway lights,
   .3 for connection of containers carrying dangerous goods,
   .4 for connection of bilge fans,
   .5 for connection of electrically-driven hatch covers.

3.9.6 When portable cables are used, they shall meet the requirement of 2.10.9 Part VI of the Rules. These cables shall be at most 18 m long and shall be laid in such a way as to prevent damage to them.

3.9.7 The storage batteries shall be installed outside of the explosion-hazardous zones in accordance with the requirements of 8.5 Part VI of the Rules.

3.10 DOUBLE SIDE SPACE

3.10.1 The spacing between the side and the internal longitudinal bulkhead of the cargo space (double side space) shall be not less than 0.8 m.

This spacing may be reduced to 0.6 m if the following requirements are met:
   .1 in case of longitudinal side framing system:
      frame spacing shall not exceed 0.6 m,
      partial bulkheads with cutouts for passage of people shall be installed in the frame plane along the side with spacing of at least 1.8 m
   .2 in case of transversal side framing system:
      at least two side stringers shall be installed with spacing of 0.8 m max between them or between the upper stringer and the deck. The height of the stringers shall not be less than the height of the web frames, and the sectional area of the stringer flange shall not be less than 15 cm².

The stringers shall rest on the transversal partial bulkheads fitted with spacing of 3.6 m max with cutouts for lightening and passage of people, or the partial bulkhead with cutouts for lightening and passage of people shall be installed in plane of each web frame.

3.11 EMERGENCY EXIT

3.11.1 The spaces, the entrances or exits of which are likely to become partly or completely immersed in the damaged condition, shall have an emergency exit which is situated not less than 0.10 m above the damage water-line.

This requirement does not apply to forepeak and afterpeak.

3.12 FLOODABILITY

3.12.1 Dimensions of hull side damages in floodability calculations shall be taken as follows:
   .1 Damage length is 0.10L, but not less than 5.0 m;
   .2 Damage depth measured from the inner surface of the skin at right angle to the centre plane is 0.59 m;
   .3 vertical extent: from the base line upwards without limit;

3.12.2 Dimensions of bottom damages in floodability calculations shall be taken as follows:
.1 Damage length is $0.10L$, but not less than 5.0 m;
.2 Damage width is 3.0 m;
.3 Vertical damage size is from the baseline upwards to 0.49 m, exclusive of the drain well.

3.12.3 Floodability requirements shall be met when the following spaces are flooded:
.1 two adjacent side compartments
.2 two adjacent bottom compartments in transversal (longitudinal) direction
.3 machinery space.

3.12.4 At the final stage of flooding, the lower edges of all open openings (see 1.2.1.20 Part II of the Rules) shall be at least 0.10 m higher than the damaged waterline.

3.12.5 For all cases of unsymmetrical flooding, the heeling angle at the final stage of flooding shall not exceed 12°.

3.12.6 Area of damaged stability curve with positive arms shall not be less than 0.0065 m$^2$ rad to angle of 27° or to downflooding angle, whichever is less. In this case, the maximum arm of the damaged stability curve shall not be less than 0.05 m (Fig. 3.12.6).

3.12.7 Damaged stability of inland navigation ships carrying unfixed containers with dangerous goods shall meet the following requirements (see Fig. 3.12.7):

Fig. 3.12.6. Damaged stability curve:
$\theta_1$ is angle corresponding to equilibrium and final buoyancy position; $\theta_2$ is angle equal to 27° or to downflooding angle $\theta_{downflood}$, if $\theta_{downflood}$ < 27°

3.13 SCOPE OF REQUIREMENTS DEPENDING ON CLASS OF CARRIED DANGEROUS GOODS

3.13.1 Depending on degree of danger of carried dangerous goods defined by their class, the requirements stated in 3.1 to 3.12 may be relaxed.

Permissible relaxation in requirements depending on class of carried dangerous goods is as follows:

for carriage of dangerous goods in bulk, see Table 3.13.1-1;
for carriage of dangerous goods in containers, see Table 3.13.1-2.

Permissible relaxation in requirements as per Tables 3.13.1-1 and 3.13.1-2 irrespective of class and method of carriage of carried dangerous goods is exhaustive.

**Note:**
1. Only for dangerous goods that evolve flammable vapours and gases.
2. Only for dangerous goods that evolve toxic vapours and gases.
3. In all cases, dangerous goods of class I shall be stowed at horizontal distance of 3 m from the machinery space limiting structures.
4. Only for spontaneously inflammable and spontaneously decomposable dangerous goods.
5. Only for flammable dangerous goods.
6. If this requirement is specified in the individual dangerous goods card.
7. Only for liquids (liquid dangerous goods).
8. Only for liquids with vapour flash point \(t \leq 23^\circ C\).
9. Dangerous goods are carried on deck only.

**Note:** "+" means required; "-" means not required.
4 INLAND NAVIGATION SHIPS CARRYING DANGEROUS GOODS IN BULK

4.1 GENERAL PROVISIONS

4.1.1 This section requirements apply to inland navigation ships carrying dangerous goods in bulk (including liquefied gases) listed in Table A1-1 in Appendix 1.

4.1.2 Necessity of implementing the general design requirements set in this Section as applied to tanker type is specified in Table 4.1.2, special requirements for carriage of specific dangerous goods are stated in Table A1-1 in Appendix 1.

4.1.3 The liquefied or pressurized gas installation elements on the ships carrying dangerous goods in bulk shall not be placed within the cargo spaces.

4.1.4 If this section does not contain any provisions required to make design solutions while an inland navigation liquefied gas tanker is designed or built, refer to the requirements of 6 of this Part.

4.2 MATERIALS

4.2.1 All ship structures and elements, including the equipment, which can contact with carried dangerous goods, shall be manufactured of materials which do not react when contact with carried dangerous goods or shall have insulating coating of material which does not react when contacts with carried dangerous goods.

Wood, aluminium alloys or plastic materials shall not be used in ship structures and elements, including equipment, mounted within the cargo area. These requirements do not apply to:

</tbody>
</table>

**Note.** "+" means required; "—" means not required.

- gangways and external ladders
- moving parts of ship equipment
- fasteners of cargo tanks which are independent of ship’s hull and fasteners of ship’s machinery and equipment
- masts and similar mast timbers
- parts of ship’s machinery
- parts of electrical equipment
- lids of boxes located on the deck
- supports and stops (with regard to use of timber and plastics)
- gaskets (with regard to use of rubber and plastics)
- electric cables (with regard to use of rubber and plastics);
- loading and discharge hoses (with regard to use of rubber and plastics);
- insulation of cargo tanks and loading and discharge hoses (with regard to use of rubber and plastics).

#### 4.2.2 The paint used in the cargo area shall not be liable to produce sparks in case of impact.

#### 4.2.3 The ship’s boats may be made of plastics provided that these plastics are hardly inflammable (incapable of inflammation in air under long-time effect of low-energy fire source, for example, flame of a match at temperature of 750 to 800 °C or smoldering of a cigarette at temperature of 700 to 750 °C, also see 2.1.4.1 Part III of the Rules).

#### 4.3 PROTECTION AGAINST PENETRATION OF GASES

#### 4.3.1 The lower edges of the door openings in the sidewall of the superstructures and the coamings of the access hatches to the under-deck spaces shall be at height of not less than 0.50 m above the deck.

These requirements do not apply provided that the wall of the superstructures facing the cargo area extends from one side of the ship to the other and has the doors the coamings of which have a height of not less than 0.50 m. The height of this wall shall not be less than 2.00 m. The lower edges of the door openings in the sidewall of the superstructures and the coamings of the access hatches behind this wall shall be at a height of not less than 0.10 m above the deck. The coamings of the machinery space doors and access hatches shall always be at a height of not less than 0.50 m.

#### 4.3.2 The bulwark in its bottom part on the main deck shall have openings whose area in the cargo area shall be equal to that calculated by the following formula, m2:

with bulwark length \( l \) of 20 m and less
Inland Navigation Ships Carrying Dangerous Goods in Bulk

$F_{\text{min}} = 1 + 0.05l$; \hspace{1cm} (4.3.2-1)
with bulwark length $l$ exceeding 20 m

$F_{\text{min}} = 0.1l$. \hspace{1cm} (4.3.2-2)

The lower edges of the openings shall be located at the deck level.

4.3.3 For all spaces located within the cargo area, it shall be possible to monitor concentration of gas mixtures.

4.4 HOLD SPACES AND CARGO TANKS

4.4.1 The maximum permissible capacity of the cargo tanks shall not exceed values determined according to Table 4.4.1.

**Table 4.4.1**

<table>
<thead>
<tr>
<th>$L_{\text{max}}$, $B_{\text{max}}$, $H$, m$^3$</th>
<th>Maximum permissible capacity of the cargo tank, m$^3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>up to 600</td>
<td>$0.3L_{\text{max}}B_{\text{max}}H$</td>
</tr>
<tr>
<td>600–3750</td>
<td>$180 + 0.0635(L_{\text{max}}B_{\text{max}}H - 600)$</td>
</tr>
<tr>
<td>over 3750</td>
<td>380</td>
</tr>
</tbody>
</table>

Note: $L_{\text{max}}$ is maximum ship’s hull length (m); $B_{\text{max}}$ is maximum ship’s hull breadth (m); $H$ is design side height within the cargo area (m).

For trunk ships, $H$ in product $L_{\text{max}}B_{\text{max}}H$ shall be replaced by $H'$ to be obtained from the following formula:

$H' = H + h_t b_t l_t / (B_{\text{max}} L_{\text{max}})$;

where $h_t$ — trunk height (m);

$b_t$ — trunk breadth (m);

$l_t$ — trunk length (m).

4.4.2 If the ship’s length is 50 m and less, the cargo tank length shall not exceed 10 m; if the ship’s length exceeds 50 m, the cargo tank length shall not exceed $0.20L_{\text{max}}$. This requirement does not apply to ships with cylindrical independent cargo tanks with length-to-diameter ratio $l/d$ less or equal 7.

High-pressure cargo tanks shall have ratio $l/d$ less than or equal to 7.

4.4.3 Trunks shall not be installed within the cargo area of type C tankers (except for cofferdams).

4.4.4 The cargo tanks that are not parts of the ship’s hull shall be fastened so that they cannot float.

4.4.5 The capacity of the cargo tank suction well shall not be more than 0.10 m$^3$.

4.4.6 The cargo tanks shall be separated from the accommodation spaces, machinery space and service spaces located outside the cargo area or, if such spaces are unavailable, from the ship ends by cofferdams of at least 0.60 m wide.

When the cargo tanks are placed in the hold space, a space of not less than 0.50 m shall be provided between these cargo tanks and the end bulkheads of the hold space. If the requirement is met, Class A-60 fire protection insulation may be installed on the transversal end bulkheads instead of cofferdams.

4.4.7 The holds, spaces, and cargo tanks shall be capable of being inspected and stripped.

4.4.8 The bulkheads limiting the cargo tanks, cofferdams, and hold spaces shall be watertight. The cargo tanks, cofferdams, and bulkheads limiting the cargo area shall have no openings or passages below the main deck. These requirements do not apply to passages intended for laying electric cables and pipelines of instrumentation and alarm systems, as well as passages of drive shafts of drain and ballast pumps through the bulkheads that separate a service space and a machinery space. These allowed passages shall be gastight.

4.4.9 Type G tankers within the cargo area may be designed as both double hull and single hull. If the double sides and the double bottom are available, the double side space breadth shall not be less than 0.8 m, and the double bottom space height shall not be less than 0.6 m. If the double sides are unavailable, the side stringer space shall not exceed 0.6 m, and the space between the web frames supporting the side stringers shall not exceed 2.0 m. The height of the side stringers and web frames shall not be less than 10% of the side height, but not less than 0.3 m. The free flange cross-section area for the side stringers and web frames shall not be less than 7.5 cm$^2$.
and 15 cm$^2$, respectively. The distance between the side plating of the ship and the cargo tanks shall not be less than 0.8 m, and that between the bottom plating and the cargo tanks shall not be less than 0.6 m. This distance below the cargo tank suction wells may be reduced to 0.5 m. The horizontal distance between the cargo tank suction wells and the bottom framing shall not be less than 0.1 m.

Other design solutions as applied to the ship hull in the cargo area may be used, if calculations confirm that in case of side collision with another ship having straight stem, energy of 22 MJ will be absorbed without rupturing the cargo tanks and the cargo piping connected to the cargo tanks.

4.4.10 The double side space width for type C tankers shall not be less than 1.0 m. This width may be reduced to 0.8 m provided that the hull is additionally reinforced as compared to the requirements of Part I of the Rules by:

1. increasing thickness of deck stringer by 25%;
2. increasing thickness of side plating by 15%;
3. decreasing distance between side stringers to 0.8 m (for transversal side framing system), here, stringer profile height shall not be less than 0.15 m, and free flange section area of shall not be less than 7 cm$^2$;
4. assigning profile height of longitudinal T-section stiffeners which shall not be less than 0.15 m with free flange section area of not less than 7 cm$^2$ (for longitudinal side framing system).

When longitudinal stiffeners with non-T section are used, equality of section moduli shall be provided between the used section and required tee section.

4.4.11 To provide access of the crew members wearing the protective clothes to the cofferdams, double side and double bottom compartments, cargo tanks and other hold spaces located within the cargo area, the cut-outs necessary to enter these cofferdams, compartments, tanks and spaces shall have the cross-section area of not be less than 0.36 m$^2$ and minimum side length of 0.5 m. Cutouts shall be arranged so as to allow injured or unconscious persons to be removed by means of fixed equipment. In these spaces the distance between the framing beams shall not be less than 0.5 m. In the double bottom space this distance may be reduced to 0.45 m. The round access hatches to the cargo tanks shall have clear diameter of at least 0.68 m.

4.4.12 The high pressure cargo tanks shall be rated at cargo temperature of +40 °C.

4.4.13 Separate wells of more than 0.1 m deep may be fitted in the deck of cargo tanks of type C tankers for installation of cargo pumps if the following conditions are satisfied:

1. The well depth shall not be more than 1 m;
2. The well shall be at least 6 m clear off the entrances and openings of the accommodation and service spaces located out of the cargo area and 0.25 of ship breadth clear off the sides;
3. If the well depth exceeds 0.5 m, it shall be provided with a fixed gas detection system which outputs light and sound signals when concentration of gases reaches 20% of lower explosive limit and automatically disconnects the ship cargo system;
4. If in the cargo area is provided with a water spraying system, the electrical equipment in the well shall be protected from flooding;
5. The well shall be drained by means of the drain system installed on the deck within the cargo area and independent of other systems;
6. The well shall be fitted with a device which measures its degree of filling, actuates its drain system and outputs light and sound signals when liquid accumulates on the well bottom.

4.5 VENTILATION

4.5.1 The double side and double bottom spaces and the cofferdams located within the cargo area shall be equipped with air pipes and ventilation system.

The air pipe outlet ends shall be equipped with permanent automatically operating clo-
sures which provide easy access of air and prevent ingress of air into the double side and double bottom spaces and cofferdams.

The air pipe outlet ends shall be provided with float-type closures capable of operating at any heel and trim. The closures and their fastenings shall be resistant to effect of dangerous goods and sea water.

Each service space within the cargo area below deck shall be fitted with forced ventilation system which provides at least 20-fold air exchange per hour based on the whole space volume.

Air for ventilation of double side and double bottom spaces and cofferdams shall be supplied through an air duct to the bottom part of a space 400 mm clear off the floor (bottom). Air shall exit through the air pipes.

The ventilation system inlet openings shall be located at a height of not less than 2 m above the deck and at a distance of not less than 2 m from the tank openings and 6 m from the safety valve openings.

4.5.2 The fans used to ventilate the spaces according to 4.5.1 shall have electrical equipment with type of explosion protection “i” (Exi).

4.5.3 Operating instructions, including information on conditions under which these openings are to be closed, shall be placed at the ventilation system inlet openings. All ventilation system inlet openings of the accommodation and service spaces facing the outside shall be equipped with fire dampers. These openings shall be located at a distance of not less than 2 m from the cargo area.

It is allowed to arrange the ventilation system inlet openings of the service spaces located in the cargo area below deck within this area.

4.5.4 The ventilation system inlet openings of the machinery space shall be at a distance of not less than 2 m from the cargo area.

4.5.5 Each hold space shall be ventilated in any part of it. To fulfil this requirement, each hold space shall have two closable deck openings to provide this ventilation. If such openings are unavailable, an inerting system for the hold spaces shall be provided.

4.5.6 The ventilation system shall be designed so as to exclude possibility of ingress of dangerous gases into the accommodation spaces, wheelhouse or machinery space.

4.5.7 The air pipe openings of each fuel oil tank shall be at a height of not less than 0.50 m above the deck. These openings and the openings of the overflow pipes connecting to the deck shall have a protection consisting of a wire mesh or a perforated plate.

4.6 SERVICE AND ACCOMMODATION SPACES

4.6.1 The service spaces may be located within the cargo area below deck provided that these spaces are enclosed with watertight walls extending from the deck to the bottom plating. Access to such service spaces shall be provided from the deck only. The cargo piping shall not be laid through these spaces.

4.6.2 The crew shall be enabled of accessing the service spaces mentioned in 4.6.1 and operating therein, and it shall be made possible to evacuate people in protective clothing therefrom.

4.6.3 The service spaces mentioned in 4.6.1 shall not be used as cargo pump rooms and shall not accommodate the loading and discharge systems unless the following conditions are satisfied:

.1 There is a cofferdam or a fire-insulated bulkhead of type A-60 or a service or hold space between the pump room and the machinery space or between the service spaces located out of the cargo area;

.2 No drive shafts of ballast or bilge pumps go through the bulkhead of type A-60 required in 4.6.3.1;

.3 The ventilation outlet openings are located at a distance of not less than 6 m from the entrances and openings of the accommodation and service spaces out of the cargo area;

.4 The access hatches and the ventilation inlet openings are provided with outer closures;
5 All loading and discharge pipelines and stripping pipelines are equipped with the shut-off devices on the suction inlet of the pump in the cargo pump room. Operating the controls located in the pump room, starting the pumps and monitoring the fluid flow shall take place from the main deck;

6 All loading and discharge pipelines (filling and supplying ones) shall be laid on the deck over the pump room;

7 The oily water space of the cargo pump room shall be equipped with an instrument for measuring the filling level in the oily water space which activates light and sound alarm in the wheelhouse when the upper filling level is reached;

8 The cargo pump room is equipped with a fixed gas detection system which automatically informs on presence of explosive gases or oxygen deficiency by means of direct measurement sensors and activates light and sound alarm when concentration of gases reaches 20% of the lower explosive limit;

9 The wheelhouse and the cargo pump room are equipped with sound and light alarm, and when alarm is signalled, the loading and discharge system is deactivated. If the gas detection system fails, the sound and light alarm shall operate in the wheelhouse and on the deck;

10 The ventilation system shall provide at least 30-fold air exchange per hour based on the total volume of the service space.

4.6.4 The accommodation spaces and the wheelhouse shall be located out of the cargo area.

4.6.5 The space entrances and the superstructure openings shall not face the cargo area. The hinges of the doors, which open outwards and are located out of the recesses the depth of which is equal to or exceeds the door breadth shall be located from the side of the cargo area.

4.6.6 The entrances and openable windows of the superstructures and accommodation spaces and other openings of these spaces shall be located at a distance of not less than 2 m from the cargo area. This requirement does not apply to the wheelhouse doors and windows, if there is no access from the wheelhouse to the accommodation spaces or if this access is provided through the gas-tight doors.

4.6.7 The seal assembly at the place where the bilge or ballast pump shaft penetrates the bulkhead separating the service space and the machinery space shall be gas-tight.

4.7 COFFERDAMS

4.7.1 Each cofferdam that adjoins the service spaces shall be provided with an access hatch. The access hatches and the ventilation outlet openings shall be arranged in accordance with the requirements of Part II of the Rules and shall be located at least 0.5 m above the deck.

4.7.2 It shall be possible to fill the cofferdams with water and drain them with the pumps. It shall take not more than 30 minutes to fully fill the cofferdams with water. The cofferdams shall have no inlet valves.

This requirement does not apply to the cofferdams that have common separating bulkhead with the machinery space if the bulkhead separating them has fire insulation of type A-60 and if the cofferdam is used as a service space.

4.7.3 It is not allowed to integrate the cofferdam systems with the other systems located out of the cargo area.

4.7.4 The cofferdam ventilation openings shall be equipped with flame arresters.

4.8 OPENINGS OF CARGO TANKS

4.8.1 The cargo tank openings with cross-sectional area of more than 0.10 m² shall be located above the deck at a height of not less than 0.5 m. This requirement also applies to the openings of the safety devices designed to prevent overpressure, on type C and N tankers with enclosed cargo tanks.

4.8.2 The cargo tank openings shall be equipped with the gas-tight closures which
can withstand test pressure equal to test pressure of cargo tanks

4.8.3 Each cargo tank or a group of cargo tanks which have common gas-freeing pipe-line shall have:

.1 a safety device for preventing overpressure or vacuum. This safety device shall be designed so as to prevent water ingress into the cargo tanks;

.2 a connection for safe return ashore of gases expelled from the cargo tanks during loading

.3 a device for safe depressurization in the cargo tanks, including a stop valve and a flame arrester. The stop valve position shall be marked.

4.8.4 The safety device mentioned in 4.8.3.1 shall have a vacuum valve with flame arrester and a pressure relief valve representing a quick-acting vent valve with flame arrester. The gas shall be returned upwards. The opening pressure for the quick-acting vent and vacuum valves shall comply with the values specified in col. 7 of Table A1-1 in Appendix 1 and shall be indicated on the respective valve.

4.8.5 The openings of the quick-acting vent valves (or overpressure valves for type G tankers) shall be located above the deck at a height of not less than 2 m and at a distance of not less than 6 m from the accommodation and service spaces located out of the cargo area. The above distance may be reduced provided that no equipment is placed and no work is performed within the radius of 1 m from the quick-acting vent valve (overpressure valve for type G tankers) opening. In this case, maximum permissible working pressure limits shall be marked on the vent valve. The quick-acting vent valves shall be adjusted so that they do not open during carriage until maximum permissible working pressure is reached in the cargo tanks.

4.8.6 When operated, the shut-off devices used during loading or discharge shall not cause sparking.

4.9 STABILITY AND FLOODABILITY

4.9.1 Intact stability of ships that have cargo tanks with total breadth in excess of 0.70B shall meet the following requirements:

The stability curve area with positive arms shall not be less than 0.024 m-rad to angle of 27° or to downflooding angle, whichever is less.

Here, the maximum arm of the stability curve shall not be less than 0.10 m.

The metacentric height shall not be less than 0.10 m.

These requirements shall be met with consideration of free surface effect in the cargo tanks under the most unfavourable loading condition.

4.9.2 Floodability requirements shall be met when the following spaces are flooded:

.1 two adjacent side compartments

.2 two adjacent bottom compartments in transversal direction

.3 machinery space.

4.9.3 For all cases of unsymmetrical flooding, the heeling angle at the final stage of flooding shall not exceed 12°.

4.9.4 The area of damaged stability curve with positive arms shall not be less than 0.0065 m-rad to angle of 27° or to downflooding angle, whichever is less. In this case, the maximum arm of the damaged stability curve shall not be less than 0.05 m (see Fig. 3.12.6).

4.9.5 Dimensions of hull side damages shall be taken as follows:

.1 Damage length is 10% of ship’s length L, but not less than 5 m;

.2 Damage depth measured from the inner surface of the skin at right angle to the centre plane is 0.79 m for type G and C tankers and 0.59 m for type N tankers;

.3 vertical extent: from the base line upwards without limit;

4.9.6 Dimensions of bottom damages shall be taken as follows:

.1 Damage length is 10% of ship’s length L, but not less than 5 m;
2. Damage width is 3 m;
3. Vertical damage size from the baseline upwards: to 0.59 m for type G and C tankers and to 0.49 m for type N tankers, exclusive of the drain well.

4.9.7 At the final stage of flooding the lower edges of all open openings shall be at least 0.10 m higher than the damaged waterline.

4.9.8 In checking calculations of floodability the design volume of flooded compartments shall be taken with due consideration of volume permeability factors of each room of the compartment which shall be taken as equal to:

<table>
<thead>
<tr>
<th>Room Type</th>
<th>Permeability Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Machinery spaces</td>
<td>0.85</td>
</tr>
<tr>
<td>Accommodation spaces</td>
<td>0.95</td>

<td>0.95 if considered empty, otherwise 0.85</td>
</tr>
</tbody>
</table>

4.10.1 The machinery space entrance shall not face the cargo area and shall be located at a distance of not less than 2 m from the cargo area. If the entrance doors are not located in the superstructure recess the depth of which is not less than the door breadth, they shall open towards the cargo area.

4.10.2 The piping from the machinery space may be laid through the adjacent service space located within the cargo area and through the cofferdams and hold spaces as well. In this case, the pipeline wall thickness shall not be less than 4 mm, and the pipeline shall have no detachable joints and branches in the spaces through which the pipeline passes. Besides, the pipelines going through the service spaces shall have shut-off devices at the wall from the side of the machinery space.

6.24.3 Ventilation of the closed machinery space shall provide temperature in the machinery space of max. 40 °C at ambient temperature of 20 °C.

4.11 TIGHTNESS TEST

4.11.1 The integral cargo tanks and the residual cargo tanks shall be tested for tightness in accordance with Appendix 10 to RTSC, and type C independent cargo tanks shall be tested with pressure equal to 1.1 of working pressure.

4.12 PUMPS AND PIPELINES

4.12.1 The cargo system (liquid cargo system) and all its elements shall be located within the cargo area.

4.12.2 In addition to capability of switching off the cargo pumps from the control station located within the cargo area, it shall be possible to remotely switch off the cargo pumps from the station located out of the cargo area.

4.12.3 The cargo pumps shall be located at a distance of not less than 6 m from the entrances or openings of the accommodation and service spaces located out of the cargo area.

4.12.4 The cargo piping shall not be placed under the deck, except for the cargo pumps located on the main deck.

4.12.5 The cargo system pipelines shall be designed so that it can be possible to drain residuals of dangerous goods (on completion of loading and discharge processes) from the system to the shore or ship tanks.

4.12.6 The cargo piping of type G tankers, gas-freeing manifolds, except for valves for shore connection, and stop, safety and other valves shall be located inside the zone limited in width to the outer boundaries of the cargo area.
tank domes and shall be clear off the ship’s side at least one quarter of the hull breadth. However, if there is only one dome across the breadth of the ship, these pipelines and valves shall be placed at a distance of not less than 2.7 m from the ship’s side. This requirement does not apply to the pipelines located behind the safety valves. The connections of the adjacent tanks shall be located on the line connecting the centres of the domes. The closing devices shall be located on the dome.

The shut-off system of the cargo piping shall consist of two devices, one of which shall be remotely operated quick-acting stop device.

4.12.7 The shore connections shall be located at a distance of not less than 6 m from the entrances to or openings of the accommodation and service spaces outside the cargo area.

4.12.8 The connections of the gas-freeing and cargo systems used during loading and discharge shall have the shut-off device. If these connections are not used during loading and discharge, they shall be blanked off.

4.12.9 The connections of the loading and discharge pipes used during loading or discharge shall be equipped with a device for removing residuals of dangerous goods.

4.12.10 The ship shall be provided with a fixed cargo tank stripping system. The stripping system shall provide the following maximum residual quantity of stripping solution (m³):

- for each cargo tank $5 \times 10^{-3}$
- for the entire stripping system $15 \times 10^{-3}$

4.12.11 When dangerous goods that can form substances aggressive to material of pipelines in contact with water (goods of class 8), flanges and stuffing boxes shall be protected from water splashes.

4.12.12 Distances mentioned in 4.12.3 and 4.12.7 may be reduced to 3 m if the cargo area is limited by a side-to-side cross wall as high as one tier of superstructure or more with no openings and entrances of accommodation spaces.

4.12.13 The cargo piping of type G tankers may not be used as ballast ones.

If washing water of type C and N tankers is supplied to the cargo tanks through the cargo piping system, inlet branches of these pipelines shall be within the cargo area, but out of the cargo tanks.

4.12.14 The cargo piping and gas-freeing manifolds shall have no flexible connections with swing joints.

4.13 RESIDUAL DANGEROUS GOODS TANKS AND SETTLING TANKS

4.13.1 The ship shall be provided with a tank for residual dangerous goods and a tank for settling with cannot be pumped out. These tanks shall be placed within the cargo area only. Independent tank containers may be used instead of stationary residual dangerous goods tanks. In this case, the ship shall be equipped with a device for collecting possible leakages of dangerous goods while the tank containers are being filled.

4.13.2 Maximum permissible capacity of dangerous goods residual tanks shall not exceed 30 m³.

4.13.3 The dangerous goods residual tanks shall be equipped with the following:

.1 for C type tankers:
  - quick-acting outlet pressure-relief valves
  - vacuum valves with flame arresters
  - closable opening for measurements
  - connections with stop valves for pipelines and hoses

.2 for type N tankers with open cargo tanks:
  - a pressure equalization device which shall have a flame arrester
  - opening for measurements
  - connections with stop valves for pipelines and hoses

.3 for type N tankers with enclosed cargo tanks:
  - pressure relief valves and vacuum valves with flame arrester
  - a device for measuring filling ratio
  - connections with stop valves for pipelines and hoses.
4.13.4 The residual dangerous goods tanks shall not be equipped with crossover pipes connecting them with the gas-freeing system of the cargo tanks.

4.13.5 The cargo containers, tank containers, and portable tanks used to take residues of dangerous goods or settlings shall be equipped with:
- a branch pipe for freeing gases expelled during loading
- a filling ratio indicator
- connections with shut-off devices for pipelines and hoses.

The residual dangerous goods tanks, cargo containers, tank containers or portable tanks shall not be connected with the gas-freeing manifold of the cargo tanks, except for connection to fill them.

The residual dangerous goods tanks, cargo containers, tank containers, and portable tanks located on the deck shall be removed from the side for a distance of not less than a quarter of the ship breadth.

4.14 WATER SPRAYING SYSTEM

4.14.1 To reduce volume of vapours expelled by dangerous goods, cool the tops of the cargo tanks and meet the requirements of Appendix 1, a water spraying system shall be provided on the deck within the cargo area (see 3.5 Part III of the Rules).

The water spraying system shall be activated from the ship wheelhouse.

4.14.2 It shall be possible to feed the water spraying system from shore.

4.14.3 The water spraying system pump shall provide water flow of at least $5 \times 10^{-2} \text{ m}^3/\text{h}$ per square meter of the deck area.

4.15 ENGINES AND GAS EXHAUST PIPING

4.15.1 Closed-cup vapour flash point of liquid fuel used for the main and auxiliary engines shall be higher than 60 °C, and for the emergency diesel generators, not less than 55 °C.

4.15.2 Temperature on the outside surfaces of the engines used during loading and discharge and that of their air intake and gas vent ducts shall not exceed the permissible values set in view of temperature class of carried dangerous goods as specified in the accompanying documentation for goods. This requirement does not apply to the engines installed in the service spaces which comply with the following requirements:

1. These spaces shall be equipped with a ventilation system providing positive pressure of 0.1 kPa. All windows (scuttles) of these spaces shall not be openable. The ventilation system inlet openings of the spaces considered shall be placed at a distance of 6 m min. from the cargo area and at a height of 2 m min. from the deck;

2. These spaces shall be equipped with a continuously operating gas detection system with sensors located as follows:
   - in ventilation system inlet openings at upper edge of coamings of doors of accommodation and service spaces;
   - when gas concentration in the spaces considered reaches 20% of lower explosive limit specified in the dangerous goods documentation, the fans shall be activated. In this case and when positive pressure is not maintained any more or the gas detection system fails, the electrical equipment not intended for operation in explosion-hazardous spaces of category 2 and above shall be deactivated.
   - Type of explosion protection of electrical equipment of ventilation system, gas detection system and alarm shall comply with working conditions in explosion-hazardous spaces of category 1.

4.15.3 The gas exhaust pipelines of the main and auxiliary engines shall not be laid through the cargo. The gas exhaust pipeline outlets shall be located at a distance of not less than 2 m from the cargo area.
4.16 BILGE AND BALLAST PUMPS

4.16.1 Bilge and ballast pumps for spaces located within the cargo area shall be installed within this area.

This requirement does not apply to the double side and double bottom spaces that have no common bulkhead with the cargo tanks, as well as to the cofferdams and hold spaces if ballasting is performed by means of the fire extinguishing system pipeline located in the cargo area, and unballasting, by means of ejectors.

4.16.2 If a ballast pump is installed in the cargo area, the delivery pipe and its side suction branch pipe for water ballasting shall be located within the cargo area, but out of the cargo tanks.

4.16.3 The cargo pump room located under the deck shall be drained by means of the autonomous system located within the cargo area and not connected with another system. Such a system shall be placed outside of the cargo pump room.

4.17 ADDITIONAL FIRE SAFETY REQUIREMENTS

4.17.1 The smoke funnel outlets shall be at a distance of not less than 2.00 m from the cargo area boundaries. Measures shall be taken to prevent flyout of sparks\(^1\) from the funnel outlets and ingress of water into the funnels.

4.17.2 The heating and cooking devices shall not use oil fuel, gas or solid fuel, except for the heating devices or boilers installed in the machinery space which are fired with oil fuel with vapour flash point of 60 °C and above.

The cooking or air cooling devices may be installed in the accommodation spaces only.

4.18 INERT GAS SYSTEM

4.18.1 The inert gas system shall maintain constant minimum pressure of 7 kPa in the spaces being protected. When operated, the inert gas injection installation shall not cause pressure increase in the cargo tank above pressure on which the overpressure valve is adjusted. The vacuum valve operation pressure shall be equal to 3.5 kPa.

4.18.2 If the ship is not provided with the inert gas generator, the inert gas storage shall be made available in amount required to inert the tanks during loading and discharge with consideration of possible loss of inert gas during carriage.

4.18.3 The inert gas pressure and concentration shall be monitored in the space being protected. In case of pressure drop and increase of concentration of inert gas, light and sound alarms shall be transmitted to the wheelhouse. The same signals shall be transmitted to the spaces wherein at least one crew member is present.

4.19 DANGEROUS GOODS HEATING SYSTEM

4.19.1 The boilers used to heat dangerous goods shall be fired with oil fuel with vapour flash point of above 60 °C. These boilers shall not be installed within the cargo area.

4.19.2 The dangerous goods heating system shall be designed so as to exclude ingress of dangerous goods into the boiler when the coils of this system become untight.

4.19.3 If the dangerous goods heating system is used during loading and discharge processes, the electrical equipment of the dangerous goods heating system located on the deck out of the cargo area shall be of explosion-proof design. The inlet openings of the ventilation system in the spaces, wherein the electrical equipment of the dangerous goods heating system is placed, shall be at a height of not less than 2 m from the deck.

---

\(^1\) Here, sparks are understood as incandescent particles of fuel or its inclusions unburned in the engine cylinders and boiler furnaces and brought out by flow of gases into the gas exhaust system or smoke funnel.
level and shall be located at the following minimum distance (m):

- from the cargo area: 2
- from the openings of residual dangerous goods tanks, cargo pumps located on the deck, pressure relief valves and connections of cargo piping for reception from shore and the openings of the quick-acting outlet valves: 6

4.20 DANGEROUS GOODS COOLING SYSTEM

4.20.1 If the dangerous goods containment system is not rated for full positive pressure of dangerous goods vapours under conditions of maximum ambient temperature, pressure in the cargo tank shall be maintained below the maximum permissible set pressure of the safety valve by using one or several systems mentioned below:

- .1 Pressure control systems in the cargo tanks
- .2 Systems which use dangerous goods vapours as fuel for aboard ship or excessive heat recovery systems. If means are available for dissipating excessive energy (heat) produced by the above systems, these systems may be used when the ship is underway or at rest or in manoeuvring;
- .3 Systems which provide safety by preventing heating of dangerous goods and associated increase of cargo pressure. The insulation used in the cargo tanks shall make it possible to maintain temperature of dangerous goods in these tanks while the ship is being loaded and en route below the maximum temperature which corresponds to the maximum permissible activation pressure for the safety valves. In this case, the insulation design and strength properties of the cargo tank shall be rated for service life equal to at least three-fold specified service life of cargo tank at design pressure and temperature;
- .4 Other systems approved by the River Register.

4.20.2 Materials used to manufacture elements of systems mentioned in 4.20.1 shall not react and interact with goods to be carried or with their vapours. When the ship is in operation, the maximum design environmental temperature shall be taken equal to 20 °C for fresh water, 32 °C for sea water and 45 °C for air.

4.20.3 The cargo tanks of type G tankers shall withstand pressure of dangerous goods vapours at maximum design environmental temperature irrespective of a system provided for operating gas vapours.

4.20.4 The cooling system shall consist of one or several refrigerating units which make it possible to maintain design pressure and temperature of dangerous goods at maximum design environmental temperature. The heat-exchangers of these units (evaporators and condensers) shall have heat-exchange surface area which exceeds the required one by at least 25%.

In addition to the main refrigerating unit, the cooling system shall be equipped with a standby refrigerating unit (units) with refrigeration capacity equal to or exceeding the main refrigerating unit refrigeration capacity. The standby refrigerating unit shall include the control system and valves required for the autonomous operation of the refrigerating unit.

The cargo tanks, pipelines, and auxiliaries shall have heat insulation and sealing which can maintain a temperature which does not cause the safety valves to open for at least 52 h when all dangerous goods cooling systems go out of operation.

4.20.5 The safety devices and connecting pipelines of the cooling systems shall be connected to the cargo tanks above the liquid phase of dangerous goods when the cargo tanks are filled to their maximum permissible filling ratio. They shall remain in the gas phase at ship heel of up to 12°.

4.20.6 When two and more cooled dangerous goods which can chemically react are carried simultaneously, their cooling systems shall prevent these goods from mixing.

When these dangerous goods are carried simultaneously, the individual main and standby refrigerating units complying with the requirements of 4.20.4 shall be provided for
each dangerous goods. It is allowed not to install separate refrigerating units if dangerous goods are cooled by an indirect cooling system (see 4.20.9.2) or a combined cooling system (see 4.20.9.3), and leakage in the evaporator does not cause dangerous goods to mix.

4.20.7 If the ship simultaneously carries two and more cooled dangerous goods which under conditions of carriage do not dissolve in each other, but, when mixed, evolve vapours creating additional pressure, these cooling systems shall be designed so as to prevent these dangerous goods from mixing.

4.20.8 If sea water is used in the cooling system, a separate sea water pump intended to serve this system only shall be installed. This pump shall receive sea water from two kingston valves located on the different sides of the ship.

Besides, each cooling system shall be provide with a standby pump of the same capacity as the main one, and it shall receive sea water from two kingston valves located on the different sides of the ship too.

A pump intended for other purposes with capacity and head equal to those of the main pump may be used as a standby one, if its function of cooling dangerous goods does not interfere with its main function.

4.20.9 One of the following systems may be used to cool dangerous goods:

.1 direct cooling when vapouring dangerous goods are compressed, condensed and returned to the cargo tanks
.2 indirect cooling when dangerous goods (fluid fraction) or vapouring dangerous goods are cooled or condensed, carrying heat off to the cooling agent, without compression
.3 combined cooling when vapouring dangerous goods are compressed, condensed and cooled in the refrigerating unit evaporator and then cooled liquid dangerous goods are returned to the cargo tanks.

4.20.10 Specifications for delivery of cooling medium and cooling agent shall consider their compatibility with each other and with dangerous goods which they can contact with. Dangerous goods may be cooled in the heat exchanger located out of the cargo tank or by means of the condenser coils mounted inside or outside of the cargo tank.

4.20.11 If the cooling system is located in a separate service space, such service space shall meet the requirements of 4.6.1 and 4.6.3.

4.20.12 Heat flows to the environment shall be calculated for all cargo systems. Calculations shall be validated by results of heat-balance tests.

4.21 INSTRUMENTS

4.21.1 The cargo tanks shall be equipped with:

.1 level indicator
.2 alarm device operating when cargo tank filling ratio reaches 86% for type G tankers and 90% for type C and N tankers
.3 limit level sensor operating when filling ratio reaches 97.5%
.4 cargo tank gas pressure monitor
.5 cargo temperature monitor for C and N type tankers if dangerous goods require heating or limitations of maximum temperature of dangerous goods are present
.6 sampling device for closed type G tankers, for closed or partly closed C and N type tankers and/or sampling opening depending on requirements specified in Appendix 1 as applied to carried dangerous goods.

4.21.2 Permissible error for determination of filling ratio shall not exceed 0.5%.

4.21.3 The level indicator shall be located so that its indications can be seen from the respective tank shut-off device control station. In case of remote cargo control, it is allowed to transmit level indications over the loudspeaker communication or by means of hand radio.

4.21.4 The level indicator and the level alarm device shall be independent from each other.

When operated, the level alarm device shall give light and sound alarms to the cargo control station and to the wheelhouse. These sig-
nals shall differ from the high level sensor signals.

The light signal shall be visible from each cargo tank stop valves control station located on the deck. It shall be possible to check operability of sensors and electric circuits or these sensors and circuits shall be of safe type in view of operating principle.

4.21.5 When operated, the limit level sensor shall give light and sound alarms and simultaneously provide deactivation of the ship cargo pump or initiate deactivation of the shore pump.

4.21.6 The limit level sensor shall be independent of the alarm sensor (detector), but can be integrated with the level sensor.

4.21.7 The gas pressure and dangerous goods temperature monitor shall give light and sound alarms to the wheelhouse, continuous watchkeeping positions and cargo control station when the set pressure is exceeded or lowered. When the set pressure is exceeded during loading of dangerous goods, the transmitted alarms shall cause the cargo pump to be off and the shore pump to stop.

4.21.8 The pressure monitor shall operate when the quick-acting outlet valve operation pressure is exceeded by 1.15 times and the vacuum valve operation pressure is lowered by 1.1 times. The maximum permissible operation temperature of the temperature monitor shall be set for particular carried dangerous goods in accordance with the dangerous goods declaration. The above temperature value necessitates presence of dangerous goods cooling system or heating system onboard the ship (in addition to the requirements of Appendix 1).

4.21.9 The alarm devices mentioned in 4.21.7 may be integrated with high level sensor signalling device.

4.21.10 If pressure gauges are used to measure positive or negative pressure, their scale shall be at least 0.14 m in diameter, and positive or negative pressure limit values shall be marked on the scale with a red line.

4.21.11 Indications of pressure gauges or other indicators which perform the same function shall be visible from the cargo control position. If this requirement is not met, this information shall be transmitted to the cargo control position by means of loudspeaker or portable radio communication.

4.21.12 If cargo handling is controlled from the cargo control station, the light and sound signals mentioned in 4.21.7 shall be transmitted to the cargo control station in addition to the main deck. Here, the main deck shall receive the generalized signal which shall be detailed in the cargo control station. The cargo control station shall be designed so as all cargo area on the main deck can be visible.

4.21.13 The closed-type sampling device shall be designed so that possibility of leakages of cargo or its vapours can be eliminated during sampling.

4.21.14 The partly closed-type sampling device shall be designed so as to prevent leakage of cargo or its vapours during sampling, while leakage of dangerous goods or their vapours in amounts not endangering people is allowed.

4.21.15 Diameter of sampling openings shall not exceed 0.3 m. If the cargo is fire-hazardous, each sampling opening shall be provided with a closure with flame arrester which automatically closes the opening after sampling.

4.21.16 The sampling openings shall make it possible to measure filling ratio of cargo tanks with dipsticks. Openings for taking measurements shall be equipped with a self-closing cover.

4.21.17 It shall be possible to remotely close the quick-acting shut-off valve mounted on the flexible pipeline connecting the ship to the shore by means of switches. These switches shall be installed on the ship in two places (at bow and at stern).

4.22 ELECTRICAL EQUIPMENT

4.22.1 The onboard distributing networks shall not use the ship’s hull as a feedback, except for insulation resistance monitors pro-
vided that the leakage current does not exceed 30 mA.

4.22.2 The independent cargo tanks, tank containers, and all sealing flanges of connectors of cargo piping and hoses shall be grounded to the hull.

4.22.3 The technical documentation available on the ship shall contain the layout of explosion-hazardous zones and spaces agreed on with the River Register and the list of electrical equipment in these zones and spaces.

4.22.4 The cables laid in the explosion-hazardous spaces shall be connected to the electrical equipment installed in these spaces and areas only.

The transit cables may be laid through these spaces only if the requirements are met as specified in 2.10.9 to 2.10.11 Part VI of the Rules.

4.22.5 The movable cables intended for signal lights and gangway lighting fittings shall meet the requirements of 2.10.9 Part VI of the Rules, and the cable core cross-section shall not be less than 1.5 mm².

4.22.6 The cargo tanks, residual cargo tanks, and loading and discharge pipelines (zone 0) may accommodate only measuring, adjusting and signalling devices with type of explosion protection (Exia), and their cables shall meet the requirements of 2.10.13 Part VI of the Rules.

4.22.7 The cofferdams, double side spaces, double bottom spaces, and hold spaces (zone 1) may accommodate the following electrical equipment:

- measuring, adjusting and signalling devices with type of explosion protection (Exib)
- lighting fittings with type of explosion protection (Exd)
- sealed echo-sounder vibrators cables to which are laid in corrosion-resistant steel seamless tubes with gastight connections up to the main deck
- cables of active cathodic protection of hull plating which are laid in protective steel tubes.

4.22.8 The service spaces located within the cargo area below deck may accommodate the following electrical equipment:

- measuring, adjusting and signalling devices with type of explosion protection ‘ib’ (Exib)
- lighting fittings with type of explosion protection (Exd)
- main equipment driving motors (for example, for ballast pumps) with type of explosion protection (Exd) or (Exp).

4.22.9 Instruments and safety devices of electrical equipment mentioned in 4.22.6 through 4.22.8 shall be located out of the cargo area, unless they are explosion protected according to the Rules.

4.22.10 Electrical equipment located within the cargo area on the deck shall meet the requirements of 4.22.12 through 4.22.13.

4.22.11 Storage batteries shall be placed out of the cargo area.

4.22.12 The electrical equipment used during loading, discharge and degassing at the pier and located out of the cargo area depending on operation conditions shall be:

- with type of explosion protection (Exe) for apparatuses and devices which can spark or are exposed to heating up to 80 °C
- without explosion protection for apparatuses and devices which cannot spark or are not exposed to heating up to 80 °C. Enclosure shall have degree of protection depending on site of installation in accordance with 2.3.6 Part VI of the Rules.

4.22.13 The requirements of 4.22.12 do not apply to:

- lighting fittings located in accommodation spaces, except for switches located at entries of accommodation spaces
- communication facilities located in accommodation spaces or wheelhouse;
- electrical equipment installed in the accommodation spaces, wheelhouse or service spaces located out of the cargo area if the following conditions are satisfied:

These spaces shall be equipped with a ventilation system providing positive pressure of 0.1 kPa min.
All windows (scuttles) of these spaces shall not be openable.

Inlet openings of ventilation system of these spaces shall be placed at a distance of 6 m min. from the cargo area and at a height of 2 m min. from the deck.

4.22.14 The electrical equipment which do not conform to the requirements of 4.22.12 to 4.22.13 and its switches shall have red marking.

4.22.15 The sockets, which navigation lights and gangway lighting fittings are connected to/disconnected from, shall be designed so that connection to and disconnection from electric circuit are possible only if they are deenergized. These sockets shall be protected from mechanical damages.

4.22.16 When the electrical equipment located in the cargo area is deenergized, the respective light and sound signals informing on the fact shall be transmitted to the continuous watchkeeping position.

4.22.17 The cables to connect to the electrical equipment mentioned in 4.22.6 and 4.22.7 shall be laid in accordance with the requirements of 2.10.13 Part VI of the Rules.

4.23 SHOWER AND WASHBASIN

4.23.1 A shower and a washbasin shall be provided on the ship at a location which is directly accessible from the cargo area.

4.24 EMERGENCY EXIT

4.24.1 Spaces the entrances or exits of which are likely to become partly or completely immersed in the damaged condition shall have emergency exits with their lower edges situated not less than 0.10 m above the damaged waterline. This requirement does not apply to forepeak and afterpeak.
5.1 GENERAL PROVISIONS

5.1.1 This section requirements apply to river–sea navigation ships carrying in bulk liquid dangerous goods listed in Appendix 2.

5.1.2 This section sets general requirements for design of ships mentioned in 5.1.1. Additional special requirements stipulated by necessity of safety during carriage of particular dangerous goods are stated in Appendix 2.

5.1.3 The requirements of this section supplement the requirements stated in 4 of this Part. If the requirements stated in 4 and 5 of this Part with regard to the same object differ, the stricter requirements of the Rules shall be applied.

5.2 MATERIALS

5.2.1 If col. 13 “Structural materials” of Table A2-1 in Appendix 2 contains digits from 1 to 8, the following component metals and elements shall not be used to manufacture cargo tanks, pipelines, valves, fittings and other equipment which may contact with dangerous goods or their vapours:
- digit 1 — aluminium, copper, copper alloys, zinc, galvanized steel
- digit 2 — copper, copper alloys, zinc, and galvanized steel
- digit 3 — aluminium, magnesium, zinc, galvanized steel
- digit 4 — copper and copper alloys
- digit 5 — aluminium and aluminium alloys, copper and copper alloys
- digit 6 — copper, silver, magnesium, metal compound acetylides, and their alloys
- digit 7 — copper and alloys containing more than 1% of copper
- digit 8 — aluminium, zinc, and galvanized steel.

5.2.2 If col. 13 “Structural materials” of Table A2-1 in Appendix 2 contains digits from I to V, the following materials shall be used to manufacture cargo tanks, pipelines, valves, fittings and other equipment which may contact with dangerous goods or their vapours:
- digit I — steel with suitable protective lining or coating
- digit II — corrosion-resistant steel, if dangerous goods concentration is 98% or more
- digit III — special acid-resistant corrosion-resistant steel, if dangerous goods concentration is less than 98%
- digit IV — cryogenic austenitic corrosion-resistant steel (hardened)
- digit V — corrosion-resistant steel or steel with protective lining or coating.

5.2.3 If col. 13 “Structural materials” of Table A2-1 in Appendix 2 contains letter “Ý”, all materials used in the electrical equipment (copper, aluminium) and insulating materials require protection against contact with carried dangerous goods or their vapours.

5.2.4 Structural materials with melting temperature of less than 925 °C shall not be used to manufacture the outer pipelines used for handling dangerous goods on ships intended to carry dangerous goods with closed-cup vapour flash point of less than 60 °C.
5.3 SIDE DRAIN HOLES

5.3.1 The drain system pipelines for the spaces located below the watertight bulkheads deck or for the superstructures and houses provided with the weathertight doors shall be provided with a remotely operated non-return valve. The non-return valve shall be located at the side drain hole and shall be controlled from a position located above the watertight bulkheads deck.

5.3.2 If the vertical distance between the upper edge of the side drain system hole and the maximum load waterline exceeds 0.01L (where L is ship length along maximum load waterline, m), the drain system pipelines shall have two non-return valves located at a distance of 0.5 m max. from each other. Remote operation of these valves is not required, if access to them is provided under operation conditions.

5.4 CARGO TANKS

5.4.1 The cargo tanks of type 1 ships shall be removed:
   from the side plating to a distance of not less than B/5
   from the bottom plating along the centre plane to a distance of not less than B or 760 mm, whichever is less.

5.4.2 The cargo tanks of type 2 ships shall be removed from the bottom plating along the centre plane to a distance of not less than B or 760 mm, whichever is less.

5.4.3 The suction wells of cargo tanks, except for cargo tanks of type 1 ships, may be ignored in determination of damaged compartments if the suction well is located below the inner bottom plating at a distance of not more than 25% of the double bottom depth or not more than 350 mm, whichever is less.

5.4.4 If several types of dangerous goods capable of reacting with each other are carried, the cargo tanks with such goods shall be separated from each other with a cofferdam, empty space, cargo pump room of empty tank or of cargo tank with dangerous goods which do not react in contact with goods in the adjacent tank.

5.4.5 The volume of dangerous goods in one cargo tank of type 1 ship shall not exceed 1250 m³.

5.4.5 The volume of dangerous goods in one cargo tank of type 2 ship shall not exceed 3000 m³.

5.5 VENTILATION IN CARGO AREA

5.5.1 The cargo pump rooms and other enclosed spaces, wherein cargo handling equipment is installed, and the spaces wherein dangerous goods are handled, shall be equipped with the forced ventilation systems controlled from the outside.

5.5.2 These spaces shall be ventilated before people enter them and before the equipment located in them is started. A warning notice shall be placed at the entrances of these spaces to notify of necessity of such ventilation.

5.5.3 The ventilation system capacity shall not be less than 30 air changes per hour in the entire volume of the space. As applied to specific carried dangerous goods, other requirements for ventilation system capacity may be applied according to 5.18 and col. 15 of Table A2-1 in Appendix 2.

5.5.4 The ventilation system shall be of stationary and exhaust type, except for ventilation of the cargo pump drive motors space which shall be of plenum exhaust type.

5.5.5 Exhaust ventilation ducts from the cargo area spaces shall be removed to a distance of not less than 10 m horizontally from ventilation inlets and openings to accommodation, service and machinery spaces, control stations and other spaces located out of the cargo area.

5.5.6 The ventilation ducts shall not go through the accommodation, service and machinery spaces.

5.5.7 When flammable dangerous goods are carried, the fan drive motors shall be located
outside of the ventilation ducts. The fans shall be designed so as to eliminate sparking; for this purpose, fan parts and assemblies shall be made of the following materials:

1. Impellers or housing — nonmetallic materials incapable of static build-up
2. Impeller or housing — non-ferrous metals
3. Impeller or housing — austenic corrosion-resistant steel
4. Impeller or housing — carbon steel with design radial gap of 13 mm min. between them.

5.5.8 The outer openings of the ventilation ducts shall be provided with protective screens with at least 13 mm mesh width.

5.5.9 The pump rooms (compartments) and other enclosed spaces not mentioned in 5.5.1 shall be equipped with forced ventilation systems controlled from outside of these spaces. These systems shall provide at least 20 air changes per hour in the entire volume of the space. Such spaces shall be ventilated before people enter them.

5.6.2 The entrance doors, air intakes and openings in the accommodation, service and machinery spaces and control stations shall not face the cargo area. They shall be located on the wall facing the side which is opposite to the cargo area and/or on the side walls at a distance of not less than 4% of the ship length, but not less than 3 m from the outer walls of the superstructure or deck house facing the cargo area.

5.6.3 The doors leading to the spaces from which there is no access to the accommodation and service spaces and to the control stations may be installed on the outer walls of the superstructures and deck houses at a distance of less than 4% of the ship length or less than 3 m from the walls facing the cargo area, whichever is more. The fire resistance of the structures (bulkheads, partitions, and decks) which limit the spaces with such doors shall comply with type A-60.

5.6.4 The metallic removable plates for dismounting the ship equipment may be installed at a distance of less than 4% of the ship length or less than 3 m from the cargo area, whichever is more.

5.6.5 In the wheelhouse, the windows (scuttles) facing the cargo area and the windows and doors on the side walls of the wheelhouse may be installed at the distance specified in 5.6.3 if such windows and doors are designed so that they provide gas tightness of the wheelhouse.

5.6.6 The scuttles and windows facing the cargo area, for which the requirement of 5.6.2 regarding the permissible distance to the cargo area is not met, shall be of blind type (see GOST 19261 and GOST 21672). Such scuttles located on the main deck shall have the internal covers made of steel or another material equivalent to steel in fire resistance and strength.

5.7 ACCESS TO SPACES LOCATED IN CARGO AREA

5.7.1 Access to the cofferdams, ballast tanks, cargo tanks and other spaces located in
the cargo area shall be provided from the weather deck.

5.7.2 Access to the spaces located in the double bottom spaces may be provided through the cargo pump room, cofferdam or pipe gallery.

5.7.3 The horizontal openings and manholes through which access to spaces is provided shall not be less than 600×600 mm so as to enable people, who wear self-contained breathing apparatuses and protective gear, of climbing and descending and to enable lifting of a casualty from the bottom of a space.

5.7.4 To provide passage through the vertical openings and manholes, their dimensions shall not be less than 600×800 mm. If the lower edge of such openings and manholes is located at a height exceeding 600 mm from the bottom plating or floor plating, the intermediate foot gratings or other footholds shall be installed.

5.8 FLOODABILITY

5.8.1 For floodability calculations, the dimensions of the side and bottom damages shall be taken according to 5.8.2 and 5.8.3.

5.8.2 Side damage dimensions shall be taken as follows:

1. longitudinal dimension — \( L^{2/3}/3 \)
2. transversal dimension — \( B/5 \)
3. vertical dimension — upwards without limitation.

5.8.3 Bottom damage dimensions shall be taken as follows:

1. longitudinal dimension:
   - within 0.3\( L \) from the fore perpendicular — \( 1/3L^{2/3} \)
   - within the test of the ship — \( 1/3L^{2/3} \) or 5 m, whichever is less
2. transversal dimension:
   - within 0.3\( L \) from the fore perpendicular — \( B/6 \)
   - within the rest of the ship — \( B/6 \) or 5 m, whichever is less
3. vertical dimension — \( B/15 \).

5.8.4 If a liquid containing cargo tank is damaged, it shall be assumed that the tank contents completely escape and are replaced with water to the waterline level complying with the equilibrium position of the flooded ship.

5.8.5 If pipes, channels, trunks or tunnels are located within the estimated damage length, the design solutions shall be made to prevent flooding of other compartments, except for those which are to be flooded when the ship is damaged.

5.8.6 Depending on ship class and her length the following requirements shall be met:

1. Type 1 ship shall meet the requirements stated in 5.8.7 and 5.8.8, when the hull is damaged to the extent specified in 5.8.2 and 5.8.3 in any place lengthwise;
2. Type 2 ship of 150 m inclusive in length shall meet the requirements stated in 5.8.7 and 5.8.8, when the hull is damaged to the extent specified in 5.8.2 and 5.8.3 in any place lengthwise, except for the bulkheads that limit the aft machinery space;
3. Type 2 ship of more than 150 m in length shall meet the requirements stated in 5.8.7 and 5.8.8, when the hull is damaged to the extent specified in 5.8.2 and 5.8.3 in any place lengthwise;
4. Type 3 ship of less than 125 m in length shall meet the requirements stated in 5.8.7 and 5.8.8, when the hull is damaged to the extent specified in 5.8.2 and 5.8.3 in any place lengthwise, except for damage to the aft machinery space. At the same time, the designer shall verify the ship floodability when the machinery space is flooded, and the calculation results shall be recorded in the stability and floodability booklet;
5. Type 3 ship of 125 m or more in length shall meet the requirements stated in 5.8.7 and 5.8.8, when the hull is damaged to the extent specified in 5.8.2 and 5.8.3 in any place lengthwise, except for the bulkheads that limit the aft machinery space.

5.8.7 At any stage of flooding, the maximum heeling angle resulted from unsymmet-
tical flooding shall not exceed 25°. This angle may be increased to 30°, if the deck is not immersed in this case.

5.8.8 At the final stage of flooding, the following conditions shall be satisfied:

.1 The length of the positive arm section of the damage stability curve until the lower edges of the openings, through which water could be spread into the intact compartments, are immersed shall not be less than 20°;

.2 The maximum arm of the damage stability curve on the positive arm section mentioned in 5.8.8.1 shall not be less than 0.1 m;

.3 Area under the damage stability curve within this part shall be not less than 0.0175 m·rad.

5.9 DRAIN AND BALLAST SYSTEMS

5.9.1 The ballast pumps, pipelines, and equipment of ballast tanks shall be isolated from the cargo tank equipment and from the cargo tanks.

5.9.2 The drain devices of the ballast tanks, which are adjacent to the cargo tanks, shall be placed outside of the machinery and accommodation spaces.

5.9.3 The cargo tanks shall be ballasted from the deck level using the ballast pumps provided that the respective pipeline has no permanent connection with the cargo tanks and cargo piping and is equipped with a non-return valve.

5.10 CARGO SYSTEM

5.10.1 The cargo piping located below the main deck may not be laid out of the cargo tank, which is serviced by this piping, and passed through the adjacent tank if the shut-off valve operated from the weather deck is fitted on the piping at the bulkhead from the side of the serviced tank and if goods carried in these adjacent tanks are compatible.

5.10.2 The cargo piping may not be laid through the accommodation, service and machinery spaces, except for the spaces and rooms in which the pumps and the cargo pumps are installed.

5.10.3 The mentioned in 5.10.1 shut-off valve on the pipeline of the cargo tank adjoining the cargo pump room may be installed on the separating bulkhead from the side of the cargo pump room provided that an additional valve is installed between the valve on the bulkhead and the pump.

5.10.4 If one cargo pump serves several cargo tanks, an individual shut-off valve shall be mounted on each cargo piping.

5.10.5 The cargo systems for the tanks containing dangerous goods, which capable of reacting with each other, shall be independent and not connected to each other. The cargo system piping shall not be laid through the cargo tanks unless this piping is laid in the tunnel.

5.10.6 The cargo piping laid in the tunnel shall meet the requirements of 5.10.1 and 5.10.2. The tunnels for this piping shall meet the requirements of the Rules applied to the cargo tank design, location and ventilation.

5.10.7 The cargo piping wall thickness shall not be less than the value determined by the following formula, mm:

\[ t = \left( t_0 + b + c \right) / (1 - 0.01a) \]

(5.10.7-1)

where \( t_0 \) — theoretical thickness determined by the following formula, mm:

\[ t_0 = p d / \left[ 20 \left( [\sigma] + p \right) \right] \]

(5.10.7-2)

\( p \) — design pressure, MPa,

\( [\sigma] \) — permissible stress, MPa,

\( a \) — negative allowance for wall thickness deviation during pipe manufacture (%),

\( b \) — bend allowance which shall not be less than that determined by the following formula, mm:

\[ b = 0.4 d t_0 / r \]

(5.10.7-3)

\( c \) — corrosion allowance, mm,

\( d \) — outer diameter, mm,

\( r \) — mean pipe bend radius, mm.
5.10.8 The design pressure shall not be less than 1 MPa, except for open-end lines, for which the design pressure shall not be less than 0.5 MPa.

5.10.9 The permissible stress $[\sigma]$ shall be determined as the lesser of the following values:

$$[\sigma] = R_m/2.7 \quad \text{or} \quad [\sigma] = R_{st}/1.8,$$

where $R_m$ — tensile strength of material at ambient temperature (MPa),

$R_{st}$ — yield point of material at ambient temperature (MPa).

5.10.11 The cargo piping heat expansion shall be compensated by installing the expansion coils or by making the bends in the piping. The expansion glands shall not be used.

The cargo control system shall consist of:

.1 a manually-operated shut-off valve on each filling and discharge line at the cargo tank pipe input. It is allowed not to install the shut-off valve on the unloading line of such cargo tank if a separate submerged pump is used to discharge this tank;

.2 a shut-off valve before each connection joint of cargo hose

.3 remotely-operated devices to switch all cargo pumps off.

5.10.12 The controls used during pumping of dangerous goods, except for those placed in the cargo pump room, shall not be installed below the main deck.

5.11 GAS-FREEING SYSTEM

5.11.1 All cargo tanks shall be equipped with gas-freeing systems. These systems shall be independent of air ducts and gas-freeing systems installed in other compartments of the ship. The gas-freeing systems for the cargo tanks containing dangerous goods, which are capable of reacting with each other, shall be independent and not connected to each other.

5.11.2 The tank gas-freeing systems shall eliminate possibility of water ingress into the cargo tanks.

5.11.3 Depending on properties of carried dangerous goods, the following types of gas-freeing systems are used:

.1 pressureless vapour release system providing pressureless inflow of cargo vapours into the cargo tanks and release of the same from these tanks during cargo handling

.2 controlled vapour release system in which pressure/vacuum relief valves are installed to limit pressure increase or vacuum creation in the cargo tank.

5.11.4 The gas-freeing pipelines of the cargo tanks made of corrosion-resistant material or of the lined or coated cargo tanks for specific dangerous goods shall have the same lining or coating or shall be made of corrosion-resistant material too.

5.11.5 The gas-freeing systems shall be connected to the top of each cargo tank. The gas-freeing pipelines shall be self-draining at all operating ship roll and pitch values. If the gas-freeing pipeline is to be drained in points located above the pressure/vacuum relief valve in the cargo tank, provision shall be made to install a drain valve in these points.

5.11.6 Shut-off valves and any other stop valves shall not be installed on the gas-freeing pipelines of the pressureless vapour release system.

5.11.7 The controlled vapour release system outlets shall be located at a height of not less than 6 m over the upper deck or over the catwalk if they are placed within 4 m from the catwalk and at a distance of not less than 10 m horizontally from the nearest air intake or opening leading to the accommodation, service and machinery spaces and from the open flame sources.

5.11.8 The height of the outlets mentioned in 5.11.7 over the deck or over the catwalk may be decreased to 3 m if such outlets are provided with high-velocity valves in which upward vapour release velocity is not less than 30 m/s.

5.11.9 The controlled vapour release system on the tanks, which carry dangerous
goods with vapour flash point below 60 °C, shall be equipped with a device preventing ingress of flame into the cargo tanks.

5.11.10 When selecting the gas-freeing system type and considering the special requirements for carriage of dangerous goods, follow the requirements stated in Appendix 2.

5.12 DEGASSING OF CARGO TANKS

5.12.1 Degassing of cargo tanks carrying dangerous goods which require the controlled vapour release system to be used shall take place:

.1 through the outlets of the controlled vapour release system pipelines

.2 through the outlets located at least 2 m over the upper deck. Here, vapour shall be released vertically at velocity of not less than 30 m/s which shall be maintained throughout all process of degassing;

.3 through the outlets located at least 2 m over the upper deck. Here, vapour shall be released vertically at velocity of not less than 20 m/s, and the openings shall be provided with devices preventing ingress of flame.

5.12.2 If concentration of flammable vapours at the outlets decreases to 30% of the lower flammability limit, degassing may be continued at the level of the deck above the cargo tanks.

5.12.3 Vapour release mentioned in 5.12.1.2 and 5.12.1.3 can be carried out both through stationary and removable piping.

5.13 CARGO TEMPERATURE CONTROL SYSTEMS

5.13.1 If properties of carried dangerous goods require a cargo temperature control system (dangerous goods heating or cooling system) to be fitted on the ship, such system shall meet the following requirements:

.1 Materials used to manufacture this system shall be compatible with carried dangerous goods (see 5.2);

.2 Type of heat transfer medium or refrigerant shall comply with carried dangerous goods (see Appendices 1, 2);

.3 Surface temperature of heating coils or channels shall be such that possibility of local overheating or supercooling of dangerous goods will be eliminated;

.4 The system at any loading of the ship, except for light ship condition, shall keep inside higher pressure as compared to maximum hydrostatic pressure of dangerous goods which have effect on the system;

.5 The dangerous goods heating or cooling system shall be fitted with valves to shut the system off each cargo tank and to enable manual control of parameters.

5.13.2 To prevent dangerous goods from overheating or supercooling a dangerous goods temperature monitoring alarm system shall be provided.

5.13.3 Additional requirements to the temperature control systems for specific dangerous goods are set in 5.18.

5.14 CARGO TANK ATMOSPHERE CONTROL

5.14.1 The following methods (and systems corresponding to these methods) may be used to control the cargo tank atmosphere:

.1 Inerting — filling of cargo tank and piping connected to it and, if necessary, spaces which surround cargo tanks, with inert gas or vapours which do not sustain combustion and do not react with dangerous goods, and maintenance of such state

.2 creation of insulating layer — filling of cargo tank and piping connected to it with fluid, gas or vapour which separate dangerous goods from air and maintenance of such state

.3 draining — filling of cargo tank and piping connected to it with dry gas or vapours with dew point of –40 °C or lower at atmospheric pressure and maintenance of such state

.4 ventilation.

5.14.2 The inert gas and insulating layer systems shall continuously keep a positive pressure of at least 7 kPa within the cargo area. The pressure produced by these systems shall not exceed the cargo tank safety valve operation pressure.
5.14.3 If the inert gas or insulating layer systems are used, the ship shall have inert gas reserves or this gas shall be generated in amount sufficient for its intended use considering natural loss during carriage.

5.14.4 In order to maintain the required atmosphere, the aids shall be provided for monitoring the underdeck hold area which is not filled with dangerous goods and contains gas surface layer.

5.14.5 The inerting and insulating layer systems shall exclude possibility of static charge generation during inflow of inert (insulating) substance.

5.14.6 If the dehumidified nitrogen dehydrating system is used as atmosphere control system, dehydrator amount calculation shall allow for diurnal air temperature and humidity fluctuations.

5.15 ELECTRICAL EQUIPMENT

5.15.1 When selecting electrical equipment to be used in explosion-hazardous areas, follow chemical activity characteristics of carried dangerous goods regarding explosion hazard of mixtures evolved by them as specified in columns 7 to 9 of Table A2-1 in Appendix 2.

5.15.2 The autonomous cargo tanks shall be grounded to the hull. All sealing gaskets of cargo piping and hose connectors shall be grounded to the hull. Piping and hose connections that have gaskets and sealing flanges of cargo piping and hose connectors shall be grounded to the hull.

5.16 FIRE EXTINGUISHING SYSTEM

5.16.1 The cargo pump room shall be equipped with a fixed fire extinguishing system, including the carbon dioxide fire extinguishing system conforming to the requirements of the Rules for carbon dioxide fire extinguishing systems of machinery spaces or the halogenated hydrocarbon fire extinguishing system.

5.16.2 The carbon dioxide fire extinguishing system and the halogenated hydrocarbon fire extinguishing system shall not be used for inerting.

5.16.3 Amount of carbon dioxide in the carbon dioxide fire extinguishing system shall be sufficient to completely fill a space equal in volume to 45% of the total cargo pump room volume with gas.

5.16.4 Amount of halon in the halogenated hydrocarbon fire extinguishing system shall not be less than the following values:

- For halon 1301: 7% of the cargo pump room volume
- For halon 1211: 7% of the cargo pump room volume
- For halon 2402: 0.3 kg/m³

5.16.5 If the ship is intended to carry goods, which cannot be extinguished by the fire extinguishing systems mentioned in 5.16.1, the cargo pump room may be provided with a fixed water spraying system or high-expansion foam fire extinguishing system.

5.16.6 To extinguish fire in the cargo area, each ship shall be provided with a fixed deck foam extinguishing systems complying with the requirements of 5.16.7 to 5.16.17.

5.16.7 The foam fire extinguishing system shall use one type of foaming agent only. If the foaming agent cannot extinguish whole spectrum of the carried dangerous goods, and/or it is incompatible with carried dangerous goods, additional fire extinguishing means shall be provided for such dangerous goods.

5.16.8 The foam generators shall be capable of supplying foam to all the deck area and to any cargo tank.

5.16.9 The main control panel of the foam fire extinguishing system shall be placed outside of the cargo area and be easily accessed to operate it in case of fire in a zone protected with the fire extinguishing system.

5.16.10 The foam solution supply rate shall not be less than the greatest of the following values:
2 L/min per square meter of the deck area above the cargo tanks. The deck area is determined by the following formula, m²:

$$S_d = B_{\text{max}} \cdot l,$$

where $B_{\text{max}}$ — maximum ship breadth (m),

$l$ — length of area occupied by the cargo tanks (m).

20 L/min per square meter of plan area of a cargo tank having maximum value of this area.

10 L/min per square meter of an area protected by the highest power foam supply monitor and completely located in front of it, but not less than 1250 L/min.

5.16.11 Quantity of foaming agent shall provide foam supply for at least 30 min with the maximum rate specified in 5.16.10.

5.16.12 Foam shall be supplied with monitors and foam-supply fire hose nozzles. Each monitor shall supply foam solution at a rate of not less than 50% of that required in 5.16.10.1 and 5.16.10.2. Capacity of any monitor shall not be less than that required in 5.16.10.3.

5.16.13 The distance from the foam-supply monitor location to the most distant boundary of the protected area located in front of it shall not be more than 75% of length of jet from the monitor under no wind conditions.

5.16.14 A foam-supply monitor and a foam-supply fire hose nozzle connector shall be installed at each side at the forward poop bulkhead or accommodation spaces that have entrances facing the cargo area.

5.16.15 The foam-supply fire hose nozzle capacity shall not be less than 400 L/min, and its jet length under no wind conditions shall not be less than 15 m. At least four fire hose nozzles shall be installed. The number and location of fire hydrants shall provide foam supply to any place of the deck above the cargo tanks from at least two foam-supply fire hose nozzles.

5.16.16 Valves shall be installed on the foam supply main and on the fire main, if it is an integral part of the deck foam fire extinguishing system, before each monitor to cut off the damaged sections of these mains.

5.16.17 Two portable powder-type fire extinguishers located within the cargo area with capacity of at least 12 kg of powder shall be provided in addition to others available on the ship.

5.17 PERSONNEL PROTECTION

5.17.1 A ship carrying toxic dangerous goods shall have not less than two complete sets of personnel safety equipment.

5.17.2 Each complete set of safety equipment mentioned in 5.17.1 shall consist of:

- one self-contained air-breathing apparatus (use of compressed oxygen is not allowed)
- protective clothing, shoes, gloves and goggles
- fire-resistant rescue line with belt
- portable explosion-proof lamp.

5.17.3 An adequate supply of compressed air shall be provided for equipment mentioned in 5.17.1 as follows:

- one set of fully charged air bottles for each breathing apparatus and air compressor suitable for supply of high-pressure air of required purity with a charging manifold capable of dealing with sufficient spare breathing apparatus air bottles, or
- fully charged spare air bottles with a total free air capacity of at least 6000 L for each breathing apparatus.

5.17.4 One set of equipment shall be kept in an accessible locker at the cargo pump room.

5.17.5 Respiratory protection and eye protection means shall be provided for evacuation of people onboard the ship; these means shall comply with the following requirements:

- Operating principle of respiratory protection means shall not be based on use of filter.
- Self-contained breathing apparatus shall operate for at least 15 min.
- Emergency escape respiratory protection means shall not be used for fire-fighting or cargo handling purposes.
This requirement applies to the ships carrying dangerous goods that have a respective mark in col. 14 of Table A2-1 in Appendix 2.

5.17.6 Medical first-aid equipment including oxygen resuscitation equipment and antidotes for goods carried shall be provided on board.

5.17.7 Decontamination showers and eye wash eye wash means shall be available on the ship deck.

5.18 SPECIAL REQUIREMENTS

5.18.1 Special requirements for ships carrying specific dangerous liquid goods, which are resulted from properties of these goods, are specified in 5.18.2 to 5.18.104. Necessity to comply with the respective requirement imposed to specific dangerous goods is indicated in col. 15 “Special requirements” of Table A2-1 in Appendix 2.

Ships carrying ammonium nitrate solution (concentration of 93% or less)

5.18.2 The tanks and equipment of these ships shall be independent from the cargo tanks and equipment containing other dangerous goods. Such tanks shall not be used to take sea water for ballast.

5.18.3 Before carriage of ammonium nitrate solutions, the cargo tanks and the equipment shall be cleaned to remove residuals of other dangerous goods.

5.18.4 When ammonium nitrate solutions are carried, the temperature of the heat transfer medium circulating in the cargo tank heating system shall not exceed 160 °C. The heating system shall be equipped with controls to keep bulk temperature of dangerous goods at 140 °C. The sensors (detectors) shall operate when the upper level of 145 °C and 150 °C and the lower level of 125 °C are reached. The signal shall also be given when the heat transfer medium temperature will exceed 160 °C. The signals shall be transmitted to the wheelhouse.

5.18.5 A fixed system shall be installed to inject gaseous ammonia into dangerous goods bulk. The system control panel shall be located in the wheelhouse. The ship shall have ammonia reserves in amount of 300 kg of ammonia per 1000 t of ammonium nitrate solution.

5.18.6 The gas exhaust piping shall be equipped with protective mushrooms which shall be accessible for visual inspection and cleaning.

Ships carrying carbon disulfide

5.18.7 During loading and unloading, the water blanket shall be created and maintained in the cargo tanks. During carriage, there shall be inert-gas blanket in the empty part of the cargo tank.

5.18.8 A closed opening for the instrument shall be provided to measure dangerous goods level in the emergency situation.

5.18.9 The cargo piping and gas exhaust pipes shall be independent from the piping and gas-freeing pipes used for other dangerous goods.

5.18.10 The submerged pumps used for unloading shall be installed in trunks or shall be hydraulically operated. The trunk-mounted pump drive shall be designed so as to eliminate sparking, and its elements shall not to be heated above 80 °C.

5.18.11 If the carbon disulfide cargo tanks are discharged by displacing it with water or with inert gas, the cargo system shall be rated for pressure and temperature which occur during discharging.

5.18.12 The safety valves shall be made of corrosion-resistant steel.

Ships carrying diethyl ether

5.18.13 The empty spaces located around the cargo tanks shall be inerted or shall have ventilation. The forced ventilation blowers shall be intrinsically safe. The forced ventilation equipment shall not be placed in the empty spaces located around the cargo tanks.
5.18.14 The safety valves mounted on the pressure cargo tanks shall be adjusted on pressure of not less than 20 kPa.

5.18.15 If inert gas displacement is used for discharging cargo, the cargo system shall be rated for the expected pressure.

5.18.16 Open flame and/or heat sources shall not be located in the cargo area.

5.18.17 The cargo pumps shall be designed so as to prevent transfer of fluid pressure to the shaft seal. If this requirement is not met, the hydraulically operated submerged pumps applicable to the specific dangerous goods according to their intended purpose shall be installed.

5.18.18 During loading, discharge and carriage of dangerous goods, the inert-gas blanket shall be maintained.

**Ships carrying hydrogen peroxide solutions (concentration of 60% to 70%)**

5.18.19 These hydrogen peroxide solutions shall be carried on the ships intended for these dangerous goods only, and other dangerous goods shall not be carried on these ships.

5.18.20 The cargo tanks and equipment connected to them shall be made of pure aluminium (99.5%) or corrosion-resistant steel, and their surfaces shall passivated. The pipelines located on the deck shall not be made of aluminium. All nonmetallic materials used to manufacture the cargo system shall not react with carried dangerous goods.

5.18.21 The pump rooms shall not be used for cargo handling.

5.18.22 The cargo tanks shall be separated with cofferdams from the fuel oil tanks and other spaces containing flammable and combustible materials.

5.18.23 The cargo tanks shall not be used for ballasting.

5.18.24 The temperature sensors shall be installed at the top and bottom parts of the cargo tank to provide continuous temperature monitoring for dangerous goods. If temperature exceeds 35 °C, sound and light alarm shall operate in the wheelhouse.

5.18.25 A fixed system of continuous oxygen monitoring (or gas sampling lines with periodic sampling) shall be installed in the empty spaces adjoining the cargo tanks. If oxygen concentration exceeds 30% by space volume, sound and light signals shall operate in the wheelhouse. In addition to the above fixed system, two portable instruments shall be provided to measure oxygen contents.

5.18.26 A system for emergency discharge of dangerous goods overboard shall be provided on the ship. The system shall be activated, if the cargo temperature increases by more than 2 °C per hour for five hours or if the cargo tank temperature exceeds 40 °C.

5.18.27 The cargo tank gas-freeing systems shall be equipped with pressure/vacuum relief valves and safety membranes for emergency discharge of gases.

5.18.28 The ship shall be fitted with a water spraying system to dilute and wash off hydrogen peroxide solution of any concentration spilled on the deck. The system shall cover the deck of those cargo tanks in which hydrogen peroxide solution is carried and connections of cargo manifold with hoses. The system capacity shall be determined from the following:

1. Within 5 min after spillage, dangerous goods shall be diluted to 35% mass concentration as related to their initial concentration;

2. The spillage intensity and the design parameters of a space occupied by spilled dangerous goods are determined considering the maximum expected intensity of loading and discharge, time required to stop dangerous goods flow in case of overfilling of cargo tank or damage to pipeline/hose, and time to be spent in the cargo control station or in the wheelhouse to prepare for water supply in order to dilute spilled dangerous goods.

5.18.29 The crew members participating in cargo handling shall be provided with protec-
Ships carrying hydrogen peroxide solutions
(concentration of 8% to 60% by mass)

5.18.30 The cargo tanks of these ships shall be separated from the ship hull plating.

5.18.31 The cargo tanks of these ships and the equipment connected to them shall be made of pure aluminium (95.5%) or corrosion-resistant steel which do not react with hydrogen peroxide. The pipelines located on the deck shall not be made of aluminium. All nonmetallic materials used to manufacture the cargo system shall not contribute to cargo decomposition.

5.18.32 These hydrogen peroxide solutions shall not be carried with any other dangerous goods. The cargo tanks in which these dangerous goods were carried may be used for carriage of other substances only after the tanks are stripped.

5.18.33 The cargo tanks shall be separated by the cofferdams from the fuel oil tanks or any other space containing materials which react with hydrogen peroxide.

5.18.34 The temperature sensors shall be installed at the top and bottom parts of the cargo tank to provide continuous temperature monitoring for dangerous goods. If temperature exceeds 35 °C, light and sound alarms shall operate in the wheelhouse.

5.18.35 In the empty spaces that have common bulkheads and decks with the cargo tanks, a fixed continuous oxygen monitoring system (or gas sampling lines with periodic sampling) shall be provided. If oxygen concentration exceeds 30% by space volume, light and sound alarms shall operate in the wheelhouse. In addition to the fixed system, the ship shall be provided with two portable instruments for measuring oxygen contents.

5.18.36 A system of emergency discharge of dangerous goods overboard shall be provided on the ship. The system shall be activated, if temperature of dangerous goods increases by more than 2 °C per hour for five hours or if the cargo tank temperature exceeds 40 °C.

5.18.37 The cargo tank gas-freeing systems shall be equipped with pressure/vacuum relief valves and safety membranes for emergency discharge of gases.

5.18.38 The ship shall be fitted with a water spraying system to dilute and wash off hydrogen peroxide solution of any concentration spilled on the deck. The system shall protect the cargo area of those tanks in which hydrogen peroxide solution is to be carried and the connections of cargo manifold with hoses. The system capacity shall be determined from the following:

1. Within 5 min after spillage, dangerous goods shall be diluted to 35% mass concentration as related to their initial concentration;
2. The spillage intensity and the design parameters of a space occupied by spilled dangerous goods are determined considering the maximum expected intensity of loading and discharge, time required to stop dangerous goods flow in case of overfilling of cargo tank or damage to pipeline/hose, and time to be spent in the cargo control station or in the wheelhouse to prepare for water supply in order to dilute spilled dangerous goods.

5.18.39 The crew members participating in cargo handling shall be provided with protective clothing capable of resisting effect of these hydrogen peroxide solutions.

5.18.40 The cargo piping used for pumping of hydrogen peroxide shall be insulated from all other systems.

Ships carrying engine fuel anti-knock additives that contain alkyl lead

5.18.41 The cargo tanks of these ships shall not be used to carry other cargo, except for substances used in production of engine fuel anti-knock additives containing alkyl lead.

Ships carrying yellow or white phosphorus

5.18.42 The cargo tanks of these ships shall be rated for pressure equal to or more than
water head of 2.4 m high over the top of the tank.

5.18.43 The ship shall have a system for filling the cargo tank space with water to create a water blanket over carried dangerous goods. When the ship is unloaded, the system shall be used to displace phosphorus from the space being emptied. All water pumped off the cargo tank shall be delivered to the shore.

5.18.44 When the cargo tanks are designed, the minimum interfacial area between phosphorus and water blanket shall be provided.

5.18.45 The cargo tank void space volume over the water blanket shall be filled with inert gas or naturally ventilated through two ventilating ducts with outlets located at different levels: at a height of not less than 6 m above the deck and not less than 2 m above the deck limiting the pump room from the top.

5.18.46 The dangerous goods heating system shall enable control of heat transfer medium temperature so that phosphorus temperature does not exceed 60°C.

5.18.47 A water sprinkling system which automatically operates in case of phosphorus leakage shall be provided in all empty spaces located around the cargo tanks.

5.18.48 The spaces mentioned in 5.18.47 shall be provided with forced ventilation, and it shall be possible to close inlet and outlet ventilation ducts in these spaces in emergency.

5.18.49 The cargo control system shall:
prevent overfill of tanks (for this purpose the system shall be provided with alarm which operates when the upper level of dangerous goods is reached in the cargo tank)
stop cargo handling in case of emergency on the ship or on the shore.

Ships carrying propylene oxide and mixtures of ethylene oxide with propylene oxide containing not more than 30% of ethylene oxide in mass

5.18.50 The cargo tanks of these ships shall be made of steel.

5.18.51 The cargo tanks of these ships may be used to carry other dangerous goods only after these tanks and the piping systems connected to them are cleaned by washing or blowing down.

5.18.52 All valves, flanges, fittings, and auxiliary equipment shall be made of steel. Disks or surfaces of disks and valve pockets shall be made of corrosion-resistant steel with chromium content of not less than 11%.

5.18.53 The insulating and sealing materials shall not react with propylene oxide and mixtures of ethylene oxide with propylene oxide containing not more than 30% of ethylene oxide in mass, dissolve in them and reduce their spontaneous ignition temperature.

5.18.54 The following materials shall not be used to make seals, cups and glands to be used in the cargo systems:
neoprene or natural rubber if they contact with such dangerous goods
asbestos or materials with asbestos
materials containing magnesium oxides, for example, mineral wool.

5.18.55 Thread joints shall not be used in the pipelines intended for pumping liquid dangerous goods mentioned in 5.18.53 and their vapours.

5.18.56 The filling and discharge pipelines shall be located at a distance of not more than 100 mm from the bottom of the cargo tank or any sump.

5.18.57 The cargo system of the tank in which dangerous goods specified in 5.18.53 are carried shall have a valved connection for returning cargo vapours.

5.18.58 The cargo and gas-freeing systems of the tank mentioned in 5.18.57 shall be designed so as to exclude possibility of vapour release from the tank into the atmosphere during cargo handling. The system used to return vapours of dangerous goods to the shore, which is connected with the cargo system of the cargo tank intended for dangerous goods, shall be independent of other cargo systems.
5.18.59 During discharge, positive pressure of more than 7 kPa shall be maintained in the cargo tank.

5.18.60 Dangerous goods mentioned in 5.18.53 are discharged by means of the trunk-mounted cargo pumps, hydraulically operated submerged cargo pumps or by displacing dangerous goods with inert gas. The cargo pump shall be designed so as to prevent heating of pumped cargo when the discharge pipeline of the pump is closed or blanked off by some means or other.

5.18.61 Gases from the tanks in which these dangerous goods are carried shall be exhausted independent of the cargo tanks in which other dangerous goods are carried. Cargo tank contents shall be mandatorily sampled by means of closed-type devices which prevent escape of dangerous goods or their vapours into the atmosphere during sampling.

5.18.62 The cargo tanks, empty spaces, and other spaces that have common bulkheads and decks with the integrated pressure cargo tank with propylene oxide shall contain dangerous goods compatible with propylene oxide or these spaces shall be inerted. Any hold space containing an autonomous cargo tank shall be inerted too. These spaces and cargo tanks shall be monitored for ingress of carried dangerous goods from other cargo tanks and for oxygen concentration in atmosphere which shall be less than 2%.

5.18.63 The cargo system shall be designed so as to prevent ingress of air into the system filled with cargo.

5.18.64 Propylene oxide shall be carried in pressure tanks, autonomous tanks or integrated tanks. Mixtures of ethylene oxide/propylene oxide shall be carried in autonomous tanks or pressure tanks. The tanks shall be designed with consideration of maximum pressure which can occur during loading, carriage or discharge of dangerous goods mentioned in 5.18.53.

5.18.65 The cargo tanks designed to carry propylene oxide with design positive pressure of less than 60 kPa and the cargo tanks designed to carry mixtures of ethylene oxide/propylene oxide with design positive pressure of less than 120 kPa shall be equipped with the dangerous goods cooling system.

5.18.66 The cooling system mentioned in 5.18.65 shall keep temperature of dangerous goods below their boiling temperature at the given pressure. For this purpose, at least two refrigerating units automatically controlled depending on temperature variation in the cargo tanks shall be used. The refrigerating units control system shall be capable of changing over to manual control. If the temperature controls become inoperable, the respective alarm shall operate. The refrigerating capacity of each refrigerating unit shall sufficient to keep temperature of dangerous goods at a level lower than the design one.

5.18.67 As an option, three refrigerating units may be used, any two of which have total refrigerating capacity sufficient for keeping temperature of dangerous goods at a level below the design one.

5.18.68 Refrigerating agent separated from carried dangerous goods by a single wall shall be inert to such dangerous goods.

5.18.69 The cooling systems that require compression of dangerous goods mentioned in 5.18.53 shall not be used.

5.18.70 The safety valves shall be adjusted to operate at overpressure of not less than 20 kPa, and if they are mounted on pressure cargo tanks, this pressure shall not exceed 700 kPa for carriage of propylene oxide and 530 kPa for carriage of mixtures of ethylene oxide with propylene oxide.

5.18.71 The piping system which serves the cargo tanks designed to carry dangerous goods mentioned in 5.18.53 shall be autonomous (isolated from other piping systems serving other cargo tanks). If this system is not autonomous, it shall be isolated as required by removing the removable spool pieces or valves of other pipeline sections and replacing them with the blank flanges.
Each joint between the blank flange and the respective pipeline flange shall be sealed with a safety seal.

5.18.72 An automatic nitrogen inflating system shall be provided to keep pressure in the cargo tank at least 7 kPa in order to form the insulating layer. Commercially pure nitrogen (99.9% by volume) reserves shall be available on the ship to automatically keep pressure and replenish possible losses.

5.18.73 The ship shall be provided with a water spraying system the sprayers of which shall protect the cargo manifold area, deck cargo piping and covers of cargo tanks used for carriage of dangerous goods mentioned in 5.18.53. The water spraying system shall provide water supply at rate of 10 l/(m²·min). The remote system control position shall be located outside of the cargo area and shall remotely start the pumps supplying water to the water spraying system and remotely control the valves in this system.

5.18.74 A remotely operated shut-off valve with adjustable closing speed shall be installed in each cargo hose connection point.

Ships carrying sulphur melt

5.18.75 The cargo tanks with these dangerous goods shall be ventilated so that concentration of hydrogen sulphide during carriage will be less than the value equal to half its explosive limit (1.85% by volume).

5.18.76 If the forced ventilation system is used, this system shall be provided with alarm which signals in case of inoperability of this system.

5.18.77 The ventilation system shall be designed so as to prevent deposition of sulphur inside the system itself.

5.18.78 A provision shall be made for sampling and analyzing vapours in the empty spaces adjoining the cargo tanks. The openings in these spaces shall prevent ingress of water, sulphur or dangerous goods vapours.

5.18.79 The dangerous goods heating system shall maintain their temperature at a level which does not exceed 155 °C.

Ships carrying acids

5.18.80 The walls of the cargo tanks which carry inorganic acids shall not be parts of the hull plating.

5.18.81 Screens to localize splashing of dangerous goods and trays to prevent spillage of dangerous goods to the deck shall be fitted at the flange joints of the loading and discharge manifold.

5.18.82 The electrical equipment to be installed in the cargo area shall meet the requirements of 2.10 Part VI of the Rules.

5.18.83 The cargo tanks shall not adjoin the fuel oil tanks, their location shall meet the requirements of 4.4.6.

5.18.84 Cargo leakage monitors shall be installed in the spaces adjoining the cargo tanks.

5.18.85 The drainage system equipment mounted in the cargo pump room shall be made of materials resistant to corrosion in an environment containing mixture of hydrogen with air.

Ships carrying toxic dangerous goods

5.18.86 The outlets of the cargo tank gas-freeing systems shall be located as follows:

1. at the height equal to B/3 or 6 m, whichever is more, above the upper deck level or above the raised passage, if any
2. at the height of not less than 6 m above the longitudinal catwalk level if the outlets are not removed from this catwalk by more than 6 m
3. at the distance of 15 m from any opening or air intake of any accommodation or service spaces.

5.18.87 The gas exhaust piping openings may be located at the height of 3 m above the deck or the longitudinal catwalk if the high-velocity gas exhaust valves are installed to release mixture of vapours upwards with mixture jet velocity of not less 30 m/s.
5.18.88 The gas-freeing systems of the cargo tanks shall be equipped with fittings to connect the dangerous goods vapour ashore return pipeline.

5.18.89 Toxic dangerous goods shall not be placed in the cargo tanks adjoining the fuel oil tanks. They shall be placed in the cargo tanks with separate piping systems and in the cargo tanks the gas-freeing systems of which are separated from other cargo tanks containing non-toxic dangerous goods.

5.18.90 The safety valves of the cargo tanks shall be adjusted on positive pressure which shall not be less than 20 kPa.

Ships carrying dangerous goods protected by additives

5.18.91 The cargo tanks and the dangerous goods pumping system on the ships carrying dangerous goods protected by additives shall not use structural materials or contaminants that can behave as a catalytic agent in relation to cargo.

5.18.92 The ships in which air is removed from the cargo tanks to prevent oxidation of dangerous goods shall meet the requirements of 5.14.2 to 5.14.5.

5.18.93 The gas-freeing systems shall be designed so as to eliminate their clogging with polymerization products. It shall be possible to check the overall performance of the gas exhaust equipment.

5.18.94 To prevent overheat of dangerous goods and their further polymerization in the dangerous goods heating system using vapour as heat transfer medium of pairs, a double-loop low-temperature heating system shall be used.

Ships carrying dangerous cargoes with vapour pressure above 101.3 kPa at 37.8 °C

5.18.95 To keep temperature of dangerous goods at a level below their boiling temperature at the rated pressure of the cargo tank, a cooling system with refrigerating unit shall be used.

5.18.96 It is allowed not to install the cooling system, if the cargo system is rated for pressure of dangerous goods vapours at temperature of 45 °C. At the same time, the cargo tank safety valve operation pressure shall be adjusted.

5.18.97 Provision shall be made to connect to the pipeline of the shore system used to return dangerous goods vapours during loading.

5.18.98 Each cargo tank shall be provided with a pressure gauge indicating pressure in the cargo area, and with thermometers installed in the top and bottom parts of the cargo tank if the cooling system is available.

Ships carrying dangerous goods which may not be watered

5.18.99 When dangerous goods which may not be watered are carried, the following requirements shall be met:

.1 Pressure/vacuum relief valves of cargo tanks shall be located at a height of not less than 2 m above the upper deck level;

.2 The dangerous goods temperature system shall not use water or vapour as heat transfer medium;

.3 The cargo tanks shall not adjoin the ballast tanks or other tanks containing water, except for emptied or drained tanks;

.4 The cargo tanks shall not adjoin the settling tanks or the cargo tanks with ballast, washings or other watered dangerous goods. The pumps and pipelines serving such cargo tanks shall be isolated from the similar equipment serving the cargo tanks with the same dangerous goods. The pipelines going out of the settling tanks or the ballast pipelines shall not pass through cargo the tanks with these dangerous goods, except for the pipelines laid in the tunnel.

High-intensity ventilation

5.18.100 The ventilation system mentioned in 5.5 shall have the minimum performance of not less than 45 air changes per hour based on all space volume. The ventilation system
exhaust duct outlets shall be located at a distance of at least 10 m from the openings of accommodation spaces and working areas and at least 4 m above the deck over the cargo tanks.

**Tank overflow prevention**

**5.18.101** The cargo tanks shall be equipped with the light and sound alarm according to the requirements of 5.18.102 and 5.18.103 to inform that dangerous goods reach the upper level and the cargo tank overflow prevention system complying with requirements of 5.18.104.

**5.18.102** The dangerous goods limit level alarm shall be independent of the overflow prevention system mentioned in 5.18.104 and from the measuring equipment.

**5.18.103** When the safety system is deenergized during loading, light and sound alarm signal shall be transmitted to the control station.

**5.18.104** The cargo tank overflow prevention system shall:

1. operate, if during tank loading, the dangerous goods level continues raising after the filling level is reached
2. transmit cargo tank overfilling light and sound signal to the control station
3. transmit signal informing on necessity of deactivating the shore pumps and/or closing the shore shut-off valves and necessity of closing the ship shut-off valves.
6 RIVER – SEA NAVIGATION SHIPS CARRYING LIQUEFIED GASES IN BULK

6.1 GENERAL PROVISIONS

6.1.1 This section requirements apply to river – sea navigation liquefied gas tankers. Gases which may be carried by these ships in liquefied state in bulk are listed in Appendix 3.

6.1.2 The requirements set in this section supplement the requirements stated in 4 and 5 of this Part. If the requirements stated in 4, 5 and 6 of this Part to the same object are not identical, the strictest requirements of the Rules shall be applied.

6.1.3 If a liquefied gas tanker is designed to carry several types of dangerous goods, the safety requirements shall be based on total of properties of most dangerous carried goods.

6.2 HULL DESIGN

6.2.1 The ships intended to carry dangerous goods with boiling temperature below –10 °C shall mandatorily have the double bottom. The inner bottom shall extend throughout the length of the cargo area.

6.2.2 The bottom grillages shall be designed so as to take up forces transmitted to them by the cargo tanks.

6.2.3 The liquefied gas tanker double bottom design shall consider the requirement to lower COG of cargo tanks, peculiarities of attachment of cylindrical skirts of cargo tanks to inner bottom and transmission of forces from them to bottom grillage.

6.2.4 The liquefied gas tankers intended to carry dangerous goods with boiling temperature of –55 °C and below shall be provided with double sides throughout the length of the cargo area.

6.2.5 If the liquefied gas tanker hull design within the cargo area differs from that mentioned in 6.2.1 and 6.2.4, calculation shall be made to confirm that in case of side collision with another ship having straight stem, energy of 22 MJ will be absorbed without rupturing the cargo tanks and the cargo piping connected to the cargo tanks.

6.3 CARGO TANKS

6.3.1 The midship cargo tanks may be used, if they are of the following shapes:
- spherical
- cylindrical
- spherocylindrical with conical bottom
- prismatic.

6.3.2 When the cylindrical independent cargo tanks of more than 12 m long are installed horizontally along the ship (Fig. 6.3.2), a swash bulkhead shall be provided in the middle of length of each cargo tank.

Fig. 6.3.2 Diagram of installation of cylindrical independent cargo tanks horizontally along ship

6.3.3 The cylindrical independent cargo tank plating may be supported with internal
framework. Transversal support of cargo tank only is allowed.

The connected cylindrical cargo tanks shall be provided with a longitudinal bulkhead which separates the tanks. In this case, the tank’s framing members shall be located in one plane with the stays of the longitudinal bulkhead which separates the connected cargo tanks.

6.3.4 The spherical cargo tanks may have no framing. In this case, the plating is formed by strakes (Fig. 6.3.4).

6.3.5 Permissible out-of-roundness of strake shall be calculated by the following formula, m:

$$
\Delta D = |D_1 - D_2| < 0.005D_{nom},
$$

where $D_{nom}$ — nominal strake diameter, m; $D_1$ — maximum strake diameter, m; $D_2$ — minimum strake diameter, m;

Dimension lines $D_1$ and $D_2$ shall be perpendicular to each other.

6.3.6 Permissible deviation $a$ for two strakes joined (Fig. 6.3.6) shall be calculated by the following formula, m:

$$
a = 0.1t,
$$

where $t$ — thickness $t_1$ or $t_2$ of the strakes, whichever is less.

6.3.7 Maximum deviation of strake curvature shall not exceed the value shown in Fig. 6.3.7. Radius of curvature mold shown in Fig. 6.3.7 is equal to theoretical radius of spherical cargo tank.

6.3.8 The prismatic independent cargo tank plating shall be supported by framing members. The framing members shall be placed inside the cargo tank plating. The prismatic cargo tank shall have a longitudinal bulkhead installed in plane of longitudinal axis of symmetry and a transversal bulkhead, including that of swash type, installed in the middle along the cargo tank.

6.3.9 Squared manholes shall be made in the bottom part of the transversal bulkhead. The manhole plan size shall not be less than $0.8 \times 0.8$ m. The manholes shall be located on either side from the longitudinal bulkhead and shall be edged with coamings.

6.3.10 The prismatic cargo tanks shall not rise above the upper deck.

6.3.11 The membrane cargo tanks shall be designed so as to provide tightness of their shell when exposed to deformations related to
6.3.12 The designs utilizing nonmetallic membranes or membranes built in insulation and connected to insulation is allowed if technical feasibility study and calculations confirming feasibility of such designs are submitted to the River Register. Thickness of such membranes shall not exceed 10 mm.

6.3.13 Dangerous goods vapour design pressure in the membrane cargo tanks shall not exceed 0.025 MPa. Design pressure may be increased to 0.07 MPa provided that the ship hull structure is reinforced and technical feasibility study and calculations confirming that heat insulation is capable of transmitting loads from the membrane cargo tank to the hull structures without break are submitted to the River Register.

6.3.14 If the design of the membrane cargo tank shell includes primary (in relation to dangerous goods) and secondary membranes, a layer of heat insulation shall be placed between these membranes. The space between the secondary membrane and the ship hull structure shall be filled with heat insulation.

6.3.15 The membrane cargo tank design are allowed for use only after models of shell structure components, including corner membrane structures, are tested. Results of model tests shall confirm that the cargo tank is capable of withstanding stresses caused by static and dynamic loads specified in 6.7.1 to 6.7.16 that occur in operation of liquefied gas tanker.

6.3.16 The space between the secondary barrier of the support-type semimembrane cargo tank and the hull structures shall be filled with heat insulation (Fig. 6.3.16).

6.3.17 Height of grillage bars of support-type semimembrane cargo tank shall be equal to insulation thickness which is selected in accordance with the requirements of 6.5. Material of bars (balsa wood or material close to balsa in hardness, strength, vibration resistance and resistance to low temperatures) shall withstand loads from adjacent structures. The bars shall be installed over the keelsons or over the supported double bottom beams, as well as at the side stringers or double side platforms.

6.3.18 In case of leakage through the support-type semimembrane cargo tank shell, the secondary barrier shall provide tightness for liquefied gas.

6.3.19 The suspension-type semimembrane tank shall be attached to the hull structures so that its shell can expand to the design dimensions.

6.3.20 Rigidity of cylindrical sections at corners of suspension-type semimembrane cargo tank, as well as that of spheroidal corners located in joins of three planar tank sections shall be selected in view of conditions of shape retention for the suspended unstressed tank.

6.3.21 Meeting the requirement of 6.3.20, the semimembrane suspension-type cargo tank design shall provide flexibility required to take up thermal deformations and ship hull bending deformations.

6.3.22 The cargo tank dome is designed to accommodate the pipelines of the ship systems and the cargo pumps and to provide access to the cargo tank.

6.3.23 The independent prismatic cargo tank dome shall be installed symmetrically in relation to the longitudinal tight bulkhead with the manhole offset from the intersection of longitudinal and transversal symmetry axes of the cargo tank along the longitudinal sym-
metry axis of the tank to the nearest bulkhead web.

6.3.24 The cargo tank dome shall have the same heat insulation as the cargo tank has.

6.3.25 Meeting the requirement of 6.3.24, the cargo tank dome heat insulation shall provide strength enough for transfer of loads capable of displacing the cargo tank to the hull structures.

6.3.26 The cargo tank dome shall be connected with the ship hull structures so as to provide compensation of thermal deformations of cargo tank confirmed by positive calculations for the tank and its dome which occur during cargo handling and preparation of cargo tanks for reception of liquefied gas.

6.3.27 Access of people to the cargo tank shall be provided through a manhole representing a hermetically closable opening in the cargo tank dome. Minimum permissible manhole dimensions are 380×460 mm. If the cargo tanks shall be accessible by people who wear protective gear with self-contained breathing apparatus, the manhole plan dimensions shall not be less than 800×800 mm.

6.3.28 The drain wells of the liquefied gas tankers with the independent prismatic, membrane or semimembrane cargo tanks of each hold space shall be displaced to their aft bulkhead.

6.3.29 On the liquefied gas tankers with the independent spherical cargo tanks the drain wells shall be located under the vertical axis of each cargo tank.

6.3.30 The drain wells of the independent prismatic cargo tanks shall be installed symmetrically relative to the internal longitudinal bulkhead of the cargo tank (see 6.3.8) on either side of this bulkhead.

6.3.31 The drain wells of the independent prismatic cargo tanks shall have curved joints to provide minimum thermal stresses.

6.3.32 The drain wells shall be separated from the hull structures with heat insulation.

6.3.33 A temperature sensor for draining dangerous goods shall be provided in the drain well.

6.3.34 The cargo tanks shall be supported in a manner which will prevent the cargo tanks from displacement relative to the ship’s hull under static and dynamic loads resulted from ship movement on waves.

6.3.35 When the cargo tank supports are designed, calculations shall be made to confirm possibility of thermal deformation of the cargo tank.

6.3.36 The cargo tank support structures shall operate at ship heel of up to 30°.

6.3.37 The cargo tank attachment structures shall include stops to take up horizontal forces that occur during collision of ships.

6.3.38 The horizontal force applied from stern to bow is taken equal to a half of gravity force of completely filled cargo tank. The horizontal force applied from bow to stern is taken equal to a fourth of gravity force of completely filled cargo tank.

6.3.39 When strength of cargo tank support structures is calculated, it may be assumed that forces caused by the greatest possible resultant acceleration imparted to the cargo tank and its supports while in use and forces caused by collision of ships have independent effect on the support structures.

6.3.40 The vertical plates of the independent cylindrical cargo tank support shall be installed in the same plane as the floors are installed and shall support on the web side frames (Fig. 6.3.40).

6.3.41 The independent cylindrical cargo tanks shall be installed on at least two supports throughout their length.

6.3.42 One of cargo tank bracing members shall lie in plane of vertical support plate (see Fig. 6.3.40).

6.3.43 The spherical cargo tank supports shall be located in the equatorial part of the tank (see Fig. 6.3.4).
6.3.44 The following types of supports shall be used for the spherical cargo tanks:

1. Pole-type supports which provide cargo tank support on hull structures through a system of poles (Fig. 6.3.44, a);

2. Suspension-type supports which provide suspension of cargo tank by means of hinged supports located around equatorial zone of tank (Fig. 6.3.44, b);

3. Shell-type supports which provide cargo tank support on cylindrical shell reinforced with framing members (Fig. 6.3.44, c).

6.3.45 If a pole-type support is used for the spherical cargo tank, the support strake shall be located in the equatorial part of the cargo tank and shall have movable connection with the pole system.
6.3.46 The pole system shall be arranged around the circumference of the cargo tank. The pole system shall be provided with support bars to transmit forces to the hull structures (see Fig. 6.3.44, a).

6.3.47 Forces from the support bars to the hull structures shall be transmitted through isolating spacers. The isolating spacers shall prevent the support bar from lateral movements but they shall enable the support bar to radially move as a result of thermal deformations of the cargo tank.

If a suspension-type support is used for the spherical cargo tank, this support shall provide freedom of movement of the cargo tank under effect of thermal deformations.

6.3.48 If a shell-type support is used for the spherical cargo tank, the equatorial strake shall have a cross-section shown in View C of Fig. 6.3.44, c.

6.3.49 The shell-type support plating shall be supported with a framing consisting of vertical stays and horizontal stiffeners.

6.3.50 Attachment of spherocylindrical cargo tank with conical bottom with constricting tapes shall provide compression of cargo tank and heat insulation support (Fig. 6.3.50).

6.3.51 The drain well shall restrain the spherocylindrical cargo tank from horizontal displacement. The drain well shall rest with its walls against the tray. The tray shall be located in the double bottom of the liquefied gas tanker (see Fig. 6.3.50).

6.3.52 The membrane and semimembrane cargo tanks shall be attached together with cargo tank heat insulation and plating.

6.3.53 The supports of the independent prismatic cargo tanks are divided into:

1. load-bearing supports, i.e. supports that support the cargo tank only and do not prevent it from displacement relative to the vertical axis

2. retaining and load-bearing supports, i.e. supports that support the cargo tank and retain it from lateral displacement (displacement relative to the vertical axis).

6.3.54 The retaining and load-bearing supports shall be installed along the ship centre plane and along the midsection of the prismatic cargo tank (Fig. 6.3.54).
The load-bearing supports shall be evenly distributed throughout the remaining part of the prismatic cargo tank supported by them.

6.3.55 The retaining and load-bearing supports only may be installed in the top part of the prismatic cargo tank (Fig. 6.3.55).

6.3.56 If the independent prismatic cargo tank design does not comply with strength conditions when forces originating under dynamic cargo effect on the side walls of these tanks, the lateral load-bearing supports may be installed. These supports shall be arranged depending on peculiarities of application of these dynamic forces which shall be transmitted to the liquefied gas tanker hull structures by means of lateral load-bearing supports.

6.3.57 The design of the independent cargo tanks shall provide for fixtures (wedges, stops and so on) which prevent them from floating-up under buoyancy force having effect on the empty tank when the hold is flooded to the full load draught. At the same time, stress in the ship hull structure elements shall not exceed yield point $R_{yH}$.

6.4 SECONDARY BARRIER

6.4.1 If the carried liquefied gas boiling temperature at the atmospheric pressure is equal to $-10^\circ C$ and below, a secondary barrier shall be installed on the liquefied gas tanker. If the dangerous goods boiling temperature at the atmospheric pressure is higher than $-10^\circ C$, it is allowed not to install the secondary barrier.

The hull structures may be used as a secondary barrier if the carried liquefied gas boiling temperature at the atmospheric pressure is within $-10^\circ C$ to $-55^\circ C$; if so, the hull material shall comply with the requirements of Part X of the Rules and may be used in the specified temperature range.

6.4.2 If the hull structures are used as a secondary barrier, availability and type of secondary barrier shall be determined in accordance with Table 6.4.2. The hull structures shall not be used as a secondary barrier for the integral cargo tanks.

Table 6.4.2

\[1\] In the case of semi-membrane tanks which comply with the requirements applicable to type B independent tanks, except for the structure of support, a partial secondary barrier may be installed.

6.4.3 The secondary barrier design shall meet the following requirements:

.1 The secondary barrier shall be capable of containing the liquefied gas;

.2 The secondary barrier shall be capable of protecting the ship’s hull structures from cooling to an unsafe level in case of leakage of dangerous goods through the primary barrier;

.3 A failure of the primary barrier shall not cause any failure of the secondary barrier and vice versa;

.4 The secondary barrier fulfil its functions at a heel angle of up to $30^\circ$.

6.4.4 Where a partial secondary barrier is required according to Table 6.4.2, its extent shall be determined on the basis of cargo leakage volume corresponding to the length of a crack in the cargo tank wall. The crack
length shall be determined on the basis of loading condition as specified in 6.7.1 to 6.7.14 with liquid dangerous goods evaporation rate, leakage rate, and pumping capacity taken into account.

It shall not be possible for liquid dangerous goods to penetrate into the double bottom space.

6.4.5 If the secondary barrier is not required for the entire cargo tank or for a part of it, spray shields shall be installed (Fig. 6.4.5) or another structural protection may be used to protect the double bottom from cooling to an unsafe temperature.

Fig. 6.4.5. Spray shield installation diagram:
1 — spherical cargo tank foundation, 2 — bilge tank, 3 — double bottom space, 4 — spray shield, 5 — cargo tank body

6.4.6 The secondary barrier shall be capable of being periodically checked for its impermeability while the ship is in use.

6.5 INSULATION OF CARGO TANKS

6.5.1 The design of the cargo tanks intended for carriage of liquefied gas at temperature of −10 °C and below shall provide for insulation to keep temperature of hull structures higher than minimum permissible design temperature specified in 5 Part X of the Rules.

6.5.2 The design temperature for selecting heat insulation parameters is temperature of hull structures at air temperature of 5 °C and water temperature of 0 °C.

6.5.3 If the liquefied gas tanker is operated in latitudinal zones with higher air and water temperatures as compared with those specified in 6.5.2, the design temperatures higher than those specified in 6.5.2 are allowed.

6.5.4 If the ship is operated in latitudinal zones with lower air and water temperatures as compared with those specified in 6.5.2, the design temperatures specified in 6.5.2 shall be decreased.

6.5.5 Heat insulation calculations shall be made for navigation at calm water (see 2.2.1 Part I of the Rules) under no wind conditions.

6.5.6 When the secondary barrier is installed, it shall be assumed that its temperature will be equal to the temperature of carried dangerous goods at the atmospheric pressure.

Heat insulation calculations with the secondary barrier available shall allow for cooling effect of evaporation of dangerous goods leakage.

6.5.7 Use of devices for heating the hull structures is not a ground to change the design characteristics.

6.5.8 When steel grade is selected for the structural elements connecting the secondary barrier with the ship hull, the design temperature shall be determined as arithmetic mean of temperatures of dangerous goods and environment.

6.5.9 In cases mentioned in 6.5.1 to 6.5.4, devices for heating the transversal hull framing members may be installed to prevent drop of their temperatures below the minimum permissible value.

6.5.10 The devices for heating the cargo tank hull structures shall meet the following requirements:
.1 Amount of heat input shall be enough to keep temperature of hull structures above the minimum permissible temperatures specified in 6.5.2;
.2 The heating system shall be designed so that its undamaged part can provide not less than 100% of design amount of heat if any its part fails;
3. The heating system shall be considered as critical auxiliary equipment.

6.5.11 Determination of insulation thickness depending on temperature of dangerous goods shall consider quantity of evaporated dangerous goods and operation of onboard dangerous goods reliquefaction unit, main engines using dangerous goods as fuel or other system that has effect on temperature of dangerous goods or controls this temperature.

6.5.12 Insulation shall withstand loads from the adjacent structures which it may be exposed to while the liquefied gas tanker is in operation.

6.5.13 Insulation shall provide protection from mechanical damages and ingress of water vapours.

6.5.14 If powder or granular insulation is used, measures shall be taken to prevent it from compaction under vibration.

6.5.15 Insulation shall keep its properties and shall not press on elements of cargo system and other ship systems.

6.6 FABRICATION AND TESTING OF CARGO TANKS

6.6.1 All weld joints of independent cargo tank plating shall be made with full penetration butt welds. Weld joints of dome with plating and those of nozzles, branch pipes and manholes shall be made with full penetration.

6.6.2 Weld joints of parts of type C independent cargo tanks shall meet the following requirements:

.1 All weld joints of tank walls shall be made with full penetration butt welds with X- or U-shaped edge preparation. Another shape of edge preparation is allowed on condition that positive results of tests performed for approval of welding process are submitted to the River Register;

.2 All welds in the cargo tank structure (connection of parts and welding of branch pipes, nozzles and manholes) shall be made with full penetration.

6.6.3 Tests of weld joints, including non-destructive inspection, for all types of cargo tanks, except for type C independent cargo tanks, shall be performed in accordance with the requirements of 8 Part X of the Rules.

6.6.4 The internal insulation of the cargo tanks shall be visually inspected to check condition of its surface after the third trip of the loaded ship, but not later than six months of operation of the ship after building or after major repair of internal insulation cargo tanks.

6.6.5 The semimembrane cargo tanks shall meet the requirements imposed on the independent cargo tanks or membrane cargo tanks depending on requirements considered.

6.6.6 The integral cargo tanks shall be subject to hydraulic or air tightness test. Stresses that occur during tests shall be close to the design stresses, and pressure at the top of the cargo tank shall comply with the maximum permissible set pressure of the safety valve.

6.6.7 On the ships with the membrane and semimembrane cargo tanks all spaces containing liquid dangerous goods and having common hull structures with membrane supporting hull structures shall be subject to hydraulic or air tightness testing.

The membrane supporting hull structures of the ship shall be subject to tightness testing.

Tunnels for pipes and other compartments, which do not contain liquids, do not require hydraulic tightness testing.

6.6.8 For this chapter, the internal insulation cargo tanks are divided into two types:

.1 Cargo tanks of type I1 — cargo tanks in which insulation or combination of insulation and one or several layers of internal liner performs the main barrier function. The inner hull or the independent reservoir structure shall perform the secondary barrier function;

.2 Cargo tanks of type I2 — cargo tanks in which insulation or combination of insulation and one or several layers of internal liner performs the main and secondary barrier functions.

The internal liner is a protective layer not exposed to loads and made of metallic or
composite materials, which forms a structural part of the internal insulation cargo tank. The internal liner is used to prevent cracking or improve mechanical properties of insulation. Tightness requirement does not apply to the internal liner.

6.6.9 If the double bottom and double sides of the liquefied gas tankers equipped with the internal insulation tanks of type I2, are structures which support this insulation, all the structure of double bottom and double sides shall be subject to hydraulic or air test considering the maximum permissible set pressure of the safety valve.

6.6.10 If the structure of double bottom and double sides of the liquefied gas tanker or the independent tank structure is used as a secondary barrier for internal insulation tanks of type I1, these structures shall be tested for impermeability.

Impermeability tests shall be performed before insulation is installed.

6.6.11 If the liquefied gas tankers equipped with the internal insulation cargo tanks of type I2 have the independent cargo tanks which structurally support this insulation, such independent tanks shall be tested in accordance with 6.6.14.

6.6.12 Type C independent cargo tanks shall be subject to visual and instrumental check and impermeability tests. Here, the following shall be considered:

1. Visual and instrumental check shall ascertain whether dimensions and shape of ready cargo tank structure comply with requirements of technical documentation and quality of structure assemblage;

2. Scope of impermeability tests shall be as follows:
   - non-destructive testing
   - radiographic testing for 100% of butt welds
   - surface crack testing for 100% of welds of manholes, branch pipes and nozzles and 10% of all remaining welds
   - ultrasonic testing for all welds of manholes, branch pipes and nozzles.

6.6.13 The heating systems provided in accordance with 6.5.9 to 6.5.10 shall be tested for required heat flow and heat transfer coefficient.

6.6.14 Each independent cargo tank shall be tested by pressure with consideration of the following:

1. When type A independent cargo tanks are tested, measured stresses in the structural elements shall close to the design stresses, and pressure at the top of the cargo tank shall comply with the maximum permissible set pressure of the safety valve;

2. Type B independent cargo tanks shall be tested in accordance with the requirements of 1., and the maximum stresses in the primary membrane or the maximum bending stress of the main framework elements shall not exceed 90% of material yield point at the test temperature.

If the design stresses during test exceed 75% of material yield point, structure model tests with measurement of stresses shall also be performed;

3. Each type C independent cargo tank shall be tested by pressure of not less than 1.5ρ0 measured in the tank top, and the primary membrane stress in any point of its structure shall not exceed 90% of material yield point. If the design stresses during test exceed 75% of material yield point, structure model tests with measurement of stresses shall also be performed;

4. Temperature of water used for testing of type C cargo tanks shall be at least 30 °C higher than the critical fracture transition temperature of cargo tank material;

5. Time of pressure test of type C independent cargo tanks shall be set at the rate of 2 h per every 25 mm of tank wall thickness.

6.6.15 The cargo tanks of all types shall be subject to impermeability test which may be performed together with the pressure test mentioned in 6.6.14.

6.6.16 When the cargo tanks and the residual cargo tanks are tested, the test pressure shall not be less than 1.3 of design pressure. When the cofferdams and the open cargo
tanks are tested, the test pressure shall not be less than 0.01 MPa.

**6.6.17** If engineering solutions taken during design and fabrication of liquefied gas tankers with type B independent cargo tanks have not been confirmed in full by results of trial operation of the ship of the same series, at least one tank and its supports shall be equipped with sensors and instruments capable of detecting level of actual stresses.

**6.6.18** The instruments mentioned in 6.6.17 may be installed on the structural elements of type C independent cargo tanks.

**6.6.19** During initial cooling, filling and unloading of cargo tanks, all performance parameters of the cargo system shall be checked to compare them with the design parameters. The documents substantiating that parameters determined in operation comply with design parameters shall be submitted to the River Register.

**6.7 STRENGTH CALCULATIONS**

**Design loads**

6.7.1 Strength of the cargo tank structural components shall be verified by calculations under loads and their combinations in operation including the following:

.1 Loads arising during the tests;
.2 Increase of design gas vapours pressure $p_0$ when in port;
.3 Loads arising at list of 30°.

6.7.2 Design pressure of gas vapours $p_0$ for all types of cargo tanks, except for independent cargo tanks of type C, shall not exceed 0.025 MPa. When increasing the scantlings of the hull structures compared to the calculated scantlings and considering thermal insulation strength, it is allowed to increase design pressure, but in any case it shall not exceed 0.070 MPa.

6.7.3 Maximum overpressure for the independent cargo tank of type C shall not exceed the value calculated by the formula, MPa:

$$p_0 = 0.2 + 0.1ACp^{1.5},$$

where $A = 0.0185\left(\frac{\sigma_m}{\Delta\sigma_A}\right)^2$;

$\sigma_m$ — design stresses in the tank wall, MPa

$\Delta\sigma_A$ — permissible dynamic stresses in the cargo tank wall (double amplitude of the stress cycle complying with wave load exceedence probability of $10^{-4}$), components for steel 55 MPa and for aluminum alloys — 25 MPa

$C$ — characteristic size in the vertical direction, m, taken as maximum of the following values: 0.75$b$ or 0.45$l$.

Here $b$, $l$ — breadth and length of the tank in the vertical, transverse and longitudinal directions respectively, m

$\rho$ — relative (i.e. related to fresh water density) cargo density at the design temperature.

6.7.4 Design load from internal pressure in the cargo tank $P_i$ shall be calculated by the formula, MPa:

$$P_i = p_0 + (p_{hp})_{max},$$

(6.7.4)

where $(p_{hp})_{max}$ — maximum internal excessive hydrostatic pressure determined by gravity force and inertia forces caused by acceleration of cargo liquid due to ship motions.

6.7.5 Internal excessive hydrostatic pressure of the completely filled cargo tank is calculated by the formula, MPa:

$$p_{hp} = 9.81 \times 10^{-6} a_{\beta} \zeta_{\beta} \rho,$$

(6.7.5)

where $a_{\beta}$ — dimensionless acceleration expressed in percentage of gravity which is the result of gravity and dynamic accelerations in the direction at angle $\beta$ (Fig. 6.7.5-1)

$\zeta_{\beta}$ — liquid column height, m, above the point on the cargo tank plating, for which internal pressure shall be found; it is measured from the cargo tank plating in the direction of acceleration vector $a_{\beta}$, whose angle of deflection $\beta$ from the vertical is selected in the interval of 0 to $\beta_{max}$ (Fig. 6.7.5-2)

$\rho$ — cargo density at the design temperature, kg/m³.
Accelerations acting on cargo tanks are determined based on the assumption that acceleration vectors are applied in the centres of gravity of the tanks and that they include the following components:

- Vertical acceleration — an acceleration caused by heave, pitch and roll and directed perpendicular to the baseline of the ship;
- Transverse acceleration — an acceleration caused by sway, yaw and roll, as well as gravitational component of roll;
- Longitudinal acceleration — an acceleration caused by surge and pitch, as well as gravitational component of pitch.

For constructions specified in 6.7.7, maximum dimensionless (i.e. related to gravity) accelerations are used in the respective directions (in calculations they are considered to be separate) $a_x$, $a_y$, $a_z$:

- $a_x$ — includes a component of static weight in the longitudinal direction because of pitch
- $a_y$ — includes a component of static weight in the transverse direction because of roll
- $a_z$ — does not include a component of static weight.

6.7.7 When plotting acceleration ellipse required to determine angle $\beta_{\text{max}}$ (see 6.7.5), a line shall be laid from the centre of gravity of the tank with length taken as 1 (the scale of relative accelerations). The bottom end of the line is the centre of acceleration ellipse.

From the centre of acceleration ellipse, dimensionless accelerations $a_y$ and $a_z$ are laid in the horizontal and vertical directions respectively, and are taken as ellipse radii.

Angle at which vector of dimensionless acceleration $a_\beta$ passes tangential to the plotted ellipse shall be taken as angle $\beta_{\text{max}}$.

6.7.8 In order to determine height $z_\beta$, from the point on cross-section outline of the tank plating where internal pressure shall be determined, a set of angle $\beta$ values shall be specified from interval 0 to $\beta_{\text{max}}$, and height $z_\beta$ shall be graphically determined for each angle value in the specified range (Fig. 6.7.5-2).

6.7.9 In the calculation (see 6.7.5) a pair of values $z_\beta$ and $a_\beta$ shall be taken with maximum multiplication.

6.7.10 When determining internal excessive hydrostatic pressure in cargo tanks, whose longitudinal dimensions exceed their breadth, it may be required to consider the longitudinal acceleration of the centre of gravity of the cargo tank. In this case, instead of ellipse shown in Fig. 6.7.5-1, an ellipsoid with radii $a_x$, $a_y$ and $a_z$ shall be used.

The procedure of determining the values of the resulting dimensionless acceleration $a_\beta$
and liquid height \( z \), described in 6.7.7 and 6.7.8 is applicable to the acceleration ellipsoid. The requirement of 6.7.9 shall be met.

6.7.11 The domes of cargo tanks shall be considered when determining \( \beta \), except for the cases when total volume \( V_d \) doesn’t exceed the value, \( m^3 \):

\[
V_d = V \left( 100 - \frac{V}{V'} \right), \quad (6.7.11)
\]

where \( V \) — volume of the cargo tank without dome, \( m^3 \); \( V' \) — limit of cargo tank filling according to 6.20.1 and 6.20.3, \( \% \).

6.7.12 Design load of external pressure shall be determined as a difference between simultaneous minimum internal pressure (maximum vacuum) and maximum external pressure that may occur in operation.

6.7.13 Design dynamic loads caused by roll of the gas tanker and acting on the elements of cargo tanks shall be determined from consideration of long-term distribution of all types of ship motion at irregular waves; here, design exceedence probability for the maximum wave loads shall be taken equal to \( 10^{-8} \).

6.7.14 If data on inertia forces acting on cargo tanks due to ship motion at waves are not available, the following formulae shall be used to determine the acceleration components:

For vertical acceleration

\[
a_v = \pm a_0 \left[ 1 + \left( \frac{5.3 - 45/L}{2} \right)^2 \times \left( \frac{x/L + 0.05}{0.6/\delta} \right)^{1.5/0.5} \right]; \quad (6.7.14-1)
\]

For transverse acceleration

\[
a_y = \pm a_0 \left[ 0.6 + 2.5 \left( \frac{x/L - 0.05}{2} \right)^2 + K \left( 1 + 0.6Kz/B \right)^{0.5} \right]; \quad (6.7.14-2)
\]

For longitudinal acceleration

\[
a_x = \pm a_0 \sqrt{0.6 + A^2 - 0.25A} \quad (6.7.14-3)
\]

if

\[
A = 0.6 \left( 0.7 - \frac{L}{1200 + 5z/L} \right)/\delta, \quad (6.7.14-4)
\]

where \( L \) — ship length between perpendiculars, \( m \)

\( \delta \) — block coefficient

\( B \) — ship breadth, \( m \)

\( x \) — distance between the centre of gravity of the cargo tank and midship (positive value is forward from midship), \( m \)

\( z \) — vertical distance between actual waterline and centre of gravity of the cargo tank with dangerous cargo (positive value is above waterline, negative is below waterline), \( m \)

\( v \) — operating speed of the ship, \( km/h \)

\( K \) — coefficient for specific loading conditions and hull lines is determined by the formula:

\[
K = 13h_0/B \geq 1, \quad (6.7.14-6)
\]

where \( h_0 \) — metacentric height corresponding to the loading condition, \( m \).

6.7.15 Strength of cargo tanks shall be checked for the cases of their partial filling at dynamic loads which arise due to free surfaces.

6.7.16 In strength calculations of cargo tanks at temperature of the carried dangerous cargo below \(-55^\circ C\), thermal loads arising during cooling period shall be considered.

**Strength of membrane tanks**

6.7.17 Simultaneously with strength calculation of membrane cargo tanks, the test results of the membrane structure models and their angle joints confirming reliability of the calculation results shall be submitted to the River Register. The test conditions shall comply with most unfavorable operating conditions of the cargo tank determined by the designer and approved by the River Register.

6.7.18 The test results of the membrane cargo tank materials, which prove that ageing of the materials does prevent from intended
strengthen the structures, shall be submitted to the River Register.

6.7.19 If data on external loads on cargo tanks is not confirmed in full scope by the results of operational trials for the ships of the same design, the tests shall be performed with types and values of test loads assigned compliant with all possible load combinations in operation.

It shall be substantiated that under over-pressure in interbarrier space, vacuum inside the membrane cargo tank, impacts in presence of free surfaces or vibration, membrane integrity will not be compromised.

6.7.20 Strength of the membrane cargo tank case shall be calculated considering internal pressure specified in 6.7.4. The specified calculation shall consider the possibility of deformation of the membrane and adjacent insulation jointly with hull members.

Strength of independent tanks

6.7.23 Strength of the independent cargo tanks of type A shall be calculated according to the requirements of Part I of the Rules considering internal pressure according to 6.7.4 and corrosion allowances according to 6.7.46 to 6.7.48.

6.7.24 For the structures in the place of supports, the design stresses shall be determined considering the loads specified in 6.7.1 and hull deformation.

6.7.25 Strength of the independent cargo tanks of type B shall be calculated considering all possible static and dynamic loads and their combinations in operation. The requirements on restricting plastic deformation, maintaining stability and fatigue endurance as well as prevention of cracks shall be met. The following shall be performed:

.1 Static estimation of wave loads (see 6.7.5 to 6.7.9);
.2 Strength calculations of structures;
.3 Calculation of crack rate in the structural components of the cargo tank cover;
.4 Calculation of the structure strength under load transferred to the cargo tank structures from its supports and fasteners using a 3D FEM model.

6.7.26 If data for the ships of the design in question are not available, then a complete calculation of ship accelerations and motions at irregular waves as well as ship and cargo tank reaction to inertial loads shall be made.

6.7.27 Stability calculation shall consider maximum fabrication tolerances of the structures.

6.7.28 Design values of stress concentration coefficients and parameters of fatigue life of the newly constructed independent cargo tank components shall be verified by the test results on the models of these components.

6.7.29 Action of load causing fatigue damage of the structure shall comply with the following inequality:

$$\sum \frac{n_i}{N_i} + 1000/N_j \leq C_w,$$  \hspace{1cm} (6.7.29)

where \(n_i\) — number of cycles of each stress level over whole service life of the ship

\(N_i\) — number of cycles until fracture for the respective stress level \(\sigma\) according to fatigue curve \(\sigma = f(N)\)

\(N_j\) — number of cycles until fracture for fatigue load caused by handling operations

\(C_w\) — parameter which is usually taken \(C_w \leq 0.5\) depending on the test method and data used to plot fatigue curve \(\sigma = f(N)\);

value \(C_w > 0.5\) not exceeding 1.0 may be used.

6.7.30 Strength of the independent cargo tanks of type C shall be calculated considering the following requirements:

.1 Wall thickness of the independent cargo tanks of type C shall be determined considering the shape of their parts according to the procedures developed by the designer and approved by the River Register;

.2 If visual inspection and non-destructive testing are provided, design weld strength factor shall be taken equal to 0.95. It may be increased to 1.0 depending on the properties of the material, connection type, welding
process and loading conditions. For process pressure vessels, it is allowed to decrease the scope of non-destructive testing; here, design weld strength factor shall be taken not more than 0.85;

.3 If the independent cargo tanks of type C are subject to load action causing compression stress in the tank walls in operation, a technical justification for wall thickness and cargo tank shape shall be provided. Strength of such tanks shall be calculated considering fabrication tolerances;

.4 Design load due to external pressure $P_{e}$ shall be determined by the formula, MPa:

$$P_{e} = p_{1} + p_{2} + P_{3} + P_{4},$$

(6.7.30)

where $p_{1}$ — safety valve setting, for cargo tanks without safety valves $p_{1}$ shall be taken equal to min. 0.025 MPa;

$p_{2}$ — safety valve setting for hull compartments with cargo tanks or their parts; otherwise $p_{2} = 0$;

$P_{3}$ — compression stress due to any forces (influence of weight and insulation shrinkage, plating weight including corrosion allowance, etc.) which the cargo tank is subject to. These forces may include weight of dome, raised parts and pipelines, cargo in partially filled tank, load of hull deformation and inertia forces. Besides, local action of external and/or internal pressure shall be considered;

$P_{4}$ — assumed external load due to water washing the tanks or parts thereof on the open deck; otherwise $P_{4} = 0$;

.5 Stress in the places of supports of the cargo tanks (in the tank wall and in the hull structures) shall be calculated at load action specified in 6.7.1 to 6.7.16. The results of structure fatigue strength evaluation and calculations considering secondary and thermal stress shall be submitted to the River Register;

.6 Wall thickness of the independent cargo tanks of type C shall be not less than that obtained by calculations considering corrosion allowance, but in any case not less than, mm:

- for carbon-manganese and nickel steels 5
- for austenitic steels 3
- for aluminum alloys 7

**Strength of cargo tanks with internal insulation**

6.7.31 Strength of cargo tanks with internal insulation shall be calculated considering all the static and dynamic loads and their combinations possible in operation. Structural components forming walls of the cargo tank shall be evaluated for fatigue strength, tendency to crack propagation, adhesion of insulation, strength under compression, tension and shear. Besides, the following shall be made:

.1 Statistic analysis of wave loads considering 6.7.5 to 6.7.9;

.2 Strength calculations of structures;

.3 Damage mechanism analysis.

6.7.32 Stress level and respective structural deformations of the inner hull or independent cargo tank using a 3D FEM model shall be calculated. Such calculations shall confirm that the specified deformations do not lead to peeling or breakdown of the insulation material. The calculation shall consider pressure load inside the cargo tank (see 6.7.5) and dynamic loads due to wave generation in ballast compartments, if those compartments are adjacent to the cargo tank walls.

6.7.33 Permissible stresses arising in the cargo tank walls and permissible combined structural deformations of the cargo tank walls jointly with insulation shall be verified by a technical justification to be prepared by the designer and approved by the River Register.

6.7.34 Results of the cargo tank structure model testing including tests under combined effect of static, dynamic and thermal loads shall be submitted to the River Register.

6.7.35 The test conditions shall comply with the design operating conditions including heat cycling. The minimum number in this case shall be 400 heat cycles on the basis of 19 voyages per year. The 400 heat cycles may be divided into 20 complete cycles (tank wall temperature of up to 45 °C) and 380 partial cycles (cargo tank wall temperature reaches the set value set for ballasted voyage).

6.7.36 The cargo tank structure models shall be geometrically similar to the tested
prototype structure, including angles, connections, pump mounts, passages of pipelines and other stress concentration points; different properties of the cargo tank materials, fabrication process and quality control shall be considered too.

**6.7.37** Tensile tests and fatigue strength tests shall be performed to evaluate insulation material behavior as regards crack propagation in case of through crack development in the inner hull or independent cargo tank. The structure in the place of crack shall be subject to maximum hydrostatic pressure of ballast water.

**6.7.38** Action of load causing fatigue damage is to be determined according to 6.7.29.

**6.7.39** For the cargo tanks with internal insulation, when preparing the test program for the prototype structure to be tested, designer shall develop a repair technique for the insulation material and inner hull or independent tank structure.

### Permissible stresses

**6.7.40** For built-in cargo tanks, permissible stresses are determined according to 2.2 Part I of the Rules.

**6.7.41** For designing, permissible stresses for the structures of the independent cargo tanks of type A formed by flat surfaces shall be taken out of two values, whichever is less, MPa:

\[
[\sigma_A] = \frac{R_m}{2.66} \quad \text{or} \quad [\sigma_A] = \frac{R_{eh}}{1.33}
\]

where \(R_{eh}\) — yield point of the material, MPa;

\(R_m\) — tensile strength of material, MPa;

**6.7.42** If calculations consider bending deformations, axial displacement of the cargo tank, shear and torsional deformations, as well as hull and cargo tank interaction forces caused by deformations of gas tanker's double bottom and cargo tank bottom, then, in case of technical justification submitted to the River Register, stress values exceeding those obtained from calculations as per 6.7.17 to 6.7.39 are allowed.

**6.7.43** For the independent cargo tanks of type B with revolutional shape, actual stresses shall not exceed the following values:

\[
\begin{align*}
[\sigma_m] & \leq f, \\
[\sigma_L] & \leq 1.5f, \\
[\sigma_B] & \leq 1.5F, \\
[\sigma_L] + [\sigma_B] & \leq 1.5F, \\
[\sigma_m] + [\sigma_B] & \leq 1.5F,
\end{align*}
\]

where \(\sigma_m\) — equivalent membrane total stresses, MPa (stresses in shells outside the stress concentration or support areas)

\(\sigma_L\) — equivalent membrane local stresses, MPa (stresses in shells caused by pressure or other mechanical loads, or in the shell elements which serve as the main structure reinforcement, or in other stress concentration areas)

\(\sigma_B\) — equivalent shell stresses at bending, MPa

\(f\) — the lower of \(R_m/n_A\) or \(R_{eh}/n_B\);

\(F\) — the lower of \(R_m/n_C\) or \(R_{eh}/n_D\);

\(n_A, n_B, n_C, n_D\) — coefficients taken from Table 6.7.43.

**Table 6.7.43**

</tbody>
</table>

The \(R_{eh}\) or \(R_m\) in the annealed state shall be used for the welded joints of the structures made of aluminum alloys.

The said characteristics shall comply with minimum specified mechanical properties of the materials including deposited metal of the welds.

**6.7.44** Equivalent stresses shall be calculated by the formula, MPa:

\[
[\sigma_{eq}] = \sqrt{[\sigma_x]^2 + [\sigma_y]^2 - \sigma_x\sigma_y + 3\tau_{xy}^2},
\]

\(\sigma_{eq}\) — equivalent membrane stresses, MPa.
where $\sigma_x$ — total normal stresses in X-direction;
$\sigma_y$ — total normal stresses in Y-direction;
$\tau_{xy}$ — total tangent stresses in the XY plane.

If static and dynamic stresses are determined separately and use of other methods is not reasonable, total stresses shall be calculated by the formulae:

$$\sigma_x = \sigma_{x,s} + \sqrt{\sum \sigma_{x,dyn}^2};$$  \hspace{1cm} (6.7.44-2)

$$\sigma_y = \sigma_{y,s} + \sqrt{\sum \sigma_{y,dyn}^2};$$  \hspace{1cm} (6.7.44-3)

$$\tau_{xy} = \tau_{x,y,s} + \sqrt{\sum \tau_{x,y,dyn}^2},$$  \hspace{1cm} (6.7.44-4)

where $\sigma_{x,s}$, $\sigma_{y,s}$, $\tau_{x,y,s}$, $\sigma_{x,dyn}$, $\sigma_{y,dyn}$, $\tau_{x,y,dyn}$ — static and dynamic stress components respectively which are determined separately from the acceleration components and hull stress components caused by sagging and twisting.

6.7.45 For the independent cargo tanks of type C, permissible membrane stress in the strength calculations shall be taken equal to $f$ (see 6.7.43)

**Corrosion allowance**

6.7.46 If active materials are carried in the cargo tanks or cargo tank environmental is not controlled, it is required to make a corrosion allowance for the cargo tank wall thicknesses as obtained from calculations, performed by the designer and approved by the River Register.

6.7.47 It is not required to make corrosion allowance for the cargo tank walls, if their external surfaces are protected by inert gas or insulation is resistant to dangerous cargo vapours.

6.7.48 Use of paint or other thin coatings for the cargo tank walls may not be considered as corrosion protection of these walls.

**6.8 STRUCTURAL FIRE PROTECTION**

6.8.1 Depending on hazard degree of the carried dangerous cargo, the following types of structural protection shall be provided for the liquefied gas tankers:

- **Type 1G** — maximum degree of structural protection for carriage of dangerous cargo, for which respective requirement (1G) is specified in column 4 of Table A3-1 in Appendix 3.
- **Type 2G** — degree of structural protection for carriage of dangerous cargo, for which respective requirement (2G) is specified in column 4 of Table A3-1 in Appendix 3.
- **Type 2PG** — degree of structural protection for carriage of dangerous cargo, for which respective requirement (2PG) is specified in column 4 of Table A3-1 in Appendix 3.

On liquefied gas tankers with structural fire protection 2PG, dangerous cargo shall be carried in the independent cargo tanks of type C designed for maximum permissible safety valves setting not less than 0.7 MPa and design temperature in the dangerous cargo containment system equal to $-55 \degree C$ or above.

Liquefied gas tanker complying with these requirements and more than 120 m in length shall have structural protection 2G.

- **Type 3G** — degree of structural protection for carriage of dangerous cargo, for which respective requirement (3G) is specified in column 4 of Table A3-1 in Appendix 3.

6.8.2 Open flame sources are not allowed in the spaces with inflammable vapours.

6.8.3 Machinery, accommodation and service spaces, chain lockers, drinking water tanks, water for domestic needs and food stores shall be separated from the cargo area of the liquefied gas tanker depending on availability of an additional barrier. If separation of the cargo tank with a barrier is not prescribed by the Rules, these spaces shall be protected using cofferdams or gas-tight bulkheads of type A-60. If open flame sources are not available in the adjacent spaces, it is allowed to use bulkheads of type A-0.

6.8.4 If dangerous cargo is carried in the cargo tanks which require installation of an additional barrier according to the Rules, the spaces specified in 6.8.3 as well as spaces located below or outside the bilge space and containing an open flame source shall be
separated from the cargo spaces using cofferdams. If no open flame source is available, it is allowed to install one bulkhead of type A-0.

6.8.5 Air lock designed for communication between the gas-hazardous and gas-safe spaces shall include two steel gas-tight self-closing doors without arresters. Simultaneous opening of the doors (to be signalled by audible and visual alarm) is not allowed. Height of the door coaming in the locks shall be at least 300 mm, and distance between the doors shall be at least 1.5 and not more than 2.5 m from each other.

6.8.6 Entrances and other openings in accommodation spaces, service spaces and control stations shall not face the cargo spaces or bow or stern cargo handling equipment. Entrances are arranged in bulkheads of the superstructures and outer walls of the wheelhouses \( L/25 \) apart, where \( L \) — ship length, but not less than 3 m and not more than 5 m from the outer side of the wheelhouse with the passage opening facing the cargo spaces.

6.8.7 Scuttles in side bulkheads of the superstructure within the specified boundaries shall be of blind type (see GOST 19261 and GOST 21672). It is allowed to fit scuttles of flapper type in the wheelhouse, if such scuttles are gas-tight. Side scuttles below the main deck level and at the first tier of the superstructure shall be only of blind type.

6.8.8 Cargo tank openings with a cross-sectional area of more than 0.10 m\(^2\) and safety device openings designed to prevent overpressure shall be located at height of at least 0.60 m above the deck level.

6.8.9 The design and arrangement of cargo tanks, bilge spaces and compressor rooms shall enable access of people with self-contained breathing apparatuses and in protective equipment, lifting the injured, and access to and inspection of all valves. Access to cargo tanks shall be provided from the open deck. Minimum dimensions of the vertical cutouts for passage along the length and breadth of the space shall be 800 \( \times \) 800 mm, and if there are no gratings, they shall be at height no more than 600 mm from the bottom plating. Access from the service spaces free of gas to gas-hazardous spaces is allowed only through air locks. If an air lock is not available, entry from the open upper deck to a gas-safe space shall be located at a height of at least 2.4 m above the open deck.

6.9 FLOODABILITY

6.9.1 For floodability calculations, the dimensions of the side and bottom damages shall be taken according to 6.9.2 and 6.9.3.

6.9.2 Side damage dimensions shall be taken as follows:

1. longitudinal dimension — \( 1/3 L^{2/3} \);
2. transversal dimension — \( B/5 \);
3. vertical dimension — upwards without limitation.

6.9.3 Bottom damage dimensions shall be taken as follows:

1. longitudinal dimension:
   - within 0.3 \( L \) from the fore perpendicular — \( 1/3 L^{2/3} \);
   - within the rest of the ship — \( 1/3 L^{2/3} \) or 5 m, whichever is less;
2. transversal dimension:
   - within 0.3 \( L \) from the fore perpendicular — \( B/6 \);
   - within the rest of the ship — \( B/6 \) or 5 m, whichever is less;
3. vertical dimension — \( B/15 \).

6.9.4 If a tank containing liquid is damaged, it shall be assumed that the tank contents completely escape and are replaced with water to the waterline level complying with the equilibrium position of the flooded ship.

6.9.5 If pipes, channels, trunks or tunnels are located within the estimated damage length, the design solutions shall be made to prevent flooding of compartments, except for those which are to be flooded when the ship is damaged.

6.9.6 Depending on the type of structural fire protection of the liquefied gas tanker and its length, the following requirements shall be met:

1. a ship with structural fire protection of type 1G shall comply with the requirements
specified in 6.9.7 and 6.9.8 if the hull is damaged in any place along its length;

.2 a ship 150 m long or less with structural fire protection of type 2G shall comply with the requirements specified in 6.9.7 and 6.9.8 if the hull is damaged in any place along its length, except for damage of bulkheads enclosing the aft machinery space;

.3 a ship over 150 m long with structural fire protection of type 2G shall comply with the requirements specified in 6.9.7 and 6.9.8 if the hull is damaged in any place along its length;

.4 a ship with structural fire protection of type 2PG shall comply with the requirements specified in 6.9.7 and 6.9.8 if the hull is damaged in any place along its length, except for damage of bulkheads, the distance between which exceeds the longitudinal length of the damage specified in 6.9.2.1;

.5 a ship less than 125 m long with structural fire protection of type 3G shall comply with the requirements specified in 6.9.7 and 6.9.8 if the hull is damaged in any place along its length, except for damage of bulkheads, the distance between which exceeds the longitudinal length of the damage specified in 6.9.2.1 and except for damage of the aft machinery space. In floodability calculations, flooding of the machinery space shall be taken into account;

.6 a ship over 125 m long with structural fire protection of type 3G shall comply with the requirements specified in 6.9.7 and 6.9.8 if the hull is damaged in any place along its length, except for damage of bulkheads, the distance between which exceeds the longitudinal length of the damage specified in 6.9.2.1. In floodability calculations, flooding of the machinery space shall be taken into account.

6.9.7 At any stage of unsymmetrical flooding, a maximum angle of heel shall not exceed 30°.

6.9.8 At the final stage of flooding, the following conditions shall be met:

.1 the length of the positive arm section of the damage stability curve until the lower edges of the openings, through which water could be spread into the intact compartments, are immersed shall not be less than 20°;

.2 the maximum arm of the damage stability curve on the section mentioned in 6.9.8.1 shall not be less than 0.1 m;

.3 area under the damage stability curve within this section shall be not less than 0.0175 m rad.

6.9.9 In floodability calculations, the dimension of the possible vertical damage of the bottom in case of use of membrane and semi-membrane cargo tanks shall be measured to the double bottom plating, in other cases – to the cargo tank bottom. The transverse length of the possible side damage in case of use of membrane and semi-membrane cargo tanks shall be measured to the longitudinal bulkhead, in other cases – to side walls of cargo tanks. For cargo tanks with internal insulation, the dimension of the possible damage shall be measured to the supporting plating of cargo tanks.

6.9.10 Except for liquified gas tankers with structural fire protection of type 1G, suction wells in cargo tanks may be installed within the vertical length of the possible bottom damage if they extend beyond the inner bottom plating for a distance not exceeding 25% of the double bottom height or for a distance of 350 mm, whichever is less. For single-bottom ships, a drain well shall not extend beyond the upper limit of the damaged bottom section for more than 350 mm.

6.10 CONTROL STATIONS

6.10.1 Control stations shall not be located in the cargo area. In ships equipped with the dangerous cargo containment system which requires installation of a secondary barrier, the control station bulkheads facing the cargo area with their plane shall be located so that to prevent gas penetration into the control station from the bilge space in case of deck or bulkhead damage.

6.10.2 Air intakes and openings leading to control stations shall be located at a distance
of not less than 2 m from the cargo pipeline, cargo gas-freeing systems and exhaust pipes of gas burners in machinery spaces.

6.10.3 Doorways of entrances, air intakes and openings leading to machinery spaces and control stations shall not face the cargo area. They shall be located on the end bulkhead facing the side which is opposite to the cargo area and/or on the side wall of the wheelhouse at a distance of not less than 4% of the ship length \( L \), but not less than 3 m and not more than 5 m from the superstructure or wheelhouse end facing the cargo area.

6.10.4 All air intakes and openings leading to control stations shall be equipped with locking arrangements. In case of toxic gas emission, these arrangements shall be actuated from the place located inside the control station.

6.10.5 Any cargo loading/unloading control station which shall be located above the upper deck may be located in the cargo area. The cargo loading/unloading control station may be located within accommodation or service spaces or control stations if the following requirements are met:

1. the cargo loading/unloading control station is a gas-safe space;
2. if openings to enter accommodation or service spaces or control stations comply with the requirements in 6.10.3, access to these spaces or control stations is allowed from the cargo loading/unloading control station;
3. if openings to enter accommodation or service spaces or control stations do not comply with the requirements in 6.10.3, access to these spaces from the cargo loading/unloading control station shall be prohibited and the boundaries of such spaces shall be insulated to A-60 class standard.

6.10.6 If the cargo loading/unloading control station is a gas-safe space, the instruments shall be installed according to the requirements in 6.11.6.

6.10.7 If cargo operations are controlled from the cargo loading/unloading control station, all visual and audible alarms, except for the main deck shall be duplicated in the cargo loading/unloading control station. Alarm with interpretation of the signal shall be installed in the cargo loading/unloading control station on the main deck. The cargo control station shall be designed so as the entire cargo area on the main deck can be visible.

6.10.8 If in the ships carrying inflammable dangerous cargo, the cargo loading/unloading control station is gas-hazardous, arrangement of open flame sources is not allowed.

6.10.9 Communication aids shall be provided between the cargo loading/unloading control station and the place of cargo hose connection to the shore.

6.11 DETECTION OF DANGEROUS CARGO VAPOURS (GAS)

6.11.1 The ship shall be equipped with gas detection equipment complying with the requirements in 6.11.2 to 6.11.15, if such a requirement for the carried dangerous cargo is included in column 11 "Cargo vapour detection system" of Table A3-1 in Appendix 3.

6.11.2 For all the spaces located within the cargo area, it shall be possible to monitor gas concentration.

At fixed sampling device locations designed for dangerous cargo carriage it shall be possible to measure vapour density and decrease vapour concentration by purging or venting the spaces.

6.11.3 If the installation of a secondary barrier is required, at least two sets of fixed sensors (temperature or gas detectors) shall be available to indicate liquid leakage through any point of the primary barrier or contact of dangerous liquid cargo with the secondary barrier in any place.
6.11.4 The pipelines from sampling devices shall not pass through gas-safe spaces except for the cases specified in 6.11.6.

6.11.5 Gas detection systems (see 6.11.8) shall be equipped with audible and visual alarms transmitting signals to the wheelhouse, to the cargo loading/unloading control station and to the place of taking readings from the gas detection system equipment.

6.11.6 Gas detection equipment may be located in the cargo loading/unloading control station, in the wheelhouse or other gas-safe spaces, if the following requirements are met:

.1 the sampling pipelines shall have shut-off valves to avoid communication with gas-hazardous spaces;

.2 gas from the gas analyzer shall be released into the atmosphere at a distance of not less than 10 m from the nearest air intake or openings in the accommodation and service spaces and control stations or from other gas-safe spaces.

6.11.7 Gas detection equipment shall be designed to be tested and calibrated. For this purpose, respective equipment and gas samples shall be available on board.

6.11.8 A fixed gas detection system as well as audible and visual alarms shall be installed:

.1 in spaces containing cargo pumps;

.2 in spaces containing cargo compressors;

.3 in spaces containing electric drives of handling equipment;

.4 in the cargo loading/unloading control station;

.5 in other closed spaces in the cargo area where vapours accumulate, including bilge and interbarrier spaces for independent tanks, except for cargo tanks of type C;

.6 in the vent hoods and gas channels;

.7 in air locks.

6.11.9 Gas detection equipment shall provide sampling and atmospheric composition analysis in the location of each sampling device at intervals not exceeding 30 min, except for sampling for gas detection in vent hoods and gas channels, specified in 6.11.8.6, which shall be continuous. Common sampling pipelines shall not be connected to gas detection equipment installed in such hoods or channels.

6.11.10 Sensors/detectors for detection of dangerous cargo vapours in air locks (at least two in each air lock) shall actuate when vapour concentration reaches 30% of the lower flammable level of dangerous cargo vapours.

6.11.11 If tanks of the dangerous cargo containment system other than independent cargo tanks are used for inflammable dangerous cargo, the bilge and interbarrier spaces shall be equipped with a fixed gas detection system providing measurement of gas concentration in the range of 0 to 100% by volume. These bilge and interbarrier spaces shall be equipped with at least two low temperature sensors for detection of dangerous cargo leakage in the trays for liquefied gas collection.

6.11.12 Using gas detection equipment with audible and visual alarm, sampling and atmospheric composition analysis shall be performed at each sampling device location at intervals not exceeding 30 min. Signalling devices of such equipment shall actuate when vapour concentration reaches 30% of the lower flammable level in the air. Common sampling pipelines shall not be connected to gas detection equipment.

6.11.13 If gases are toxic, the bilge and interbarrier spaces shall be equipped with fixed pipeline system for gas sampling from these spaces. Gas samples from these spaces shall be taken for analysis at each sampling device location using fixed or portable equipment at intervals not exceeding 4 h before anyone enters the space and every 30 min when people stay in these spaces.

6.11.14 Each ship shall be equipped with at least two sets of portable gas detection equipment approved by the River Register. This equipment shall be designed so as to detect dangerous cargo subject to carriage.

6.11.15 A device for measuring oxygen content in inert gas environment shall be installed.
6.12 ARRANGEMENT OF POWER INSTALLATION UNITS AND SYSTEMS

Cargo compressor and cargo pump rooms

6.12.1 Cargo pump and compressor rooms/spaces in liquefied gas tankers shall be located within the cargo area above the upper deck, except for the specified spaces in liquefied gas tankers designed for carriage of liquefied mixtures of hydrocarbon gases, propane and butane. For fire safety, the requirements to cargo pump spaces of oil tankers apply to cargo pump and compressor rooms/spaces of liquefied gas tankers.

6.12.2 If cargo pump and compressor rooms/spaces are located above or below the upper deck in the aft of the bilge space closest to the aft or in the fore of the bilge space closest to the fore, the length of the cargo area shall be such as to accommodate the cargo pump and compressor rooms/spaces located throughout the entire breadth of the ship and its freeboard as well as deck areas above these spaces.

6.12.3 If the cargo area boundaries are extended according to 6.12.2, the bulkhead separating the cargo pump and compressor spaces from accommodation and service spaces, control stations and machinery spaces, shall be located so that to prevent possible gas penetration into these spaces in case of deck or bulkhead damage.

6.12.4 If pumps and compressors are shaft driven, gas-tight lubricated glands shall be installed at shaft penetrations through the bulkheads or decks.

6.12.5 The design and arrangement of cargo pump and compressor rooms/spaces shall provide access for people wearing self-contained breathing apparatuses and protective equipment and lift of the injured as well as access to and inspection of all the valves used for cargo operations. Drain arrangements for pump and compressor rooms/spaces shall be provided.

Bow and stern handling equipment

6.12.6 Cargo pipelines for loading and discharge from the bow or stern shall comply with the requirements in 6.12.7 to 6.12.13.

6.12.7 Bow or stern handling pipelines laid near accommodation or service spaces or control stations shall not be used for transfer of cargo carried by liquefied gas tankers with structural fire protection of type 1G.

6.12.8 Use of portable handling equipment is not allowed.

6.12.9 Cargo pipelines and its connected equipment shall comply with the requirements in 4.12. Except for the specified, cargo pipelines and its connected equipment shall meet the following requirements:

1. the cargo pipelines and its connected equipment located outside the cargo area shall have only welded joints. The pipelines located outside the cargo area, except for the pipeline connected to the shore-based system shall be laid on the open deck and at a distance of not less than 760 mm from the ship's side. Such pipelines shall be marked and the points of their connection to the cargo pipeline system within the cargo area shall be equipped with shut-off valves. Such points shall be equipped with devices for cutting off these pipelines if they are not used with the help of removable inserts and blind flanges;

2. cargo pipelines shall be butt welded on a step-by-step basis. Then welded joints shall undergo complete X-ray examination irrespective of the pipeline diameter and design temperature. Flange connections of pipelines and drip trays for dangerous liquid cargo may be installed only within the cargo area as well as at points of the pipeline connection to the shore;

3. measures shall be taken to ensure purging and degassing of such pipelines after their use and further dismantling of removable inserts and plugging off the pipeline ends with blind flanges. Gas-freeing pipes connected to the purging system shall be located in the cargo area.
6.12.10 Entrances, air intakes and openings leading to accommodation, service and machinery spaces as well as to control stations shall not face connection points to the shore-based system or bow or stern handling equipment. They shall be located on the superstructure or wheelhouse side at a distance of not less than 4% of the ship length \( L \), but not less than 3 m and not more than 5 m from the superstructure or wheelhouse end facing the connection point to the shore-based system of bow or stern handling equipment. Side scuttles with openings facing the side where the shore connection devices are located and on the superstructure or wheelhouse sides within the specified distance shall be of a blind type. Besides, during use of the bow or stern handling equipment, all the doors, ports and other openings located on the respective superstructure or wheelhouse side shall be closed.

6.12.11 Deck openings and air intakes in spaces located at a distance of 10 m from the connection point of bow or stern handling equipment to the shore shall be capable of closing all the time this equipment is in use.

6.12.12 Electric equipment located within 3 m from the specified equipment connection point to the shore-based system shall comply with the requirements of Part VI of the Rules.

6.12.13 Installation of communication aids is required between the cargo loading/unloading control station and the cargo hose connection point to the shore-based system.

**6.12.15** If a ballast pump is installed in the cargo area, the delivery pipe and its side suction branch pipe for water ballasting shall be located within the cargo area, but out of the cargo tanks.

6.13 **HULL STRUCTURE HEATING SYSTEM**

6.13.1 Boilers used to heat the hull structures shall be fired with oil fuel with vapour flash point of above 60 °C. These boilers shall not be installed within the cargo area.

6.13.2 The hull structure heating system shall be designed so as to exclude ingress of dangerous goods into the boiler when the coils of this system become untight.

6.13.3 If the hull structure heating system is used during cargo handling operations, the ventilation system openings in spaces accommodating the hull structure heating system components shall be located at a height of at least 2.4 m from the deck level and at a distance of at least 3 m from the cargo area, at least 6 m from the residual dangerous cargo tank openings, deck mounted cargo pumps, pressure relief valves and connections of cargo piping for reception from shore, and at least 10 m from the openings of the quick-acting outlet valves.

6.14 **PIPELINES, VALVES AND FITTINGS**

6.14.1 Pipelines, valves and fittings of the power installation and general ship systems in liquefied gas tankers shall comply with the requirements of 10, Part IV of the Rules. The requirements of this Chapter apply to pipelines of special systems of liquefied gas tankers.

6.14.2 Pumps, pipelines, valves and other fittings of systems in the cargo tanks area shall have identification marking.

6.14.3 It is not allowed to integrate the cofferdam systems with similar systems located out of the cargo area.

6.14.4 Pipelines and fittings for media with operating temperatures between 0 °C and
–165 °C shall be made of materials listed in Table 5.5, Part X of the Rules.

6.14.5 Materials with melting point below 925 °C shall not be used in pipelines outside the cargo tanks, except the pipes connected to cargo tanks with fire-resistant insulation.

6.14.6 When selecting materials for pipelines and components of systems designed for cargo with temperature less than –165 °C, technical justification confirming the possibility of their use shall be submitted to the River Register.

6.14.7 Wall thickness of pipes operating under internal pressure shall be not less than that determined by the formula (10.2.12-1) Part IV of the Rules, and parameters $p$ (design pressure) and $c$ (corrosion allowance) shall be taken considering the following:

.1 for pipelines or their parts, maximum of the following compared pressures shall be taken as design pressure $p$:

- for pipelines or their parts which contain dangerous cargo vapours or some amount of dangerous liquid cargo and may be disconnected from the safety valves — pressure of the dangerous cargo saturated vapours at a temperature of 45 °C;
- for pipelines or their parts which always contain only dangerous cargo vapours and may be disconnected from the safety valves — pressure of the overheated vapours at a temperature of 45 °C. It is assumed that saturated vapour is generated in the system at working pressure and temperature;

maximum permissible preset actuation pressure of safety valves fitted on cargo tanks and their service cargo systems;

preset actuation pressure of the bypass safety valve fitted on the pump or compressor;

total maximum head in the cargo pipeline at ship loading or discharge;

preset actuation pressure of the safety valve on the pipeline.

In any case, design pressure $p$ shall be taken not less than 1 MPa and for open end pipelines — not less than 0.5 MPa;

.2 wall thickness corrosion allowance increases as compared to that established in 10.2.12, Part IV of the Rules at intense corrosion or erosion of the pipeline exposed to dangerous cargo. In this case corrosion allowance shall be taken considering the declared period of the pipeline operation.

6.14.8 Minimum safety factors accepted for the cargo pipeline when determining permissible stresses and used design characteristics (yield point or tensile strength) shall be specified in the certificate of ship fitness for carriage of liquefied gases in bulk.

6.14.9 Minimum wall thickness shall be adopted Table 10.2.13, Part IV of the Rules.

6.14.10 If design ambient temperature is –110 °C and below, a complete strength calculation shall be made considering all the stresses which can occur under pipe weight (including acceleration loads), internal pressure, thermal contraction as well as loads arising due to ship bending for each piping system branch.

For temperatures above –110 °C, stress calculations considering the structure features, material selection or system stiffness shall be submitted to the River Register.

The specified calculations shall be made using the methods approved by the River Register.

Temperature stresses shall be taken into account.

6.14.12 Pipelines shall be welded in compliance with the requirements in 7.5.9 Part X of the Rules.

6.14.13 Flange connections of pipelines, valves and fittings shall comply with the requirements in 10.2.19 Part IV of the Rules.

Flange connections shall not be used for design temperatures below –10 °C and nominal pipe diameters above 100 mm.

Flange dimensions shall be determined at design pressure according to 6.14.7.1.

6.14.14 Sleeve welded joints may be used only for open end pipelines with an outside
diameter of 50 mm or less and at design temperature of not less than 

-55 °C.

6.14.15 No sleeve threaded joints are allowed.

6.14.16 If expansion joints are used in pipelines, their number shall be sufficient to protect the pipelines of the cargo system and cargo tanks from stresses, arising as a result of thermal expansion of cargo tanks, pipelines and hull deformation.

Only bellows expansion joints shall be installed outside the cargo tanks. Expansion joints of other types shall be installed only inside the cargo tanks.

Means are to be provided to prevent the formation of ice on bellows expansion joints.

6.14.17 Pipelines designed for low temperature applications shall be thermally insulated from adjacent hull structures to avoid hull structure temperature decrease below the design temperature.

If pipelines for dangerous liquid cargo are subject to regular disassembling or leakage of dangerous liquid cargo is possible (e.g. at connections with shore mains or at pump glands), the hull structures located below shall be protected against exposure to low temperature dangerous cargo at pipeline disassembling points or possible dangerous cargo leakage points.

6.14.18 Any piping system which may contain dangerous cargo or dangerous cargo vapours shall comply with the following requirements:

1. the system shall be isolated from other piping systems, except for connections required for cleaning, gas removal and inert gas supply. In this case measures preventing penetration of dangerous cargo or its vapours into other piping systems through these connections shall be taken;

2. pipelines shall not pass through accommodation and service spaces, control stations and machinery space. This requirement doesn't apply to cargo pump and compressor rooms/spaces.

Emergency arrangements for dangerous cargo removal may be located in the aft part of the ship in accommodation and service spaces, control stations and machinery spaces. The pipelines shall not pass through these spaces;

3. the piping system shall be located in the cargo area on the open deck, except for the cases of bow or stern load according to 6.12.7 to 6.12.9 and use of cargo as fuel.

6.14.19 The cargo system pipelines shall not be located under the deck, except for the pipelines of the cargo tanks and cargo pump room.

6.14.20 The cargo system pipelines shall be designed so that it can be possible to drain residuals of dangerous cargo (on completion of loading and discharge processes) from the system to the shore or ship tanks.

6.14.21 The cargo system pipelines located on the deck, except for shore connections, shall be at a distance of not less than one quarter of the hull breadth from the ship's side.

6.14.22 The shore connections shall be located at a distance of not less than 6 m from the entrances to or openings of the accommodation and service spaces outside the cargo area.

6.14.23 The connections of the gas-freeing and cargo systems used during loading and discharge shall have the shut-off device. If these connections are not used during loading and discharge, they shall be blanked off.

6.14.24 For pressure relief and removal of liquid residuals from loading and discharge headers and cargo hoses, devices for their purging and degassing shall be installed in the cargo tanks prior to disconnection of cargo hoses.

Gas-freeing pipes connected with devices for removing residuals of dangerous goods shall be arranged in the cargo area.

6.14.26 Pipelines for bow and stern loading and discharge shall be isolated from the main
cargo pipeline with shut-off valves, detachable branch pipes and blind flanges in the cargo area.

6.14.27 The design and actuators of valves installed on the overboard discharges of pipelines running from spaces located under the freeboard deck or from closed superstructures and wheelhouses on the freeboard deck shall comply with the requirements in 10.4 Part IV of the Rules.

6.14.28 The valves shall be selected with consideration of the following:

1. overboard discharges shall be equipped with one automatic non-return valve with forced means of closure above the freeboard deck;

2. if the vertical distance from the summer waterline to the upper edge of the side drain opening of the discharge pipeline inside the hull of the liquefied gas tanker exceeds 0.01 L m (where L is the ship length along the maximum load waterline, in m), overboard discharges shall be equipped with two automatic non-return valves without forced means of closure if access to the valve located inside the hull for valve inspection is provided.

6.14.29 The cargo system pipelines to every cargo tank shall be equipped with emergency shut-off valves.

6.14.30 For cargo tanks equipped with safety valves adjusted for maximum permissible preset pressure of 0.07 MPa or less, all the connections for liquids and gas, except safety valves and closed-type instruments to determine liquid level mounted in the cargo tank, shall have shut-off valves fitted at the cargo tanks. These valves shall be equipped with manual controls ensuring their complete closure.

Remotely controlled emergency shut-off valves shall be installed on board the ship to stop transfer of liquid or gas between the ship and shore corresponding to the requirements in 6.14.33 and 6.14.34.

6.14.31 For cargo tanks equipped with safety valves adjusted for maximum permissible preset pressure more than 0.07 MPa, all the connections for liquids and gas, except safety valves and closed-type instruments to determine liquid level mounted in the cargo tank, shall have a manual stop valve and automatic remotely controlled shut-off valve.

If the pipe diameter exceeds 50 mm, it is allowed to use bypass valves instead of stop valves. It is allowed to use one by-pass valve instead of two, if it complies with the requirements in 6.14.34, is manually controlled and provides complete closure of the pipeline.

6.14.32 Branch pipes of the cargo tank to fit the instruments may have no by-pass or emergency shut-off valves if flow from the cargo tank does not exceed the flow rate from the cargo tank through a circular hole with a diameter of 1.5 mm.

6.14.33 A remotely controlled emergency shut-off valve shall be installed at each cargo hose connection.

Connections not used during transfer shall be blanked off with the help of blank flanges.

6.14.34 All the emergency shut-off valves required by the Rules shall be controlled from separate stations located in at least two places on board the ship spaced from each other. The control station or cargo loading/unloading control station shall be one of these places.

Emergency shut-off valve control system shall be equipped with fuse elements designed for melting temperature of 98 to 104 °C for automatic closing of the emergency shut-off valves in the event of fire. Fuse elements shall be located in the domes of cargo tanks and at loading stations.

6.14.35 Emergency shut-off valves shall be designed so that to close in case of the actuator failure (power supply failure) and be manually controlled.

Emergency shut-off valves on the liquid cargo pipelines shall fully close at all operating conditions in 30 s after sending the cut-off signal.

6.14.36 In order to avoid pressure rise in the cargo main above the permissible value when closing the valve connected to the
structure of the high liquid level alarm and sensor for their automatic closing and full filling of the cargo tank, total time of valve closing (time from feeding a signal to start closing to total closing of the valve) shall not exceed, in s, $3600 \frac{V_{res}}{Q_{max}}$, where $V_{res}$ is residual volume of the cargo tank, in m$^3$, above the level at which the alarm actuates; $Q_{max}$ is the maximum flow rate at loading considering compliance of the ship and shore loading facilities, in m$^3$/h. Measures shall be taken to avoid water hammers when closing the valve.

6.14.37 Information on closing time of valves and their performance shall be stored on board the ship. Provision shall be made for checking and displaying the time of valve closing.

6.14.38 The pipeline with valves, fittings and other components protected by a bypass valve shall have a larger capacity than design flow rate at the moment of valve closing.

Bypass valves may be equipped with an equalizing line to equalize pressure after the valve stops; the diameter of the equalizing line shall not exceed 1.0 mm.

6.14.39 All the pipelines or their sections designed to be isolated from cargo systems and tanks when filled with dangerous liquid cargo shall be equipped with safety valves. Dangerous cargo shall be drained from safety valves installed on cargo pipelines to cargo tanks. It is allowed to drain to gas venting masthead riser (column) if means for detection and removal of dangerous liquid cargo which may penetrate into the ventilation system are installed.

Dangerous cargo shall be drained from safety valves installed on cargo pumps to the pump suction.

6.15 CARGO SYSTEM

6.15.1 Cargo pumps shall be designed so that pressure decrease of elastic saturated vapour of liquid dangerous cargo at maximum temperature minimally affects the pump suction.

6.15.2 If dangerous cargo is transferred by cargo pumps which has no access for repair from the cargo tank side in operation, at least two independent dangerous cargo transfer arrangements shall be provided for dangerous cargo transfer from each cargo tank. These cargo transfer arrangements shall be designed so that when one of the cargo pumps or one of the transfer arrangements fails, the other cargo pump (pumps) or other dangerous cargo transfer arrangements shall remain serviceable.

6.15.3 Safety valves shall be installed if discharge pressure of cargo pumps and compressors exceeds design pressure in the cargo system.

6.15.4 When transferring dangerous cargo by its displacement with compressed gases, the possibility of safety valve actuation shall be excluded.

6.15.5 Cargo pumps and compressors shall be equipped with automatic cut-off devices in the following cases:

1. if emergency shut-off valves installed on pressure pipelines according to the requirements in 6.14.29 are closed by emergency shut-off valve control system prescribed in 6.14.34;

2. when the dangerous cargo filling level in the cargo tank reaches the designed value;

3. when pressure in the cargo tank drops to the minimum permissible value.

Cargo pumps and compressors shall be stopped from the local control station and shall be additionally capable of being stopped remotely from the station outside the cargo area.

6.15.6 If part of dangerous cargo not pumped by the cargo pumps remains in the cargo tank, the means to remove residual dangerous cargo shall be installed during replacement of dangerous cargo or repair.

6.16 PRESSURE REDUCTION SYSTEM

6.16.1 All the cargo tanks shall be equipped with the pressure reduction system by releasing excessive evaporated dangerous cargo to the gas-freeing piping through pressure relief valves.
Hold spaces, interbarrier spaces and cargo pipelines which pressure can exceed the design value according to design, shall be equipped with pressure reduction systems by releasing evaporated dangerous cargo. Pressure reduction systems shall be connected to the gas-freeing pipings. Provision shall be made to prevent dangerous cargo vapour from accumulating on decks and penetrating into accommodation, machinery and other spaces as well as control stations.

The pressure reduction systems shall be independent from other pressure regulation systems specified in 6.22.

6.16.2 Each cargo tank with capacity over 20 m$^3$ shall be equipped with at least two pressure relief valves of equal flow rate.

Cargo tanks with capacity of 20 m$^3$ or less shall be equipped with one pressure relief valve.

6.16.3 Interbarrier spaces shall be equipped with pressure reduction devices approved by the River Register.

6.16.4 Pressure relief valves shall be adjusted for actuation pressure not exceeding the pressure for which the cargo tank is designed. If the tank is equipped with two pressure relief valves or more, the valves may be adjusted for actuation pressure exceeding the design pressure by 5% if these valves take max. 50% of the total load at pressure relief.

6.16.5 The pressure relief valves shall be connected to the highest part of the cargo tank above the deck level. The pressure relief valves fitted on cargo tanks with design temperature below 0 °C shall be designed so that they always operate even if iced in closed position. The valves shall be made of materials with melting temperature above 925 °C.

6.16.6 If pressure relief valves of cargo tanks may be adjusted for actuation at several values of the preset pressure according to the design documentation, it may be achieved by installation of:

1. two or more sealed pressure relief valves adjusted for actuation and capable of being isolated from the cargo tank if not used; 2. pressure relief valves which actuation mode can be changed by using orifices or springs or other means not requiring pressure test to verify proper selection of a new set pressure.

6.16.7 The procedures of adjusting the preset pressure according to 6.16.6 and resetting the emergency sensors/detectors to a new pressure value shall be described in the operating manual for the ship. The master shall supervise the specified procedures and record the preset pressure value changes in the ship log.

6.16.8 Shut-off valves and other means of isolating the pipelines between the cargo tanks and pressure relief valves designed for maintenance and repair of these pipelines, shall be installed only in case of using the following:

1. means to prevent simultaneous failure of more than one pressure relief valve;
2. automatic alarm indicating which pressure relief valve is faulty;
3. pressure relief valves with the flow rate which shall be such that if one of the valves fails, the total capacity of the remaining valves is not less than that specified in 6.19. The total capacity of all the pressure relief valves may be not less than that specified in 6.19 only if a spare valve completely ready for installation is available on board the ship.

6.16.9 Each pressure relief valve installed on the cargo tank shall be connected to the gas-freeing system.

6.16.10 In case of simultaneous carriage of dangerous cargo which may react with each other, an autonomous pressure reduction system shall be provided for each carried dangerous cargo.

6.16.11 Pressure relief valves and pipelines shall be designed so that no liquid accumulates in them.

6.16.12 Pressure relief valves shall be located on the cargo tank so that they remain under influence of gaseous phase of the dangerous cargo at heel of 15° and trim of 0.015$^\circ$. 
6.17 ADDITIONAL PRESSURE REDUCTION SYSTEM FOR LIQUID LEVEL ADJUSTMENT

6.17.1 If there is a risk of early full filling of the cargo tank at its loading (see 6.20.4.2), such a tank shall be equipped with the pressure reduction system comprising the following:

1. one or more pressure relief valves adjusted for actuation at excessive pressure of dangerous cargo vapours and design temperature (see 6.20.4.2);
2. shut-off device providing system stop in normal mode. This device shall include elements which fuse at a temperature of 98 to 104 °C to actuate the pressure relief valve (valves) specified in 6.17.1.1. Fuse elements shall be located near the pressure relief valve (valves).

The pressure reduction system shall remain serviceable in case of power supply failure.

The shut-off device shall be independent of any ship’s power source.

6.17.2 Total capacity of the additional pressure reduction system at vapour pressure specified in 6.17.1.1 at standard temperature of 0 °C and pressure of 0.1013 MPa shall be not less than the minimum required air release rate \( Q \) determined by the formula, m³/s:

\[
Q = F_k g A^{0.82},
\]  

(6.17.2-1)

where \( F \) — ignition susceptibility coefficient, which depends on the type of cargo tanks. Values of \( F \) are taken equal to:

- for non-insulated cargo tanks located on the deck
- for cargo tanks located above the deck, which are insulated with fire resistant material with low thermal conductivity approved by the River Register
- for non-insulated independent cargo tanks installed in the holds
- for insulated independent cargo tanks installed in isolated holds
- for insulated independent cargo tanks installed in the holds accommodating inert gas and for non-insulated independent cargo tanks installed in inertized isolated holds
- for membrane and semi-membrane cargo tanks

\[
k_g = 12.4 \sqrt{ZT/M} \left[ D \left( r + \overline{\rho}_{liq} \right) \right],
\]  

(6.17.2-2)

where \( Z \) — gas compressibility factor at pressure reduction, i.e. under pressure exceeding the actuation pressure for which the pressure relief valve of the additional pressure reduction system is adjusted by 20%. If \( Z \) is unknown, \( Z \) shall be taken equal to 1.0;

\( T \) — temperature under pressure drop, K;

\( M \) — molar weight of dangerous cargo, kg/kmol;

\( D \) — constant adopted from Table 6.17.2-1 depending on the value of specific heat capacity \( c_u \) or taken equal to 0.606. If specific heat capacity is unknown, it shall be calculated by the formula, kJ/(kg·K):

\[
c_u = 8.314/M,
\]  

(6.17.2-3)

</table>

\( r \) — latent heat of evaporation at unloading, kJ/kg;
\( \bar{\rho}_{\text{liq}} \) — ratio of liquid dangerous cargo density to fresh water density at pressure reduction \( (\bar{\rho}_{\text{liq}} = 1 \text{ for fresh water}) \);

\( m \) — gradient of liquid dangerous cargo enthalpy reduction depending on increase of liquid dangerous cargo density at pressure reduction, in kJ/kg,

\[
m = - \frac{d h}{(d \bar{\rho}_{\text{liq}})}.
\]

For installations with pressure not exceeding 0.206 MPa, the values specified in Table 6.17.2-2 shall be used. For dangerous cargo not specified in Table 6.17.2-2 and for installations with higher pressure, the value \( m \) shall be determined on the basis of thermodynamic characteristics of dangerous cargo;

Note: The values \( m \) are given for pressure not exceeding 0.206 MPa.

\( h \) — dangerous cargo enthalpy, kJ/kg;

\( A \) — outer surface area of the cargo tank, \( \text{m}^2 \). For cargo tanks depending on their shape and type, the area \( A \) shall be taken equal to:

- outer surface area — for cargo tanks with revolutioned shape;
- outer surface area without projected area of its bottom — for cargo tanks without revolutioned shape.

For cargo tanks of pressure vessel type which are arranged in rows (Fig. 6.17.2), the area \( A \) is taken equal to:

outer surface area of the holds without projected area of its bottom, if the hull structure is insulated;

outer surface area of pressure vessels arranged in rows, excluding insulation, without projected area of their bottom (in Fig.6.17.2 the area \( A \) is dotted), if the pressure vessel structure is insulated.

6.17.3 If according to 6.17.1.1 it is required to change adjustment of pressure relief valves, it shall comply with the requirements in 6.16.6.

6.17.4 Pressure relief valves specified in 6.17.1.1 can be adjusted according to the requirements in 6.16 if their preset pressure and flow rate comply with the requirements in 6.17.

6.17.5 Gas released from pressure relief valves shall be discharged to the gas-freeing system.

6.18 VACUUM PROTECTION SYSTEM

6.18.1 The vacuum protection system shall be provided in the cases when cargo tanks are designed for difference between external and internal pressure of 0.025 MPa or less and cannot withstand maximum difference between external and internal pressure in the cargo tank which may occur at high unloading rates without vapour return to cargo tanks or at use of dangerous cargo cooling system.

6.18.2 Cargo tanks which are provided with the vacuum protection according to the design shall be equipped with the following:

two independent pressure sensors to transmit an alarm signal and to stop liquid and gas dangerous cargo suction from the cargo tank
6.18.3 Vacuum safety valves shall provide supply of inert gas, dangerous cargo vapours or air to the cargo tank. They shall be designed to exclude ingress of water or snow into the tank.

If at actuation of vacuum safety valves, dangerous cargo vapours are supplied to the cargo tank, their ingress from vapour outlet pipes shall be excluded.

6.18.4 Means shall be provided to test the operating vacuum protection system at design pressure.

6.19 SAFETY VALVE DIMENSIONS

6.19.1 The cargo tank safety valves shall have total flow rate required for discharging each cargo tank at the rate equal to one of the values given below. Pressure in the cargo tank shall not exceed the maximum permissible preset pressure of safety valve actuation by more than 20%:

1. maximum efficiency of the system for cargo tank filling with inert gas, if maximum working pressure in the cargo tank inerting system exceeds the maximum permissible preset pressure of the cargo tank safety valve actuation pressure;

2. vapour formation rate if the cargo tank is exposed to high temperatures in case of fire calculated by the formula (6.17.2-1).

The gas factor \(k_g\) in the formula is determined according to the formula:

\[k_g = 12.4 \sqrt{Z T / M (r D)}\]

where \(r, D, Z, T\) and \(M\) — see 6.17.2.

6.19.2 When determining the flow rate specified in 6.17.2, back-pressure in gas-freeing mains shall be taken into account. Pressure drop in the gas-freeing pipeline from the cargo tank to the safety valve outlet shall not exceed 3% of the preset valve actuation pressure. For uncontrolled safety valves, back-pressure in the exhaust pipeline shall not exceed 10% of overpressure in the safety valve inlet, connected to the pipes for releasing vapour resulted from cargo tank exposure to high temperature in case of fire as specified in 6.19.1.2.

6.20 CARGO TANK FILLING LIMITS

6.20.1 The cargo tank shall be filled with liquid cargo for not more than 91% of the volume at design temperature taken according to 6.20.4, except for the provisions specified in 6.20.3.

6.20.2 The maximum volume \(V_L\) of liquid cargo filled into the cargo tank shall be calculated by the formula, m³:

\[V_L = 0.01 z \rho_R / \rho_L\]

where \(z\) — accepted limit of liquid cargo filling according to 6.20.1 or 6.20.3, %;

\(\rho_R\) — dangerous cargo density at the design temperature, kg/m³;

\(\rho_L\) — dangerous cargo density at temperature and pressure in the tank during its filling, kg/m³;

\(V\) — volume of the cargo tank without dome, m³.

6.20.3 A cargo tank may be filled with dangerous liquid cargo for 91% to 98% of its volume at the design temperature specified in 6.20.4 if the design organization submits relevant technical justifications and calculations to the River Register. In this case, the following shall be considered: tank shape, location of safety valves, liquid level and temperature measurement accuracy as well as difference between dangerous cargo temperature during loading and temperature when dangerous cargo vapour pressure corresponds to the preset safety valve actuation pressure. The valves
shall be located according to the requirements in 6.16.12.

Tank filling for more than 98% of its volume is not allowed.

6.20.4 For the purposes of this chapter, design temperature means:

.1 temperature at which dangerous cargo vapour pressure corresponds to the pressure for which safety valves are adjusted, if the temperature and pressure regulation system for dangerous cargo vapours complying to the requirements specified in 6.22 is not installed;

.2 maximum dangerous cargo temperature upon completion of loading, during transportation or discharge, if the temperature and pressure regulation system for dangerous cargo vapours complying to the requirements specified in 6.22 is installed. If a cargo tank is completely filled at such a design temperature before dangerous cargo temperature raises to the value corresponding to the dangerous cargo vapour pressure for which the safety valves are adjusted according to the requirements in 6.16.2, additional pressure reduction system complying with the requirements in 6.17 shall be installed.

6.20.5 If technical justifications and calculations are submitted to the River Register by the design organization, it is allowed to load tanks of type C to the limit determined by the formula specified in 6.20.2, where \( \rho_R \) is dangerous cargo density at maximum temperature which the dangerous cargo may reach upon completion of loading, during transportation or discharge carried out at ambient temperature specified in 4.20.2. These requirements do not apply to dangerous cargo carried by liquefied gas tankers of type 1G.

6.20.6 Maximum permissible filling limits for each cargo tank and for each carried cargo at loading condition temperatures as well as for maximum possible temperature shall be specified in operating documentation. This documentation shall also specify the preset pressure of safety valves, including those required according to 6.17.

6.21 GAS-FREEING SYSTEM

6.21.1 The gas-freeing system shall be installed to remove excessive gas from the cargo tank safety valves.

6.21.2 The gas-freeing system shall be designed so as to direct the outgoing gas upwards and to prevent water or snow ingress into the system.

6.21.3 Exhaust openings of gas-freeing pipes shall be located above the open deck at a height of at least \( B/3 \), where \( B \) is ship breadth, or 6 m, whichever is greater, and 6 m above the operating area platform, bow and stern catwalks. If quick-release valves are used, they shall be located at a height of at least 2.4 m above the deck level and at a distance of at least 10 m from accommodation and service spaces located outside the cargo area.

6.21.4 Exhaust openings for gas outlet from the cargo tank safety valves shall be located at a distance equal to the ship breadth or 25 m, whichever is less, from the nearest air intake or openings of accommodation and service spaces or other gas-safe spaces.

All other exhaust openings of the gas-outlet pipes connected to the dangerous cargo containment system shall be located at a distance of at least 10 m from the air intake or openings of accommodation and service spaces and control stations or other gas-safe spaces.

6.21.5 In case of simultaneous carriage of dangerous cargo which may react with each other, autonomous gas-freeing piping shall be laid from safety valves for each carried dangerous cargo.

6.21.6 Means providing liquid removal from places of its accumulation shall be installed in gas-freeing systems.

6.21.7 Protective screens shall be installed at gas-freeing piping outlets.

6.21.8 All the gas-freeing pipes and their fasteners shall be designed so that to prevent pipe damage at temperature variation or under loads occurring at ship motion.
6.22 CARGO PRESSURE AND TEMPERATURE REGULATION SYSTEM

6.22.1 If the dangerous cargo containment system is not rated for full positive pressure of dangerous cargo vapours under conditions of maximum ambient temperature, pressure in the cargo tank shall be maintained below the maximum permissible set pressure of the safety valve by using one or several systems mentioned in 4.20.1.

6.22.2 For dangerous cargo which is to meet special requirements specified in Appendix 3, cargo tanks shall withstand total dangerous cargo vapour pressure at the maximum design ambient temperature irrespective of the system installed for operations with gas vapours.

6.22.3 The requirements of 4.20.2, 4.20.4, 4.20.6 to 4.20.10 shall be met.

6.23 BILGE SYSTEM FOR EVACUATING CARGO LEAKS AND BALLAST SYSTEM

6.23.1 If dangerous cargo is carried in cargo tanks not requiring a secondary barrier, bilge spaces shall be equipped with independent bilge systems not connected to machinery spaces and designed for pumping dangerous cargo which leaked through the primary barrier, e.g. in case of cargo tank leakage or primary barrier damage.

Installation of means for dangerous cargo leakage detection is required in the specified bilge spaces.

6.23.2 If a secondary barrier is used, a bilge system is required to evacuate cargo leaked into bilge spaces or isolated spaces through the ship structures.

The suction pipeline of such systems shall not be connected to the pumps located in the machinery space.

6.23.3 Bilge or interbarrier spaces in the ships with autonomous cargo tanks of type A shall be equipped with a bilge system providing pumping of liquid dangerous cargo in case of its leakage into the cargo tank or cargo tank damage. Such systems shall provide return of the dangerous cargo which leaked from the cargo tank into the cargo pipeline. Removable spool pieces shall be installed.

6.23.4 Independent bilge systems for pump and compressor rooms/spaces shall be installed.

6.23.5 The cargo pump room located under the deck shall be drained by means of the autonomous system located within the cargo area and not connected with another system. Such a system shall be placed outside of the cargo pump room.

6.23.6 Internally insulated cargo tanks do not require leakage detection means and bilge system for the interbarrier space and spaces between the secondary barrier and double sides and double bottom or structure of the independent cargo tank which are totally filled with insulation material.

6.23.7 Ballast tanks, fuel oil tanks and gas-safe spaces may be served by ballast pumps located in the machinery space.

Bottom tunnels accommodating ballast pipelines may be connected to the machinery space containing ballast pumps if the pipes are connected directly to the pumps and discharged overboard.

Gas exhaust pipes of the pumps shall have no open ends entering machinery space.

6.24 VENTILATION SYSTEM

Ventilation of spaces manned during cargo operations

6.24.1 Spaces accommodating electric motors of cargo pumps and compressors as well as other enclosed spaces containing equipment for dangerous cargo transfer and spaces from which cargo operations are controlled shall be equipped with artificial ventilation independent from other ventilation systems and controlled outside these spaces. Measures shall be provided to start the ventilation system of these spaces before personnel enters them. The warning sign to start the ventilation system shall be placed at the entry of these spaces.
6.24.2 Inlet and outlet openings of artificial ventilation shall be located so that to provide air supply to the space to avoid accumulation of inflammable or toxic vapours of dangerous cargo and provide safe atmosphere.

The ventilation system shall provide at least 30 air changes per hour based on the total volume of the space. As an exception, for gas-safe cargo loading/unloading control stations, 8 air changes per hour are allowed.

6.24.3 Ventilation systems of spaces shall be fixed. Exhaust ventilation systems shall provide air intake from upper and lower parts of the space depending on the density of the carried dangerous cargo vapours.

6.24.4 Supply ventilation shall be provided in spaces containing electric motors of cargo compressors and pumps, in spaces accommodating inert gas generators, in cargo loading/unloading control stations if they are gas-safe as well as in other gas-safe spaces within the cargo area.

6.24.5 Exhaust ventilation shall be provided in cargo compressor and pump spaces/rooms and in cargo loading/unloading control stations if they are gas-hazardous.

6.24.6 Exhaust ventilation ducts shall provide air removal upwards from gas-hazardous spaces. Outlet openings shall be located above the cargo deck at a height of at least 4 m and at a distance of at least 10 m in the horizontal direction from inlet ventilation ducts and openings in accommodation and service spaces, control stations and other gas-safe spaces.

6.24.7 Inlet openings of the ventilation system shall be located so that to prevent return of dangerous vapours from outlet ventilation openings.

6.24.8 Ventilation ducts of gas-hazardous spaces shall not pass through machinery, accommodation and service spaces and control stations.

6.24.9 Electric motors of fans shall be located outside ventilation ducts in case of inflammable dangerous cargo carriage.

Fans shall not be the source of ignition of dangerous cargo vapours in the ventilated space and in the ventilation system serving this space.

Fans and ventilation ducts for gas-hazardous spaces at fan locations shall be designed so as to exclude sparking.

6.24.10 Fans of each type used in cargo areas shall be provided with a set of spare parts: impellers with a shaft, bearings and electric motors.

6.24.11 For protection of ventilation ducts, their outer openings shall be equipped with tight covers and protective strainers with cells the sides of which do not exceed 13 mm.

6.24.12 If engines suck air from the machinery space, the inlet ventilation openings of the machinery space shall be located at a distance of not less than 2 m from the cargo area. This requirement also applies to the location of engine air intakes.

6.24.13 Ventilation of the closed machinery space shall provide temperature in the machinery space of max. 40 °C at ambient temperature of 20 °C.

Ventilation of occasionally manned spaces

6.24.14 Bilge spaces, interbarrier spaces, cofferdams, cargo piping spaces and other spaces where dangerous cargo vapours may accumulate, shall have ventilation providing safe atmosphere if these spaces are to be manned. If such spaces are not equipped with a fixed ventilation system, portable means of artificial ventilation approved by the River Register shall be provided.

Fans shall comply with the requirements in 6.24.9 and shall not prevent access of the personnel to this space.

6.24.15 The space and cofferdam purging shall be ensured with portable or fixed fans providing at least 20 air changes per hour based on the total volume of the space.

Air for space and cofferdam purging shall be supplied through an air duct to the bottom part of a space 400 mm clear off the floor (bottom). Air shall exit through the air pipes.
The purging system inlet openings shall be located at a height of not less than 2.4 m above the deck and at a distance of not less than 5 m from the tank openings and 10 m from the safety valve openings.

6.24.16 Fans used for purging of spaces according to 6.24.15 shall be explosion-proof.

6.24.17 The cofferdam ventilation openings shall be equipped with flame arresters.

**Ventilation of other spaces**

6.24.18 Inlet ventilation openings of accommodation and service spaces as well as control stations shall be located on the outer walls of superstructures or wheelhouses not facing the cargo area, bow or stern handling equipment or on the side walls of the superstructure or wheelhouse at a distance equal to at least 4% of the ship length but not less than 3 m and not exceeding 5 m from the wall of the superstructure or the wheelhouse facing the cargo area or bow or stern handling equipment.

Location of ventilation system inlet openings as related to cargo pipelines, gas-freeing piping as well as exhaust piping of devices running with liquefied gas shall be also taken into account.

The specified requirements do not apply to liquefied gas tankers designed for carriage of dangerous cargo posing no toxic or fire hazards or small liquefied gas tankers which are not technically capable of meeting the specified requirements.

6.24.19 All the inlet openings of the ventilation system and openings in accommodation and service spaces and control stations shall be equipped with devices locking from inside the space and providing gas tightness.

When carrying dangerous cargo emitting toxic gases, all the inlet openings of the ventilation system shall open and close from inside the spaces.

6.24.20 The air lock space shall have artificial supply ventilation from gas-safe space to maintain overpressure with respect to the gas-hazardous zone on the open deck.

Air circulation rate shall not be less than 30 air changes per hour.

6.24.21 An independent ventilation system to exclude dead air and stagnation shall be provided in machinery spaces of type A where liquefied gas is used as fuel.

**6.25 FIRE-FIGHTING SYSTEMS**

**Fire smothering systems**

6.25.1 Requirements in 6.25.2 to 6.25.4 complement the requirements in 2.1 to 2.4.

6.25.2 Cargo compressor and pump spaces/rooms shall be equipped with one of the fire smothering systems (aerosol, water mist, chemical smothering). If the carbon dioxide fire extinguishing system according to 3.8 Part III of the Rules is used, the coefficient $\phi$ in the formula (3.8.9) in Part III of the Rules shall be taken equal to 0.45.

Starting arrangements of the fire smothering system shall have marking specifying that the system is to be used only for fire extinguishing, not for inerting.

6.25.3 Cargo compressor and pump spaces/rooms in the ships designed for carriage of dangerous cargo which cannot use the carbon dioxide fire extinguishing system shall be equipped with a fire smothering system.

6.25.4 Audible alarm devices which warn of the carbon dioxide fire extinguishing system start in the cargo compressor and pump spaces/rooms shall have protection required for use in the spaces which contain inflammable vapours of dangerous cargo in their air area.

**Fire water mains system**

6.25.5 In addition to the requirements in 2.1.1 the fire water mains system shall comply with the following requirements:

1. water pressure at any fire hydrant shall be at least 0.5 MPa;
2. shut-off valves shall be installed on bypass pipelines and on the fire main at the point where it exits from the quarter deck superstructure and every 40 m on the deck in the cargo area;
.3 Fire pump capacity and head as well as diameter of the fire main shall be such that water jets supplied from at least two fire nozzles reach any deck part in the cargo area as well as areas of the dangerous cargo containment system and covers of cargo tanks located above the deck. The length of fire hoses on open decks shall not exceed 33 m;

.4 At least three doubled fire nozzles shall be installed within the cargo area. A return spring valve shall be installed on the fire main to avoid gas penetration into accommodation or service spaces.

**Water sprinkling system**

6.25.6 In ships carrying inflammable or toxic dangerous cargo, a water sprinkling system to cool the structures, restrict fire spread and protect people shall be installed. This system shall protect the following areas:

.1 Domes and other projections of cargo tanks having no fire protection;

.2 Deck cargo tanks for storage of inflammable or toxic gases having no fire protection;

.3 Cargo manifolds for liquid and vapours as well as valve control stations and other areas accommodating control valves. The area of these locations shall be not less than the area of available water drip trays;

.4 Outer walls of superstructures and wheelhouses facing the cargo area as well as cargo pump and compressor rooms/spaces, cargo loading/unloading control station, storerooms for highly inflammable materials and substances.

6.25.7 The water sprinkling system shall protect all the areas specified in 6.25.6 by uniformly sprayed water at water flow rate of at least 10 l/m² per minute for horizontal surfaces and 4 l/m² per minute for vertical surfaces. For structures having no horizontal or vertical surfaces, capacity of the water sprinkling system shall be taken equal to the greatest of the following values determined as:

.1 Horizontal surface area multiplied by 10 l/m² per minute;

.2 Actual surface area multiplied by 4 l/m² per minute.

If sprayers located on vertical surfaces spray only the lower parts, the estimated drain from the upper parts may be considered. The water sprinkling line shall be equipped with shut-off valves which are to be adequately spaced to cut off the damaged sections. The water sprinkling system may be divided into two or more sections which are to operate independently provided that control devices are installed at the same location abaft the cargo area. The sprinkling system section protecting the areas specified in 6.25.6.1 and 6.25.6.2 shall protect the entire group of the cargo tanks related to this section in transverse direction relative to the centreline.

6.25.8 Capacity of the water sprinkling system pumps shall be sufficient for simultaneous distribution of the required amount of water to all sections. If the water sprinkling system is divided into sections, its devices and pump capacity shall provide simultaneous water supply to one of its sections and to the surfaces specified in 6.25.6.3 and 6.25.6.4. If it is impossible to comply with the specified requirements, fire pumps of the fire water main system may be used for water sprinkling if their total capacity is increased taking into account the water flow rate required for the water sprinkling system operation. The fire main of the fire water main system and the water sprinkling system line shall be interconnected outside the cargo area. A shut-off valve shall be installed at their connection point.

6.25.9 It is allowed to use sanitary service, ballast, bilge and other sea water pumps for the water sprinkling system, if their capacity and head comply with the requirements for the water sprinkling system.

6.25.10 The pumps serving the water sprinkling system as well as manually closed valves shall be remotely controlled from fire-safe places outside the cargo area.

**Dry powder fire extinguishing system**

6.25.11 Ships designed for carriage of inflammable dangerous cargo shall be equipped with a dry powder fire extinguishing system to protect the cargo area, bow and stern areas.
used for cargo handling operations and cargo manifolds.

6.25.12 The dry powder fire extinguishing system shall provide supply of the dry powder approved by the River Register from at least two hoses with hand fire nozzles or from a fire monitor/hose with a hand fire nozzle to any part of the cargo area above the deck subject to fire risk and including an above-deck cargo pipeline. The system shall be actuated using nitrogen or other inert carrier gas of the powder used solely for this purpose and stored in high-pressure vessels located near the containers for powder.

6.25.13 The dry powder fire extinguishing system in the cargo area shall consist of at least two independent dry powder stations with respective controls, fixed pipeline for the media maintaining the pressure, fire monitors or hoses with hand fire nozzles. It is allowed to install only one such station for ships with cargo carrying capacity less than 1000 m³. A fire monitor shall be provided for protection of the cargo manifold location. The fire monitor shall be actuated from the local dry powder station or remotely controlled. Remote control of the fire monitor is not required, if it supplies powder to all the parts of the serviced zone from one position. All the fire hoses with hand fire nozzles and fire monitors shall be actuated from the place at reels for the fire hose or monitor. One fire hose with hand fire nozzle or fire monitor shall be located in the stern cargo area.

6.25.14 Additional dry powder station equipped with at least one fire monitor and one fire hose shall be installed in the ships equipped with bow or stern handling equipment. This additional station shall be located so that to protect bow or stern handling equipment. The cargo pipeline forward or abaft the cargo area shall be protected with fire hoses with hand fire nozzles.

6.25.15 The dry powder station with two or more fire monitors, fire hoses with hand fire nozzles or both shall be equipped with independent pipes with a manifold at the container for powder.

6.25.16 The system shall be remotely started from any dry powder station. The dry powder fire extinguishing system shall be ready for operation not later than 30 s after opening the starting bottle at the most distant fire station operating from this station.

6.25.17 Each container at the dry powder station shall contain the design quantity of powder which is to ensure continuous operation of all hand fire nozzles and fire monitors served by this station with rated consumption for at least 45 s.

Fire hoses shall be equipped with fire nozzles operating in a two-position mode at powder consumption of at least 3.5 kg/s providing a powder jet min. 8 m long. Fire hoses shall not twist. A maximum operation zone for each hand fire nozzle shall be determined depending on the length of its fire hose. The maximum efficiency of the fire nozzle shall be such that the one person can use the nozzle. The fire hose length with a hand fire nozzle shall not exceed 33 m.

Powder consumption through each fire monitor shall be at least 10 kg/s, maximum range of fire monitors with supply of 10, 25 and 45 kg/s shall be taken equal to 10, 30 and 40 m respectively.

6.25.18 Quantity of powder for protection of emergency power source rooms and store-rooms for highly inflammable materials and substances shall be determined for operation of the dry powder station with powder supply rate of 0.1 (kg/s)/m³ for 10 s.

6.25.19 Quantity of carrier gas shall provide single release of all powder from the container.

6.25.20 If two or more dry powder installations are connected to the dry powder station, the powder shall be supplied to each installation from the manifold of the dry powder station via a separate pipeline equipped with a starting valve.

The dry powder station shall provide both separate and simultaneous operation of all the dry powder installations.

6.25.21 If a stationary pipeline is installed between the powder container and fire hose
with a hand fire nozzle or fire monitor, the length of such a pipe shall not exceed the length of the pipeline when powder is maintained in the free flowing condition during continuous or periodic operation and when it can be removed by purging if the dry powder fire extinguishing system is switched off. The material of fire hoses and nozzles shall be weather resistant, otherwise they shall be stored in accessible places in weather resistant lockers or boxes.

6.25.22 A hand fire nozzle shall be equipped with a device for switching on/off powder supply.

6.25.23 The cross-sectional area of the fire nozzle shall be equal to the cross-sectional area of the fire hose or less by max. 50%.

6.25.24 Starting bottles shall be equipped with pressure gauges.

6.25.25 The operating instruction containing a guidance for starting the system shall be available at each dry powder fire extinguishing station.

6.25.26 A flow tube not reaching the container bottom by 100 mm shall be fitted in the powder container.

6.25.27 A device for gas passage into the container preventing powder penetration into the gas main shall be installed in the lower part of the powder container.

6.25.28 The powder filling ratio of the container shall not exceed 0.95.

6.25.29 The system pipelines and fittings shall not have cross-sectional contractions or extensions.

6.25.30 The cross-sectional area of the manifold in the dry powder station shall be not less than the total cross-sectional area of pipelines connected to it for simultaneous powder supply or exceed it more than twice.

6.25.31 A device for purging the pipelines after switching off the system shall be installed on the distribution manifold of the dry powder station.

6.25.32 The bending radius of the powder pipeline shall be at least 10 pipeline diameters.

6.25.33 Powder shall be supplied to the emergency power source rooms and store-rooms for highly inflammable materials and substances through sprayers. Their design, location and quantity shall provide even spraying of the powder in the total volume of the space. The pressure at the most distant sprayer shall be taken equal to a minimum pressure at which even spraying of the powder is provided in all directions from the sprayer.

6.26 INERT GAS SYSTEM

Bilge space inerting

6.26.1 If a ship is designed for carriage of inflammable dangerous cargo, interbarrier spaces and bilge spaces which are adjacent to the dangerous cargo containment system which require complete or partial barrier shall be inerted with dry inert gas. Inert atmosphere shall be maintained using the ship gas plant or inert gas storage facilities designed to provide the required gas consumption for at least 30 days.

6.26.2 It is allowed to fill the spaces and bilge spaces specified in 6.26.1 with dry air if the inert gas system or inert gas storage facility is available on board the ship and their efficiency or volume provide inerting of the maximum of these spaces provided that their configuration, gas detection system and efficiency of the inert gas system detect leakage from the cargo tanks or their inerting before unsafe atmosphere may occur.

Equipment providing generation of dry air sufficient for inerting shall be installed.

6.26.3 Spaces adjacent to the cooled independent cargo tanks of type C shall be inerted with dry inert gas or filled with dry air. This condition shall be maintained using the ship facilities specified in 6.26.1 or using equipment providing dry air supply.

6.26.4 Interbarrier spaces of internally insulated cargo tanks as well as spaces between the secondary barrier and double bottom and
double sides or independent tank structures completely filled with insulation do not require inerting.

Cargo tank and system inerting

6.26.5 A ship shall be equipped with a piping system to degas each cargo tank and purge the pipelines of this system with gas cargo after degassing. This system shall be designed so as to exclude formation of gas or air pockets which will remain after degassing or purging.

6.26.6 The required amount of places shall be provided for each cargo tank. Branch pipes for gas sampling shall be equipped with valves and located under the hoods above the main deck.

6.26.7 For flammable gases, the piping system specified in 6.26.5 shall be designed so as to exclude the presence of flammable mixture in the cargo tank at any stage of degassing by using inert gas at intermediate stage of degassing. In addition, this system shall provide purging of the cargo tank with inert gas prior to its filling with vapourous or liquid fraction of cargo. The presence of flammable mixture shall be avoided throughout purging of this tank.

6.26.8 Piping systems carrying dangerous cargo shall provide their degassing and purging as specified in 6.26.5 and 6.26.7.

6.26.9 Inert gas used for degassing and purging may be supplied from shore or generated/stored on board the ship.

Inert gas generator

6.26.10 An inert gas generator shall generate inert gas with oxygen content not exceeding 5% by volume.

According to the requirements specified in Appendix 3, devices for permanent monitoring of oxygen content with a sensor/detector giving a signal if oxygen content exceeds 5% by volume shall be installed on the inert gas supply pipeline from the generator.

If inert gas is generated on board the ship by air fractionation which requires storage of low-temperature liquefied nitrogen on board for its further use, liquefied nitrogen shall be checked for presence of oxygen traces before being placed in storage on board the ship to avoid enrichment of inerting gas with oxygen.

6.26.11 The inert gas supply system shall be equipped with pressure regulators and instruments which correspond to the cargo containment system. A device preventing cargo penetration into the inert gas system shall be installed in the cargo area.

6.26.12 Spaces containing inert gas generators shall not be connected to accommodation and service spaces as well as control stations. The specified generators may be installed in machinery spaces. If such inert gas generators are located in the machinery or other space located outside the cargo tanks, two return valves shall be located on the inert gas main within the cargo area. It is not allowed to lay the inert gas pipeline though accommodation/service spaces or control stations. If the inert gas system is not used, it may be switched off or disconnected from the cargo system in the cargo area. This requirement does not apply to connection joints of the inert gas system with bilge or interbarrier spaces.

6.26.13 It is allowed not to locate equipment to receive inert gas using open flame in the cargo area.

6.27 TESTS OF SYSTEMS

6.27.1 Tests of fittings shall comply with the requirements of 6.2.55, 6.2.56 and 6.2.58 RTSC. Besides, the valves of each type and size used at working temperature below –55 °C shall be leak tested at or below the minimum design temperature and at pressure not less than the design pressure of valves. During the tests, the serviceability of valves shall be checked.

6.27.2 Bellows used in cargo pipeline located outside and inside the cargo tank shall undergo the following type tests:

.1 the bellows element not pre-compressed shall be tested by pressure exceeding the design one at least five times for
not less than 5 min; the wall of such element shall not break;

.2 a typical compensating connection of all fittings (flanges, links, articulated joints) shall be tested by pressure exceeding the design one two times in the extreme displacement positions causing no residual deformation and recommended by the manufacturer;

.3 cyclic test, including those for thermal fatigue, shall be carried out on the fully assembled connection that shall withstand, without breaking, so many cycles of pressure, temperature, axial displacement, rotational displacement and lateral displacement as it will occur in operation.

It is allowed to run the tests at a room temperature if the test conditions are the same as the test conditions at working temperature;

.4 cyclic fatigue tests shall be carried out on completely assembled connection without internal pressure by simulating bellows displacement over a length corresponding to the length of expansion pipe for not less than 2·10⁶ cycles at a frequency not more than 5 cycles per second. Such tests are required only when the pipelines are exposed to loads due to ship deformation.

It is allowed not to perform the above mentioned tests if the technical documentation and calculations confirming that the compensating connections can withstand the specified operating loads is submitted to the River Register.

If the maximum internal pressure exceeds 0.1 MPa, the technical documentation and calculations shall contain the test results data justifying the calculation method used and comparing the results of calculations and tests.

6.27.3 Safety valves installed on cargo tanks according to 6.16.2 shall be tested to verify that the throughput capacity corresponds to that required in 6.19.

Besides, each valve shall be tested for opening at the set pressure with maximum tolerance (%) for pressure (MPa):

<table>
<thead>
<tr>
<th>Pressure range (MPa)</th>
<th>Tolerance (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 to 0.15</td>
<td>±10</td>
</tr>
<tr>
<td>0.15 to 0.3</td>
<td>±6</td>
</tr>
<tr>
<td>0.3</td>
<td>±3</td>
</tr>
</tbody>
</table>

Safety valves shall be tested and lead-sealed. The appropriate record shall be made in the report issued to the ship. Maximum permissible set pressure of safety valves shall also be specified in the report.

6.27.4 All pipeline systems, including fittings, valves and equipment for operation with dangerous cargo and dangerous cargo vapours, shall undergo the tests to verify their operation under operating conditions during the first reception of dangerous cargo.

6.28 PERSONNEL PROTECTION

6.28.1 Liquefied gas tanker shall have firefighting outfit complying with Table 6.28.1.

<table>
<thead>
<tr>
<th>Ship cargo capacity, m³</th>
<th>Number of firefighting outfit sets</th>
</tr>
</thead>
<tbody>
<tr>
<td>≤5000</td>
<td>4</td>
</tr>
<tr>
<td>&gt;5000</td>
<td>5</td>
</tr>
</tbody>
</table>

6.28.2 Any breathing apparatus included in firefighting outfit shall be a self-contained breathing apparatus with at least 1200 litres of atmosphere air.

6.28.3 The crew members participating in cargo handling shall have protection outfit, including eye protection, appropriate for the particular dangerous cargo.

6.28.4 In addition to the firefighting outfit required according to 6.28.1, the ship shall be also fitted with at least two whole outfits providing safety of personnel working in a room filled with gas.

6.28.5 One whole safety outfit shall comprise the following:

.1 one self-contained breathing apparatus in which compressed oxygen cannot be used and whose capacity is not less than 1200 litres of atmosphere air;

.2 protective clothing, shoes, gloves, head ware and tightly fitting mask to protect face and eyes;

.3 life line with steel core and belt;

.4 lamp of explosion-proof design.
6.28.6 The ship shall have compressed air supply from one of the following compressed air sources:

.1 one set of bottles completely filled with air for each breathing apparatus required according to 6.28.4, a dedicated air compressor capable of delivery of high-pressure air of the required purity, and a pipe header to fill the spare bottles of breathing apparatuses with air according to 6.28.4;

.2 spare bottles completely filled with air with total capacity of not less than 6000 litres for each breathing apparatus required according to 6.28.4.

6.28.7 It is allowed to install low pressure air pipes with an assembly for connection of hose suitable for use with breathing apparatus required according to 6.28.4. Such a system shall be capable of supplying high pressure air through reducers to obtain a low pressure sufficient for work of two persons in a gas hazardous space within at least one hour without use of air bottles of breathing apparatuses. It is necessary to provide the means for recharge of stationary air bottles and bottles of breathing apparatuses with the help of an air compressor capable of supplying high pressure air.

6.28.8 Protection equipment stated in 6.28.3 and safety outfit according to 6.28.4 shall be stored in the marked cabinets installed in accessible places.

6.28.9 Equipment of compressed air system shall be inspected and tested at least once a year.

6.28.10 Each person onboard the ship shall have means for protection of breathing organs and eyes in case of emergency evacuation. The following conditions shall be met:

.1 do not use breathing organs protection means of filtering type;

.2 emergency breathing apparatus (self-rescuer) shall operate as stated in the technical documentation but not less than 15 min;

.3 breathing organs protection means designed for emergency evacuation shall not be used in case of fire extinguishing or dangerous cargo transfer and they shall have appropriate warning inscription;

.4 two additional sets of the above mentioned protection means for breathing organs and eyes shall always be available in the wheelhouse. The rooms where the crew get together, for example, the mess room, shall be equipped with a training self-rescuer;

.5 it shall be possible to arrange additional (at least two sets) protection means for breathing organs and eyes in extremities (forecastle and aft superstructure) of a ship subdivided by cargo area, if it is impossible to evacuate people to the aft superstructure without protection means.

6.28.11 On the deck, there shall be showers for decontamination and arrangements for eye washing with appropriate inscriptions. Showers and eye washing arrangements shall remain operational at any ambient conditions.

6.28.12 Ships with cargo carrying capacity of 2000 m³ and more shall be provided with two whole outfit sets in addition to the equipment according to 6.28.1 and 6.28.4. For each self-contained breathing apparatus, there shall be at least three spare bottles filled with air with total capacity of at least 3600 litres or there shall be at least three spare self-contained breathing apparatuses if the bottles are not replaceable. The spare bottles (apparatuses) shall not be stored in one place.

6.28.13 To protect the ship’s personnel from the consequences of dangerous cargo leakages, a special enclosed space (collective protection space) shall be provided onboard the ship near the superstructure. The area of this space shall be sufficient to accommodate the entire crew of the ship and it shall be provided with air source with capacity sufficient for the crew to stay in this space for at least 4 hours.

This space can be accesses from the deck and other accommodation spaces through an air lock. Near the air lock to such space, there shall be a shower for decontamination.

6.28.14 It is necessary to provide access to enclosed space of collective protection from the open deck and from accommodation
spaces and possibility of tight closing this space.

6.29 ELECTRIC EQUIPMENT

6.29.1 In addition to the electrical equipment specified in Part VI of the Rules, the following electrical equipment is subject to technical supervision:

.1 dangerous cargo containment system;
.2 reliquefaction units;
.3 inert gas systems;
.4 dangerous cargo pressure and temperature regulation systems;
.5 drives and controls of liquefied gases cooling systems;
.6 cargo pumps and compressors;
.7 ventilation systems of explosion-hazardous spaces and air locks;
.8 measurement, alarm and indication systems for:
   cargo level in cargo tanks;
   temperatures in cargo pipelines;
   pressure in cargo tanks and pipelines;
   pressure in ventilation systems that produce overpressure in air locks, spaces and enclosures of explosion-proof electrical equipment;
.9 systems of automatic and remote cutoff of drives;
.10 systems for remote control of valves for hull structure heating arrangements.

6.29.2 Requirements of Part VI of the Rules to electrical equipment of explosion-hazardous zones, areas and spaces apply to gas-hazardous areas of liquefied gas tankers.

6.29.3 Electrical equipment installed in the spaces with gas detection devices and spaces for handling the boil-off gas used as a fuel is not considered an electrical equipment of gas-hazardous spaces.

6.29.4 Electrical equipment or cables shall not be installed in gas-hazardous spaces or areas, except for the equipment for operation in these areas, provided the requirements of 6.29.5 to 6.29.38 are met.

6.29.5 A space, which accommodates dangerous cargo heating system, shall have electrical equipment of explosion-proof design.

6.29.6 Cables to be laid in explosion-hazardous rooms and spaces shall remain serviceable at temperatures maintained in these spaces in operation.

6.29.7 All gas-hazardous spaces and areas with constant explosion-hazardous gas-and-air mixture shall be fitted only with explosion-proof electrical equipment.

6.29.8 The spaces of dangerous cargo containment system may be fitted with submersible cargo pumps and their power supply cables. Protection devices shall be provided to automatically cut off electric motors when the liquid gas level reduces below the permissible one. These protective devices shall be made based on sensitive elements responding to:

.1 pressure reduction when the pump is being unloaded;
.2 reduction of electric motor load current;
.3 reaching dangerous low level of liquefied gas.

As the protection operates, the alarm signal shall be fed to the cargo loading/unloading control station.

6.29.9 Electric motors of cargo pumps shall be provided with devices for electrical disconnection from supply systems (including power lines) during degassing operations. It shall be possible to operate these devices prior to degassing.

6.29.10 In cargo areas equipped with dangerous cargo containment system with additional barrier, it is allowed to lay electric power cables of electric motors of submersible cargo pumps.

6.29.11 In cargo areas with dangerous cargo containment system, which does not require additional barrier, and in the spaces separated from dangerous cargo areas with
one gastight bulkhead, it is allowed to install the following electrical equipment:
- transit cables;
- lighting equipment with protection type (Exp) or (Exd);
- electric level sensors, speed log components and anodes (electrodes) of impressed current cathodic protection system. These instruments and devices shall have gastight enclosure.

In the areas separated from cargo areas by means of gastight bulkheads the following may be installed:
- electric motors of explosion-proof design for remote control of cargo valves or ballast system;
- acoustic devices of explosion-proof design, general alarm system.

6.29.12 Electric motors of cargo pumps or compressors of reliquefaction units shall be separated from pump (compressor) compartments (spaces) by means of a gastight bulkhead or deck.

Flexible couplings shall be used for alignment of shafts of electric motors and machinery driven from them. Glands shall be installed in places where the shafts go through the gastight bulkheads and decks. Electric motors of cargo pumps and compressors and their control systems shall be arranged in explosion-hazardous spaces.

6.29.13 If operational or design limitations make it impossible to fulfill the requirements of 6.29.12, the following shall be used to drive the cargo pumps or cargo compressors:
- 1 electric motors of enhanced reliability in explosion-proof case with type of explosion protection (Exe) or (Exd);
- 2 electric motors in pressurized enclosure with type of explosion protection (Exp).

6.29.14 Acoustic devices of general alarm shall be of explosion-proof design with type of explosion protection (Exd).

6.29.15 In areas or semi-closed spaces on the open deck at a distance of up to 3 m from any opening of the cargo tank, gas exhaust equipment, flanged joints of cargo pipes, valves of cargo system or inlets or ventilation holes leading to compartments (space) of cargo pumps and cargo compressors, in areas on the open deck above the cargo area and 3 m back and forth from the cargo area on the open deck and upwards to the altitude of 2.4 m above the deck, in the areas at a distance of 2.4 m from external surface of dangerous cargo retention system in which such surface is exposed to weather conditions and atmospheric precipitations, the following is allowed:
- installation of explosion-proof equipment;
- laying of transit cables.

6.29.16 In closed or semi-closed spaces through which pass the pipelines of dangerous cargo and in cargo hoses store rooms, the following is allowed:
- 1 installation of lighting equipment with type of explosion protection (Exp) or (Exd);
- 2 laying of transit cables.

6.29.17 In closed of semi-closed spaces with opening leading to any gas-hazardous space/area, it is allowed to install electrical equipment that complies with requirements to electrical equipment to be fitted in the spaces/area to which those openings lead.

6.29.18 Electrical equipment arranged in spaces protected by means of air locks shall be of explosion-proof design. It is allowed to use electrical equipment without protection type if it is de-energized with the help of automatic cutoff devices in case of air over-pressure loss in the room and is not started until the pressure returns to the preset value.

Electrical equipment without protection type used for maneuvering, anchoring and mooring, as well as emergency fire pumps shall not be arranged in spaces to be protected with air locks.

6.29.19 Electrical equipment arranged in double pipes or ducts shall be intrinsically safe.

6.29.20 Grounding of electrical equipment and pipelines of liquefied gas tanker shall comply with the requirements of 2.6, 12.6.5, 16.2.23 to 16.2.29 Part VI of the Rules.
6.29.21 Metal mechanical protections for cables laid on the upper deck and passing through the explosion-hazardous areas shall be grounded at both ends of each protection (casing, steel pipe, armouring braid).

6.29.22 Metallic cargo tanks, including independent tanks, container tanks, pipelines separated from hull structures with use of heat insulation, joints of pipelines and hoses with gaskets, sealing flanges of connecting parts of cargo pipelines and hoses, shall be grounded to the hull.

6.29.23 Electric drive of cargo pumps, booster pumps and compressors shall be fitted with automatic cutoff devices to be cut off in case of closing of quick closing valves on pipelines.

6.29.24 Electric drives of submersible cargo pumps shall be fitted with automatic cutoff devices operating at low level of liquid in the cargo tank.

6.29.25 Electric motors of booster pumps and gas/air blowers shall be arranged in the spaces separated from explosion-hazardous spaces by means of a gastight bulkhead and they shall comply with the requirements of 6.29.12.

6.29.26 Electric drives of fans providing overpressure in air locks, spaces protected by air locks and cases of electrical explosion-proof equipment shall not be used for other purposes.

6.29.27 Electric motors of fans shall not be installed in ventilation ducts of supply or exhaust ventilation of explosion-hazardous spaces.

6.29.28 Opening doors and switching-on of electrical equipment installed in explosion-hazardous spaces shall be interlocked with fan drive to make it possible to enter the spaces and switch on the electrical equipment only after start of fans and their operation within a time period sufficient for 3 to 4 air changes in this space.

6.29.29 Electric drives of ship machinery stated in 6.29.23 to 6.29.26 shall have cutoff devices, one of which shall be outside the spaces in which the drives are installed, but in the immediate proximity from the exits of these spaces, and the second remote cutoff device shall be arranged in the wheelhouse or in the cargo loading/unloading control station.

6.29.30 Lighting network of explosion-hazardous rooms and spaces, including compartments (spaces) of cargo pumps, cargo compressors, closed or semi-closed spaces accommodating pipelines with dangerous cargo, spaces for cargo hoses, cargo areas equipped with dangerous cargo containment system which does not require additional barrier and spaces separated from spaces with dangerous cargo with the help of one gastight bulkhead, shall be divided into at least two lines and shall receive power supply from different switchboards.

6.29.31 Cutoff switches and protective devices of lighting network of rooms and spaces specified in 6.29.29 shall be double-pole switches and shall be installed outside these rooms and spaces.

6.29.32 Lighting system of rooms and spaces specified in 6.29.29 shall be made with use of explosion-proof devices (lanterns) with type of explosion protection (Exp) or (Exd).

It is allowed to illuminate these rooms and spaces from adjacent spaces through gastight glass holes. However, the lights of such adjacent spaces shall be explosion-proof as well.

6.29.33 The rooms and spaces specified in 6.11.8 shall be equipped with stationary alarm system for detection of dangerous cargo vapours.

6.29.34 Light and sound signals about dangerous concentration of dangerous cargo vapours shall be fed to gas sampling places (space), to the wheelhouse and cargo loading/unloading control station.

Generalized alarm on gas concentration above the preset limits shall be fed to the places of permanent watch keeping.
6.29.35 Two independent power supply sources shall be provided for the alarm system.

6.29.36 The alarm on automatic cutoff of submersible cargo pumps, closing of quick closing valves of cargo pipelines, water in interbarrier spaces, dangerous cargo leakages in condensate of dangerous cargo heaters and operation of inert gas system shall be fed to the cargo loading/unloading control station.

The alarm on water in interbarrier spaces shall also be fed to the wheelhouse.

6.29.37 When dangerous cargo is used as a fuel, the alarm on pressure drop in the fuel oil pipeline or stop of gas fuel supply to machinery space equipment shall be provided in the central to control position.

6.29.38 The alarm on reduction/loss of excessive pressure in air locks and electrical equipment with type of explosion protection (Exp) shall be provided in central control station and in places of permanent watch keeping.

6.30 SPECIAL REQUIREMENTS

6.30.1 Special requirements to ships carrying dangerous liquid loads depending on the properties of such dangerous cargo are specified in 6.30.2 to 6.30.77. The need of fulfillment of this or that requirement as pertaining to the particular dangerous cargo is specified in column 10 “Special requirements” of Table A3-1 in Appendix 3.

Construction materials

6.30.2 Materials which during normal operation of the ship are exposed to dangerous cargo, shall be resistant to corrosive action of gases. Besides, for transportation of some dangerous cargoes, the following materials shall not be used for fabrication of cargo tanks and their pipelines, valves, fittings and other components:

.1 mercury, copper, copper alloys and zinc;

.2 copper, silver, mercury, magnesium and other metals which form acetylides;

.3 aluminium and aluminium alloys;

.4 copper, copper alloys, zinc or galvanized steel;

.5 aluminium, copper and their alloys;

.6 copper and alloys containing more than 1% of copper

Independent cargo tanks

6.30.3 Dangerous cargo shall be transported only in independent cargo tanks.

6.30.4 Dangerous cargo shall be transported in independent cargo tanks of type C considering the requirements of 6.22.2. For calculating pressure in cargo tank, it is necessary to take into account supercharge pressure or pressure of vapours during unloading.

Cooling systems

6.30.5 Is allowed to use only indirect cooling system (see 4.20.9.2).

6.30.6 Onboard the ship which transports dangerous cargoes producing dangerous peroxides, it shall be ensured that the repeatedly condensed dangerous cargo has no stagnation zones with non-inhibited fluid. This may be reached through one of the following ways:

.1 use of an indirect cooling system with condenser inside the cargo tank;

.2 use of a direct cooling system or combined cooling system (see 4.20.9.1 and 4.20.9.3) or a indirect cooling system with condenser outside the cargo tank, or designing the cooling system in such a way as to prevent from condensate accumulation and retention areas.

6.30.7 If the ship is engaged on voyages with any of the dangerous cargoes specified in 6.30.6 and there are ballast transits between these voyages, then, prior to the ballast transit, all the non-inhibited fluid shall be removed. If after voyage with one of the dangerous cargoes it is required to transport another dangerous cargo, the reliquefaction system shall be dried and blown prior to loading such a dangerous cargo. Inert gas or dangerous cargo vapours or another compatible dangerous cargo vapours shall be used for this blowing.
Deck cargo pipelines

6.30.8 All butt welds in cargo pipelines, whose diameter exceeds 75 mm, shall undergo 100% X-ray testing.

Air release from vapour spaces

6.30.9 Prior to loading, air shall be released from cargo tanks and pipelines connected to them in a way to prevent from its return by one of the following methods:

.1 introduction of inert gas to maintain overpressure. Inert gas reserve or inert gas system capacity shall be sufficient for standard operation needs and compensation of leakages through the safety valve. Oxygen content in the inert gas at any time shall not exceed 0.2% by volume;

.2 adjustment of dangerous cargo temperature to continuously maintain overpressure.

Gas moisture content control

6.30.10 It is necessary to control the moisture content of non-flammable gases which can become corrosive or dangerous in case of contact with water. To meet this requirement, the cargo tanks shall be kept dry before loading and filled with dry air with dew point of – 45 °C or less at the atmospheric pressure, or with dangerous cargo vapours during unloading to prevent excessive vacuum.

Inhibition

6.30.11 Measures shall be taken to inhibit dangerous cargoes throughout the entire voyage to prevent them from polymerization. The ships shall have a certificate issued by the shipper. The certificate shall include the following:

.1 name and amount of the used inhibitor;

.2 date of inhibitor introduction and expected duration of its action under normal conditions;

.3 temperature limits for efficiency of the inhibitor;

.4 measures to be taken if the duration of voyage exceeds the inhibitor expiry date.

Sampling pipelines

6.30.12 Gas sampling pipelines shall not be brought to or laid through gas-safe spaces.

Transducers/sensors specified in 6.11.3 shall operate when concentration of vapours reaches the permissible limits.

6.30.13 The use of portable equipment specified in 6.11.14 is not allowed.

Flame retention shields on gas release holes

6.30.14 For transportation of dangerous cargoes specified in Appendix 3, the gas release holes of cargo tanks shall be fitted with flame retention shields or safety mouthpieces. The design of flame retention shields and mouthpieces of gas-freeing pipes shall prevent them from closing due to freezing of dangerous cargo vapours or icing.

Maximum permissible amount of cargo in cargo tank

6.30.15 When a dangerous cargo specified in Appendix 3 is transported, its amount in any cargo tank shall not exceed 380 m3.

Submersible electrical cargo pumps

6.30.16 Prior to loading inflammable liquids and during their transportation and unloading, the vapour spaces of cargo tanks fitted with submersible electrical cargo pumps shall be inerted and overpressure shall be maintained in them.

Ships carrying ammonia

6.30.17 Cargo tanks, high pressure process vessels and cargo pipelines shall be manufactured of a fine-grained carbon-manganese steel with certified minimum yield point not exceeding 355 MPa and actual yield point not exceeding 440 MPa. One of the following design or operational measures shall be taken:

.1 it is necessary to use material with lower yield point, whose certified minimum breaking strength does not exceed 410 MPa; or
cargo tanks, high pressure process vessels and cargo pipelines shall undergo thermal treatment to relief post-welding stresses; or

measures shall be taken to keep the ammonia temperature during transportation close to its closed-vessel boiling point (–33 °C), but in any case the temperature shall not exceed 20 °C; or

ammonia shall contain at least 0.1% of water by mass.

If carbon-manganese steels with higher yield properties as compared to those specified in 6.30.17 are used, the complete cargo tanks and pipelines shall undergo thermal treatment to relief post-welding stresses.

If high pressure process vessels and pipelines from the condensing part of the cooling system are manufactured of carbon-manganese steel or nickel steel, they shall undergo thermal treatment to relief post-welding stresses.

The yield point and ultimate tensile strength of the weld built-up metal shall exceed the same characteristics of the materials used for manufacture of cargo tank or pipeline.

Nickel steel with more than 5% of nickel and carbon-manganese steel which does not meet the requirements of 6.30.17 and 6.30.18 are susceptible cracking due to corrosive action of ammonia. Such steels may not be used in dangerous cargo containment system and pipeline systems designed for transportation of this dangerous cargo.

Nickel steel with more than 5% of nickel may be used if the temperature of ammonia during transportation meets the requirements of 6.30.17.3.

To prevent from cracking due to corrosive action of ammonia, the dissolved oxygen level in the tank atmosphere shall be below 2.5 ppm by mass, also by reducing the mean content of oxygen in the tanks prior to loading of liquid ammonia as compared to the following values by volume (%) depending on ammonia transportation temperature \( t \), °C:

<table>
<thead>
<tr>
<th>Temperature ( t )</th>
<th>Oxygen Content (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>+30</td>
<td>0.03</td>
</tr>
<tr>
<td>+20</td>
<td>0.05</td>
</tr>
<tr>
<td>+10</td>
<td>0.10</td>

</tbody>
</table>

Oxygen content for intermediate temperatures of ammonia may be obtained by linear interpolation.

**Ships carrying chlorine**

Dangerous cargo containment system shall comply with the following requirements:

1. capacity of each tank shall not exceed 380 m³, and total capacity of all cargo tanks shall not exceed 760 m³;
2. design pressure of vapours in the tank shall be not less than 1.35 MPa;
3. parts of tanks protruding above the upper deck shall have protection against heat radiation from adjacent tanks if on fire;
4. each cargo tank shall have two safety valves. A safety diaphragm shall be installed between the tank and the safety valves. Bursting pressure of the diaphragm shall be 0.1 MPa less than the safety valve opening pressure which is to be set equal to design pressure of vapours in the tank, but not less than 1.35 MPa. The space between the diaphragm and the safety valve shall be connected to a pressure gauge and gas detection system through a bypass valve. During operation of the tank, measures shall be taken to keep the pressure in this space equal to the atmospheric pressure within ±5%;
5. exhaust outlets of safety valves shall exclude the possibility of creating hazard to the ship and the environment.

The gas coming out from the safety valves shall go through an absorption unit to reduce its concentration. On the pipeline section near the fore extremity of the ship, it is necessary to install a device able to release the vapours overboard at the deck level from any side, as well as a mechanical interlocking device to keep one of the pipelines always open.
6.30.25 Cargo pipeline system shall comply with the following requirements:

1. liquefied gas tanker shall be unloaded with the help of compressed vapours of chlorine received from the shore, dry air or with the help of submersible pumps. Pressure in vapour space of the cargo tank during unloading shall not exceed 1.05 MPa. Compressors installed on the ship may not be used for unloading of liquefied gas tankers;

2. design pressure in cargo pipeline system shall be not less than 2.1 MPa. Inner diameter of cargo pipes shall not exceed 100 mm. It is allowed to use pipe bends only as a mean of thermal expansion compensation. If flange connections are used, the flanges shall be welded to pipe end, and the edges shall be prepared for welding as a tongue-and-groove joint;

3. gases from safety valves of cargo pipeline system shall be released to an absorption unit; the backpressure in the gas-freeing pipelines as specified in 6.19.2 shall be taken into consideration.

6.30.26 Materials shall comply with the following requirements:

1. cargo tanks and pipelines of cargo pipeline system shall be manufactured of steel suitable for safe transportation of dangerous cargo at temperature of –40 °C even if higher temperatures in transportation are expected;

2. cargo tanks shall undergo thermal treatment to relief internal thermal stresses. Mechanical relief of internal stresses is not allowed.

6.30.27 Safety devices shall comply with the following requirements:

1. an absorption unit connected to pipelines of cargo pipeline system and cargo tanks shall be installed onboard the ship for chlorine absorption. The absorption unit shall neutralize the chlorine with absorption intensity of not less than 2% of dangerous cargo of total cargo capacity of the ship;

2. during degassing of cargo tanks, the chlorine vapours shall not be released to atmosphere;

3. a gas detection system shall be installed to monitor concentration of chlorine vapours, it shall be capable of detecting at least 1 ppm by volume. Sampling points shall be arranged in the following places:

   - at the bottom of hold spaces;
   - in the pipes going from safety valves;
   - at the outlet hole of absorption unit;
   - at the inlet hole of ventilation systems of accommodation, service and machinery spaces and control stations;
   - on the deck at the fore boundary of, in the middle part of, and at the aft boundary of, the cargo area (to be used only in the course of cargo handling and degassing).

   Gas detection system shall be provided with sound and light alarm actuating in case of gas concentration of 5 ppm;

4. each cargo tank shall be provided with emergency pressure transducer/sensor which generates sound signal when overpressure reaches 1.05 MPa.

6.30.28 In addition to the requirements to protection stated in 6.28, it is necessary to provide an air compressor and equipment for filling air bottles.

6.30.29 The following requirements to cargo tank filling limits shall be met:

1. requirements 6.20.4.2 are not applied for transportation of chlorine;

2. the content of gas chlorine in vapour space of cargo tank after loading shall exceed 80% by volume.

6.30.30 The dangerous cargo shall be unloaded only with the help of submersible pumps installed in trunks or hydraulically driven pumps. The design of such pumps shall exclude the possibility of liquid pressure transfer to shaft seal.

6.30.31 Independent tanks of C type may be unloaded by displacing the dangerous cargo by means of inert gas, provided the cargo pipeline system is designed to withstand such inert gas pressure.

Ships carrying diethyl ether and vinyl ethyl ether

6.30.32 For transportation of ethylene oxide, requirements of 6.30.50 shall be taken
into consideration along with requirements of 6.30.33 to 6.30.42.

6.30.33 Deck tanks shall not be used for transportation of ethylene oxide.

6.30.34 Stainless steels and cast iron may not be used for manufacture of dangerous cargo containment system tanks and cargo pipeline system pipelines used for ethylene oxide.

6.30.35 Prior to loading, the cargo tanks and pipelines connected to them shall be cleaned from all remains of earlier transported dangerous cargoes, except for the remains of ethylene oxide, propylene oxide or mixtures of these products. Tanks used for ammonia transportation shall be cleaned as well.

6.30.36 Ethylene oxide shall be unloaded only with the help of pumps installed in trunks or by its displacement by inert gas. The design of pumps shall comply with the requirements of 6.30.62.

6.30.37 Ethylene oxide shall be transported refrigerated and its temperature during transportation shall be less than 30 °C.

6.30.38 Safety valves shall operate at pressure of not less than 0.55 MPa.

6.30.39 Protective layer of gaseous nitrogen specified in 6.30.74 shall be sufficient to ensure nitrogen concentration in vapour spaces of cargo tanks of not less than 45% by volume at any time.

6.30.40 Before loading liquid or vaporous ethylene oxide and as long as it remains in the cargo tank, the latter shall be inerted with nitrogen.

6.30.41 In case of fire spread over the dangerous cargo containment system, the waterspraying system according to 6.30.76 shall operate automatically.

6.30.42 Equipment for emergency discharge of ethylene oxide shall be provided.

Ships carrying isopropylamine and monoethylamine

6.30.43 A system of separate pipelines not connected to pipelines of other cargo or gas-freeing systems shall be provided.

Ships carrying methyl acetylene and propadiene mixtures

6.30.44 Mixtures of methyl acetylene and propadiene shall be stabilized to be transported. Besides, it is necessary to prescribe the maximum temperatures and pressures permissible for cooling such mixtures.

6.30.45 Possible compositions of stabilized mixtures admitted to transportation:

   option 1:
   - maximum molar ratio of methyl acetylene to propadiene: 3:1;
   - maximum concentration of methyl acetylene and propadiene in mixture: 65 mole %;
   - minimum concentration of propane, butane and isobutane in mixture: 24 mole %;
   - the mixture shall contain at least 1/3 of butanes (from total number of moles in the mixture) and 1/3 of propane; and
   - maximum concentration of propylene and butadiene in the mixture: 10 mole %.

   option 2:
   - maximum concentration of methyl acetylene and propadiene in mixture: 30 mole %;
   - maximum concentration of methyl acetylene: 20 mole %;
   - maximum concentration of propadiene: 20 mole %;
   - maximum concentration of propylene: 45 mole %;
   - maximum concentration of butadiene and butylene in the mixture: 2 mole %;
   - minimum concentration of saturated hydrocarbon C₄: 4 mole %;
   - minimum concentration of propane: 25 mole %.

6.30.46 Ships carrying mixtures of methyl acetylene and propadiene shall be equipped with an indirect cooling system specified in 4.20.9.2 or a cooling system with direct compression of mixture vapours. For mixtures
with composition specified in 6.30.45 the following is required:

.1 vapour compressor operating under conditions excluding the possibility of increase of vapour temperatures and pressures over 60 °C and 1.75 MPa, respectively, and the possibility of compressor clogging by the vapour;

.2 pipelines for gas removal from compressor at each compression stage or from each cylinder of piston compressor after compression equivalent to compression at the corresponding stage; these pipelines shall be fitted with the following:

- two temperature switches set to 60 °C or less;
- pressure switches set to 1.75 MPa or less;
- safety valve set to 1.8 MPa or less;

.3 safety valve set to 1.8 MPa or less that shall remove vapours to mast uprise according to requirements of 6.16.9, 6.16.10, 6.21.4 and 6.21.7. Removal of vapours from safety valve to compressor suction is not allowed;

.4 transducer/sensor that feeds a sound signal to the cargo loading/unloading control station and the wheelhouse on the switch actuation in case of pressure or temperature increase.

6.30.47 Pipelines, including dangerous cargo cooling system pipelines, servicing the cargo tanks for methyl acetylene and propadiene mixture, shall be independent or shall be isolated from pipeline systems and cooling systems servicing other tanks. This requirement applies to all pipelines for transfer of liquids and vapours and to other joints.

**Ships carrying nitrogen**

6.30.48 Structural materials and coatings of cargo system components shall be resistant to high concentration of oxygen in nitrogen appearing in case of nitrogen condensation or enrichment at low temperatures. Possible places of nitrogen condensation shall be ventilated.

Ships carrying propylene oxide and mixtures of ethylene oxide with propylene oxide containing not more than 30% of ethylene oxide in mass

6.30.49 Transported dangerous cargo shall not contain acetylene.

6.30.50 Prior to loading, the cargo tanks and pipelines connected to them shall be cleaned from all remains of earlier transported dangerous cargoes, except for the cases when the tanks are loaded immediately after unloading of propylene oxide or ethylene oxide / propylene oxide mixture.

6.30.51 Efficiency of washing of cargo tanks and pipelines connected to them shall be determined by tests or inspections to make sure that there are no traces of any acid or alkaline materials.

6.30.52 Prior to each first loading of propylene oxide and its mixtures, the cargo tanks shall be inspected to make sure that they are free of dirt, including rust deposits, and visible damages of the shell. If cargo tanks are continuously used for transportation of the specified dangerous cargoes, such inspections shall be carried out at least once in two years.

6.30.53 Tanks for transportation of propylene oxide and its mixtures shall be made of steel.

6.30.54 Tanks containing propylene oxide and its mixtures may be used for transportation of other dangerous cargoes after cleaning these tanks and pipeline systems connected to them by washing or blowing.

6.30.55 All valves, flanges, fittings and auxiliary equipment shall be made of steel suitable for their safe operation in the medium of propylene oxide and its mixtures. Disks or surfaces of disks, seats and other valve surfaces subject to wear shall be made of corrosion resistant steel with chromium content of not less than 11%.

6.30.56 Gaskets shall be made of materials, which do not react with propylene oxide and its mixtures, do not dissolve in them, do not contribute to reduction of their self-ignition temperature, and are fireproof. The surface of
gaskets contacting with dangerous cargo shall be made of teflon or other materials that ensure the similar degree of safety due to their inactivity. For manufacture of gaskets with teflon or similar fluorinated polymer filler, it is allowed to use reinforcing coils of stainless steel.

6.30.57 Insulating and sealing materials, if used, shall not react with propylene oxide and its mixtures, dissolve in them or reduce self-ignition temperature.

6.30.58 The following materials are considered unsuitable for manufacture of gaskets, seals and similar purposes in keeping systems of propylene oxide and its mixtures:
   .1 neoprene or natural rubber if they contact with propylene oxide and its mixtures mentioned above;
   .2 asbestos or bonding agents comprising asbestos;
   .3 materials comprising magnesium oxides, such as mineral wool.

6.30.59 Intake and discharge pipelines shall be up to 100 mm above the tank bottom or any bilge well bottom.

6.30.60 Propylene oxide and its mixtures shall be loaded and unloaded so as to prevent release of gases from cargo tank to atmosphere. If simultaneously with loading of tanks the vapours are returned to shore, the vapour return system connected to the dangerous cargo retention system designed for the given dangerous cargo shall be independent from the retention systems of other dangerous cargoes.

6.30.61 During unloading, the pressure in the cargo tank shall be kept above 0.007 MPa.

6.30.62 Discharging shall be carried out by means of the trunk-mounted cargo pumps, hydraulically operated submerged cargo pumps or by displacing dangerous goods with inert gas. It is necessary to prevent heating of dangerous cargo if the outlet pipeline of the pump is closed or blocked.

6.30.63 The gas from tanks used for transportation of propylene oxide and its aforementioned mixtures shall be released independently from gas release from tanks used for transportation of other dangerous cargoes. There shall be fitted sampling devices for cargo tank sampling that prevent communication of the dangerous cargo with atmosphere.

6.30.64 The “ONLY FOR ALKYLENE OXIDE” inscription shall be applied on the cargo hoses used for transfer of propylene oxide and mixtures of ethylene oxide and propylene oxide with not more than 30% of ethylene oxide by mass.

6.30.65 It is necessary to check the content of vapours of propylene oxide and its mixtures in bilge spaces. Bilge spaces surrounding standalone tanks of type A and B shall be inerted with measuring the content of oxygen in their atmosphere. Oxygen content in these spaces shall be less than 2%. It is allowed to use portable sampling equipment.

6.30.66 Prior to disconnection of shore pipelines, the pressure in pipelines for transfer of liquid and vapours shall be reduced with the help of the appropriate valves installed on cargo manifold. Release of liquid and vapours from these pipelines to atmosphere is not allowed.

6.30.67 Cargo tanks shall be designed with consideration of maximum pressure of dangerous cargo, which can appear during loading, transportation or unloading.

6.30.68 Cargo tanks for transportation of propylene oxide with design vapour pressure less than 0.06 MPa and cargo tanks for transportation of ethylene oxide and propylene oxide mixtures with design vapour pressure less than 0.12 MPa shall be equipped with a cooling system to keep the temperature of the given dangerous cargo below the design temperature.

6.30.69 The safety valve installed on independent cargo tanks of type C shall be set to overpressure varying within 0.02 MPa to 0.7 MPa for transportation of propylene oxide and up to 0.53 MPa for transportation of ethylene oxide and propylene oxide mixtures.
6.30.70 The pipeline system servicing the cargo tanks intended for loading of propylene oxide and its mixtures shall be independent (isolated from cargo compressors and pipeline systems servicing other cargo tanks, including empty ones). If the pipeline system for cargo tanks loaded with the specified dangerous cargoes is not independent, such pipelines shall be isolated by removing demountable spool pieces, valves or other pipeline sections and installing blind flanges in their place. All pipelines for transfer and discharge of liquid and vapours and other pipelines, for example, common pipelines for inert gas supply shall be isolated as specified above.

6.30.71 Propylene oxide and its mixture shall be transported only in accordance with the cargo handling plans. Each loading equipment to be used shall be specified in the separate cargo handling plan. Cargo handling plan shall outline the entire system of cargo pipelines and blind flanges installed to comply with the requirements to isolation of pipelines in accordance with 6.30.70.

6.30.72 Prior to every first loading of propylene oxide and its mixtures and prior to each further unloading, an organization having the River Register recognition certificate for accomplishment of isolation operations shall issue the certificate to certify that the pipelines have been isolated according to the requirements. This certificate shall be kept onboard the ship. The representative of this organization shall lockwire every blind flange to pipeline flange connection and lead-seal it to prevent inadvertent removal of this blind flange.

6.30.73 Maximum permissible loading levels of each cargo tank for each possible loading temperature and the specific maximum design temperature shall be specified in the list. The copy of this list shall always be kept by the master on board the ship.

6.30.74 Dangerous cargo shall be transported under protective layer of nitrogen, the requirements to which are specified in 6.30.39. An automatic nitrogen pumping system shall be installed to prevent pressure drop in the tank below 0.007 MPa in case of dangerous cargo temperature reduction under environment conditions or as a result of cooling system failure. A reserve of nitrogen for automatic control of pressure shall be available onboard the ship. Commercially pure nitrogen (99.9% by volume) shall be used to form protective layer of nitrogen.

6.30.75 Prior to loading and after unloading, the composition of cargo tank vapour space shall be checked. Oxygen content in it shall not exceed 2% by volume.

6.30.76 It is necessary to provide a water spraying system, whose capacity and arrangement shall enable treatment of the area around the loading manifold and the deck pipeline, which is not protected from fire hazard and is used for transfer of dangerous cargo, and the tank domes. The arrangement of pipelines and trunks shall ensure treatment of the entire area with the same intensity of 10 L/m² per minute. Manual control of water spraying system shall be both local and remote. The arrangement of water spraying system shall ensure outwash of any amount of spilled dangerous cargo. Operation of water spraying system with manual remote control shall be organized in a way so that the remote start of pumps for water supply to this system and manual control of any closed valves of this system is carried out from a place outside the cargo area near the accommodation spaces, accessible and fit for control of the equipment arranged in it in case of fire on the sections serviced by this system. Moreover, fire hose with nozzle shall be connected to the water spraying system to supply for water delivery under pressure during loading and unloading.

Ships carrying vinyl chloride

6.30.77 When polymerization of vinyl chloride is prevented by an inhibitor, the requirements of 6.30.11 shall be followed. If the inhibitor was not added or its amount is insufficient, any inert gas used according to the requirements of 6.30.9 shall contain not more than 0.1% of oxygen. Prior to the beginning of loading, samples of the inert gas shall be
taken from the cargo tanks and pipelines for the analysis. During transportation of vinyl chloride and during ballast passages between successive voyages with this dangerous cargo, an overpressure shall be continuously maintained in the tanks.
## DANGEROUS LIQUID CARGOES AND SPECIAL TECHNICAL REQUIREMENTS TO INLAND NAVIGATION SHIPS CARRYING SUCH CARGOES

**Notes.**

1. The ignition temperature has not been determined in accordance with IEC 60079-4; therefore, provisional assignment has been made to temperature class T3 which is considered safe.

2. The ignition temperature has not been determined in accordance with IEC 60079-4; therefore, provisional assignment has been made to temperature class T2 which is considered safe.

3. The ignition temperature has not been determined in accordance with IEC 60079-4; therefore, provisional assignment has been made to temperature class T4 which is considered safe.

4. No maximum safe gap has been measured in accordance with IEC 60079-1A; therefore, provisional assignment has been made to explosion group IIA.

5. No maximum safe gap has been measured in accordance with IEC 60079-1A; therefore, provisional assignment has been made to explosion group IIB.

6. Maximum safe gap is between explosion groups IIA and IIB.

7. No maximum safe gap has been measured in accordance with IEC 60079-1A; therefore, provisional assignment has been made to explosion group IIC.

*For mixtures free of other components and representing perils to safety and in case of contaminant class C or lower.*

**Notes.**
1. Numbers in the “Type of ship” column mean: 1 — ship of type 1; 2 — ship of type 2; 3 — ship of type 3.
2. Numbers in the “Type of tank” column mean: 1 — independent tank; 2 — integral tank; G — gravity tank; P — pressure tank.
3. Numbers in the “Release of vapours from tank” column mean: 1 — free release of vapours; 2 — controlled release of vapours.

4. Numbers in the “Tank atmosphere control” column mean: 1 — by inerting; 2 — by isolating layer of liquid or gas; 3 — by drying; 4 — by natural or forced ventilation.

5. Characters and symbols in the “Vapours flash point over 60 °C” column mean: HP — non-flammable product; ++ — vapour flash point over 60°C; ” — vapour flash point of 60°C and less.

6. Numbers in the “Taking measurements” column mean: 1 — with the help of open type device; 2 — with the help of semi-closed device; 3 — with the help of close type device.

7. Characters in the “Vapours detection” column mean: Â — flammable vapours; Ò — toxic vapours.

8. Numbers in the “Fire protection” column mean: 1 — alcohol-type or universal-type foam; 2 — ordinary foam (all non-alcohol foams); 3 — water-spraying; 4 — dry chemical.

10. The “+” sign in the "Eye and respiratory protection" means "required".

</table>

**Notes.** 1. Chemical formula (column 1) is only informative.
2. Density (column 3) is only informative and to be ascertained by the shipper’s data.
3. Numbers in the “Tank atmosphere control” column 6 mean: 1 — by inerting; 2 — by drying.
4. Characters in the “Cargo vapour detection system” column 7 mean: B — detection of flammable vapours; T — detection of toxic vapours; O — detection of oxygen (dissolved oxygen meter); B+T — detection of flammable and toxic vapours.
5. Numbers in the “Type of instrumentation” column 8 mean: 1 — semi-closed devices; 2 — close type devices; 3 — indirect measurement devices.
6. Numbers as per MFAG (Medical First Aid Guide) Table of the International Maritime Organization (IMO) (column 9) are given to inform about actions to be taken in case of accidents linked to substances to which the requirements of this Part of the Rules apply.
7. If any of the specified substances is transported at negative temperature which can cause freezing injury, No. 620 as per MFAG Table shall be used as well.
8. Requirements of Section 5 of this Part of the Rules also apply to the substances marked with asterisk “*”.

End of Table A3-1
Part X

MATERIALS AND WELDING
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 Requirements of the present part of the Rules apply to:
- Materials (including welding consumables) subject to the supervision by the River Register;
- Engineering procedures of welding and welded joints examination.

1.1.2 In addition to compliance with the requirements of the present part, materials shall meet the requirements of other parts of the Rules relevant to the application of materials.

1.1.3 Manufacture of materials shall be carried out in compliance with the technical documentation agreed by the River Register.

1.1.4 Methods of materials testing are stated in Appendices 1 – 12.

1.2 TERMS AND DEFINITIONS

1.2.1 The following terms are used in this Part of the Rules:
- **High temperature brazing** is a brazing method at which the melting temperature of the solder is above 450 °C;
- **Quality control documents** is a document issued by a manufacturer which includes results of materials testing and results of materials acceptance by the manufacturer’s technical control service;
- **Heat-affected zone (HZ)** is the layer of the base metal adjacent to a weld (or to the deposited metal) where structural changes were caused by the welding heat;
- **Weld metal** is the metal obtained by the merging of the fused base metal and the deposited metal or by fusion of the base metal only;
- **Deposited metal** is the metal obtained by the melting of an electrode or a wire and not containing inclusions of the base metal;
- **Specimen** is a test piece of specified shape and size prepared from a sample and used for determination of mechanical, technological and other properties of the material by testing;
- **Base metal** is the metal of items being welded;
- **Semi-finished product** is a consumable made by casting, forging, rolling, drawing or other similar methods and intended for machining or technological treatment during its proper use;
- **Sample** is a portion of a semi-finished product or a specially fabricated blank of which test specimens shall be machined;
- **Penetration** is the merging of the base metal with the deposited one or the merging of the metal of both components being welded;
- **Welding consumable** is an electrode, welding wire, flux and shielding gas used in welding;
- **Lamellar tearing** is breaking of welded construction elements made of rolled plates or tubes due to considerable welding stresses and/or external loads applied in the direction perpendicular to the plate surface.

1.3 MARKING

1.3.1 Marking shall be carried out according to the national standards taking into consideration the following requirements:

1 GOST 52927, GOST 5520, GOST 26358, GOST 1060.
1. In the case of semi-manufactured products delivered in single pieces each one of them shall be marked. For semi-finished products delivered in bundles two weather-resistant labels containing the marking shall be provided and firmly fastened to the opposite ends of the bundle.

Marking shall be legible and framed with a light paint resistant to atmosphere.

2. In the general case, the stamp shall include the following information:
   - name of material or semi-finished product;
   - name and address of the manufacturer and/or manufacturer's brand mark;
   - material category and/or trademark;
   - serial number (no. of the semi-manufactured product, cast no., etc.);
   - the date of manufacturing;
   - weight;
   - disposal method;
   - lifting points;
   - stamp of the manufacturer's technical control service;
   - the River Register brand (in cases described by Appendix 1 to RTSC);
   - other information to describe marked material or semi-manufactured product;

3. If the semi-manufactured product does not withstand the tests required by the Rules or defects are revealed which make its use in accordance with the purpose impossible, the River Register brand and the material grade designation shall be removed or cancelled.

4. The label attached to the packing shall be marked with the inscription: Approved by Russian River Register.
2 STEEL AND CAST IRON

2.1 GENERAL REQUIREMENTS

2.1.1 The present requirements are applied to hull structural steel, steel for boilers and pressure vessels, steel pipes and tubes, steel for cable chains, steel forgings and casting, high strength steel in accordance with GOST R 52927, reinforcing-bar steel in accordance with GOST R 5781 and iron castings.

2.1.2 Semi-manufactured products may be used if manufactured in compliance with national standards or in compliance with the technical documentation agreed by the River Register.

2.2 HULL STRUCTURAL STEEL

General requirements

2.2.1 The requirements of the present Chapter are applied to weldable hot-rolled plates, strip and sections up to 50-mm thick as well as steel shapes.

Steel differing by its chemical composition, the method of deoxidation, heat treatment or mechanical properties including clad steel shall have a special identification mark: S added to the grade symbol.

Chemical composition

2.2.2 The chemical composition of normal strength steel shall comply with the requirements of Table 2.2.2-1 and that of higher strength steel — Table 2.2.2-2.

Notes. 1. Up to a thickness of 12.5 mm and less the manganese content may be reduced to 0.70 %.
2. Where steel is thermomechanically treated, the chemical composition shall be determined in accordance with GOST R 52927.

1 GOST R 52927, GOST 5520, GOST 26358, GOST 1050, GOST 1060.
Tables 2.2.2-1 and 2.2.2-2 give data on the content of acid soluble aluminum. If the total aluminum content is determined, it shall be at least 0.020 %.

In case if the content of elements in normal strength steel is other than specified in Tables 2.2.2-1 and 2.2.2-2, then chromium, nickel and copper content shall not exceed 0.30 % for each element.

For normal strength carbon steel the total carbon content and 1/6 of the manganese content is not to exceed 0.40 %.

The carbon equivalent, in per cent, for higher strength steel is determined during type approval testing using the data of the ladle analysis and is calculated by the formula:

$$C_{eq} = C + \frac{Mn}{6} + (Cr + Mo + V)/5 + (Ni + Cu)/15.$$ (2.2.2);

The arsenic content in steel of all grades shall not to exceed 0.08 %.

If normal and high strength hull structural steel is treated by one grain refining element, for example niobium, vanadium or aluminum, its content shall comply with that specified in Tables 2.2.2-1 and 2.2.2-2. When a combination of the elements is used, the content of one or several elements in the steel shall comply with that specified in the Tables 2.2.2-1 and 2.2.2-2.

Where the content of aluminum or other grain refining elements is lower than required by Tables 2.2.2-1 and 2.2.2-2., the austenite grain size to be determined in accordance with GOST 5639 and not exceed grain size 5. Grade D steel of thickness exceeding 25 mm shall be killed, fine-grained and shall contain Al ≥ 0.015 %.

**Mechanical properties**

2.2.3 The mechanical properties of normal strength steel shall comply with the requirements of Table 2.2.3-1 and those of higher strength steel – with the requirements of Table 2.2.3-2.

The impact energy at impact testing may be determined either on longitudinal ($KV_L$) or on transverse ($KV_T$) specimens (see Appendix 10).

</tr>
</tbody>
</table>

Notes. 1. For the plate thickness less than 5 mm maximum under-thickness tolerances are adopted according to GOST R 52927.
2. Thickness shall be measured at the distance of not less than 25 mm from the plate edge.

The semi-manufactured articles shall be free from cracks, slag inclusions or other defects prejudicial to the use of the material for its intended application.

The surface of semi-manufactured articles shall be clean and not be subject to impact flattening.

Total removal of pipes shall be proved by check tests. The test procedure shall be developed with regard to requirements of GOST 22727, GOST 12503 and agreed with the River Register.

Removal of the surface defects by local grinding is allowed only for the depth not exceeding 7% the nominal thickness but in all cases not exceeding 3 mm. The total area of grinding shall not exceed 2% of the product surface.

The surface defects which cannot be removed by local grinding may be removed by chipping or grinding followed by welding provided that:

1. The product thickness before welding is not reduced by more than 20% after removal of the defects;
2. Welding is carried out in accordance with the procedure developed according to re-
requirements of Section 7 of the present Part of the Rules and agreed with the River Register;

The welded area is ground to the nominal thickness of the product;

The area of single weldings shall not exceed $25 \cdot 10^{-4}$ m$^2$;

The total welded area shall not exceed 1% of the product surface;

Heat treatment shall be carried out after welding of the surface defects. Method and necessity of heat treatment shall be determined by the manufacturer proceeding from the chemical composition, purpose and shape of the casting.

Marking

2.2.6 The steel manufacturer shall have a system for identification of ingots, slabs and semi-manufactured articles which enables the material to be traced to its original cast.

Each semi-manufactured article shall have the brand of the River Register and the marking according to requirements of 1.3.

When the steel is supplied after thermomechanically controlled processing, the index TM shall be added after identification of the grade (e.g. E36TM).

2.3 STEEL FOR BOILERS AND PRESSURE VESSELS

General provisions

2.3.1 Requirements of the present Chapter are applied to rolled steel intended for marine boilers, heat exchangers and pressure vessels.

2.3.2 Rolled steel manufactured and tested in accordance with requirements of the present Chapter is intended for operation at room (20±10) °C or elevated temperature.

2.3.3 The rolled steel shall be free from defects prejudicial to the application of the material. The soundness shall be proved by non-destructive testing.

Surface defects due to the specific method of manufacture may be allowed when their depth does not exceed the permissible limits of values normalized by GOST 5520.

Chemical composition

2.3.4 The chemical composition of steel is determined in accordance with GOST 5520 depending on the required mechanical properties at room or elevated design temperatures; the content of base elements in per cent shall not exceed:

For carbon and carbon-manganese steel (ladle analysis):

- Carbon ............... 0.20
- Phosphorus .......... 0.040
- Silicon .............. 0.50
- Nickel .............. 0.30
- Manganese ......... 1.6
- Chromium .......... 0.30
- Sulphur ........... 0.040
- Copper ............ 0.30

The use of steel with carbon content more than 0.2% is permitted, if the proper weldability was preliminarily tested (see 4 of Appendix 10);

For low-alloy steel (ladle analysis), %:

- Carbon ............... 0.18
- Phosphorus .......... 0.040
- Silicon .............. 0.50
- Chromium .......... 2.50
- Manganese ......... 0.80
- Nickel .............. 1.10
- Sulphur ........... 0.040
- Vanadium .......... 0.35

2.3.5 Using of rimming steel is not permitted.

The steel may be treated with grain-refining elements.

Carbon and carbon-manganese steel intended to operate at temperatures over 400 °C shall not contain aluminium.

Mechanical properties

2.3.6 Mechanical properties of steel at the room and rated elevated temperature are specified by GOST 5520.

The properties of steel shall be confirmed by the following tests to be carried out in accordance with the requirements of Appendix 10:

- Tensile test (with tensile strength, yield stress and percentage elongation to be determined);
- Bend test;
- Impact test ($KCU$ or $KV$).

Strength characteristics

2.3.7 Strength characteristics of steel for boilers are stated in Tables 2.3.7-1 and 2.3.7-2.

### Marking

**2.3.8** Marking shall be provided in accordance with the requirements of 1.3.

### 2.4 STEEL PIPES AND TUBES

#### General requirements

**2.4.1** Requirements of the present Chapter apply to hot and cold-formed steel pipes and tubes as well as welded pipes and tubes which are intended for manufacturing of boilers, heat exchangers, pressure vessels, shipborne systems and piping.

**2.4.2** The pipes and tubes manufactured and tested in accordance with the present requirements are intended for operation both at room and elevated temperatures.

**2.4.3** The welded pipes and tubes may be manufactured by means of electric induction welding, pressure contact welding or fusion welding.

**2.4.4** The surface of the pipes and tubes shall be free from cracks, skins, fissures and laps.

A certain number of minor nicks and dents, marks, thin layer of scale, traces of defects grinding and small skins are permitted if they do not decrease the wall thickness below the allowable under-thickness tolerances.

Hydraulic tests may be omitted if all the pipes and tubes undergo non-destructive ultrasonic or other testing (see 8.1.2).

The welds in welded pipes and tubes are to undergo the ultrasonic testing.
Chemical composition

2.4.5 The chemical composition of steel is determined in accordance with national standards\(^1\) depending on the required mechanical properties at room or elevated design temperatures; the content of base elements in per cent shall not exceed:

for carbon and carbon-manganese steel (ladle analysis), %:
- Sulphur .............. 0.04
- Phosphorus........ 0.04
- Manganese......... 1.50
- Chromium......... 0.30
- Silicon................ 0.50
- Nickel................ 0.30
- Carbon............... 0.23
- Copper............... 0.30

for low-alloy steel (ladle analysis), %:
- Sulphur ............ 0.035
- Phosphorus...... 0.035
- Manganese.......... 1.0
- Chromium......... 2.50
- Silicon................ 0.50
- Molybdenum ..... 1.20
- Carbon............... 0.20
- Vanadium.......... 0.35

2.4.6 The steel shall be killed. Unkilled steel is not permitted for manufacturing pipes and tubes. Semi-killed and fine-grained steel is permitted on condition that values of mechanical properties are provided according to the Rules.

Carbon and carbon-manganese steel intended for working temperatures above 400 °C shall not contain aluminum.

Mechanical and technological properties

2.4.7 The mechanical and technological properties of steel intended for pipes and tubes at room and elevated design temperature are set by national standards\(^2\).  

2.4.8 In the process of manufacture the pipes and tubes shall undergo the following tests:

- Tensile test (determination of tensile strength, yield stress and elongation) according to 2.2 of Appendix 10;
- Tensile test at elevated temperature (determination of proof stress) according to 2.2 of Appendix 10;
- Flattening test according to 2.15 of Appendix 10 or tensile test of rings according to 2.17 of Appendix 10;
- Expanding test according to 2.16 of Appendix 10.

Tensile test at elevated temperature, flattening test, tensile test of rings and expanding test shall be carried out when required by national standards\(^2\) or by technical documentation approved by the River Register on the basis of which the test results are estimated. The results of long-term stress tests of steel for pipes and tubes at elevated temperature shall be submitted to the River Register, when such tests are stipulated by the relevant parts of the Rules or by national standards mentioned above.

Heat treatment

2.4.9 The pipes and tubes shall be heat treated, when stipulated by the relevant parts of the Rules, by national standards mentioned in 2.4.8 or technical design documentation approved by the River Register. The cold-formed and electrically welded pipes and tubes shall in any case be heat-treated: normalized, normalized and tempered or quenched and tempered. The method and conditions of heat treatment chosen by the manufacturer shall be stated in the quality control document.

All steel alloy pipes as well as the following carbon steel pipes require heat treatment after bending and prior to hydraulic test:

1. For steam with a working pressure exceeding 1.6 MPa;
2. For fuel oil with a working pressure exceeding 1 MPa;
3. For other media with a working pressure exceeding 3 MPa.

Heat treatment of carbon steel pipes is not required at cold bending of pipes with a radius of \(4d\) \((d \text{ — outside diameter of the pipe})\) and over, and at hot bending at 850 – 950 °C.

Heat treatment is required after cold bending of carbon and alloyed steel pipes with a radius of \(4d\) and below.

\(^1\) GOST 380, GOST 1050, GOST 4543.
\(^2\) GOST 8731, GOST 8733, GOST 1060.
Heat treatment with stress relief for 0.3% carbon-molybdenum pipes with wall thickness exceeding 15 mm shall be carried out at temperature 580–640 °C in all cases, for 1 Cr – 0.5 Mo chromium-molybdenum pipes with wall thickness exceeding 8 at temperature 620–680 °C. Heat treatment with stress relief for 2.25 Cr – 1 Mo chromium-molybdenum and 0.5 Cr – 0.5 Mo – 0.25 V chromium-molybdenum-vanadium pipes with wall thickness exceeding 8 mm, diameter above 100 mm and working temperature above 450 °C shall be carried out at 650–720 °C.

Pipes made of copper and copper alloys, except for pipes of monitoring and control devices, require annealing prior to hydraulic test.

For carbon-manganese, and carbon-molybdenum steel pipes subsequent heat treatment after hot bending is not required.

Marking

2.4.10 The marking shall be in accordance with 1.3.

2.5 STEEL FOR CHAIN CABLES AND ACCESSORIES

General requirements

2.5.1 The requirements of the present Chapter apply to rolled steel used for the manufacture of chain cables.

2.5.2 Technical documentation for rolled steel, which confirms that the steel is in compliance with requirements of this Chapter, shall be submitted to the River Register for the approval together with the test reports. The documents shall contain the data on the melting and deoxidation procedures, required chemical composition, condition of supply and mechanical properties of the steel.

2.5.3 Depending on the value of tensile strength of the steel used stud chain cables are divided into grades 1, 2 and 3, and studless chain cables — into grades 1 and 2.

2.5.4 The rolled bars are supplied in a rolled condition.

2.5.5 The admissible tolerances of rolled bars diameter are set down in compliance with 3.7.6, Part V of the Rules and shall be stated in the manufacturer’s quality control document.

2.5.6 The rolled bars shall be free from inner and surface defects that might impair proper workability and use. The surface defects may be removed by grinding within the limits of admissible diameter tolerances, specified by GOST 228.

Chemical composition

2.5.7 The chemical composition of steel based on ladle analysis shall comply with Table 2.5.7.

Table 2.5.7

<table>
<thead>
<tr>
<th>Chemical composition of rolled steel bars</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chain cable grade</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

¹ Aluminium may be replaced partly by other fine graining elements.

² Additional alloying elements may be added.

The rolled bars shall be manufactured of killed steel: the steel for chain cables of grades 2 and 3 steel shall be fine grain treated.

Mechanical properties

2.5.8 The mechanical properties of rolled steel bars shall ensure the properties of finished chain according to Table 3.7.8. of Part V of the Rules.

Marking

2.5.9 The marking of the rolled bars shall be made on each product in accordance with 1.3.

2.6 STEEL FORGINGS

General requirements

2.6.1 The present requirements are applicable to forgings intended for hull and machinery applications.
2.6.2 The requirements are applied also to rolled billets used instead of forgings and to rolled sections of a diameter not exceeding 250 mm used for manufacturing (only by machining) of shafts, bolts and similar items of simple shape. For rolled bars used as a substitute for forgings the reduction ratio shall be not less than 6:1.

2.6.3 The technical documentation for forgings intended for service at low or elevated temperature, as well as forgings of alloy steel with special properties (corrosion resistance, heat resistance, high temperature oxidation resistance, etc.) shall be submitted to the River Register for agreement and contain detailed information on the chemical composition, mechanical and special properties, heat treatment, methods and scope of testing.

2.6.4 The plastic deformation ratio shall be such as to ensure soundness, structure uniformity and the required mechanical properties. The plastic deformation ratio shall comply with the requirements of Table 2.6.4.

<table>
<thead>
<tr>

</tr>
<tr>
<td>From ingot or forged billet</td>
</tr>
<tr>
<td>From rolled billet</td>
</tr>
<tr>
<td>From rolled billet</td>
</tr>
</tbody>
</table>

Notes:
1. \( L \) and \( D \) — the length and diameter of a forging or its part respectively.
2. The forging ratio shall be calculated with reference to the average cross-sectional area of the ingot. The initial upsetting of the ingot may be also taken into consideration.

The thickness of any part of a disc-type forging, e.g., gear wheel forging, shall not exceed one-half the length of the billet from which it was formed by upsetting, provided that the initial forging reduction is not less than 1.5:1. Where the piece used has been cut directly from ingot or the initial reduction is less than 1.5:1, the thickness of any part of the disk-type forging shall not exceed one-third the length of the original piece.

Rings and other types of hollow forgings shall be made from hollow billets by expanding or drawing on a suitable mandrel. Hollow cast billets may be used as well. The wall thickness of the forging shall not exceed one-half the wall thickness of the hollow billet; otherwise the adequate pre-processing shall be given to the billet with reduction 2:1.

2.6.5 Surface imperfections are permitted within machining allowances only. Small surface imperfections revealed through visual examination or by non-destructive testing may be removed by local grinding or by chipping and grinding. Complete rectification of imperfections shall be proved by magnetic particle or dye penetrant testing.

2.6.6 Defect repairs by welding shall be restricted to the rectification of defects of the minor nature and in areas not subject to considerable working stresses. After welding all locations of welded-up defects and the results of inspection shall be shown in a drawing or sketch of the forging.

Chemical composition

2.6.7 The chemical composition of steel for forgings shall be appropriate for the particular type of steel and the required mechanical and special properties.

The forgings are to be made from killed steel.

2.6.8 For carbon and carbon-manganese steel forgings the chemical composition of ladle samples shall comply with the following overall limits in %:

- Carbon................. 0.60
- Silicon ............... 0.45
- Copper............... 0.30
- Manganese 0.30–1.50
- Chromium........... 0.30
- Sulphur.............. 0.040
- Molybdenum..... 0.15
- Phosphorus...... 0.040
- Nickel ............... 0.40

2.6.9 For alloyed steel forgings the chemical composition of ladle samples shall comply with the following overall limits in %:

- Carbon................. 0.45
- Sulphur .............. 0.035
- Silicon ............... 0.45
- Phosphorus...... 0.035

2.6.10 The content of grain refining components is to be reported in the ladle analysis.
### Mechanical properties

**2.6.11** Proceeding from the required minimum tensile strength the values of yield stress, percentage elongation, percentage area reduction and results of impact tests for carbon and carbon-manganese forgings shall comply with the values specified in Table 2.6.11-1, forgings of alloyed steels after quenching and tempering — Table 2.6.11-2, forgings from of alloyed carburizing steel — Table 2.6.11-3.

When using the data in Tables 2.6.11-1 – 2.6.11-3, the following shall be considered:

1. The tensile strength values obtained at tensile testing at required $R_m$ (MPa) shall not exceed the specified values by more than (MPa):

<table>
<thead>
<tr>
<th>$R_m$</th>
<th>600 &gt; 900</th>
<th>900 &gt; 1000</th>
</tr>
</thead>
<tbody>
<tr>
<td>$&lt; 600$</td>
<td>120</td>
<td></td>
</tr>
<tr>
<td>$600$-900</td>
<td>150</td>
<td></td>
</tr>
<tr>
<td>$&gt; 900$</td>
<td>200</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

</tr>
<tr>
<td>760</td>
</tr>
</tbody>
</table>

**Notes.** 1. Requirements for testing longitudinal specimens are adduced in the numerator, in the denominator — for testing transverse specimens.

2. For intermediate tensile strength values the minimum values of yield stress, elongation reduction of area and impact energy $KV$ or impact toughness $KCU$ may be obtained by linear interpolation.

3. The requirements given in these Tables relate to the specimens taken with their axes at a distance up to 10 % of the diameter or thickness from the surface.

</tr>
</tbody>
</table>

**Note.** See notes to Table 2.6.11-1.

If not specially specified by the River Register, the impact energy $K_{V}$ and $K_{U}$ or impact toughness ($K_{C U}$) shall be determined via impact testing at the manufacturer’s discretion. These are determined on specimens according to Figs. A10.2.8-2 and A10.2.8-1 of Appendix 10.

3. Where more than two or more tensile test specimens are taken from a forging, the variation in tensile strength $R_{m}$ (MPa) shall not exceed:

- **required $R_{m}$**: 70
  - $<600$
  - $600-900$: 100
  - $>900$: 120

4. The variation in hardness for an individual forging or in a batch of forgings at required $R_{m}$ (MPa) shall not exceed (HB):

- **required $R_{m}$**:
  - $<600$: 25
  - $600-900$: 35
  - $>900$: 42

### Heat treatment

2.6.12 All the forgings shall be suitably heat treated to obtain the required metal structure and mechanical properties as well as grain refining. The heat treatment procedure shall be chosen by the manufacturer proceeding from the chemical composition of steel, the purpose and dimensions of the forging. The following conditions shall be also observed:

The tempering temperature shall not be less than 550°C;

If a forging after being heat treated is subject to further heating during hot processing, it shall be reheat treated;

Where induction hardening, carburising or nitriding shall be carried out after machining, the forging shall be heat treated (either by full annealing or by normalizing and tempering) to a condition appropriate for this subsequent surface treatment;

If any straightening operation is performed after the final heat treatment, the forging shall be subject to subsequent stress relieving;

The method of heat treatment shall be stated in the quality control document.

#### Ultrasonic testing

2.6.13 Ultrasonic testing shall be carried out in accordance with 2.21 of Appendix 10.

#### Marking

2.6.14 The marking of steel forgings shall meet the requirements of 1.3.

### 2.7 STEEL CASTINGS

#### General requirements

2.7.1 Steel castings shall be manufactured and tested in accordance with the requirements of 2.7.2 – 2.7.11.

2.7.2 The requirements of the present Chapter are applicable to carbon and carbon-manganese steel castings used in hull and machine construction, the purpose of which is
established proceeding from their properties determined at room temperature.

2.7.3 The technical documentation for castings intended for service at low or elevated temperature, as well as castings of alloy steel with special properties (corrosion resistance, heat resistance, high temperature oxidation resistance, etc.) shall be submitted to the River Register for agreement and shall contain detailed information on the chemical composition, mechanical and special properties, heat treatment, methods and scope of testing.

2.7.4 Surface defects lying within machining allowances may be removed by machining.

2.7.5 Defects may be eliminated by welding in accordance with 7.6.3. Prior to carrying out weld repairs of large-sized defects alloy steel castings, castings for crankshafts and other essential components shall be heat treated in accordance with the requirements of 2.7.10. The welded spots are subjected to non-destructive testing.

Chemical composition

2.7.6 The chemical composition of steel for castings is established proceeding from the required mechanical and special properties. The castings shall be made from killed steel.

2.7.7 For carbon and carbon-manganese steel castings the chemical composition of ladle samples shall comply with the following overall limits in %:

<table>
<thead>
<tr>
<th>Element</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon</td>
<td>0.40</td>
</tr>
<tr>
<td>Silicon</td>
<td>0.60</td>
</tr>
<tr>

<td>0.040</td>
</tr>
<tr>
<td>Nickel</td>
<td>0.40</td>
</tr>
<tr>
<td>Phosphorus</td>
<td>0.040</td>
</tr>
<tr>
<td>Molybdenum</td>
<td>0.15</td>
</tr>
</tbody>
</table>

It is permitted to use castings provided that the chemical composition and mechanical properties are in compliance with GOST 977.

2.7.8 The content of grain refining components is to be reported in the ladle analysis.

Mechanical properties

2.7.9 Proceeding from the required minimum tensile strength $R_m$ the values of yield stress, percentage elongation, percentage area reduction and results of impact tests for carbon and carbon-manganese castings shall comply with the values specified in Table 2.7.9.

The tensile strength values obtained at tensile testing shall not exceed the required minimal values specified by Table 2.7.9 by more than 150 MPa and for castings mentioned in Note 1 for Table 2.7.9 – by more than 120 MPa.

<table>
<thead>
<tr>
<th>Tensile strength $R_m$ (MPa)</th>

</tr>
</tbody>
</table>

Notes. 1. The elongation, reduction of area, impact energy and impact toughness mentioned in the denominator are established for castings of main (responsible) components (crankshafts, turbine parts, propellers).

2. The impact energy KV and KU or impact toughness (KCU) shall be determined via impact testing at the manufacturer’s discretion. These are determined on specimens according to Figs. A10.2.8-2 and A10.2.8-1 of Appendix 10.

3. For intermediate tensile strength values the minimal values of yield stress, elongation, reduction of area and impact energy or impact toughness may be determined by linear interpolation.
2.7.10 Heat treatment

To ensure the structure and mechanical properties required by Table 2.7.9, the castings shall undergo heat treatment. The heat treatment procedure shall be chosen by the manufacturer proceeding from the chemical composition, the purpose and shape of castings when meeting the following conditions:

The tempering temperature shall be not less than 500 °C;

The stress relief heat treatment of castings for components where dimensional stability and absence of internal stresses are of great importance, e.g. crankshafts, engine bedplates etc., shall be carried out at a temperature of not less than 550 °C followed by furnace cooling to 300 °C or lower;

2.7.11 Marking

The marking of steel castings shall meet the requirements of 1.3.

2.8 STEEL PROPELLER CASTINGS

General requirements

2.8.1 The requirements of the present Chapter apply to castings of solid-cast propellers, propeller blades and hubs of propellers with detachable blades made of carbon, low alloyed and alloyed steels. Requirements of 2.7 shall be met as applicable.

Alloy steel with chemical composition or mechanical properties not in compliance with requirements of 2.8.3 and 2.8.4 may be used. In this case steel corrosion fatigue tests results shall be submitted. Fatigue strength which is determined on the base of 10 cycles shall be not less than 75 MPa.

2.8.2 The surface of the castings shall undergo dye penetrant or magnetic particle testing. The pressure and suction surfaces of the blade as well as the transition zone between the blade and the hub or between the blade and the flange shall undergo testing by one of the above methods.

The scope and procedure of testing as well as the norms of permissible defects shall be in accordance with technical documentation agreed with the River Register.

The revealed defects may be rectified by machining or welding.

The places of defect rectification or welding spots shall undergo non-destructive testing. The dimensions and location of the welded defects shall be indicated in the drawing attached to the propeller casting quality control document.

Chemical composition

2.8.3 The chemical composition of steel castings for propellers shall comply with Table 2.8.3.

For all steel grades S and P content shall not exceed 0.035 % for each element.

Mechanical properties

2.8.4 The mechanical properties of steel for propellers are determined during the testing of specimens machined from samples cast either separately or integrally to the hub or the flange portion of the blade; they shall be in accordance with Table 2.8.4.

Heat treatment

2.8.5 Propeller castings shall be heat treated in conformity with Table 2.8.4. Stress relieving heat treatment shall not adversely affect the mechanical properties of the casting metal and its corrosion resistance. The heat treatment procedure is set by the manufacturer.

</tbody>
</table>

The chemical composition of steel shall be determined by the manufacturer from each cast or ladle and shall comply with the requirements of technical specification agreed with the River Register. Steel shall be fully killed and fine grain treated.

#### Heat treatment

2.9.3 The steel shall be quenched and tempered. This requirement does not apply to precipitation-hardening steel.

#### Mechanical properties

2.9.4 The mechanical properties of steel at tensile and impact testing shall conform to those stated in Table 2.9.4.

2.9.5 The marking shall meet the requirements of 1.3 and 2.2.6.

2.10 STEEL REINFORCEMENT

2.10.1 Requirements of the present Chapter apply to the following types of reinforcement for hulls of reinforced-concrete ships:

- Plain reinforcement of carbon steel of grades BCr3CN2 and BCr3nC2 GOST 5781, class A-I (A240);
- Die-rolled section of carbon steel of grades Cr5cn2 and Cr5nC2 GOST 5781, class A-II (A-300);

</table>

1 Testing for Grade D steel shall be carried out at temperature –20 °C, E — at –40 °C, F — at –60 °C.

Note. \( L \) — for longitudinal specimen, \( T \) — for transverse specimen.

2.10.2 Reinforcing-bar steel that has undergone hardening and profiling by means of cold treatment as well as thermo-strengthening is not allowed for ordinary (non-pre-tensioned) reinforced-concrete.

2.10.3 For ships operating in extra inclement conditions (month average temperature of the most cold month below –20 °C) the use of semi-killed steel reinforcement is not allowed.

2.10.4 The use of grade 35ГС GOST 5781 steel reinforcement is forbidden for structures subject to variable or alternating loads (shipborne machinery foundations etc.).

2.10.5 Steel reinforcement of different grades may be used in the same cross-section of reinforced-concrete product provided that yield points differ by not more than 30 %.

2.10.6 Embedded items shall be made of killed and semi-killed steel which comply with the requirements of 2.2 related to welding hull structural steel; anchors of embedded items shall be made of steel which comply with the requirements of 2.10.1 – 2.10.5.

2.10.7 For pre-tensioned steel reinforcement of the ship structures the following shall be used:

1 High-tensile reinforcement wire of types B, Bp GOST 7348 and reinforcement ropes K-7 GOST 13840;

2 Thermo-strengthened reinforcement steel bars of classes Ar 800 and Ar 1000 GOST 10884;

3 Hot-rolled and thermo-strengthened reinforcement steel bars of class A-IV (A600) GOST 5781;

4 Hot-rolled reinforcement steel bars of classes (A300) and (A400) GOST 5781.

2.11 NODULAR GRAPHITE IRON CASTINGS

General requirements

2.11.1 The requirements of the present Chapter apply to nodular graphite iron castings used in hull and ship machinery construction, which purpose is established proceeding from their properties determined at room temperature.

2.11.2 The technical documentation for castings intended for service at low or elevated temperature shall be submitted to the River Register for agreement and shall contain detailed information on the chemical composition, mechanical and special properties, heat treatment, methods and scope of testing.

2.11.3 The castings shall be free from defects which would be prejudicial to their application in service. Repairing of defects by welding is not permitted. The surface defects may be removed by grinding.

Chemical composition

2.11.4 The chemical composition is set proceeding from the required mechanical properties of the castings. The chemical composition of ladle samples shall be reported in technical documents for the castings.
Mechanical properties

2.11.5 The mechanical properties of the castings shall conform to Table 2.11.5.

Table 2.11.5

<table>
<thead>
<tr>
<th>Composition of wire</th>
<th>Tensile strength $R_m$ (MPa)</th>

</tbody>
</table>

While performing the tensile test of the casting material the tensile strength and percentage elongation shall be determined.

The minimum tensile strength shall conform to the norms stated in Table 2.11.5.

In order to determine intermediate tensile strength values minimum elongation and yield limit values may be obtained using the linear interpolation of the data stated in Table 2.11.5.

2.11.6 Where impact testing is required, the dimensions and type of specimen shall be in compliance with GOST 7293 or the technical documents agreed with the River Register.

2.11.7 The microstructure of the castings shall include not less than 90 % of nodular graphite. No flaked graphite is permitted.

Heat treatment

2.11.8 The castings shall be supplied in either as the cast or heat treated condition.

The necessity of heat treatment and the relevant procedure are determined by the manufacturer proceeding from the chemical composition, purpose and shape of the casting.

The stress relieving heat treatment shall follow the structure refining heat treatment prior to its machining.

2.11.9 If the local surface hardening is required, its procedure shall be agreed by the River Register.

Marking

2.11.10 The marking of nodular iron castings shall comply with the requirements of 1.3.

2.12 GREY IRON CASTINGS

General requirements

2.12.1 The requirements of the present Chapter apply to grey iron castings used in hull and machinery construction.

2.12.2 The castings shall be free from defects which would be prejudicial to their application in service. The surface defects may be removed by local grinding. The soundness of the casting shall be proved by non-destructive testing.

Chemical composition

2.12.3 The chemical composition is set by the manufacturer proceeding from the required mechanical properties of the castings. The chemical composition of ladle samples shall be reported in technical documents for the castings.

Mechanical properties

2.12.4 The required minimum tensile strength shall be in compliance with the technical documentation for the casting, but in any case it shall be not less than 200 MPa.

Heat treatment

2.12.5 Castings may be supplied in the cast or heat treated condition.

The necessity of heat treatment and the relevant procedure are determined by the manufacturer proceeding from the chemical composition, purpose and shape of the casting.

The stress relieving heat treatment shall follow the structure refining heat treatment prior to its machining.
Marking

2.12.6 The marking of grey iron castings shall comply with the requirements of 1.3.

2.13 MALLEABLE CAST IRON

General requirements

2.13.1 Malleable cast iron may be used for the manufacture of products for hull and machinery construction which are intended to operate at a temperature not exceeding 300 °C and the working pressure not exceeding 2 MPa.

2.13.2 The chemical composition, mechanical properties and scope of testing of items made of malleable cast iron shall comply with the technical documents agreed by the River Register and proceeding from the intended use of castings.
3 COPPER AND COPPER-BASE ALLOYS

3.1 SEMI-MANUFACTURED PRODUCTS OF COPPER AND COPPER-BASE ALLOYS

General requirements

3.1.1 The requirements of the present Chapter apply to semi-manufactured products of copper and copper-base alloys (rolled, forged, drawn, press-formed etc.) and castings which are used in hull and machinery construction.

3.1.2 The chemical composition and mechanical properties of copper and copper-base alloy products such as pipes, plates, bars, rolled sections, forgings and castings shall comply with the requirements of appropriate national standards1 and technical documents approved by the River Register.

For each batch the following shall be determined:

- Chemical composition (heat analysis);
- Mechanical properties ($R_m$, $R_{0.2}$, $A$);
- Technological tests.

Heat exchanger tubes made of CuZn alloy shall undergo mercury nitrate or ammonium nitrate testing, flattening and expanding testings, microstructure investigation and hydraulic testing.

The average grain size shall be 0.01 to 0.05 mm.

Test pressure shall be set according to the technical documents. The test pressure for heat exchanger tubes shall be 5 MPa and for tubes (bushes) on propeller shaft platting — 2 MPa.

When choosing copper-base alloys, the required level of mechanical properties at room or elevated temperatures, corrosion resistance and other properties determined by their application shall be considered.

Supply condition

3.1.3 The heat treatment procedure shall be determined by the manufacturer proceeding from the required mechanical properties of copper and copper-base alloys semi-manufactured products. The method of heat treatment shall be stated in the quality control document.

Rolled semi-manufactured products made of CuZn alloys (brass) shall be annealed for stress relieving.

Products in solid and semi-solid condition may be used only if in compliance with the technical documents approved by the River Register and on condition that the justified data is submitted.

3.1.4 The semi-finished products and the castings shall be free from defects prejudicial to their proper operation as per their application.

Marking

3.1.5 The marking of semi-manufactured products and castings of copper and copper-base alloys shall comply with the requirements of 1.3.

3.2 PROPELLER CASTINGS

General requirements

3.2.1 The requirements of the present Chapter apply to castings of solid-cast propell-
3 Copper and Copper-Base Alloys

3.2.2 Casting surfaces shall undergo dye penetrant and visual inspection. Non-destructive testing to be conducted on castings for checking the absence of internal defects.

The revealed defects may be rectified by machining or welding.

The places of defect rectification and/or welding spots shall undergo non-destructive testing.

Stresses arisen due to welding of defects shall be relieved.

Welding of defects shall be performed by welders who has got the admission Certificate.

The dimensions and location of the welded defects shall be indicated in the drawing attached to the propeller casting quality control document.

Chemical composition

3.2.3 The chemical composition shall meet the requirements of Table 3.2.3.

Table 3.2.3
Typical chemical composition of steel alloys used for propeller castings

<table>
<thead>
<tr>
<th>Chemical element</th>

Note. The total content of admixtures of any grade to be agreed by the River Register.

Unless otherwise specified the present Chapter, zinc content in alloys of grades 1 and 2 calculated according to the formula in per cent

\[ C_{Zn} = 100 - 100 Cu / (100 + A) \]  

shall not exceed 45%.

In formula (3.2.3):

- \( Cu \) — copper content in the alloy, %;
- \( A \) — parameter of the alloy:
  \[ A = 1Sn + 5Al - 0,5Mn - 2,3Ni - 0,1Fe; \]
- \( Sn, Al, Mn, Ni, Fe \) — content of tin, aluminium, manganese, nickel and iron content in the alloy, %.

The content of Alpha phase in alloys of grades 1 and 2 shall be not less than 25%. Alpha phase content is determined by the manufacturer.

Alloys with the base elements content exceeding the specified limits, as well as alloys with different chemical composition compared to specified above, may be used provided that their properties in expected operating conditions are as good as the properties of alloys with chemical composition specified above.

Mechanical properties

3.2.4 The mechanical properties of alloys for propellers are determined during the testing of specimens machined from samples cast separately; they shall be in accordance with Table 3.2.4.

Table 3.2.4
Mechanical properties for propeller alloys

<table>
<thead>

</table>

When testing specimens machined from samples integrally cast or taken directly from the casting, mechanical properties may be up to 30% lower than those specified in Table 3.2.4.

Marking

3.2.5 The marking of propeller castings shall comply with the requirements of 1.3.
4 ALUMINIUM ALLOYS

4.1 WROUGHT ALUMINIUM ALLOYS

General requirements

4.1.1 The requirements of the present Chapter apply to aluminium alloy forgings, punchings, rods, sections, pressed panels and plates of thickness exceeding 1.5 mm which are intended for hull and machinery construction.

4.1.2 Plates, sections, forgings, punchings and panels shall be free from defects prejudicial to their proper application.

All semi-manufactured products of the batch shall undergo visual examination.

The manufacturing process is to ensure that the products are free from internal or surface defects.

Metallographic examination and non-destructive testing of semi-manufactured products for soundness shall be performed according to the technical documentation approved by the River Register.

Mechanical properties

4.1.3 Determined during the testing of specimens mechanical properties of wrought aluminium alloy semi-manufactured products shall comply with the requirements of Table 4.1.3.

Chemical composition

4.1.4 The chemical composition of wrought aluminium alloys shall comply with the Table 4.1.4.

The total content of admixtures not indicated in the Table is not to exceed 0.1 %.

Titanium and zirconium may be partially or totally substituted by other grain refining elements.

Heat treatment

4.1.5 Proceeding from the required mechanical properties aluminum alloy semi-manufactured products shall be supplied in hot-rolled, hot-pressed or annealed condition.

The supply condition shall be indicated in the quality control document for product.

Application of products in semi-hardened and hardened condition in welded structures is subject to is allowed on condition that the required properties of these structures are provided.

Performing of process operations accompanied with local heating, cold hardening and deformation of structures shall not bring to change of properties being prejudicial to proper application of the products.
4 Aluminium Alloys

| 5 | 5.8-6.8 | 0.5-0.8 | 0.02-0.1 | — | ≤0.40 | 0.40 | — |
| 6 | 0.4-1.5 | 0.2-1.0 | ≤0.2 | — | 0.6-1.6 | 0.50 | — |

1 For all grades aluminium content shall not exceed the residual values.
2 For all grades copper content — max 0.10 %, zinc — max 0.20 %.

Marking

4.1.6 The marking of plates, sections, rods, forgings, punchings, stampings and panels made of wrought aluminium alloys shall be made according to 1.3.

The manufacturer shall have the marking system which allows to trace back the whole manufacturing procedure of the material and to determine the origin of the relevant batch.

4.2 CAST ALUMINIUM ALLOYS

General requirements

4.2.1 The requirements of the present Chapter apply to parts and structures of cast aluminium alloys for hull and machinery construction.

4.2.2 The castings shall be free from defects which would be prejudicial to their strength and application in service.

Surface defects may be removed by grinding or machining if they are within the dimensional tolerances specified by the technical documentation approved by the River Register.

Casting defects may be rectified by welding in accordance with the procedure developed according to requirements of Section 7 of the present Part of the Rules and agreed with the River Register.

Where the material of the castings shall undergo hydraulic tightness pressure tests, the working pressure in the tested chamber and the test pressure values shall be stated in the casting drawing.

Non-destructive testing shall be conducted on castings intended for items subject to high loads for checking the absence of internal defects.

Chemical composition and mechanical properties

4.2.3 The chemical composition and mechanical properties of products cast of aluminium alloys are to meet the requirements of Table 4.2.3.

In case of die or chill casting the mechanical properties required and the sampling procedure shall comply with the technical documents agreed by the River Register.

Corrosion resistance check shall be performed for alloys differing in chemical composition from those given in Table 4.2.3. according to applicable national standards.

Heat treatment

4.2.4 If aluminium alloy castings are heat treated, the type of heat treatment is stated by the manufacturer and recorded in quality control document.

Marking

4.2.5 The marking of the castings shall comply with the requirements of 1.3.

5 MATERIALS USED FOR LNG CARRIERS

5.1 GENERAL REQUIREMENTS

5.1.1 The requirements of this Section apply to rolled plates and sections, pipes, forgings and castings intended for:

.1 Cargo tanks and process pressure vessels operated at the design temperature of 0 °C and above;

.2 Hull structures providing an additional barrier, cargo tanks, process pressure vessels operated at the design temperature of 0 to –55 °C;

.3 Hull structures providing an additional barrier, cargo tanks, process pressure vessels operated at the design temperature of –5 to –165 °C;

.4 Cargo and process pipelines operated at the design temperature of –165 to 0 °C;

.5 Hull structures not providing an additional barrier and not specified in 5.1.1.1 – 5.1.1.3, that can be exposed to negative temperature due to cargo carried at such temperatures.

Materials specified in 5.1.1.3 – 5.1.1.4 may be used at the design temperature below –165 °C on condition that values of structure properties are provided according to the Rules. Detailed information on the chemical composition, mechanical and special properties, heat treatment, scope and methods of castings testing shall be submitted to the River Register.

5.1.2 If the design temperature of hull structures is below –5 °C, steel grade and maximum thickness shall be determined from Table 5.1.2.

If minimum design temperature of hull structures is below –30 °C, the temperature of impact bending test as specified in 5.3.3 shall be lower than the design temperature for 5 °C.

<table>

</tr>
</tbody>
</table>

* This grade of steel is not permitted.

5.1.3 Design temperature of full or partial additional barrier is taken to be equal to the cargo temperature at atmospheric pressure.

Main barrier design temperature for cargo tanks not having additional barrier is taken to be equal to the cargo temperature.

5.1.4 If hull structures provide additional barrier, materials used for manufacture of hull structures shall be selected taking into account requirements of 5.3.1 – 5.3.2.

If the additional barrier is not integral to a hull structure, a material used for manufacture of the additional barrier shall be selected taking into account requirements of 5.3.1 – 5.3.2 and 5.4.1 – 5.4.2 in accordance with the temperature of the cargo carried.

If the additional barrier is provided by a deck plating section or the outer shell plating, a material used for manufacture of the additional barrier shall be selected taking into account requirements of 5.3.1 – 5.3.2.

5.1.5 If materials heat treatment is carried out after welding, properties of heat-treated...
base metal shall comply with requirements of 5.2.3, 5.2.4, 5.3.3, Table 5.4.1, and Table 5.5.1, properties of welded joint after treatment shall comply with requirements of section 7 and 8 of this Part of the Rules.

5.2 MATERIALS TO BE USED AT DESIGN TEMPERATURES OF 0 °C AND ABOVE

Chemical composition

5.2.1 Rolled plates and sections, forgings used for cargo tanks, process pressure vessels, for design temperature of 0 °C and above shall be made from carbon manganese killed steel. Fine grained steel shall be used for materials with wall thickness exceeding 20 mm.

Heat treatment

5.2.2 Steel shall be heat treated i.e. normalized or quenched and tempered. Rolling with controlled temperature may be used instead of normalization or quenching and tempering.

Tests

5.2.3 Each plate shall undergo tensile and impact testing. Rolled sections and forgings are submitted for testing in batches. Designed minimum yield stress shall not exceed 410 MPa.

5.2.4 Impact tests for steel plates are conducted on transverse specimens and impact tests for steel sections and forgings are conducted on longitudinal specimens. Minimum average value of the impact energy $KV$ for steel plates is $27 \, \text{J}$, for steel sections and forgings — $41 \, \text{J}$. Test temperature is dependent on the material thickness as per Table 5.2.4;

<table>
<thead>
<tr>
<th>Thickness of the material S (mm)</th>
<th>Test temperature (°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 20</td>
<td>0</td>
</tr>
<tr>
<td>Over 20 to 40</td>
<td>−20</td>
</tr>
</tbody>
</table>

5.2.5 Seamless pipes and fittings shall comply with the requirements of 2.4. Welded pipes with longitudinal and spiral welds may be used on condition that required properties of pipes are provided.

5.3 MATERIALS TO BE USED AT DESIGN TEMPERATURES OF 0 TO MINUS 55 °C

Chemical composition

5.3.1 Rolled plates and sections, forgings used for hull structures providing an additional barrier, cargo tanks, process pressure vessels, for design temperature of 0 to minus 55 °C shall be made from fine-grained, aluminum treated carbon manganese killed steel.

The chemical composition of steel based on ladle analysis shall comply with the following maximum values in per cent:

- Carbon.............. 0.16
- Chromium.......... 0.25
- Silicon .......... 0.10–0.50
- Molybdenum..... 0.08
- Manganese 0.70–1.60
- Copper ............. 0.35
- Sulphur.......... 0.035
- Columbium....... 0.05
- Nickel.............. 0.80
- Vanadium......... 0.10

The carbon content may be increased to 0.18 provided that the design temperature is not below minus 40 °C.

Heat treatment

5.3.2 Steel shall be heat treated i.e. normalized or quenched and tempered.

Rolling with controlled temperature may be used instead of normalization or quenching and tempering. Specially treated steel or steel which complies with the requirements of 5.4.1 – 5.4.2 shall be used for materials more than 25 mm thick tested at temperatures of minus 60 °C and below.

Tests

5.3.3 Each plate shall undergo tensile and impact testing. Rolled sections and forgings are submitted for testing in batches.

Impact tests for steel plates are conducted on transverse specimens and impact tests for steel sections and forgings are conducted on longitudinal specimens. Minimum average value of the impact energy $KV$ for steel plates is $27 \, \text{J}$, for steel sections and forgings — $41 \, \text{J}$. Test temperature is dependent on the material thickness as per Table 5.3.3;
Impact energy values for materials more than 40 mm thick shall be agreed with the River Register.

### Table 5.3.3

</table>

* Whichever is lower.

Materials for cargo tanks and their components subjected to stress relief heat treatment after welding, may be tested at temperature lower than the design temperature for 5 °C or at temperature of minus 20 °C, whichever is lower.

### 5.4 MATERIALS TO BE USED AT DESIGN TEMPERATURES OF MINUS 55 TO MINUS 165 °C

#### 5.4.1

The chemical composition, heat treatment procedure, impact test temperature and minimum average value of the impact energy for hull structures materials providing additional barrier, cargo tanks, process pressure vessels for the design temperature below minus 55 and to minus 165 °C are specified in Table 5.4.1.

#### 5.4.2

The impact test temperature for steels with thickness of 25 mm or less is taken from Table 5.4.1, for steels of thickness exceeding 25 mm — from Table 5.4.2. Thickness exceeding 25 mm is not permitted for steels with 9% of Ni, austenitic stainless steels and aluminium alloys.

Each plate shall undergo tensile and impact testing. Rolled sections and forgings are submitted for testing in batches. Impact tests for steel plates are conducted on transverse specimens and impact tests for steel sections and forgings are conducted on longitudinal specimens.

Test temperature shall not exceed the values specified in Tables 5.4.1 – 5.4.2.

</tbody>
</table>

\(^1\) Lower minimum design temperature may be permitted for quenched and tempered steel.

\(^2\) Steel after threefold heat treatment may be used at temperature down to −165 °C on condition that the impact tests are conducted at temperature of −196 °C.

\(^3\) Impact tests may be omitted.
5.5 MATERIALS INTENDED FOR PIPES TO BE USED AT THE DESIGN TEMPERATURE OF 0 TO MINUS 165 °C

5.5.1 The chemical composition, heat treatment procedure, impact test temperature and minimum average value of the impact energy for materials of cargo and process pipelines operated at the design temperature of 0 to minus 165 °C, are specified in Table 5.5.1.

5.5.2 Each batch of pipes, forgings and castings shall undergo tensile and impact testing. The test shall be carried out on the longitudinal samples.

5.5.3 Welded pipes with longitudinal and spiral welds may be used on condition that required operational properties of pipes are provided.

Test temperature for valves and fittings of pipelines undergone stress relieving heat treatment shall be equal to the temperature required for testing of adjacent tank plating considering the plating thickness.

5.6 TESTING OF INSULATION MATERIALS

5.6.1 Insulation materials shall be tested to determine their properties and mechanical characteristics with respect to:
- Compatibility with the cargo;
- Solvability in the cargo;
- Absorption of the cargo;
- Shrinkage;
- Ageing;
- Porosity;
- Density;
- Mechanical properties;
- Thermal expansion;
- Wear;
- Adhesion properties;
- Thermal conductivity;
- Vibration resistance;
- Non-combustibility and flame spreading.

In addition, the following properties of insulation materials for cargo tanks with inner insulation shall be tested:
- Adhesion properties;
- Resistance to compression caused by cargo pressure;
- Resistance to fatigue crack propagation;

<td>−196</td>
<td>41</td>
</tr>
</tbody>
</table>

\(^1\) Test temperature T shall be −20 °C or 5 °C lower than the minimum design temperature, whichever is lower.

\(^2\) Lower minimum design temperature may be permitted for quenched and tempered steel.

\(^3\) This steel is not used for castings.

\(^4\) Impact tests may be omitted.
Compatibility with cargo components and any other agents which can contact with the insulation in process of the ship operation;
Influence of the zone and of the water pressure on the insulation;
Gas de-absorption.
Testing of specified insulation materials shall be conducted at temperatures from maximum to 5 °C lower than minimum design temperature, but not less than –196 °C.

5.6.2 Insulation materials technical documents shall include the manufacture process, storage and assembly conditions, quality control methods and determination of the degree of solar radiation harmful effect.
6 NON-METALLIC MATERIALS

6.1 GENERAL REQUIREMENTS

6.1.1 Requirements of the present Section apply to non-metallic materials used in hull and machinery construction for the manufacture of structures and parts.

6.1.2 Unless otherwise specified, all plastics and materials of organic origin as well as structures and items incorporating them shall meet the following requirements:

1. Be assessed for combustibility, flame propagation, combustibility and fire resistance according to Appendices 1 – 5;

2. Not to release explosive gases at temperature exceeding their operation temperature;

3. To ensure reliable operation of structures and items on the open deck at temperatures from –40 to +70 °C and in the inside spaces of the ship at temperatures from –10 to +70 °C, unless service conditions provide for lower or higher operating temperatures;

4. To resist embrittlement in service and to prevent a decrease of mechanical properties by more than 30 % in comparison with the original values;

5. To resist decay and destruction by fungi as well as not to affect adversely the materials with which they come into contact.

6.1.3 Inside spaces finishes shall undergo tests for combustibility, flame spreading, inflammability and fire resistance according to Appendices 1 – 5 and nontoxicity test according to GOST 12.1.044.

6.2 REINFORCED CONCRETE

General requirements

6.2.1 The ship compartments used for the storage of oil products shall be manufactured of oil-tight reinforced concrete.

6.2.2 Reinforcement for reinforced-concrete ships hulls shall be chosen according to the requirements of 2.10.1 – 2.10.5.

Concrete

6.2.3 For hulls of floating cranes and carriers hull structural concrete of at least B40 class as per GOST 26633 shall be used, for other ships — of B30 class as per GOST 26633.

A concrete class means a concrete grade with regard to compression strength.

6.2.4 A concrete class with regard to frost-resistance for hull elements subject to moistening (bottom, sides, open parts of deck, watertight bulkhead, ballast compartments etc.) shall be assigned according to Table 6.2.4 depending on climate conditions of an area where a ship is supposed to operate. A concrete grade for non-moistened hull elements and superstructures shall be at least F50 as per GOST 26633.

6.2.5 Tests of hull structural concrete for the determination of the strength parameters, tightness, frost-resistance are carried out in accordance with national standards.

For ships with a prolonged period of construction concrete strength parameters may be

1 GOST 10180, GOST 12730.5, GOST 10060.0
### Table 6.2.4

</tr>
</tbody>
</table>

**Note.** Temperate climate conditions are determined by a month average temperature of the most cold month from 0 to –10°C, inclement conditions — from –10 to –20°C, extra inclement — bellow –20°C.

determined at the age of 60 and 90 days (GOST 10180).

6.2.6 If concrete of the same mix has been normally cured and steam-cured, tightness and frost-resistance tests may be carried out only for steam-cured concrete.

6.2.7 At construction of a series of ships using concrete of the same mix, curing conditions and strength parameters, one test of frost-resistance for several ships may be carried out.

6.2.8 Where a project provides checking of concrete strength on various terms differing from 28 days period, samples of each batch of concrete shall be taken and tested for each term.

6.2.9 Cement content both in heavy-weight and light-weight concrete according to GOST 25192 shall be at least 450 kg/m³.

In concrete for closed decks and bulkheads cement content may be reduced by 15 % from the above value provided that the resulting concrete meets the requirements of 6.2.3 – 6.2.5.

6.2.10 Hull structural concrete shall fill the mould (decking) and not to laminate at a chosen method of laying as well as shall not produce shrinkage cracks in the assigned process of curing.

6.2.11 For concreting of intersectional joints fine-grain (sand) concrete may be used.

### Concrete mix components

6.2.12 For making hull structural concrete Portland shall be used (ordinary, high-early-strength, sulfate-resistant) of at least grade 400 according to GOST 10178.

For concreting butts and sealing of reach-through holes gypsum-alumina concrete of at least grade 400 may be used as well.

For ships intended for operation in seawater concrete shall be made using sulphate-resistant Portland only of grade not less than 400.

6.2.13 Cement properties shall ensure the manufacture of hull structural concrete of the required grade provided that content of the cement is according to 6.2.9.

6.2.14 Cement shall be used only after checking of its physical and mechanical properties in accordance with national standards1. The period between the mentioned check and the utilization of cement shall not exceed 2 months for ordinary cement and 1 month for high-early-strength one.

6.2.15 As a coarse concrete aggregate for hull structural heavy-weight concrete graded breakstone from crushed hard rock or graded gravel of natural origin shall be used which meet the requirements of GOST 8267 related to materials for hull structural concrete.

6.2.16 As a coarse concrete aggregate for hull structural light-weight (claydite) concrete claydite gravel with a density of 600 – 800 kg/m³ in freely bulked condition and water absorption of not more than 15 % for 2 hours shall be used.

6.2.17 The size of concrete aggregate grains shall not exceed 20 mm or 0.25 of the smallest size of an element to be concreted, it shall also be less than minimum distance between parallel reinforcement bars.

6.2.18 As a fine concrete aggregate for hull structural concrete coarse or medium natural quartz or feldspar sands and crushed-stone or

---

1 GOST 310.1, GOST 310.2, GOST 310.3
gravel screenings shall be used which comply with requirements of GOST 26633.

6.2.19 Water for preparing hull structural concrete shall comply with requirements of GOST 23732.

6.2.20 In order to increase frost-resistance, tightness, improve technical qualities of a concrete mix, reduction the cement consumption, as well as to allow concreting at negative ambient temperatures, special additives may be added into the concrete mix.

6.2.21 For the rectification of minor defects the use of glass-reinforced plastics and epoxy-based plastic concrete as well as cement colloid glues.

Pre-tensioned reinforced concrete

6.2.22 Pre-tensioned structures shall be made of heavy-weight concrete of at least class B40 and light-weight concrete of at least class B30.

Concrete for filling of ducts shall be of at least class B30.

To the moment of transition of tension force to the concrete the latter shall have a strength not less than 70% of that corresponding to the grade as per GOST 26633.

6.2.23 Pre-tensioned reinforcement of the ship structures shall be assigned in accordance with requirements of 2.10.7.

6.3 GLASS-REINFORCED PLASTICS

6.3.1 Items made of glass-reinforced plastic shall not have delaminations, cavities, extraneous impurities and other defects which can be detected by means of non-destructive tests and would be prejudicial to their proper application in service.

Glass-reinforced plastic quality may be verified by destructive method.

When performing tests the following parameters shall be determined: tensile strength at tension and compression, Young’s modulus of elasticity at tension, compression and bending and relative mass glass content.

The value of mechanic properties is determined as arithmetic mean of test results of five specimens taken from one sample in warp and weft shoot directions.

In case of standard approval of glass-reinforced plastic in accordance with requirements of Appendix 10 the following parameters shall be determined: ageing degree, resistance to oil and sea water. Each of the tests specified shall be carried out on three specimens.

Requirements for hull material

6.3.2 As a binder for the manufacture of glass reinforced plastics and joining the hull structures cold-cured resins shall be used, e. g. polyester resins, epoxy resins, etc.

6.3.3 The resin type and binder preparation procedure shall be stated in engineering process for manufactured structures.

6.3.4 The resins used shall be self-extinguishing, i.e. not sustaining combustion when removed from fire. Self-extinguishing resins may be used only for outer layers, or surfaces may be coated with non-inflammable paints.

6.3.5 When additives or extenders are added to the resin during manufacture, its properties such as inflammability degree, corrosion resistance etc. shall be kept; strength and elasticity characteristics shall not be reduced by more than 10% of the designed values.

6.3.6 For the manufacture of glass-reinforced plastics as reinforcement materials may be used glass-fibre materials of different types as well as their combinations — cloths, plaits, mats etc.

6.3.7 Glass-fibre materials shall be made of alkali-free glass and treated with hydrophobic adhesive compounds. Application of glass-fibre materials non-treated with hydrophobic adhesive compounds shall be well-grounded.

For ships up to 15 m long alkali glass may be used when it is impregnated with hydrophobic adhesive compounds.

Glass-fibre materials are to be free from glass fibre sizers (paraffin, oil etc.).
6.3.8 Glass reinforced plastics based on cold-hardened resins with different reinforcement materials shall have physical and mechanical properties that provide the hull strength and rigidity specified in the design technical documentation.

6.3.9 After a glass reinforced material specimen has been kept in fresh water for at least 6 months in unloaded condition, the lower tensile or compression strength of the material shall be reduced by more than 20%. Prolonged exposure of glass-reinforced material to water may be replaced by immersing the specimen in boiling fresh water for 2 hours.

Fatigue strength which is determined according to test results on non-notched specimens on the base of $10^7$ cycles at symmetric loading, shall be not less than 25% of the lower limits of the tensile strength of the material.

6.3.10 If glass content in glass reinforced plastics differs from the design value, then tensile strength and modulus of elasticity values shall be re-calculated. Variation of glass mass content shall not exceed $\pm 10\%$.

6.3.11 Light fillers such as rigid foams or honeycomb plastics, used for sandwich structures, shall be non-sustaining combustion, be resistant to water, oil and liquid fuel, not subject to damage when being coated by polyester or epoxy resin as well as not subject to destruction by rodents.

6.3.12 Plastics based on hot-hardened resin may be used for ships up to 15 m long as well as for bulkheads, partitions, deckhouses and similar structures of any dimensions.

6.4 LAMINATED TEXTILES

Scope of application

6.4.1 The requirements of the present Chapter apply to textiles which have a rubber or plastic watertight coating and are intended for structures being under pressure in service conditions.

Properties

6.4.2 Laminated textiles shall be air-tight; their properties shall comply with Table 6.4.2.

Table 6.4.2

<table>
<thead>
<tr>
<th>Laminated textiles properties</th>
<th>Warp and weft properties</th>
<th>Coating adhesion (N/cm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tensile strength (kN/5cm), min</td>
<td>Breaking tensile elongation (%), max</td>
<td>Tear propagation on strength (N)</td>
</tr>
<tr>
<td>2.0</td>
<td>35</td>
<td>40</td>
</tr>
</tbody>
</table>

Note: The tensile strength may be reduced down to value considered sufficient for shells of particular structures according to the calculation agreed by the River Register, but not more than to four times the hoop stress developed in gas-filled pipes under the safety valve opening pressure.

For shells of inflatable liferafts when the material is air-tight, tensile strength in warp and weft directions may be taken not less than calculated by the formulae:

- for one-deck liferaft structure
  
  \[ T = 0.15D_r \]

- for two-deck liferaft structure
  
  \[ T = 0.095D_r \]

where \( T \) is warp and weft tensile strength of the liferaft laminated textiles (kN/5cm);

\( D_r \) is weight displacement of the liferaft with the rated number of people and provision onboard (kN).

Breaking tensile elongation of material for shells of inflatable liferafts in warp and weft directions shall not exceed 40%.

6.4.3 After ageing and bend test, the tensile strength in laminated textiles shall not differ by more than 10% of the initial value, and the shrinkage in warp and weft directions after ageing shall not exceed 2% from the initial dimensions.

When performing tensile tests of the adhesive joints of laminated textiles before and after ageing, the tear shall occur in the base material.

6.4.4 Type approval of laminated textiles in accordance with Appendix 10 requires the following tests:

- Tensile tests with the determination of break elongation on ten specimens each (five along the warp and five along the weft);
Tear propagation tests on ten specimens each (five along the warp and five along the weft);
- Delamination test on three specimens;
- Air tightness test on two specimens;
- Post-ageing tensile test;
- Bend test;
- Test of adhesive bond joints of laminated textiles before and after ageing on ten specimens each (five along the warp and five along the weft);
- Folding and shape stability tests after aging;
- Oil resistance test;
- Sea water resistance test;
- Cold resistance test;
- Ozone resistance test;
- The material mass shall be determined in accordance with GOST 32649.

Each batch of laminated textiles shall undergo the following tests:
- Tensile tests with the determination of break elongation on ten specimens each (five along the warp and five along the weft);
- Tear propagation tests on ten specimens each (five along the warp and five along the weft);
- Delamination test on three specimens;
- Air tightness test on two specimens;
- After tests for bending, ageing, post-aging folding and dimensional stability, oil resistance, cold resistance, ozone and sea water resistance the surface of laminated textiles shall be free from cracks, delaminations, colour changes, it shall not become stick.

6.4.5 The used colouring agents shall not adversely affect the properties of the base material.

6.4.6 On the surface of laminated textiles neither damages, recesses, dead folds, textile flaw marks, delaminations, spots, blisters, porosity nor other defects which may preclude their application in accordance with the purpose are acceptable.

Marking

6.4.7 Marking of laminated textiles shall be made in accordance with 1.3. In addition, the mass of material per unit of area shall be stated.

6.5 FOAM PLASTICS

General requirements

6.5.1 The requirements of the present Chapter apply to foam plastics used for the manufacture of items.

6.5.2 Type approval of foam plastics in accordance with Appendix 10 requires tests carried out to determine the following:
- Compression strength of foam plastic on three specimens in order to determine the maximum load resulting in abrupt destruction of the foam plastics structure, which shall be reached within 1 min approximately;
- Bend strength of foam plastic on three specimens;
- Apparent density of foam plastic on three specimens;
- Besides, the following tests are required:
  - Water absorption test on five specimens;
  - Oil product resistance test on three specimens;
  - Sea water resistance test on three specimens;
  - Ageing test on three specimens.

Each batch of foam plastics shall undergo tests, which determine compression strength, apparent density and water absorption of foam plastics.

Properties

6.5.3 The mechanical properties of foam plastics shall meet Table 6.5.3.

The mechanical properties of foam plastics affected by sea water and oil products shall not worse than stated in 6.5.3. The structure of foam plastics shall be of closed-cell type and shall not have shrinkage deformations in time which exceed admitted tolerances for linear dimensions specified by the technical documentation approved by the River Register.

Shrinkage of foam plastics used for filling-up cavities shall not break adhesion to boundary surfaces.
6.5.3 Mechanical properties of foam plastics

<table>

</tr>
</tbody>
</table>

6.5.4 Foam plastics shall have fine-cellular structure (cell dimension 0.1–0.5 mm) with closed cells in the cut foam plastics.

6.6 DECK PLATING

6.6.1 Deck plating shall comply with the requirements of 6.1.2.

6.6.2 Deck plating shall be manufactured and tested in compliance with the technical documentation approved by the River Register.

6.7 PLASTIC PIPING AND FITTINGS

6.7.1 The type of plastic, mechanical and electrical properties, testing scope and methods for plastic piping and fittings shall comply with the technical documentation agreed by the River Register.

6.8 ADHESIVES

6.8.1 Adhesive compounds for joining parts of structures and details subject to loading, shall have the manufacturer's documents which confirm properties of these compounds.

6.9 RETRO-REFLECTING MATERIALS FOR LIFE-SAVING APPLIANCES

6.9.1 Type approval of retro-reflecting materials for life-saving appliances in accordance with Appendix 10 requires the following tests:

- Tensile test;
- Test to determine the strength of adhesion of materials with an adhesive layer to different surfaces;
- Test to determine retro-reflection factor;
- Test to determine retro-reflection factor under a water film;
- Ageing test;
- Abrasion-resistance test;
- Sea water resistance test;
- Salt fog resistance test;
- Fungus resistance test;
- Bend test;
- Test for adhesion and resistance to contaminants.

For retro-reflective materials with an adhesive layer the strength of adhesion to different surfaces shall be determined after exposure to the ultraviolet irradiation and to distilled and sea water.

Each of the tests shall be made on three specimens only at approval tests of the type of material.

Each batch of material shall undergo tensile test, test to determine the strength of adhesion to different surfaces and test to determine the retro-reflection factor in accordance with Appendix 10.

Properties

6.9.2 The tensile strength of retro-reflective materials with an adhesive layer shall not be less than 0.6 MPa and of those with a warp for mechanical attachment — 13 MPa in the longitudinal direction and 9 MPa in the transverse direction.

6.9.3 Proceeding from the entrance angle and observation angle the values of the retro-
reflection factor \( R \) in \( \text{cd/}(\text{lx-m}^2) \) shall not be less than those specified in Table 6.9.3.

<table>
<thead>
<tr>
<th>Entrance value</th>
<th>Retro-reflection factor ( R ) (( \text{cd/}(\text{lx-m}^2) )) at observation angle</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>30°</td>
<td>140 135 70 12</td>
</tr>
<tr>
<td>45°</td>
<td>85  85  48  9.4</td>
</tr>
</tbody>
</table>

**Table 6.9.3**

6.9.4 When the material is under a water film and after ageing (see 3.19 – 3.21 of Appendix 10), the retro-reflection factor may be lowered by not more than 20% as compared to table Table 6.9.3, and after the abrasion test it may be lowered by not more than 50%.

6.9.5 Exposure to sea water, mildew, salt fog and ultimate temperatures shall not lower the retro-reflection factor of the material.

6.9.6 For retro-reflective materials with an adhesive layer the strength of adhesion to different surfaces shall not be less than 0.6 MPa.

6.9.7 Exposure to ultraviolet radiation, sea water and fresh water shall not lower the adhesion properties of retro-reflective materials with an adhesive layer.

6.9.8 After the effects of sea water during 10 min, salt fog during 4 hours, limiting temperatures in process of ageing and after the bend and adhesion tests, no cracks, delamination, bulging, stickiness, change of colour and size shall be observed.

6.9.9 The surface of retro-reflective materials shall be free from damages, recesses, creases, delaminations, stains or other defects prejudicial to the use of the material for the intended application.

**Marking**

6.9.10 The marking of retro-reflective materials shall comply with 1.3; the mass of material per unit area shall be specified.
### 7 WELDING PROCEDURE REQUIREMENTS

#### 7.1 GENERAL REQUIREMENTS

**7.1.1** The requirements of this Section cover welding of structures and elements subject to the technical supervision of the River Register in process of manufacturing.

Welding procedures and survey of welded joints of the structures shall be performed on the equipment which provides the quality required by Section 8 of the present Part of the Rules.

**7.1.2** Welding of structures and components shall be performed by certified welders (operators) who has got the Approval Certificate and using welding consumables and welding procedures in accordance with the requirements of the present Part of the Rules.

The welding site shall be protected from wind and precipitation.

**7.1.3** Welding conditions at negative air temperatures shall provide the possibility to produce welded joints in compliance with the requirements of the present Part of the Rules.

**7.1.4** Welding operations may be performed at any negative temperature of ambient air, provided that the conditions of 7.1.2 are complied with and the welding consumables have been tested in conformity with 9.2.8 at air temperature –25 °C. Otherwise the minimum permissible air temperature for non-preheated welding shall be established by the manufacturer of welding consumables and fixed at approving the welding consumables after appropriate testing has been performed.

At temperatures indicated in Table 7.1.4, the edges of connecting parts shall be preheated before welding to temperature not less than 20 °C over a width of 75 mm.

| Ambient temperature requiring heating of weldments edges |  
|---|---|
| Air temperature (°C), below | Items for welding |
| –25 | Plates over 20 mm thick |
| –15 | Forgings and castings of the ship’s hull |
| –10 | Structures of semi-killed and unkillled steel |
| –5 | Structures of low-alloy boiler steel; Boilers and pressure vessels (manufacturing and repair) |

**7.1.5** Low-alloy steel piping, piping of the steam main as well as piping which shall operate at temperatures above 350 °C shall be welded at temperatures of 0 °C and above.

**7.1.6** The structural requirements for welds aimed at ensuring their strength shall be found in the relevant Parts of the Rules.

**7.1.7** The edge preparation for welding shall comply with national standards\(^1\) or technical documents approved by the River Register.

**7.1.8** The edges of parts to be welded shall be prepared by methods, which comply with the requirements of the Rules for welded joints.

**7.1.9** The edges of the parts to be welded are to be free from oil, moisture, scale, rust, paint and other contaminating substances.

It is permitted to weld primed steel parts without removing the primer, provided that the primer is approved by result of tests (see 4 of Appendix 8).

---

\(^1\) GOST 5264, GOST 14771, GOST 8713.
7.1.10 When structures are welded at temperatures below 0 °C, the edges being welded shall be free from snow, hoar-frost, ice and shall be dry.

7.1.11 Welding operations shall be performed in such a sequence that to prevent impermissible (see Appendix 11 of RTSC) residual stresses or strains.

7.1.12 When it is necessary to preheat the parts before welding, the preheating temperature shall be determined taking into account the chemical composition of the metal, welding procedure, thickness of parts to be welded.

7.1.13 Underwater welding and cutting operations, as well as welding on structures having water on the reverse side shall be carried out according to the procedure approved by the River Register.

7.1.14 When plates or sheets shall be welded into a rigid contour, technological measures shall be taken to reduce the post-welding stresses.

Note. Rigid contour is an opening of closed perimeter with one of dimensions being less than 60 time the thickness of the plate in the given area. In complex structures a contour may be regarded rigid even at greater ratios of opening dimensions.

7.1.15 It is permitted to perform hot dressing both with mechanical effect and without it. No damages of the weld or plate surfaces are admissible. The heating temperature for hot dressing shall not exceed 650 °C, but in any case the heating shall not involve changes in the metal structure.

7.1.16 Post-weld heat treatment is required for elimination of residual stresses.

The type of heat treatment shall be determined by the manufacturer depending on the properties of material and shall be agreed with the River Register.

7.1.17 Components made of hull structural steel by cold bending may be welded as non-heat-treated, if the inner radius of bending complies with national standards indicated in 7.1.7. If there are no such standards, the radius shall be equal to at least the three times the thickness of the plate.

7.1.18 Welding consumables with controllable hydrogen content in the deposited metal shall be stored as well as annealed before use in accordance with the manufacturer’s recommendations.

7.1.19 Dimensions of fillet welds for structures shall be taken according to requirements of respective parts of the Rules; if the weld dimensions are not stated there, they shall be determined by national standards given in 7.1.17.

Throat thickness (design throat) shall be: at hand welding $a_h = a$; at machine welding (for the first pass) $a_m \geq 1.4 a$, where $a$ — the altitude of the isosceles triangle inscribed into the bead section (Fig. 7.1.19).

The relation between the leg of the fillet weld and the altitude of the isosceles triangle, inscribed into the bead section is: $k = 1.4a$ or $a = 0.7k$.

When replacing hand welding stipulated by the design by a machine one, the throat thickness or the weld leg (depending on what the calculation is based on) may be reduced, but by no more than 30% for single-pass welds.

![Fig. 7.1.19. For determination of design throat](image)

7.2 WELDING OF SHIP HULL AND EQUIPMENT

7.2.1 Welding of the parts to be assembled shall be performed using a technology which
provides the minimal post-welding stresses. Tack weld operations shall be performed by persons of the necessary qualification. Track welding shall be carried out using welding consumables of the grade required for welding of the given structure or of one grade higher. Tack welds shall be free from defects which could impair the quality of welded joints.

Cracks found in way of tack welds shall be eliminated by dressing and patch welding. Temporary fittings for assembling may be applied as less as possible, and it is necessary to dress and weld them without undercuts, cracks and other inadmissible defects (see 8.3).

Excessive cut-outs and other damages of the base metal occurred while removing temporary fittings shall be re-welded with after-grinding ensuring smooth transition to the base metal. When grinding, the base metal shall not be thinned to more than the plate thickness limit tolerances prescribed by national standards1.

Prominent remains of temporary fitting welds shall be removed with subsequent grinding from the following hull structures:

1. The strength deck (plates and longitudinal framing including continuous longitudinal coamings of cargo holds);
2. Hull bottom (plates and longitudinal framing);
3. Shipboards;
4. The sheerstrake and the bilge strake (plates and longitudinal framing);
5. Tank bulkheads;
6. Tank web framing;
7. Structures located in places subject to intensive vibration.

Thickenings are permitted if they do not exceed admissible tolerances for weld strengthening stated by the national standards. The necessity of grinding protruding weld residuals of temporary mounting fittings on other structures shall be stated by the designer.

7.2.2 When assembling butt joints, the admissible mutual relative displacement of plates is up to 0.1 plate thickness but not exceeding 3 mm.

7.2.3 Straightening of edges by deposit welding due to incorrect machining of the assembling parts or inaccurate assembling shall be performed according to the procedure approved by the River Register.

7.2.4 Welding consumables shall be chosen proceeding from the grade of steel to be welded in accordance with Table 7.2.4. Welding consumables intended for welding of steel grades A40, D40, E40 shall provide the mechanical properties \(R_{m}, R_{eH}, A_{5}\) in the deposited metal of not less than those required for these steel grades.

| Grades of welding consumables depending on the grade of steel to be welded |
|-----------------------------|-----------------------------|
| Grades of hull structural steel |
| normal strength | higher strength |
| A | B | D | E | A32, D32 | A36, D36 | A40, D40 | E32, D32 | E36, D36 | E40 |
| 1, 1S, 1T, 1M, 1TM | + | − | − | − | − | − |
| 2, 2S, 2T, 2M, 2TM | + | + | + | + | + | − | − | − |
| 3, 3S, 3T, 3M, 3TM | + | + | + | + | − | − | − | − |
| 1Y, 1YS, 1YT, 1YM, 1YTM | + | − | − | + | − | − | − | − |
| 2Y, 2YS, 2YT, 2YM, 2YTM | + | + | + | + | − | − | − | − |
| 3Y, 3YS, 3YT, 3YM, 3YTM | + | + | + | + | + | + | + | + |

The following shall also be considered:

1. For welded joints where normal strength steel is welded to higher strength steel, it is permitted to use welding consumables of lower grade from those permitted by Table 7.2.4 and the present paragraph for each particular grade of steel (e.g., in weldment of steels D32 and E32 grades welding consumables of grade 2 may be used);

2. For joints welded of steels of the same strength but differing by testing temperature at impact test it is permitted to use welding consumables of lower grade from those permitted by Table 9.2.4 for each particular grade of steel (e.g., in weldment of steels D32 and E32 grades welding consumables of grade 2Y may be used);

---

1 GOST 5521, GOST R 52927.
3 For welded joints where higher strength steels are welded or higher strength steel is welded to normal strength steel, welding consumables with controllable diffusible hydrogen content shall be used according to Table 9.2.4. Application of welding consumables with non-controllable diffusible hydrogen content is allowed only for steels with the carbon equivalent $C_{eq} \leq 0.41$ (see 2.2.2 of the present Part) after testing according to the program agreed with the River Register;

4 For weldments of higher strength steels welding consumables of grade 1Y may be used only for joints with the metal thickness up to 25 mm inclusive;

5 Welding consumables chosen according to Table 7.2.4, may be assigned also for welding steel other than prescribed by the Table if it is equivalent by the mechanical properties and chemical composition to the steel for which that welding consumable is approved;

6 Rutile-coated electrodes shall not be used for welding of the following joints:
   Intersectional field butts;
   All butts and seams of the ice strake of the outer plating;
   Butt joints of the longitudinal framing and butt joints of the hull with thickness over 20 mm;
   Stern-post, stem or butt joints welded in rigid contour conditions;

7 Acid-coated electrodes shall not be used for welding structures mentioned by Part 1 of the present Rules;

8 Welding consumables used for welding hull structures M-CTI (ice) class ships and icebreakers directly affected by ice, shall meet the requirements of 9.2.6. For this case the ratio of corrosion rates of welded joint elements shall be within 0.9 – 1.1.

Welding consumables shall be chosen proceeding from the grade of steel to be welded in accordance with Table 7.2.4.

7.2.5 Cut-outs exceeding those stated in 8.3.2 may be removed by patch welding or grinding.

7.3 WELDING OF SHIP MACHINERY CONSTRUCTION ITEMS

7.3.1 Welding consumables for ship machinery shall be chosen on the basis of particular steel grades used for their manufacturing taking the requirements of 7.2.4 into account.

7.3.2 If welded parts are intended for operation at high temperatures (above 60 °C) or in a chemically aggressive medium, those conditions shall be taken into account when selecting welding consumables.

7.3.3 Steel parts 30 mm thick or more shall be welded using welding consumables which would guarantee the cold cracking resistance of the weld; or the manufacturer shall take technological precautions (preheating, heat treatment, limiting of the minimal ambient air temperature during welding, etc) against cold cracking.

7.3.4 The welds in structures subject to dynamic loads shall be made with full penetration. The transition from the base metal to the weld shall be smooth.

7.3.5 Welding of ship shafting and crankshafts is permitted on condition that shaft properties are provided as required by the Rules. Non-destructive testing of all welds shall be carried out and the fatigue strength of welded joints shall be provided.

Before welding is commenced, the scope of the necessary experimental welding and the test program required by the Rules shall be agreed with the River Register.

7.3.6 Methods of welding, deposition welding, metal pulverization and other similar methods applied at the manufacture and repair of the ship machinery construction items shall be specified in the manufacturer's technical documents agreed with the River Register.

Ship shafts of carbon steel (hydrogen content up to 0.45 %), which are worn or have corrosive vapors, gases, liquids which can damage insulation and surfaces of parts or produce deteriorative deposits.
surface cracks may be restored by deposit welding provided that the wear or the depth cracks do not exceed 5% of the shaft diameter, but in all cases it shall not be more than 15 mm.

The whole shaft surface shall be checked for cracks prior to deposit welding. Furthermore, both places prepared for deposit welding and already welded places shall be checked for cracks. Detected cracks shall be rectified mechanically.

Prior to deposit welding the shaft shall be preheated over the entire thickness up to 350 – 650 °C.

The indicated temperature shall be maintained and monitored during the entire welding process. After welding the shaft shall be cooled at room temperature avoiding forced cooling.

Automatic single-pass or two-pass submerged arc deposit welding of the ship shafts made of carbon steel with hydrogen content of not more than 0.4% and magnesium content of not more than 0.8% may be performed without preheating.

After being mechanically treated the deposited metal shall be subject to surface cold rolling.

7.4 WELDING OF STEAM BOILERS AND PRESSURE VESSELS

7.4.1 Boiler welds shall be marked as to make it possible to identify the operator who performed the welding.

The longitudinal and circumferential welds of boiler shells shall be made with a back-sealing run with the exception of cases when the weld strength factor is to be taken 0.7 or less.

Cuts and openings in the boiler shell shall not cross circumferential or longitudinal welds of the boiler shell.

Welding of fastenings, catches and the like parts shall be prevented.

The longitudinal and circumferential welds of headers, boiler shells and pressure vessels shall be butt-welded.

7.4.2 Welding consumables for boilers and pressure vessels shall be chosen on the basis of specific steel grades used for their manufacturing taking in account the requirements of 7.2.4.

7.4.3 Rutile and oxide-coated electrodes are not permitted for the welding of boilers and pressure vessels of Class I (see 8.2.1 of Part IV of the Rules); these electrodes are permitted for boilers and pressure vessels of Class II and Class III, provided that those items are manufactured of carbon steel and the thickness of weldments does not exceed 20 mm.

7.4.4 Boilers and pressure vessels shall be heat treated according to recommendations of steel manufacturers.

The welded joints in parts which cannot be heat treated as a whole for stress relieving due to their dimensions or inappropriate structure may be subjected to local heat treatment. Such a heat treatment shall be performed by uniform warming-up of a sufficiently wide area along the weld (for a distance about 6 times the plate thickness on both sides of the weld) so as to prevent the spread of thermal stresses to other areas of the parts involved. Local treatment by means of a welding torch is prohibited.

7.4.5 Worn-out shell plates of boilers and pressure vessels may be repaired by deposit welding, in such a case the welded area shall not be larger than 500 cm², and the depth shall not exceed 30% of the plate thickness. If these conditions cannot be met, the faulty area shall be replaced by a new plate.

7.4.6 When manufacturing boilers, heat-exchangers and pressure vessels of Class I or Class II (see 8.2.1 of Part IV of the Rules), mechanical properties of welded joints shall be tested and for this purpose a control bar shall be welded in the following cases:

- Manufacturing of single products;
- Serial production — product standard sample;
- Alteration of structures of main units and parts;
- Application of new materials and welding procedures.
7.4.7 The control bars shall be attached to the longitudinal joint of a boiler or pressure vessel in such a way that the weld of the control bar is a continuation of the weld of the boiler or pressure vessel. The welding technique of the control bar shall be the same as employed in the welding of the boiler or pressure vessel weld.

The following specimens shall be cut out as shown in Fig. A12.2.5-1 and tested in accordance with the requirements of Appendix 10: one transverse tensile test specimen, two transverse bend test specimens, three impact test specimens.

The conditions of cutting specimens out of structures of Class III (see 8.2.1 Part IV of the Rules) and test conditions shall comply with 3.1 and 3.2 of Appendix 12.

7.5 WELDING OF SHIP PIPELINES

7.5.1 The type of welded joints in pipes shall comply with national standards.

7.5.2 Welding consumables for pipelines shall be chosen on the basis of steel grades used for their manufacture taking the requirements of 7.2.4 into account.

7.5.3 In the welded butt joints of pipes the complete root penetration shall be provided. Welding with the use of removable backing rings is permitted.

7.5.4 The use of the remaining backing rings in butt joints is permitted in pipelines where those rings do not adversely affect the performance. The remaining backing rings shall not be used for flange-to-pipe butt joints.

7.5.5 The welded joints in pipes shall be heat treated on pipes of low-alloyed steels or in the case of gas welding of steam mains operating at temperatures above 350 °C. Heat treatment method and the relevant procedure are determined proceeding from the chemical composition, purpose and required properties of pipes.

7.5.6 When welding pipes of chromium-molybdenum steel containing 0.8 % or more of chromium and more than 0.16 % of carbon, the edges to be welded shall be preheated to a temperature 200 to 230 °C. This temperature shall be maintained during the welding process.

7.5.7 Welding edges of the copper piping with a wall thickness of 5 mm and over shall be preheated up to 250 – 350 °C prior to welding. Nickel-copper pipes shall be welded without preheating. It is not permitted to braze joints of copper-nickel pipes.

7.5.8 When welding cargo pipelines of liquefied gas tankers, welded butt joints with the complete root penetration may be used without any restrictions. For design temperature below minus 10 °C butt welding shall be welded on both sides or be equivalent to butt joint welded on both sides. Welding may be performed with use of a backing ring, consumable insert or inert gas backup on first pass.

7.5.9 Backing rings shall be removed after welding pipelines of design pressure exceeding 1 MPa and design temperature of minus 10 °C and below. The scope of non-destructive testing shall be not less than specified in Table 8.2.3 for class I pipelines.

7.5.10 Butt-welded joints of liquefied gas pipelines made of carbon, carbon-manganese, low-alloy steel shall be heat treated after welding.

7.6 WELDING OF CASTINGS AND FORGINGS

7.6.1 Pre-heating or other technological measures which provide the necessary welding quality of steel castings and forgings independently of ambient air temperature, shall be undertaken when:

1. The carbon content of steel castings and forgings exceeds 0.25 %;

2. The carbon content of steel castings and forgings being the part of the hull structure of ships intended for navigation in ice (castings and forgings of sternframes, stems,
propeller shaft brackets and similar structures) exceeds 0.23%.

7.6.2 The preheating temperature and the heat treatment procedure for castings and forgings shall be determined depending on the design, size and service conditions in accordance with 7.1.4, 7.1.12, 7.1.16.

7.6.3 The faults in castings and forgings may be repaired by welding only if the steel has been previously checked for weldability (see 4 of Appendix 10) and the service conditions of the cast or forged part were considered.

Faults are eliminated by welding before final heat treatment is commenced. Faults which appear systematically in castings and forgings shall not be eliminated by means of welding.

7.6.4 Faults in castings shall be eliminated after sprues and heads have been removed and the castings have been thoroughly cleaned of sand, scale and extraneous inclusions. The surface subject to re-welding shall be ground to sound metal so as to ensure full penetration throughout the welded area.

The walls of areas to be re-welded shall be gently sloped and the prepared deepening surface shall not have sharp corners.

7.7 WELDING OF CLAD STEELS

7.7.1 The edge preparation for welding shall comply with technical documents approved by the River Register.

The edges shall be prepared by machining or grinding.

The edges of parts to be assembled shall be fit and shall not be out of alignment on the clad side.

7.7.2 The corrosion resistance of weld metal on the clad side shall be equal to that of the cladding. The thickness of the corrosion-resistance layer of the weld shall not be less than that of the cladding.

The chemical composition of weld metal on the clad side (except the root zone) shall correspond to the chemical composition of the cladding metal.

7.7.3 As a rule, the weld shall be made first on the base plate surface and then on the clad side. Welding on the base plate side shall be done so that no melting of the cladding layer occurs. Prior to welding of the clad side the weld root shall be ground to sound metal by machining or grinding only. For the root pass the same welding consumables shall be used as for the clad layer welding. The clad layer shall be welded so as to prevent mixing of the alloyed metal with non-alloyed one. The cladding layer shall be welded using welding electrodes and wires of the smallest diameter. The welding is carried out at a low current intensity. The weld on the clad surface shall be made up of at least two layers. When welding the cladding layer, transverse weaving of electrode is not permitted. Where the root top layer width is such that it shall be disposed in several passes, the last one shall be made along the middle of the weld.

7.7.4 When welding pipes of clad steel, where welding on both sides is impossible, the entire joint shall be welded using welding consumables corresponding to the cladding material. When welding clad sheet steel, the entire joint shall also be welded with the use of welding consumables suitable for the cladding material.

7.8 WELDING OF HIGH STRENGTH STEEL

7.8.1 The welding consumables intended for welding of high strength steels shall be approved in accordance with 9.5 and the welding methods — in accordance with 7.1.2.

7.8.2 Compliance of the method and procedure of welding with requirements of the Rules shall be agreed by the River Register after fabrication testing by an agreed program. For this purpose the manufacturer of welded structures shall submit the documented preheating temperature, the liner power consumption during welding, the post-weld heat treatment and the temperature between runs.

The manufacturer shall use a system of welding modes’ recording and control including the temperature measurement between
runs and shall submit the inspection results to the River Register upon request.

7.8.3 Welded joints shall be made by multi-pass welding.

7.8.4 It is not permitted to fire arc outside the edges prepared for welding.

Temporary mounting fittings shall be welded-on with local heating provided.

Temporary fittings are removed by machining with subsequent dressing flush with the base metal surface.

7.8.5 The edges prepared by gas cutting shall be subsequently machined. Roots shall be dressed by machining only. Heating for straightening is permitted only if the required properties of the base metal and welded joint are ensured.

7.9 WELDING OF CAST IRON

7.9.1 Defects in castings made of cast iron may be eliminated by welding using a welding procedure tested according to the program agreed with the River Register.

7.10 BRAZING

7.10.1 Brazed joints in the items shall be executed in conformity with GOST 19249 or technical documentation agreed by the River Register.

7.11 WELDING OF ALUMINIUM ALLOYS

7.11.1 Welding operations shall be performed by the most expedient method, which ensures the joints quality required by 8 of the present Part of the Rules, mechanical properties in compliance with 9.6 and corrosion resistance not worse than that of the base metal. Chemical composition of the weld shall match that of the base metal.

7.11.2 Wherever possible, welded joints shall be located in areas exposed to the lowest stresses. Welding shall be effected in the down-hand position.

7.11.3 Directly before welding (tack welding) the edges of aluminium or aluminium alloy components shall be degreased with special solvents (acetone, alcohol, turpentine) and then cleaned with wire brushes. Jacked spots shall also be cleaned with a steel wire brush before welding. In the case of multi-pass welding each pass of deposit shall be brushed before the next pass is applied.

7.11.4 Welding consumables of aluminium and aluminium alloys must be cleaned in order to eliminate oxide film.

7.11.5 Aluminium alloys welding may be welded on remaining or removable backings. The removable backings shall be made of stainless steel. The remaining backings shall be made of the same alloy grade as that used for the weldments.

7.11.6 In case of a double-pass welding it is necessary to dress the root of the weld by chipping, planning or milling to sound metal before a sealing pass is applied to the back of the weld. The root shall not be dressed by abrasive disks.

7.11.7 It is permitted to hot-straighten the structures made of aluminium and aluminium alloys. The heating temperature shall correspond to the properties of a given alloy.

7.11.8 Where a flux is used, it shall be neutral.

7.11.9 In the area where structures made of aluminium alloys shall be riveted, all welding operations shall be completed prior to riveting operations.

7.12 WELDING OF COPPER ALLOYS, HEAVY METALS AND OTHER NON-FERROUS METALS

7.12.1 Welding of copper and copper alloys, as well as of heavy metals and other non-ferrous metals shall be carried out in accordance with the technical documentation agreed with the River Register.
8 INSPECTION OF WELDED JOINTS

8.1 INSPECTION MANAGEMENT

8.1.1 Inspection of welding operations and welded joints during fabrication of structures and components shall be performed by the technical control service with the Recognition Certificate issued by the River Register. The inspection results shall be registered according to the procedure adopted at the works, filed until the commissioning of the item and submitted to the River Register for the consideration.

8.1.2 Non-destructive testing of welds may be effected by the following methods:

.1 Visual examination (visual inspection);
.2 Magnetic particle examination (magnetic particle inspection);
.3 Dye penetrant examination (dye penetrant inspection);
.4 Radiographic examination (radiographic inspection, X- or gamma-ray examination);
.5 Ultrasonic examination (ultrasonic inspection);
.6 In process of and by results of tests for tightness.

Other testing methods may be used in compliance with GOST 18353.

The application of a particular non-destructive testing method is set up in the technical documentation of the design depending on the structure and the type of welded joint.

The non-destructive testing is to be performed in compliance with the national standards or by methods agreed with the River Register.

Where the heat treatment of welded assemblies is required, the final non-destructive testing of welded joints shall be carried out upon its completion.

For welding of higher strength steels and complex shape structures (e.g. joints in cargo masts and posts), non-destructive testing shall be performed not earlier than 72 hours after welding is completed.

Non-destructive testing of welded joints shall be effected by laboratories recognized by the River Register.

8.1.3 The following requirements are imposed on testing of independent cargo tanks of types A and B (see 1.2.1.8 Part IX of the Rules), as well as semi-membrane tanks:

.1 If the design temperature is minus 20 °C or below, all butt welded joints made with full penetration of cargo tanks shell plates shall undergo 100% radiographic examination;
.2 At the design temperature above 20 °C all intersections of butt weld joints with full penetration and not less than 10% of other butt weld joints with full penetration of cargo tanks structures shall undergo radiographic examination;
.3 In each case weld joints of other cargo tanks structures including welding of stiffeners as well as other reinforcement and fittings shall undergo non-destructive testing;
.4 All testing methods and assessment criteria shall be agreed with the River Register for compliance with requirements of the Rules.

In cases prescribed by approved technical documentation ultra-sonic inspection may be carried out instead of or in addition to radiographic examination.
8.1.4 Testing of independent cargo tanks of type C (see 1.2.1.8 Part IX of the Rules) and pressure vessels shall be performed in accordance with the requirements of 6.6 Part IX of the Rules.

8.1.5 Non-destructive testing of weld joints of liquefied gas tankers structures, or independent tanks structures which provide support for tanks with inner insulation, shall be performed with respect to the requirements of 6.7.30.2 Part IX of the Rules.

8.1.6 Scope and methods of weld joints inspection to be carried out for liquefied gas tankers built-in tanks and membrane tanks shall be approved by the River Register for compliance with requirements of the Rules.

8.1.7 Non-destructive testing of liquefied gas tankers pipelines weld joints shall be performed in accordance with the requirements of 6.12.9.2 Part IX of the Rules and 8.2.3 (complete radiographic examination).

8.1.8 Weld joints of liquefied gas tankers additional barrier structures shall undergo radiographic examination in scope agreed with the River Register.

If the outer hull plating is a part of additional barrier, all butt sheerstrake welded joints and intersections of all butt welded joints with side plating shall undergo radiographic examination.

8.1.9 On completion of welding operations on a given structure the technical control service specifies locations of non-destructive testing according to the technical documentation approved by the River Register. In case of doubt the examination of additional areas may be performed.

8.1.10 In case if revealed defects parameters exceed permissible limits specified by 8.3, testing shall go on along both sides of the inspected area until satisfactory results are obtained. In addition, two lengths of the same weld shall be inspected in other areas for each radiograph with unsatisfactory rating (see 8.3).

The results of additional inspection shall be submitted together with the initial inspection documents before the defects have been rectified. Where the scope of initial and additional inspections of the weld exceeds 50 % of the weld length, the weld shall be additionally inspected along the whole length.

8.1.11 Examination of the same weld by both ultrasonic and radiographic methods is permitted.

8.1.12 When shell-planting welds are inspected, the radiograph shall be located at the intersection on the butt axis so as to partially cover the seam as shown in Fig. 8.1.12-1.

When carrying out ultrasonic examination, on each side of the butt 100 mm lengths shall be examined as shown in Fig. 8.1.12-2.

Fig. 8.1.12-1. Radiograph location when inspecting welds

Fig. 8.1.12-2. Groove examination on each side of the butt
8.2 SCOPE OF NON-DESTRUCTIVE TESTING

8.2.1 The scope of non-destructive testing of the hull welds is specified according to the technical documentation approved by the River Register according to Table 8.2.1-1.

The number of radiographs of the weld lengths in the shell plating for 0.5L amidships is calculated by the formula:

\[ N = \frac{L(B + H)T}{45}, \]

where \( N \) is number of areas subject to testing; \( L, B, H \) are length, breadth and board depth of the ship (m);

\( T \) is factor depending on the ship length which is determined according to Table 8.2.1-2.

**Table 8.2.1-2**

* Scope of welded joint visual examination — 100 % of number of butts. Results of visual examination may be supplemented by magnetic particle testing or liquid penetrant testing.

8.2.4 In addition to the structures specified in Tables 8.2.1, 8.2.2 and 8.2.3, such elements of machinery and deck gears as joints in cargo masts and posts, etc. shall undergo non-destructive testing. The weld lengths to be tested in these structures shall be established upon agreement with the River Register.

Welded joints quality of stress-bearing elements of cargo-handling appliances metal structures (see 6 Part V of the Rules) shall be inspected by radiographic or by other non-destructive method approved by the River Register. Not less than 10% of the welded joints shall be subject to inspection. The places of intersection of welded joints shall be subject to mandatory testing. Circular continuous butt-welded joints shall be examined over their whole length.

8.2.5 The River Register may determine a distribution of non-destructive testing weld lengths differing from that specified in the approved by the River Register technical documentation depending on the particular conditions under which welding is carried out.

8.2.6 The works shall determine on the basis of radiographic and ultrasonic testing the percentage of welded joint defects not less

</table>

1. Results of visual examination may be supplemented by magnetic particle testing or liquid penetrant testing.
2. All welded joints (including those not specified in the Table) shall be subject to testing.
3. The number of radiographs shall be up to 20 % of the total number of radiographs stated for the area 0.5 L amidships.
4. Where ice strengthened, the ice strake butts are particularly subject to testing.
5. Intersections between seams and butts are subject to testing.

than once in six months and report the results to the River Register.

The index of defects in welded joints $K$ (%) shall be determined by the formula:

$$K = 100/\ell,$$

where $\ell$ is the total inspected weld length, where the weld quality is found unsatisfactory (m);
s is the total inspected weld length (m).

The number of inspected weld lengths shall be increased by 10 % for every percent of rejected welds if the percentage of defects is more than 5 %.

8.2.7 At the refitting and repair of ships the number of inspected weld lengths is determined depending on the shape and purpose of structures and scope of welding taking into account the requirements of 8.2.1 – 8.2.6.

8.3 ASSESSMENT OF WELD QUALITY

8.3.1 The assessment of the weld joints quality by means of radiography or ultrasonic examination may be performed by a three-point scale, or by other scales1 agreed with the River Register.

The three-point scale assessment criteria are specified according to 8.3.3.

For other testing methods the assessment of the weld joints quality shall be performed taking in account defect dimensions permitted by national standards and by scales approved by the River Register.

8.3.2 The assessment criteria for particular methods of inspection and acceptable marks are specified in Tables 8.3.2-1 and 8.3.2-2.

Testing results are recorded to the quality control document (see 8.1.1), which shall contain the list of defective weld lengths, their dimensions, types, marks of defects and their location.

When using the data from Tables 8.3.2-1 and 8.3.2-2, the following shall be considered:

1 For defects with footnote 1 the maximum length of a single undercut shall not exceed 0.5 t, with the total length of undercuts at each controlled weld section not exceeding 5 % of its length;

2 The maximum length of a single defect with footnote 2 shall not exceed t with the total length of incomplete fusion at each controlled weld length not exceeding 5 % of its length;

3 Minimum mark of welded joints which have footnote 3 in Table 8.3.2-1 shall be raised to II for locations with high stresses or vibration.

8.3.3 Three-point quality assessment scale of welded joints in steel structures includes the following:

1 Mark III.

The welded joint is free from internal defects or the following defects are present:

- Isolated gas or metal (tungsten) inclusions, each with dimensions up to 0.1 of the weld thickness, but not more than 2 mm;
- Isolated slag inclusions each with dimensions up to 0.3 of the weld thickness, but not more than 3 mm, with the area not exceeding 5 mm².

The average number of revealed defects shall not exceed one for each 100 mm of the weld length;

2 Mark II.

The weld is free from cracks, pipes, incomplete or poor fusion. The maximum permissible length, width and total length of pores, slag or tungsten inclusions, chains and clusters of these defects as well as oxide inclusions for any 100 mm of the inspected weld length are specified in Table 8.3.3.2;

3 Mark I.

The weld is free from cracks, pipes, incomplete or poor fusion. The maximum permissible length, width and total length of pores, slag or tungsten inclusions, chains and clusters of these defects as well as oxide inclusions for any 100 mm of the inspected weld length are specified in Table 8.3.3.3.

9 WELDING CONSUMABLES

9.1 GENERAL PROVISIONS

9.1.1 The structures subject to the technical supervision of the River Register in process of manufacturing and repair, shall be welded only using the welding consumables which have documents issued by the River Register according to requirements of 2.5 RTSC.

9.1.2 For all welding materials intended for welding of liquefied gas tankers cargo tanks, deposited weld metal and butt welded joints shall be tested in accordance with the requirements of Appendix 12.

9.1.3 Chemical composition of deposited weld metal for welded joints of liquefied gas tankers is specified in accordance with the technical documentation approved by the River Register.

9.1.4 The welding consumables’ specifications shall contain at least the following data:
- The name, grade, type and purpose of the welding consumable;
- The grade of the welding consumable in accordance with the Rules;
- The chemical composition of deposited metal;
- The mechanical and technological properties of deposited metal and welded joint;
- The welding procedure and conditions;
- The brief description of the manufacture process of welding consumables as well as quality control methods;
- Testing program.

9.1.5 In general, for the purpose of welding consumables approval the following shall be determined:
- Mechanical properties of the weld metal and butt weld;
- Resistance of weld and butt weld to hot cracking at welding tee-joint assembly.
- The following shall be determined additionally, if so required by the Rules:
  - Diffusible hydrogen content in the deposited metal (see 9.2.4 and 9.2.7);
  - Resistance of the weld metal and welded joint to cold cracking at welding (see 9.2.5 and 9.2.8);
  - Corrosion resistance of the welded joint in sea water (see 9.2.6 and 9.2.9).
- The scope of test for welding consumables batch is specified according to Appendix 12.

9.1.6 Fillet weld electrodes including those for welding with sloping and lying electrode, are submitted to the following tests:
- Determination of the deposited metal properties according to 3.1 of Appendix 12;
- Tee-joint testing;
- Hydrogen test according to 9.2.7.

9.2 WELDING CONSUMABLES FOR HULL STRUCTURAL STEELS

General provisions

9.2.1 Welding consumables for normal strength hull structural steel are divided into grades 1, 2 and 3; those for welding of higher strength hull structural steel — grades 1Y, 2Y, 3Y; those for welding of high strength hull structural steel — grades 3Y, 4Y and 5Y.

Grades of welding consumables for welding high strength steel have an additional index, which indicates the minimal yield limit of the material (see 9.5).
Compositions of welding consumables which are admitted for automatic welding are marked as follows:

Two-pass welding — T;
Multi-pass welding — M;
Two- and multi-pass welding — TM.

Material compositions admitted for semi-automatic welding are marked with index S.

9.2.2 The mechanical properties and impact energy $KV$ to be determined by results of the deposited metal testing shall comply with Table 9.2.2-1, those of the welded joint — Table 9.2.2-2 for the relevant grade of welding consumable.

9.2.3 Welding consumables for hull structural steels shall be chosen in accordance with Table 7.2.4.

9.2.4 Proceeding from the diffusible hydrogen content in the deposited metal, which is determined according to 9.2.7, welding consumables may be designated (see 9.1.5) by the River Register as “I”, “II” or “III” according to Table 9.2.4. The method of determining the hydrogen content shall be indicated in the approval testing protocol. The diffusible hydrogen content calculation shall be corrected to the standard conditions by temperature and pressure ($20^\circ C$ and $101.3$ kPa).

$^1$ Deposited metal received by using welding consumables of grades 1 and 1Y shall be tested at the temperature $+20$ °C, grades 2 and 2Y — at $0$ °C, grades 3 and 3Y — at $–20$ °C.

**Table 9.2.2-1**

**Required mechanical properties of deposited metal**

**Table 9.2.2-2**

**Required mechanical properties of welded joint**

$^1$ Deposited metal received by using welding consumables of grades 1 and 1Y shall be tested at the temperature $+20$ °C, grades 2 and 2Y — at $0$ °C, grades 3 and 3Y — at $–20$ °C.

$^*$ For test assemblies welded in the vertical position — not less than 34 J.
9.2.5 Welding consumables of any grade intended for welding normal strength steel with the carbon content of 0.22 % and more or similar steel to other steels as well as for welding higher strength steel shall ensure that no post-welding cold cracks are formed in the weld metal and welded joint when the welding is conducted at a temperature down to –25 °C and the sulphur and phosphorus content in the weld metal do not exceed 0.03 % of each element.

9.2.6 Welding consumables intended for welding of hulls of river-sea navigation ships shall ensure equal corrosion rates of welded joint (the weld metal and area of thermal effect) and the base metal in sea water.

9.2.7 Hydrogen test shall be performed by method stated in Appendix 9.

9.2.8 The cold-cracking resistance of the weld metal and the welded joint is determined according to the method stated in Appendix 7.

9.2.9 The sea water corrosion resistance of the welded joint is determined by results of testing performed according to the method stated in Appendix 6. Tests to determine the mentioned resistance may be carried out also using alternative procedures if their compliance with the requirements of the Rules is approved by the River Register.

9.3 WELDING CONSUMABLES FOR BOILER STEEL

9.3.1 Welding consumables for boiler steel are fully covered by the requirements of 9.2 for welding of hull structural steel, except the cold-cracking resistance and sea water corrosion resistance testing. Additionally the requirements of the present Chapter shall be considered.

9.3.2 For the purpose of testing welding consumables for boiler steel an additional set of specimens for post-ageing impact testing in accordance with 2 of Appendix 10 shall be prepared from the deposited metal test assemblies and butt welds.

9.3.3 When testing welding consumables intended for steels to be used at 350 °C and above, tensile tests at maximum working temperature shall be carried out to determine proof stress \( R_{p0.2} \).

Tests are performed in accordance with requirements of national standards\(^1\), and tests results are assessed taking into account the same standards.

9.4 WELDING CONSUMABLES FOR WELDING STEEL INTENDED FOR MANUFACTURING OF THE SHIP MACHINERY

9.4.1 Welding consumables approved for welding of hull structural or boiler steels may be approved for welding steels intended for manufacturing of the ship machinery, arrangements and deck gears, piping without additional testing when they are made of hull structural steel or boiler steel, or steel similar to hull structural steel by its chemical composition and mechanical properties specified by the present Part of the Rules.

In all other cases welding consumables for these objects shall be tested on that steel, which they are intended for.

9.5 WELDING CONSUMABLES FOR HIGH STRENGTH STEEL

**Deposited metal tests**

9.5.1 The preparation of the test assemblies, their dimensions and quantity, as well as the deposited metal tests shall comply with the requirements of 2.1, 3.1, 4.2, 5.2 and 5.3 of Appendix 12 proceeding from the welding consumables used.

Results of the specimens tests shall meet the requirements of Table 9.5.1.

**Welded joint test**

9.5.2 The preparation of the test assemblies, their dimensions and quantity, as well as the welded joint tests shall comply with the requirements of 3.2, 4.3, 5.2 and 5.3 of Ap-

---

\(^1\) GOST 9466, GOST 2246.
pendix 12 proceeding from the welding consumables used.

Test assemblies shall be made of high strength steel with a minimum tensile strength complying with the declared grade.

Results of the specimens tests shall meet the requirements of Table 9.5.2.

**Determination of the hydrogen content**

9.5.3 Welding consumables shall undergo testing in order to determine the hydrogen content according to 9.2.7 and shall comply with the requirements for the metal with the index of hydrogen content HH.

### 9.6 WELDING CONSUMABLES FOR ALUMINIUM AND ALUMINIUM ALLOYS

9.6.1 Welding consumable intended for welding a particular alloy shall be tested on that alloy.

9.6.2 The test results obtained on specimens described in 8.2 of Appendix 12 shall satisfy the following requirements:

For welded joint specimen the tensile strength \( R_m \) shall be not less than \( 0.9 R_m \) of the base metal, the angle of bending — not less than \( 120^\circ \) over a mandrel with a diameter four-fold the specimen thickness;

For weld metal specimens the tensile strength \( R_m \), the yield point \( R_{0.2} \), the elongation \( A \) and the reduction of area \( Z \) shall be specified on agreement with the River Register.

No defects shall be revealed in the tee-joint samples fracture surface which can not be negligible in accordance with the requirements of Tables 8.3.2-1 and 8.3.2-2.

### 9.7 GROUNDINGS NOT-REMOVED PRIOR TO WELDING

9.7.1 The possibility of approval of grounding is established according to the test results of tee-joint samples. Tests of butt joints may be required there are any doubts in the uniqueness of test results of tee-joints.

1 Welded joint provided by using welding consumables of grade 3Y shall be tested at the temperature -20 °C, grade 4Y — at -40 °C, grade 5Y — at -60 °C.

Butt joint sample without grooving at manual welding is required when deep-fusion electrodes are used.

9.7.2 Grounding shall be tested on high structural steel of the highest grade from those for which it is intended. Testing is conducted by those welding methods for which the grounding shall be used.

9.7.3 Testing method is specified in Appendix 8.
TEST METHOD OF SHIP STRUCTURAL MATERIALS FOR NON-COMBUSTIBILITY

1 General requirements

The following materials shall be tested: homogeneous and composite non-metal ship structural materials: construction, finishing, insulation materials etc.

Proceeding from the test results materials are divided into two groups according to 2.1 Part III of the Rules: non-combustible and combustible ones.

2 Test specimens

Test specimens shall be of cylindrical shape with diameter \((45 \pm 2)\) mm, height of \((50 \pm 3)\) mm and volume of \((80 \pm 5)\) cm\(^3\). Five specimens shall be tested.

When the material thickness is less than 50 mm, the specimens shall be made up of single circles with diameter of 45 mm which shall be put horizontally into the holder and fixed in it. Density of the specimen shall be the same as that of the material tested. Thickness of specimens of composite materials shall be brought to the required value of 50 mm by the proportional thickness change of material of single components.

Material of the specimen end surfaces shall be the same as that of the front-face (outer) surface.

Where it is impossible to make specimens of the required dimensions, separate components shall be tested.

Each specimen shall have 2 mm-diameter opening on the top in the axis direction for thermocouple.

Prior to testing specimens shall be kept at the temperature of \((60\pm5)\) °C for 20 hours, then cooled down to the ambient temperature and weighed with 0.1 g accuracy.

3 Testing equipment

Tests shall be conducted on the device shown on Fig. A1.1.

Fig. A1.1. Testing device for non-combustibility tests;

It is an electrical furnace 6 mounted on a special pedestal 11. The furnace is a cylindrical reaction chamber formed by the tube 8
with the walls \((10 \pm 2)\) mm thick made of aluminous material with density \((3000 \pm 300)\) kg/m³. The reaction chamber is heated by one or several electric coils 7 laid outside the tube in such a way to provide uniform temperature zone of \((750 \pm 10)\) °C at least 65 mm high inside the chamber. The space between the tube and the protective housing 10 made of steel 1 mm thick is filled with insulation 9 made of non-flammable heat insulating material. From above and from below insulation is covered by cardboard or plate made of non-flammable heat insulating material \((10 \pm 1)\) mm thick.

The reaction chamber in its lower part houses a cone air stabilizer 13 made of steel 1 mm thick which is fitted with by means of a gasket made of non-flammable heat insulating material. The inner surface of the stabilizer is polished and the outer surface is insulated from the outside by fibre insulation 12 which is 25 mm thick.

At the upper open end of the reaction chamber an exhaust shroud 4 is installed which is made of steel 1 mm thick and insulated from the outside by fibre insulation 5 which is 25 mm thick. The furnace 6 shall be mounted on the pedestal 11 in such a way;

- that the distance from the lower end of the stabilizer to the device foundation is at least 250 mm.

The specimen holder 3 is suspended to the lower end of the tube which is fixed to the lath 1 moving towards the guide 2.

The cylindrical holder (Fig. A1.2) shall be made of chromium-nickel heat-resistant steel. The bottom of the holder is a perforated plate 0.5 mm thick. The weight of the holder shall be within 10–40 g.

The exhaust shroud 4 (see Fig. A1.1) is equipped with the fixation device for thermocouples inserted into the reaction chamber.

For temperature measurements chromel-alumel protected thermocouples shall be used.

Fig. A1.2. The specimen holder
with the outer diameter of 1.5 mm. The diameter of the thermocouple wire is 0.2 mm. The thermocouple response time is 15–20 s. Temperature is registered by means of secondary device with measurement limits 0 – 1000 °C and error not exceeding 0.5 %.

In order to produce constant temperature mode in the reaction chamber electric current shall be fed to the electric coils via voltage stabilizer and autotransformer. The maximum permitted voltage deviation from the nominal value is ±5 %.

4 The device calibration

Prior to the operation it is necessary to make certain that all the equipment is in working condition, i.e. the secondary device is correct, thermocouples have been installed and connected to the device and the specimen introducer operates smoothly.

When the specimen is newly introduced or the electrical coils have been replaced, it is necessary to determine the location of uniform temperature zone along the height of the furnace reaction chamber. Temperature is measured along the whole height of the reaction chamber at the distance of 10 mm from the wall in three points evenly distributed along the circumference. The zone shall be detected where temperature fluctuations do not exceed ±10 °C. This zone shall be not less than 65 mm high.

5 Testing

Prior to testing it is necessary to make certain that all the equipment is in working condition and protected from draught and direct sunlight or artificial illumination.

Before testing specimens, the furnace shall be warmed and the inside temperature of (750±10 °C) shall be maintained for 10 min.

A specimen shall be put into the holder. To measure the temperature inside the specimen a thermometer shall be inserted through 2 mm-diameter hole and fixed in the centre of the specimen.

To measure the temperature in the furnace the hot thermojunction shall be located at 10 mm distance from the reaction chamber wall in the centre of the height of uniform temperature zone.

To measure the specimen surface temperature the hot thermojunction of another thermocouple shall be located in the centre of the specimen height and be in contact with its surface in the point antipode to the thermo-couple for measuring the temperature in the furnace.

The holder with the specimen must be smoothly introduced into the reaction chamber within not more than 5 s. The specimen shall be located in the centre of uniform temperature zone and be equally distant from the chamber walls. A stop-watch and secondary device are switched on at the moment of the specimen introduction.

During tests the following shall be determined: the maximum temperatures in the furnace, on the specimen surface and inside it, initial self-ignition time and the prolongation of combustion.

The specimen shall be tested within 20 min or until reaching the maximum temperatures.

After testing the specimen shall be weighed and the percentage mass loss shall be calculated.

6 Test results

Material is found non-combustible, when during the tests of all the five specimens the following has not been observed:

- Increase of the average temperature in the furnace by more than 50 °C compared with (750±10) °C;
- Increase of the average temperature on the specimen surface or inside it by more than 50 °C compared with (750±10) °C;
- Flame burning for more than 10 s;
- The average mass loss by 50 % or more compared with the initial mass for specimens prepared for testing.

When the material does not comply with at least one of the above requirements, than it is found combustible. The test results shall be filed as follows:

Conclusion ________________________ Performer ________________________ (signature)
TEST METHOD OF SHIP STRUCTURAL MATERIALS FOR FLAME PROPAGATION

1 General requirements

The following materials shall be tested: finishing and facing materials, varnishes, paints applied on combustible or non-combustible base as well as construction and insulation materials in cases specified by Part III of the Rules, when flame propagation ability of their surfaces shall be assessed.

Proceeding from the test results materials are divided into two groups according to 2.1.3 Part III of the Rules: slowly or rapidly propagating flame along its surface.

The degree of flame propagation along the surface of the metal or composition is defined by index \( I \) which is dimensionless quantity determined by the present test method.

2 Test specimens

Test specimens shall be made of the materials or compositions to be tested and shall be \((140 \pm 2) \text{ mm wide and } (320 \pm 2) \text{ mm long. The actual thickness of the specimens is not standardised. Three specimens shall be tested.}

Test specimens shall be manufactured using the same technology as adopted for the manufacture of the given structure.

In process of testing finishing and facing materials, varnishes, paints shall be applied to the same base surface as in the structure.

Prior to testing the specimens shall be kept at the temperature of \((60 \pm 5) \text{ °C for 20 hours, then cooled down to the temperature of the room where testing is performed.}

The tested surface of the specimen shall be divided by marking into 10 equal sections (sections 0, 1, 2, ...,9). Marks on the surface shall coincide with the marks on the frame of the specimen holder.

3 Testing equipment

The test device is shown on Fig. A2.3-1. The device consists of an upright 7, a radiation panel 5, an exhaust device 2, a specimen holder consisting of the frame 4 and the prop 6, electrical-type instruments and monitoring devices. The frame is made of steel 0.8–1.0 mm thick. On the frame edges each 30 cm are shown by marks (see Fig. A2.2, No. 0–9). The radiation panel is an assembly of three infrared radiation burners that can operate on liquefied and natural gas. The heating temperature of the burner ceramics surface shall be 850–900 °C. The heat-resistant steel net screen is mounted before the ceramics in order to increase radiation and to reduce the influence of air flows.

Combustion products are collected by the exhaust device with dimensions 700×360×360 mm made of steel plate mounted above the specimen holder 45 cm higher than the panel 5 at the distance of 10 mm from it. The upper part of the device is fitted with a thermocouple 1 of 0.5 mm-diameter wire to measure the temperature of smoke gases which is connected to a secondary device with measurement limits 0–400 °C and error not exceeding 0.5 %.

The igniting gas burner 3 with 2 mm-diameter aperture is mounted in front of the radiation panel.
Fig. A2.3-1. Device for ship structural materials testing for flame propagation;

Fig. A2.3-2. Device for flame propagation testing;

The device is arranged in such a way that the igniting flame 20 mm high touches with the specimen surface in the centre of the upper (zero) section.

4 Testing

Prior to testing it is necessary to make certain that all the equipment including monitoring instruments is in working condition and have calibration documents. During the tests the normal ambient conditions shall be maintained, i.e. air temperature 18–22 °C, relative humidity 50–80 %.

During testing forced ventilation of the room where testing is being conducted shall be switched off and the equipment shall be protected from draught. The radiation panel shall be heated up to temperature (875±25) °C maintained within 10 min. For a new installation as well as after repair or replacement of the components of the installation it is necessary to calibrate the equipment and to determine:

The temperature of smoke gases $t_0$ for testing of non-combustible specimen of asbestos-cement plate;

The installation heat factor $\beta$ which is determined by the quantity of heat applied to the specimen surface per minute which is necessary for rise of the temperature of smoke gases by 1 °C.

It is determined $\beta$ on the test specimen with thickness of 10 mm and density of 1.75 g/cm³ which is fixed in the holder frame and inclined at angle of 30° to the radiation panel fixed in the vertical position. The specimen holder shall be installed in such a manner that the distance from the specimen edge to the panel grid is 70 mm.

In the beginning $t_0$ shall be measured. Then the ignited gas calibrating burner with a slot nozzle shall be installed at half-height of the specimen (the nozzle thickness is 40 mm, the slot is 0.5 mm, the gas consumption is from 2 to 6 l per min). Temperature of smoke gases $t_1$ shall be measured.

The factor $\beta$ is calculated by the formula:

$$\beta = \frac{qQ}{(t_1 - t_0)},$$

where $q$ is specific heat of combustion of the gas (kJ·l⁻¹);

$Q$ is the gas consumption of the calibrating burner (l·sec⁻¹).

For the testing purposes specimen of a material or composition shall be fixed in the holder frame and put in front of the heated radiation panel in the same way as during the
calibration procedure. Material samples of thickness less than 10 mm shall be tested on base chrysotile cement plate of dimensions 320 x 140 x 10 mm.

The following shall be determined during testing:

- \( \tau_0 \) — the time from the beginning of the test to the ignition of the upper (zero) section at permanently burning igniting flame;
- \( \tau_1, \tau_2, \tau_3 \ldots \tau_i \) — the time required for the flame front to pass the specific section of the specimen surface, sec (\( i \) is the number of sections on which flame has been propagated);
- Distance \( l \) covered by the propagated flame during tests, in mm;
- Maximal temperature of the smoke gases \( t_{\text{max}} \) (°C);
- Time \( \tau_{\text{max}} \) from the beginning of the test until the maximal temperature has been reached (sec).

The measured values shall be fixed in the test report in order to determine the flame propagation index \( I \).

The test shall be conducted either within 10 min or until the flame stops spreading over the specimen surface.

### 5 Test results

Index \( I \) shall be calculated for each specimen according to the test results:

\[
I = \left[ 0.115 \beta (t_{\text{max}} - t_0) \left( \frac{\tau_{\text{max}}}{t_0} \right) \right] \left[ 1 + 0.2 \sum_{i=1}^{n} \frac{\tau_i}{t_0} \right]^{0.5},
\]

where 0.115 — coefficient (1/W); 0.2 — coefficient (cm/m).

The arithmetic mean of indices values for three tests shall be calculated. For this purpose: for combustible materials with slow flame propagation the arithmetic mean of the flame propagation index shall be \( I \leq 20 \); for combustible materials with rapid flame propagation the arithmetic mean of the flame propagation index shall be \( I > 20 \).

The test results shall be filed as follows:

Conclusion: __________________________ Performer: __________________________

(signature)
1 General requirements

The following materials shall be tested: deck coatings 5 mm thick and over which are applied on the surface of the metal deck and cannot be withdrawn in the event of fire. Deck coatings less than 5 mm thick cannot be tested by this Method. The present Method applies to specimens of deck coatings without insulation from below the metal plate which imitates the ship’s deck.

Proceeding from the test results materials are divided into two groups according to 2.1.4 Part III of the Rules: hardly-ignitable and easily ignitable ones.

2 Test specimens

Test specimens are (625±5) mm thick, (625±5) mm long, thickness of the base steel plate is 5 mm and thickness of the coating is 5 mm. Two specimens shall be tested.

Test specimens shall be manufactured using the same technology as adopted for the manufacture of the given structure.

The material of the deck coating in the same condition as used in service conditions shall be applied on the steel plate with dimensions 625 × 625 mm and thickness 5 mm.

Prior to testing the specimens shall be kept for 5 days at air relative humidity 40–70% and temperature (20 ± 5) °C.

3 Test furnace

Coatings shall be tested in a fire furnace with rectangular opening of clear dimensions 600×600 mm. Where a fire furnace of larger opening is used, in order to decrease the furnace opening down to 600×600 mm a detachable frame made of refractory reinforced concrete shall be used.

The fire chamber of the furnace shall be of such dimensions as to prevent the contact of the flame with the lower surface of the specimen. The fire chamber shall be at least 100 mm high.

The furnace shall be made of ordinary brick with lining of refractory brick or other refractory (insulation) materials to prevent excessive loss of heat through the walls.

The furnace may be heated using low-pressure gas burners or electric coils in order to establish the temperature conditions in accordance with the standard temperature — time dependence: 5 min — 538 °C, 10 min — 704 °C, 15 min — 760 °C.

The accuracy of temperature adjustment shall be such as the area bounded by the curve of the average furnace temperature differs from the area bounded by the standard curve by not more than 15 % during the first ten minutes of the test and by not more than 10 % — to the end of the 15th minute.

The temperature conditions in the furnace during tests shall be measured by four thermocouples located symmetrically in the furnace opening.

Hot ends of thermocouples shall be located at the distance of 50 mm from the heated surface of the specimen. The surface shall be heated uniformly.

Temperature shall be registered by means of secondary device with measurement limits 0–900 °C and error not exceeding 0.5 %.
The deck coating shall be ignited using the ignition gas burner. The diameter of the burner aperture is 1–2 mm and the flame height is 20–30 mm.

The space where testing is conducted shall be equipped with the forced ventilation.

### 4 Testing

The test specimen shall be put on the furnace opening with the deck coating up.

In order to preclude the penetration of furnace gases through gaps between the specimen edges and the furnace flange, sealing rolls of non-combustible heat insulating materials shall be used.

During testing provision shall be made to prevent draught and air flows above the specimen surface.

After the specimen has been arranged, working order of testing equipment and availability of calibration certificates has been checked, the furnace shall be actuated.

During tests when smoke or degradation products of the coating material have been appeared, flame of the ignition burner shall be carried over the specimen surface within 10 s with the intervals of 1 min. The aperture of the ignition burner shall be at the distance of 5 mm from the surface of the coating. The burner inclination angle is $45^\circ$ (Fig. A3.4).

If the material of the deck coating has been deformed or distended, it is necessary to make precaution in order not to damage the coating surface by the burner.

Two test specimens shall be tested for each type of the deck coating. The prolongation of test is 15 min.

The following shall be determined during tests:

- the time from the beginning of tests to the moment of ignition and the prolongation of combustion;
- the type of combustion (along the whole surface, local), the location of combustion, the flame height etc.
- damage of the coating.

### 5 Test results

The material of the deck coating is considered as hardly-ignitable when none of the specimens demonstrate combustion with flame for more than 10 s after the igniting burner flame has been removed. Otherwise the material is considered as easily-ignitable.

The test results of the deck coating specimens shall be filed as follows:

METHOD OF FIRE TESTS OF TEXTILES

1 Purpose

The method is intended for evaluation properties of textiles to withstand ignition, steady-state combustion and flame propagation.

On the basis of the test results textiles are divided into easily ignitable and hardly-ignitable ones.

The following materials shall undergo testing: textiles and films used in shipbuilding for manufacturing curtains and drapery.

2 Definitions

The prolongation of residual combustion is the time when the material burns with flame after the combustion source has been removed.

Residual smouldering is smouldering of the material after flame burning has been stopped or the combustion source has been removed.

Surface flash is flash of the material surface involving mainly surface nap and not affecting the basic textile.

Steady-state combustion is residual combustion for 5 sec and more.

3 Test specimens

For testing purposes eight test specimens with the dimensions of 220×170 mm shall be cut out in warp and weft directions. When the textile has sides differing from each other, then the specimens shall be prepared from each side.

Prior to testing the specimens shall be kept at temperature (20±5) °C and relative humidity (65±5) % within at least 24 hours. Each specimen after having been removed from the conditioning atmosphere shall be tested for 3 min or put into the sealed container till the beginning of the tests.

Fire-proof-pretreated textiles shall undergo accelerated water leaching and be tested before this treatment and after it.

During leaching the specimen is submerged for 72 hours into a reservoir with tap water of room temperature. The water shall be changed every 24 hours. The reservoir shall be such as the ratio of the mass of the textile and water in it is 1:20. Then specimens shall be dried at 70 °C. After these operations they shall be conditioned.

4 Test device

The general view of the device is shown in Fig. A4.4-1. The device consists of test frame 1, foundation 4, vertical uprights 2, burner holder 5 and liquefied gas (propane-butane) burner 3.

Test frame is made of stainless steel stripe of 2×10 mm, which is the base for studs for the specimen fixation and limiting sprigs of diameter (2±0.1) mm. The burner holder can be moved on the metal base in the horizontal direction towards the specimen and in the opposite direction.

The holder shall ensure the arrangement of the burner case axis in one of three positions: vertically upwards, horizontally and at the angle of 60° to the horizontal. The positions that the burner can take relatively to the specimen are shown on Fig. A4.2, a, b.
During testing the device is arranged in a chamber protecting it from draughts. The chamber with dimensions $(700 \pm 25) \times (325 \pm 25) \times (750 \pm 25)$ mm is made of metal plate 0.5–1.0 mm thick. On the top of the chamber there are 32 symmetrically located ventilation holes of diameter $(13 \pm 1)$ mm. Each vertical wall of the chamber in its lower section shall also have similar holes of total area not less than 32 cm² closed by chokes. One of the walls with the dimensions of $700 \times 750$ mm is a glass door that can be closed. The chamber is provided with holes for the tube supplying gas to the burner and remote installation of the burner in the necessary position. The chamber floor is lined with non-combustible insulation material. The inner surfaces are painted black.

5 Testing

Prior to testing on the base of the testing apparatus a layer of cotton wool shall be placed (without synthetic additives) of 10 mm thickness free from threads and dust. Cotton wool is conditioned together with test samples. Before testing gas burner shall be warmed for at least 2 min. The flame height shall be $(40 \pm 2)$ mm in the vertical position of the burner. Test specimen is fastened on the frame in such a way that the bottom edge of the textile is extended over the lower stud for 5 mm. The burner is fixed in horizontal position. The chamber door is closed and the burner is being moved towards the specimen till it reaches the position shown on Fig. A4.4-2, a. After 5 sec the burner is moved away from the specimen. If no steady combustion is observed, a new specimen shall be placed on the frame and in this position the exposure time is increased up to 15 sec.

If no steady combustion is observed, the burner position shall be changed according to Fig. A4.4-2, b, in such a way that the flame touches the bottom edge of the specimen. In this position the exposure time for the new specimen is also 5 sec and, in the absence of steady-state combustion, after the used specimen has been replaced with a new one — 15 s.
For testing five specimens such ignition conditions shall be provided which allow reaching steady-state combustion during experiments in the sequence stated above. When no steady-state combustion is observed, specimens shall be tested in conditions which give the maximum length of charred section. If residual smouldering is observed during tests, the specimen is withdrawn after it has been stopped.

During the tests the prolongation of residual combustion or smouldering of cotton wool is registered.

After testing the length of charred section is measured by means of a hook and a set of weights. For this purpose the specimen is folded in two parallel to the longer side along the maximal visible part of the charred section and is slightly ironed. From one side of the charred section the hook is inserted at the distance of 8 mm from adjacent outer and bottom edges and is moved upwards inside the specimen until the tear is strong enough to hold the weight.

The weight mass for tearing the tested textile depending on its density is the following: when the surface density of the tested textile is less than 200 g/m² — 100 g, when the density is 200 to 600 g/m² — 200 g, when the density is over 600 g/m² — 400 g.

6 Determination of criteria

Textile is considered as easily combustible and not passed tests, when the following is observed at testing:

- Prolongation of residual flame burning over 5 s for any of 10 (or more) specimens tested by pilot flame from the surface;
- Burning-through till any edge for any of 10 (or more) specimens tested by pilot flame from the surface;
- Ignition of cotton wool under any of 10 (or more) specimens;
- Surface flash on any of 10 (or more) specimens spread for more than 100 mm from the ignition point either with charring of the outer layer or without charring.

Note. Where no warp-and-weft directions are present five specimens are sufficient.

Average length of charred section exceeding 150 mm is observed on any batch consisting of five specimens tested by pilot flame from the surface or the edge.

If the analysis of test data shows that any batch complies with the requirements of one or more of the first four criteria, than repeated testing of one full set comprising five specimens may be conducted. When the second set also does not comply with any of the criteria, the textile is considered as easily combustible and not passed the test.

Textile is considered as hardly combustible and passed the test, when none of the above criteria is observed in process of testing. The test results shall be stated in the test report according to the stated form.

METHOD FOR TESTING FIRE-RESISTANT STRUCTURES

1 PURPOSE

The present method is intended for determination of the degree of integrity of structures of types A and B (see 1.2.1.9 and 1.2.1.10 Part III of the Rules) including doors.

Prior to testing the drawings of samples with dimensions of all structure details, joints, cable and other penetrations, connections and methods of fastening the insulation shall be submitted (for testing doors design of hinges, locks, door-handles, air gratings, beat out panels shall be indicated as well as the materials they are made of) and specification with the list of materials used and their parameters, including name of the manufacturer, grade, composition, density, specific heat, heat conductivity, combustibility and speed of flame spread.

2 TEST SPECIMENS

2.1 Metal base of samples of structures of type A shall comply with the following:
   .1 Material — sheet steel or other equivalent material (e.g., aluminium alloy);
   .2 Base thickness: steel (4.5±0.5) mm, aluminium alloy (6.0±0.5) mm;
   .3 Base shall be supported by stiffeners located 600 mm apart from each other;
   .4 Dimensions of stiffeners (mm): steel bulkheads (65±5) × (65±5) × (6±1); steel decks (100±5) × (70±5) × (8±1); aluminium alloy bulkheads (100±5) × (75±5) × (9±1); aluminium alloy decks (150±5) × (100±5) × (9±1).

When the metal base for structures of type A is not made of steel or aluminium alloy, the samples with the shape similar to shape of the actual structure shall be prepared.

2.2 When insulation of structures of types A or B is made of panels, the samples shall contain at least one such panel of the maximum width used and one joint of panels.

2.3 Samples of ceilings of type B shall be installed at the bottom part of the steel deck and shall be tested together with it. If the ceiling structure comprises lighting or ventilation facilities, it is required to conduct tests of samples containing such facilities in order to make sure that fire-resistance properties of the ceiling are not degraded.

2.4 Samples of doors of types A and B:
   .1 Doors shall undergo testing together with door-cases which fully correspond to those which are fitted on a ship;
   .2 Doors of type A together with door-cases shall be installed in a steel bulkhead of the relevant fire resistance;
   .3 Doors of type B together with door-cases shall be installed in a bulkhead of type B or in a bulkhead that shall be tested together with the door;
   .4 Doors shall be tested together with accessories (door-handles, catches, locks, hinges etc.) provided by the door design;
   .5 Doors shall not be locked during tests;
   .6 Bulkhead sections with doors that can be exposed to fire from either side in actual service conditions shall be tested from that side where the most severe conditions are assumed. For hinged doors such conditions are provided when the door is opened in the direction of non-heated surface.
2.5 Samples of structures shall undergo testing in non-painted and non-coated condition. Where insulation materials and panels are made inseparably of coating, they may be tested in finished state.

2.6 To determine the integrity one structure sample shall be tested. Samples of decks and ceilings shall be tested from the bottom, and bulkhead samples — from that side where the worst result is assumed. If it is difficult to determine the worst result beforehand, two samples shall be tested.

2.7 Prior to testing the sample shall be conditioned at relative humidity of (55±15)% and temperature (20±5)°C for the time period required to keep the mass of insulation permanent.

The temperature of sample before tests shall not exceed 40°C.

3 TESTING

3.1 Test furnace

3.1.1 Testing of samples of fire-resistant structures shall be conducted on open-flame furnaces providing uniform distribution of heat flow along the whole surface of the specimen.

Samples of bulkheads and doors shall be tested on furnaces intended for testing specimens in vertical position, and samples of decks and ceilings — in horizontal position.

3.1.2 Samples of structures including bulkheads with doors, shall be mounted on the furnace so as the exposed area is at least 4.65 m² at the height of the bulkhead sample or length of deck (ceiling) sample of at least 2.44 m.

3.1.3 During tests the furnace shall provide the following rate of temperature rise depending on the time:

1. During first 10 and 30 min, as well as after 30 min of testing the area bounded by the mean temperature curve in the furnace shall not differ from the area bounded by standard curve by more than ±15, ±10 and ±5% correspondingly;

2. After first 10 min of testing the mean temperature in the furnace shall not differ from the standard curve by more than ±10°C.

3.1.4 The temperature inside the furnace shall be continuously measured during tests by at least four thermocouples of a diameter not less than 0.75 mm and not over than 1.5 mm, so located as to provide uniform heating.

The distance between the hot thermojunction and the nearest point of the specimen shall be about 100 mm.

3.1.5 During the tests the excessive pressure in the furnace equal to (10 ± 2) Pa (1 mm of water column) shall be measured and checked at the following points:

- When testing bulkheads and bulkheads with doors — at the point lying approximately at the level of 0.75 of the specimen height;
- When testing decks and ceilings — 100 mm below the specimen surface.

3.1.6 In the structure of the furnace for testing ceilings of type inspection openings shall be provided for the inspection over the upper part of the specimen. These openings shall be fitted with closures.

3.2 Fastening of test specimens on the furnace

3.2.1 Test specimens shall be fastened on the furnace as follows:

1. Specimen of structure of type A and of ceiling of type B together with a steel deck shall be so fastened from all sides as to prevent from shifting and to provide flame- and smoke-tightness along the whole perimeter;

2. Specimen of bulkhead of type B shall be fastened in its upper edge, while side and bottom edges shall be fastened — in a method used on a ship. If bulkheads with sliding edges are applied on a ship, such structure shall be reproduced on the specimen. Fastening of the specimen shall provide flame-tightness.

3.3 Measurement of temperature on the specimens

3.3.1 For measuring temperature of non-heated surface the following type of thermocouples shall be used:
Both wires of the thermocouple (thermoelectrodes) with a diameter of 0.5 mm shall be soldered to one side of a copper disc with a diameter of 12 mm and thickness of 0.2 mm in diametrically opposite places and overlap the copper disc by at least 4 mm. Discs shall be covered by plate made of nonflammable insulating material with dimensions 30 × 30 mm and thickness of 2 mm. Plate material shall have a density of 900 kg/m³ ±10 % and heat conductivity of 0.13 W/m·°C ±10 % at a temperature of 100 °C.

3.3.2 Plate on nonflammable material which presses the copper disc to the specimen surface shall be glued to the latter.

3.3.3 Thermocouples for measuring temperature of the base made of aluminium alloy shall be made from wire with a diameter not over 0.75 mm.

3.3.4 When lining coating of insulation materials or panels (see 2.5) is combustible, then in places of mounting of thermocouples it shall be removed in a such way that the thermocouples are in contact with the insulation material or panel material.

3.3.5 Temperature of non-heated surface of the specimen shall be measured in time intervals not exceeding 5 min by thermocouples mounted in the following points:

1. Four thermocouples — each in the centre of each one-fourth of the specimen area at least 100 mm clear of any joints;
2. One thermocouple in the centre of the whole specimen area at least 100 mm clear of any joints;
3. One thermocouple opposite each of two centre stiffeners (for structures of type A);
4. One thermocouple at a joint, if any, at the level of 0.75 of the specimen height for structure of type A;
5. One thermocouple at a vertical joint at the level of 0.75 of the specimen height for structure of type B;
6. At other points where higher temperature is assumed.

3.3.6 Thermocouples on the surface of door samples which is opposite to the exposed one, are mounted at the points according to 3.3.5.1 and 3.3.5.2 at least 100 mm clear of door edges, locks, catches or door hinges.

3.3.7 During tests temperature of the base made of aluminium alloy of structure with double-side insulation shall be measured. Metal-based thermocouples shall be mounted at points according to 3.3.5.1 and 3.3.5.2.

3.3.8 The mean temperature on non-heated surface for samples of structures of type A is determined as the arithmetic mean of temperatures measured at the points specified in 3.3.5.1 – 3.3.5.3; for samples of structures of type B it is measured — as the mean value of temperatures measured at the points specified in 3.3.5.1 and 3.3.5.2.

4 ASSESSMENT OF TEST RESULTS

4.1 Specimens of structures of type A shall be tested for 60 min, and of type B — for 30 min.

For steel-based specimens of bulkheads and decks of type A tested to determine its compliance with type either A-15 or A-30, the test may be finished after 15 min or 30 min respectively.

4.2 A specimen of structure of type A or B is considered as passed the tests due to heating feature under the following conditions:

The mean temperature determined as per 3.3.8 for structures of types A and B does not exceed the initial temperature by more than 139 °C;
Maximum temperature at any of the points specified in 3.12 does not exceed the initial temperature by more than 180 °C for structures of type A and by more than 225 °C — for type B.

Proceeding from the time during which the mentioned temperature intervals are met during tests, the following designations are assigned to the structures:

<table>
<thead>
<tr>
<th>Type A</th>
<th>Type B</th>
</tr>
</thead>
<tbody>
<tr>
<td>60 min — A-60;</td>
<td>15 min — B-15;</td>
</tr>
<tr>
<td>30 min — A-30;</td>
<td>0 min — B-0</td>
</tr>
<tr>
<td>15 min — A-15;</td>
<td></td>
</tr>
<tr>
<td>0 min — A-0</td>
<td></td>
</tr>
</tbody>
</table>
4.3 A specimen of aluminium-alloy-based load-carrying structure of type A with double-side insulation is considered as passed the tests, when the mean temperature of the base determined at the points specified in 3.3.7 does not exceed the initial temperature by more than 200 °C at any moment of the test.

4.4 When during tests a flame is observed on non-heated side of the specimen, it is considered as failed the flame-tightness tests.

4.5 The specimen is considered as passed smoke- and/or burning gases-tightness tests when during standard tests cotton wool wad when it is brought to any place of the specimen including cracks, slots or other openings which may form in the material as well as to the clearance between the door and the door frame and being held at the distance of 25 mm for 30 s is not ignited.

The cotton wool wad shall have dimensions 10×10×2 cm and weight 3 to 4 g. Each wad can be used only once.

4.6 Steel-based structure free of openings shall meet the requirements for type A structure as regards smoke- and flame-tightness.

4.7 Structures of types A and B are considered as passed the tests when the requirements of 4.2 – 4.5 are met.

4.8 During tests it is necessary to watch all parameters which are not included into assessment parameters but may cause the risk at fire (e.g., producing smoke or toxic vapours from non-exposed side of the specimen).

4.9 After finishing fire tests a report shall be drawn up containing the following data:
   - name of the manufacturer of the structure;
   - date of test;
   - the description and drawing of the specimen with the indication of its components and distinctive mark of the manufacturer;
   - test conditions;
   - test method and observations (including photographs and temperature curves);
   - test results (assigned type of fire resistance, temperature rise;
   - and points of its rise, places of cracks, sagging, shifting of door angles relatively to the door frame).
DETERMINATION OF CORROSION RESISTANCE OF WELDED JOINT IN SEA WATER

1 Corrosion resistance of welded joint in seawater shall be determined at tests of welding consumables intended for welding the shell plating, the main deck and other parts of river-sea navigation ships being permanently or occasionally in contact with seawater.

2 Three specimens shall be cut out of the test sample for testing purposes (Fig. A6.2):

Surfaces of the specimens shall be ground so that the deflection from the parallel of planes A and B does not exceed ±0.03 mm. This fact may be controlled by profile record obtained after grinding. The grinding shall be carried out no earlier than 8 days after welding the specimen.

3 The side of the specimen where the welding has been finished shall be exposed to testing. Both sides and the faces shall be degreased; then protective covering for preventing corrosion during tests shall be placed over the rear side of the specimen, the faces and the front side of 8—10 mm width along its contour (e.g. at least four layers of ethynol paint of grade ЭЖК-40).

Immediately before testing the front side of the specimens shall be again degreased and washed.

4 Corrosion-resistance tests of the specimens shall be conducted in special installations in well-aerated artificial seawater of the following composition (g/l): NaCl — 26.52; MgCl₂ — 2.45; MgSO₄ — 3.30; CaCl₂ — 1.14; KCl — 0.73; NaHCO₃ — 0.20; NaB₂ — 0.08.

The water temperature shall be 32—35 °C, the water flow rate relatively to the water surface — about 10 m/s.

Spent water shall be replaced on the basis of 1 l per each specimen per one day. The duration of tests is at least 1000 h. Interruptions in tests other than for water replacement are not allowed.
After tests the specimens shall be cleaned by methods which provide the complete removal of corrosion products and do not bring to damage or dilution of the specimen metal.

Corrosion products may be removed by etching in 15% solution of hydrochloric acid with addition of inhibitors ПБ-5 in the amount of 1.5 g/l.

After etching the specimens shall be washed by water, dried and exposed to profile recording according to the scheme in Fig. A6.5.

Fig. A6.5. Scheme of profile recording of welded specimen:
1 — line of measurements (on sections A measurements are made every 5 min, on sections B — every minute);

Depth of corrosion damage of the metal is determined relatively to the contour surface of the specimen. According to the measurement data for the base metal, heat-affected zone and the weld the average values shall be adopted for all tested specimens:

1. maximum corrosion depth (mm);
   \[ h_{\text{max}} = \sum h_{\text{b.m.}}, h_{\text{max}} ; h_{\text{max}} ; \]

2. average corrosion depth (mm);
   \[ h_{\text{av}} = \frac{\sum h_{\text{b.m.}}}{N_{\text{b.m.}}}, h_{\text{av}} ; h_{\text{av}} ; \]
   \[ h_{\text{av}} = \frac{\sum h_{\text{haz}}}{N_{\text{haz}}}, h_{\text{av}} ; h_{\text{av}} ; \]
   \[ h_{\text{av}} = \frac{\sum h_{\text{w}}}{N_{\text{w}}}, h_{\text{av}} ; h_{\text{av}} ; \]

3. average corrosion rate (mm/year);
   \[ k_{\text{b.m.}} = 365 \frac{h_{\text{av}}}{\tau}, k_{\text{haz}} = 365 \frac{h_{\text{av}}}{\tau}; k_{\text{w}} = 365 \frac{h_{\text{av}}}{\tau}; \]

where \( h_{\text{b.m.}} \), \( h_{\text{haz}} \), \( h_{\text{w}} \) — sums of corrosion depth measurements at particular measurement points in three stated areas of its location;

\( N_{\text{b.m.}}, N_{\text{haz}}, N_{\text{w}} \) — number of measured values of corrosion depth in three stated areas of its location;

\( \tau \) — test duration in moving solution (day);

365 — number of days in a year.

Welding consumables are considered corrosion-resistant, when the corrosion rates of the weld, heat-affected zone and the base metal are equal and the general character of the metal corrosion does not affect the strength of welded joint.
DETERMINATION OF CRACK-RESISTANCE OF WELDING JOINT

1 Scope of application
and design dimensions of specimen

1.1 Crack resistance of welded joint at welding of assembly butt sample shall be determined at tests of welding consumables other than intended for welding only carbon steels of thickness not over 10 mm.

1.2 Design dimensions of a sample, in mm, are shown on Fig. A7.1.2.

The sample plates 2 cooled down to −25 °C shall be connected by butt joint 1. The plates 2 and ribs 4 shall be made of steel of the same grade.

1.3 Thickness of the sample plates 2 is taken equal to the maximum thickness of the plate material of the given steel grade, for welding of which the tested welding consumable is intended.

The sample width B when testing coated metal electrodes is taken as 500 mm and that of welding wire and filler wire in combination with a flux and shielding gas at mechanical weld methods — 700 mm.

Under all testing conditions of welding consumables, where heating is used to dry the edges to be welded (see 5.3 and 6.2), the sample width shall be 1000 mm.

1.4 Scarf of the plate edges along the butt joint 1 shall have maximum depth of V- or X-form unsymmetrical preparation from those stipulated for joints of the given plate thickness at welding with using the tested welding consumables.

2 Preparation of welding consumables
and welding modes

2.1 Moisture contents in tested welding consumables (electrodes, fluxes, shielding
gases) shall reach the upper level of the permissible norm stated in the technical documentation for its supply and application.

2.2 Welding of the sample plates shall be commenced at modes which have been used or provided for welding structures of the given steel grade in manufacturing environment and, where such data are not available — at modes recommended by the electrode passport for structures of the given steel grade.

3 Cooling of the specimen

3.1 Welding of butt joint shall be commenced at plate temperature of 25 °C and with cooling of plates in the weld area down to its initial temperature after each pass.

3.2 The specimen shall be cooled by solid carbon dioxide which pieces of a mass not exceeding 1–2 kg shall be laid in a uniform layer along the whole surface of the plates excepting edges prepared for welding.

The mass of solid carbon dioxide applied simultaneously to the specimen is 40–60 kg. For the period of cooling the specimen shall be covered with tarpaulin.

3.3 The prolongation of cooling of the specimen down to the set temperature prior to welding of butt joint of the plates is not specified.

The prolongation of cooling of the specimen down to the initial temperature after each bead of the butt weld has been applied shall be determined by the curve of Fig. A7.3.3 depending on the specimen plate temperature measured by thermometers with a negative scale. Thermometers shall be placed in blind openings 3 (see Fig. A7.1.2) in the plates filled with gasoline or other liquid non-freezing at low temperatures.

4 Welding conditions of plate butt when testing coated metal electrodes

4.1 Welding of the plate butt joint when testing coated metal electrodes shall be commenced without removing solid carbon dioxide from the plate surface.

Fig. A7.3.3. Typical curve of the cooling prolongation of the specimen by solid carbon dioxide down to required temperature;

4.2 Immediately before welding the edges to be welded and adjacent plate surfaces for a width not less than 100 mm on either sides shall be cleaned from moisture, frost and ice.

5 Welding conditions of plate butt joint when testing welding consumables for automatic hidden arc welding, welding in shielding gas and powder wire

5.1 At automatic welding the plate butt joint prior to the beginning of each pass solid carbon dioxide shall be moved away from the specimen surface and shall be put back after the pass is finished to cool plates to reach the given negative temperature. The cooling time of the specimen without carbon dioxide layer shall not exceed the time required to commence the next pass.

5.2 Before commencing each pass the edges to be welded and adjacent plate surfaces for a width not less than 100 mm on either preparation sides shall be cleaned from moisture, frost and ice.

5.3 When commencing butt welding with more than two passes, in addition to the edge cleaning according to 5.2 before applying each bead the edges shall be dried by gas burner
flame. The metal temperature near the edges after drying shall not exceed 50–60 °C and on the edges it shall be maintained equal to 25 °C.

5.4 When a butt joint of the specimen is commenced by two-side automatic welding, after finishing the last pass the plate metal shall be cooled down to the initial temperature and than a set of new ribs shall be mounted and welded to this side of the specimen; then the specimen shall be turned down and the older ribs shall be cut off. An interruption of welding of the plate butt joint due to the mentioned operation shall not exceed 6 h. Before starting welding the butt joint from the other side the plates shall be cooled down again to the initial temperature.

6 Welding conditions of plate butt joint when testing welding consumables for semi-automatic hidden arc welding, welding in shielding gas and powder wire

6.1 Semi-automatic welding of plate butt joint shall be commenced in compliance with the requirements of 4.1 and 4.2 of the present Appendix.

6.2 When commencing butt joint of the specimen welding with more than two passes, the edge cleaning from moisture, frost and ice and its drying by the burner flame shall be made according to 5.2 and 5.3 of the present Appendix.

7 General requirements to welding conditions of plate butt joint of the specimen

7.1 The weld root shall be dressed after the grooving is finished from one side. The weld root may be dressed to a depth of 3 – 4 mm. Cracks revealed at the weld root dressing are considered as a sign of defect.

7.2 To prevent cracking at butt welding of assembly specimen only those means may be used which are applied or provided for mandatory application at welding manufacture using the tested materials.

8 Investigation of welded sample and estimation of test results

8.1 Welded sample after one day shall be exposed to tapping by hammer of a mass 5 kg in the immediate vicinity of the weld (but not the weld itself), after which the weld shall be inspected to reveal external cracks. If any, the welding is considered as non-satisfactory (see 8.3 of the present Part of the Rules) and no further investigation of the sample is performed.

8.2 When the external inspection results are satisfactory, the sample shall undergo further investigation. Macrosections and specimens shall be prepared as the following:

1 From the sample by means of heat cutting two samples for longitudinal macrosections and three samples for transverse macrosections and 5-fold round specimens for tensile testing shall be prepared according to Fig. A7.8.2-1. Dimensions of the samples on Fig. A7.8.2-1 are given taking into account tolerances for cutting and mechanical grinding of specimens and macrosections.

2 From each sample for transverse macrosections one macrosection shall be prepared according to Fig. A7.8.2-2, a;

3 From each sample for longitudinal macrosections the following shall be prepared:

one macrosection (Fig. A7.8.2-2, b) along the central vertical longitudinal plane of the weld and one macrosection along the horizontal longitudinal plane secant to the weld and heat-affected zone (Fig. A7.8.2-2, c), when the plate is made of carbon steel.

Several layer macrosections (Fig. A7.8.22, e) with grooving as in Fig. A7.8.2-2, d, when the plate is made of low-alloy steel. A number of macrosections depends on the ratio of the thickness of one macrosection (4 – 5 mm) and the thickness of the sample.

8.3 Macrosection surfaces shall be etched by 10% solution of nitric acid and after one day shall be inspected to reveal the cracks formed. Inspection is carried out with the naked eye and using optical devices with 50-fold magnification.
Fig. A7.8.2-1. Scheme of cutting out samples for macrosections from the sample butt joint:
0 — discard; 1, 3, 5 — samples for transverse macrosections and round breaking specimens;
2, 4 — samples for longitudinal macrosections

Fig. A7.8.2-2. Scheme of macrosections prepared from the samples

Three following variants of inspection are possible:

1. No cracks are revealed on macrosections, the test results are considered as satisfactory and no further investigation is performed;

2. On macrosections cracks are revealed with a length over 1 mm regardless of their quantity or cracks with a length less than 1 mm if their quantity per the total etched surface of the macrosection exceeds 2 cracks per 100 cm². In this case the test results are considered as not satisfactory;

3. On macrosections cracks are revealed with a length less than 1 mm with their total quantity per the total etched surface of the macrosection not exceeding 2 cracks per 100 cm². In this case additional tensile test of three round 5-fold specimens with a diameter of 6 or 10 mm shall be made. The specimens shall be prepared from the weld metal of transverse macrosections of that weld layer by the thickness which presents the maximum...
number of cracks. Such specimens shall be prepared not earlier than after 30 days after the welding is commenced or shall be exposed to boiling in water at a temperature of 100 °C for 3 days before testing.

Test results are considered satisfactory, when mean values of yield stress, tensile strength, percentage elongation and percentage area reduction correspond to the norms of Table 9.2.2-1 of the present Part of the Rules.

When the test results of breaking specimens are not satisfactory, repeated testing of two assembly samples welded under the same conditions may be conducted (see Fig. A7.1.2).
DETERMINATION OF EFFECT OF NON-REMOVED GROUNDINGS ON WELDABILITY

1 Test program

1.1 The grounding shall be tested on samples specified in Table A8.1.1. The sample length shall be sufficient for the preparation of all required specimens. Design parameters of edge preparation on the samples (i.e. clearance, the angle of preparation, the facing size) are taken according to the national standards. Grounding of the plates from which the samples are made shall be made prior to welding of the latter. Grounding is covered only on a half of the sample length; it shall be not removed before welding from the joining edges.

1.2 Thickness of the grounding layer on samples shall exceed the thickness specified by the manufacturer for common use by 20% but shall not be less than 20 μm.

1.3 Samples specified in Table A8.1.1, are welded in usual welding modes adopted for the given type of welding consumables. Tee-joint sample at manual welding in downhand position shall be so welded as the weld has the minimum leg. Tee-joint sample at welding in CO₂ medium in vertical position is welded upwards.

Samples at hidden arc welding may be made by either automatic or semi-automatic welding.

1.4 Butt joint sample without grooving at manual welding is required, when deep-fusion electrodes are used.

1.5 Butt joint sample without grooving at hidden arc welding and at welding in CO₂ medium is required, when single-side welding with weld back-formation is used.

2 Preparing specimens from samples

Butt-weld samples

2.1 Each butt-weld sample before being cut to specimens is subject to radiographic control. The control results shall confirm that the quality of welds welded by grounding complies with the requirements of 8.3 of the present Part of the Rules.

2.2 One set of test specimens shall be made of non-grounded and grounded parts of each butt-weld sample. Each set shall comprise of: two flat tensile specimens, two bend specimens (one of them shall be so bend that the weld top is in tension zone and the other that the weld root is in tension zone); three impact test specimens with a notch (see 2.8 of Appendix 10) on the weld centre (from a sample of a thickness over 10 mm); three impact test specimens with a notch on the fusion line (from a sample of a thickness over 10 mm); one transverse macrosection.

Tee-weld samples

2.3 One set of test specimens shall be made of non-grounded and grounded parts of each tee-weld sample. Each sample shall comprise of first weld tensile test specimen, second weld tensile test specimen and macrosection.

* One sample shall be prepared for each of specified welding positions.

Note: Welding position: D — downhand; V — vertical.

### 3 Test specimens

#### 3.1 Flat tensile test specimens are prepared according to 2.4 of Appendix 12.

#### 3.2 Bending test specimens are prepared and tested according to 9.2 of the present Part of the Rules and Appendix 12.

#### 3.3 Impact test specimens are prepared according to 2.1 of Appendix 12. Temperature of impact test specimens with a notch in the weld centre shall comply with that specified in Table 9.2.2-2 of the present Part of the Rules. Specimens with a notch on the fusion line shall be tested at a temperature of 20 °C.
3.4 Transverse macrosection shall have thickness of about 20 mm (measured along the weld) and width of at least for 5 mm to either side from the weld. Macrosection shall be inspected for incomplete fusion and porosity.

3.5 Fracture tee-weld specimen shall have a size along the weld of 35 mm or over. For fracture of tee-weld specimens one of welds on the specimen shall be cut off. The broken weld is inspected for porosity in the fracture and for the fracture mode.

4 Estimation of test results

4.1 Test results of specimens prepared from grounded and non-grounded parts of butt-weld sample for tensile testing, bend test and impact testing shall comply with the requirements of Table 9.2.2-2 of the present Part of the Rules.

4.2 Macrosections of welded joints prepared from grounded and non-grounded parts of the sample shall confirm the same condition of the weld. No cracks, pores of inadmissible size, slag inclusions, incomplete fusion, non-fusion or other defects shall be present on it. Special attention shall be drawn to complete fusion of tee-weld roots.

4.3 Porosity susceptibility of fillet welds at welding on grounding shall be assessed according to the fracture pattern of the tee-weld specimens. Presence of porosity in weld fracture and the fracture mode are assessed separately for the first weld and the second weld. Continuous porosity in the weld root is a sign of non-usability of that grounding for tee-weld and fillet-weld joints at the given welding method. Single small pores are not considered as a rejection sign.
METHOD OF DETERMINATION OF DIFFUSIBLE HYDROGEN CONTENTS IN DEPOSITED METAL

1 General provisions

1.1 Method of determination of hydrogen contents is based on its free diffusion from the deposited metal in vacuum.

1.2 The following definitions are used in the present Appendix:

.1 Diffusible hydrogen — is a part of hydrogen in solid metal which is removed from the weld metal by means of free diffusion at room temperature;

.2 Residual hydrogen — is a part of hydrogen solved in solid metal which may be removed from the weld metal by means of heating up to 600 – 650 °C or melting of the weld metal in vacuum;

.3 Total hydrogen — is a sum of diffusible hydrogen and residual hydrogen.

1.3 Diffusible hydrogen contents in the deposited metal is determined for the following purposes:

determination of norms of hydrogen content for the particular grade of electrodes;

checking of single batches of electrodes as delivery condition and prior to launching;

supplementary quality control of electrodes in accordance with request of the customer.

1.4 Index of diffusible hydrogen contents in the deposited metal is its volume diffused from the specimen during tests for 5 days and related to 100 g of the deposited metal.

1.5 When it is necessary to determine the total hydrogen contents \( V_{\text{total}} = V_{\text{dif}} + V_{\text{res}} \), residual hydrogen may be educed by heating or melting in vacuum of the same specimen which was used for the determination of diffusible hydrogen according to the present Appendix (see 2.3).

2 General requirements

2.1 Tests shall be performed on electrodes with a diameter of 3 to 5 mm with approximately 100% output of the deposited metal as related to the mass of the electrode rod. If powdered metal is contained in the electrode coating and, therefore, the output of the deposited metal is over 100 % as related to the mass of the electrode rod, its diameter may be chosen different with due regard of the quantity of the deposited metal. For example, an electrode with powdered metal coating giving 130 % of the deposited metal with a rod diameter of 3.5 mm is approximately equivalent to an electrode with a rod diameter of 4 mm.

2.2 Tested electrodes prior to welding shall be dried according to specifications of the manufacturer.

2.3 As material for plates on which metal shall be deposited at testing, low carbon steel shall be used with carbon content not over 0.20, silicon — 0.30, sulphur — 0.05%.

When it is necessary to determine total hydrogen contents, the plates before welding shall be degasified in conditions equivalent to hot vacuum extraction conditions.

2.4 Sample for determining hydrogen content is a plate with a deposited bead. The bead is formed at melting of approximately
150 mm of the electrode length. The deposition rate shall be assigned according to melting of 1.2 to 1.3 cm of the electrode length at deposition of 1 cm of the bead length. The bead is deposited on a steel finished plate assembled with runoff tabs. The plate size is shown on Fig. A9.2.4.

![Fig. A9.2.4 Steel finished plate assembled with runoff tabs: 1 — runoff tab, 2 — plate.](image)

2.5 Arrangement for the preparation of welded samples shall be made of copper of grades М0 – М3 GOST 859. The arrangement shall comply with GOST 23338. Prior to deposition the arrangement temperature shall be (20±5) °C.

2.6 Welding current strength at deposition shall comply with passport data of the manufacturer of electrodes, it shall be taken equal to average value from the recommended current range for tested electrode with a chosen rod diameter. Deviations of welding current strength shall not exceed ±5 A.

3 Preparation of sample before deposition

3.1 The plate and runoff tabs prior to deposition shall be together ground and marked.

3.2 The plate of dimensions 100×25×8 mm after grinding shall be sawn off at sharp edges.

3.3 The plate and runoff tabs after machining and sawing shall be washed in toluene or benzene and then in acetone and ethyl alcohol to remove dirt, oil and moisture.

3.4 The plate prior to the bead deposition shall be weighed with accuracy up to 0.01 g.

3.5 The plate and runoff tabs prior to preparation of welded samples shall be kept in dessicator with silica.

4 Preparation of test samples

4.1 For testing electrodes of one grade (batch) four parallel experiments shall be made. Deposition on each sample shall be performed by a new electrode.

4.2 On each sample consisting of a central plate and attached runoff tabs which shall be fastened in the arrangement a single bead shall be deposited along the longitudinal axis of the plate. Neither transverse oscillations of the electrode nor arc fault shall be allowed during deposition. If any external defects are revealed in the deposited bead, the sample shall be rejected.

Deposition mode shall comply with the requirements of 2.5 and 2.6. Length of deposited bead shall be 125 – 130 mm; deposition shall be started and terminated at runoff tabs.

4.3 During deposition of each sample the ambient conditions shall be recorded: the ambient air temperature (°C) and humidity (g of water per 1 m³ of air).

5 Processing of deposited samples

5.1 After deposition has been finished, the sample shall be taken out of the arrangement where the deposition was commenced and put into a vessel with icing water (with temperature equal to the ice melting point). The volume of water shall be 8 – 10 l.

5.2 Runoff tabs shall be hammered from the cooled deposited sample put in grips. Runoff tabs are not used in the analysis.

The sample shall be kept in grips in order to strip the weld surface and clean the sample from slag and drops of deposited metal. Samples shall be cleaned by metal brush which shall be periodically moistened in icing water. Drops of deposited metal shall be removed by chisel.

5.3 After stripping the sample shall be taken by pincers and shall be washed in series
in baths with ethyl alcohol, acetone and ethyl ether, for 10 s per each bath. After washing the sample shall be wiped by cotton cloth.

5.4 Washed sample shall be immediately dried in the hot air flow from residuals of solvents being kept by pincers at the distance of approximately 15 mm over the open coil of electric oven with an output of about 1 kW.

Weld fractures shall be dried from each side of the sample for 10 s, weld surfaces and the back side of the sample — for 5 s.

5.5 The sequence of operations and exposure time (sec):
- Removal of the sample from the testing arrangement 10
- Cooling of the sample in icing water 10
- Breaking of the sample and cleaning of the specimen 60
- Washing of the specimen 30
- Drying of the specimen 30
- Putting the specimen in a vessel 5
- Total time for the specimen preparation 145
- Air exhaust from the vessel up to vacuum 60–70

All operations from the end of welding till the beginning of analysis take 6 minutes.

6 Testing and calculation method of hydrogen contents

6.1 Measuring device for the determination of diffusible hydrogen content (see GOST 23338) shall be made of molybdenum glass. Recommended wall thickness is about 2 mm. The general view of the device is shown in Fig. A9.6.1.

6.2 The device shall be put in operating mode in the following way:
- Inner surfaces of the device and the manometer capillaries shall be thoroughly dried with ethyl alcohol;
- Manometer 5 shall be filled with vacuum dibutylphthalate (oil liquid);
- All vacuum joints shall be greased with fresh Ramsay grease;
- Vacuum shall be induced down to 0.8 to 1.0 Pa [(6 to 8)\(10^{-3}\) mm Hg] at opened taps 2, 3 and 4 and closed tap 1 (see Fig. A9.6.1);
- Tap 2 shall be opened and tap 3 shall be closed (tap 1 is closed, tap 4 is opened); the pressure in the device shall be checked by vacuum gauge.

Fig. A9.6.1. Device for the determination of diffusible hydrogen content:
1-4 — vacuum taps; 5 — pressure gauge; 6 — flask; 7 — vacuum-gauge lamp

6.3 After 5 days the device shall be checked for vacuum tightness:
- Vacuum of 0.8 to 1.0 Pa [(6 to 8)\(10^{-3}\) mm Hg] shall be established (tap 2 is opened, taps 1 and 3 — are closed, tap 4 — is opened);
- Tap 2 shall be opened and tap 3 shall be closed (tap 1 is closed, tap 4 — is opened); the pressure in the device shall be checked by vacuum gauge.

The device is considered vacuum-tight and ready to work when the pressure in it after 5 days is max. 13 Pa [1\(\cdot10^{-1}\) mm Hg].

6.4 Ready-to-work device shall be kept under vacuum (taps 1, 2, 3 are closed, tap 4 is opened).

6.5 Prior to each analysis the device shall be checked by the evacuation time from the atmospheric pressure to 2.7 Pa [2\(\cdot10^{-2}\) mm Hg].

In order to do it, the air is pumped into the device (taps 1, 3, 4 are opened, tap 2 is closed) and then pumped out with time from the moment of opening the tap 2 till establishing vacuum of 2.7 Pa [2\(\cdot10^{-2}\) mm Hg] measured by means of a stopwatch (taps 2, 3, 4 are opened, tap 1 is closed).

The time for establishing vacuum of 2.7 Pa [2\(\cdot10^{-2}\) mm Hg] shall not exceed 60 s.

6.6 After putting the device into the ready-to-work condition, the idle correction shall be
measured. It shall be determined after preventive washing of the polished parts and in all cases when the device has come out of normal operating conditions (failure of the pressure gauge, flasks 6, improper sequence of work with tap etc.).

6.7 In order to determine the idle correction the device shall be kept under vacuum for 5 days with a ballast of glass of 20 to 25 cm³ imitating a specimen arranged inside.

After manufacture the ballast shall be thoroughly dried with ethyl alcohol and kept under vacuum for 5 h at depression of 0.8 to 1.0 Pa [(6 to 8)·10⁻³ mm Hg] as follows:

1 Establish vacuum of 0.8 to 1.0 Pa [(6 to 8)·10⁻³ mm Hg] (taps 2 and 4 are opened, taps 1 and 3 — are closed);

2 — Open tap 3 (taps 2, 4 are opened, tap 1 is closed, forevacuum pump is operating continuously);

3 Measure the idle correction of the device;

4 After 5 h of the pump operation close taps 3 and 4 simultaneously, switch off the pump and keep the device under vacuum for 5 days (taps 1, 2, 3 and 4 are closed);

5 After the device has been kept under vacuum for 5 h the difference of the pressure gauge levels shall be measured and the value of the idle correction shall be recorded (h_{ic}, cm).

6.8 The following shall be made when the specimen is put into the device:

1 Let the air enter the device at the opened taps 1, 3, 4 and closed tap 2;

2 Separate and incline the lower part of the flask 6, put the specimen inside and then put it back by grinding thoroughly;

3 Establish vacuum in the device with the specimen at opened taps 4, 2 and 3 and closed tap 1.

6.9 Vacuum after placing the specimen into the device shall be reached up to pressure of 2.7 Pa [2·10⁻² mm Hg] for not more than 60 s.

6.10 After depression of 2.7 Pa [2·10⁻² mm Hg] has been established, close taps 3 and 4 simultaneously, then close tap 2 and switch off the vacuum pump. Such position of the taps shall be kept during the whole analysis of the specimen.

6.11 In 5 days, specimen shall be taken out from the device as follows: open tap 4, then taps 3 and 1 (tap 2 shall be kept closed), separate the lower part of the flask containing the specimen, incline it horizontally, remove the specimen from the flask with slight shaking.

6.12 Ready-to-work device shall be kept under vacuum of 13 Pa [1·10⁻¹ mm Hg] (tap 4 is opened, taps 1, 2 and 3 are closed).

6.13 When preparing the device for work after long-term downtime (for 2 to 3 months), the operations listed in 6.2 to 6.7 shall be carried out.

6.14 For testing, each specimen with the deposited bead shall be placed in a separate analysis device (see Fig. A9.6.1) not later than 5 s after drying subject to requirements of testing instructions developed by the device manufacturer. The specimens shall be kept in the device for 5 days at room temperature.

6.15 Upon expiry of time specified in 6.14, difference of the liquid levels in the pressure gauge (h) shall be recorded with an accuracy of up to 0.5 mm of oil head. After that the specimen shall be withdrawn from the device.

6.16 ±At the moment of taking the readings from the pressure gauge the air temperature in way of the measuring instruments (t\textsubscript{amb}) shall be recorded. This temperature shall be measured with a thermometer with an accuracy of up to 0.5 °C.

6.17 The specimen withdrawn out of the device shall be weighed with accuracy of up to 0.01 g.

6.18 The weight of the deposited metal shall be determined as the difference of the
specimen weight \( P_{sp} \) and weight of the plate \( P_p \) prior to deposition:
\[
P_{d.m} = P_{sp} - P_p.
\]

6.19 The specimen volume after welding shall be determined by the formula:
\[
V_{sp} = P_{sp} / 7.85,
\]
where \( P_{sp} \) — specimen weight after welding (g);
7.85 — density of low carbon steel (g/cm³).

6.20 Volume of emitted hydrogen, in cm³, reduced to 20 °C and 101.3 kPa [760 mm Hg], shall be calculated by the formula:
\[
V_{H_2} = 298 \cdot 10^{-3} \left( V_{flask} - V_{sp} \right) \left( \Delta h + \Delta h_{i.c} \right) / \left( 273 + t_{amb} \right),
\]
(A.9.6.20)
where \( 298 \cdot 10^{-3} / \left( 273 + t_{amb} \right) \) — coefficient accounting for the reduction of gas to 20 °C and 101.3 kPa [760 mm Hg] (at the oil density in the pressure gauge of 1.045 g/cm³ and mercury density of 13.55 g/cm³), cm⁻¹;
\( t_{amb} \) — air temperature in the room at the moment of taking the pressure gauge readings (°C);
\( V_{flask} \) — flask volume (cm³);
\( V_{sp} \) — specimen volume (cm³);
\( \Delta h \) — difference in liquid levels in the pressure gauge (cm);
\( \Delta h_{i.c} \) — idle correction of the device (see 6.7 of the present Appendix) determined for each particular device and being constant for all experiments (cm).

6.21 The volume of emitted hydrogen, cm³ \([V_{H_2}]\) shall be reduced to 100 g of the deposited metal:
\[
[V_{H_2}] = V_{H_2} \cdot 100 / P_{d.m}.
\]

7 Processing of the analysis results

7.1 The obtained results shall be filed as the test report.

Comparison of the test results of electrodes shall be carried out when the test report is submitted to assess the influence of test conditions.

7.2 Arithmetic mean of four determinations shall be taken as the final index of diffusible hydrogen content for electrodes of the same brand (batch).

8 Measurement error

8.1 % The difference in the liquid levels in the pressure gauge shall be measured with accuracy max. ± 0.5 mm; herewith, the measurement error of diffusible hydrogen content shall be max. ± 1.5.

8.2 When calculating the volume of diffusible hydrogen, the idle correction shall be accounted for the whole time of the analysis (5 days). The idle correction \( (h_{i.c}) \) is negative as regards the difference in liquid levels in the pressure gauge \( (h) \), shall be expressed in centimetres and in calculations according to the formula (A.6.6.20) shall be added to \( h \).
TESTING METHODS OF MATERIALS

1 GENERAL REQUIREMENTS

1.1 Requirements of this Appendix cover types and methods of testing of materials specified in 2 to 6 of the present Part of the Rules.

1.2 Requirements of the present Appendix regulate testing conditions, types and dimensions of test specimens as well as requirements to their manufacture.

1.3 Types and procedures of special tests for the materials intended for specific use and evaluation criteria unless guidelines are provided in the Rules, shall be agreed with the River Register.

1.4 During tests, requirements of national standards1 shall be also met.

1.5 Samples for specimen preparation shall have undergone the same treatment (e.g. heat treatment) as the product from which they have been taken. Test specimens shall be prepared in such a manner that the material properties are not affected.

1.6 Testing machines shall ensure the required measuring accuracy as per GOST 28840, be regularly checked and calibrated by authorized authorities.

2 TESTING OF METALS

Ambient air temperature

2.1 Unless otherwise provided by the present Appendix, the ambient temperature during the tests shall comply with the requirements of GOST 28870.

Tensile test

2.2 During tensile test in accordance with the requirements of the Rules and national standards2, the following characteristics of mechanical properties of materials shall be determined:

1. Yield stress $R_e$ is the stress value measured at the commencement of plastic deformation at yield, or the stress value measured at the first peak on the deformation curve obtained during metal yielding even when that stress does not exceed values of any of the subsequent peaks observed on the curve of plastic deformation at yielding.

2. Loading rate up to yield stress in the range of elastic deformations shall exceed $30 \text{ MPa/sec}$ for steel and cast iron and $10 \text{ MPa/sec}$ for materials for which iron is not the basic element;

3. When no well-defined yield phenomenon exists, proof stress shall be determined. Proof stress $R_p$ is the stress at which plastic deformation reaches the prescribed value expressed in percentage of the initial effective length ($0.2\%$ is the elongation for $R_{p0.2}$).

4. The rate of loading shall be as stated in 2.2.1;

5. Tensile strength $R_m$ is the stress value corresponding to the maximum load directly before the test specimen destruction.

1 GOST R 52927, GOST 5521.

2 GOST R 52927, GOST 5521, GOST 5520, GOST 977, GOST 8536.
To determine the tensile strength $R_m$ the specimen shall be subject extension up to the fracture by the smoothly rising loading. The strain rate in mm/min during this procedure for plastic materials shall not exceed the ratio of 40% of effective length to the time of the deformation process above the yield stress or the proof stress until fracture of the specimen;

4 percentage elongation after fracture $A$ is the ratio of an increment of the gauge length after fracture to the original gauge length, expressed in %;

5 percentage reduction of area after fracture $Z$ is the ratio of difference between the original and the minimum cross-sectional areas of the test specimen after fracture to the original cross-sectional area, expressed in %. It is defined on proportional cylindrical specimens;

6 When carrying out tensile tests at the increased temperature, the test temperature shall be indicated in the subscript, e.g. $R_m/350, A_{5/350}, Z_{350}$.

2.3 The tensile test is performed on specimens in accordance with Fig. A10.2.3-1 to A10.2.3-5, where:

- $d_0$ — diameter of the gauge length (mm);
- $a_0$ — thickness of the gauge length of the flat test specimen or the strip (mm);
- $b_0$ — width of the gauge length of the flat test specimen or the strip (mm);
- $L_c$ — gauge length of the specimen (mm);
- $L_0$ — effective length of the specimen (mm);
- $r$ — transition radius (mm);
- $S_0$ — cross-sectional area of the effective length (mm²);
- $D$ — outside diameter of the pipe (mm);
- $t$ — actual wall thickness of the pipe (mm);

Type of test specimen shall be selected according to Table A10.2.3.

Test specimens of rectangular cross-section with the effective length $L_0 = 5.65 \sqrt{S_0}$, or cylindrical specimens with the effective length $L_0 = 5d_0$ are called proportional.

Required percentage elongation $A_0$ of such non-proportional specimens with effective length for instance $L_0 = 200$ mm, shall be calculated as per formula, %,

$$A_0 = 2A_s \left( \frac{\sqrt{S_0}}{L_0} \right)^{0.40}, \quad (2.3)$$

where $A_s$ is the elongation norm stated for proportional specimen, in %.

2.4 Tensile testing for grey cast iron shall be carried out on the cylindrical specimen in accordance with Fig. A10.2.4.

### Impact test

2.5 In all cases, for impact tests, the specimens of the largest dimensions for a given material thickness shall be manufactured, the longitudinal axis of the specimen shall be in the middle between the surface and section centre in the thickness. The notch is to be cut perpendicular to the surface.

![Fig. A10.2.4 Tensile test cylindrical specimen for grey cast iron](image)

2.6 Tests to determine brittle fracture resistance (crack resistance), for example, drop-weight tests may be performed in addition or in lieu of impact tests.

2.7 Impact test of structural elements may be omitted for the base metal but however required for tests of welded joints.

2.8 The impact toughness $KCU$ or impact energy $KU$ shall be determined on Charpy U-notch type test specimens in accordance with Fig. A10.2.8-1 and impact energy $KV$ — on Charpy V-notch type test specimens in accordance with Fig. A10.2.8-2.

The impact energy $KV$ and $KU$ shall be determined on three test specimens and the impact toughness $KCU$ — on at least two test specimens. The impact energy $KV$ and $KU$ is determined as average from tests results of three test specimens according to Table A10.2.8, with none of three obtained results being less than 70% of the required minimum value.

When impact energy $KCU$ is determined on two specimens, each obtained result shall not be less than the required minimum value.

2.9 The impact toughness may be determined on specimens without notch. In that case the cross-sectional area of such specimens shall be $(10 \pm 0.11)\times(10 \pm 0.11)$ mm at the length of $(55 \pm 0.60)$ mm.
Fig. A10.2.8-1. Charpy U-notch type specimen for impact toughness \( KCU \) or impact energy \( KU \) tests: for impact toughness \( KCU \) test \( h \) is taken equal to \((8\pm0.10)\) mm; for impact energy \( KU \) test — \( h = (5\pm0.09) \) mm

Fig. A10.2.8-2. Charpy V-notch type specimen for impact energy \( KV \) tests: \( a = (10\pm0.10), a = (7.5\pm0.10) \) mm or \( a = (5\pm0.06) \) mm

</tbody>
</table>

Note. \( E \) — required minimum impact energy (J)

2.10 Tests shall be carried out on pendulum impact machines with the energy at least 150 J.

The distance between the supports is to be \((40\pm0.5) \) mm. The pendulum shall break the test specimen in the plane of symmetry of the notch from the side opposite to it, the distance between the planes of symmetry of the notch and the pendulum shall not exceed 0.5 mm.

For tests at low temperatures the test specimens shall be supercooled in order to reach the necessary temperature. When the tests are carried at the temperature down to minus 60 °C, the test specimens shall be supercooled to minus 4 °C; permitted deviation of temperature from the required value shall not exceed \( \pm2 \) °C.

2.11 The aging resistance shall be checked by impact tests of specimens according to Fig. A10.2.8-1. Samples for making impact test specimens shall be pre-elongated to reach a 10% residual deformation.

After that the samples shall be heat treated at temperature of \((250\pm5)°C\) within at least 30 minutes. Test specimens shall not be heated over the temperature defined during machining. Unless otherwise specified, the aged specimens shall represent the impact energy value not less than 50 % the minimum impact energy \( KV \) or impact toughness \( KCU \) as prescribed in 2 to 5 of these Rules defined at 20 °C on non-aged specimens; in all cases the impact energy shall be at least 27 J and the impact toughness – at least 290 kJ/m².

**Technological tests**

2.12 Bend tests shall be carried out on specimens made as in Fig. A10.2.12.

The specimen edges on the side being tensioned may be rounded to a radius of 1 to 2 mm.

Bend tests of plates and sections shall be carried out on the specimens with the following dimensions:

\[ a = t \ (t — \text{plate or section thickness}); \]

\[ b = 30 \text{ mm}. \]

When the plate or section thickness exceeds 25 mm, the specimen may be machined on one side up to thickness of 25 mm. During the tests the mandrel shall be arranged on the side of the machined surface.

Bend tests of forgings, castings and billets shall be carried out on specimens with the following dimensions: \( a = 20 \) mm; \( b = 25 \) mm.

The test results are considered satisfactory, if the prescribed angle of bend is reached without fracture. If the specimen straightens back after being released from the mandrel, repeated test is not required.
Appendix 10

**Hardness tests**

2.13 Hardness may be determined by Brinell (HB), Vickers (HV), Rockwell (HRC) according to GOST 9012, GOST 2999 and GOST 9013, respectively.

**Dropweight tests**

2.14 Where required by the Rules, dropweight tests and assessment of the test results are carried out according to technical documentation agreed upon with the River Register. The specimens shall have the following dimensions, mm: 25×90×360; 19×50×130; 16×50×130.

When the specimens are prepared by flame cutting, their dimensions shall be increased by 25 mm but at least by a plate thickness. At one side of the specimen the rolled surface shall be left. Unless otherwise specified, the specimens may be cut of any orientation.

**Technological tests for pipes and tubes**

2.15 Flattening tests are carried out on pipes or tubes with outside diameter \( d \leq 400 \text{ mm} \) and the wall thickness \( t \leq 0.15 \).

The length of the pipe test specimen \( L \) shall be equal to 1.5d and be 10 to 100 mm. Distance \( H \) between the pressure plates shall be calculated as per formula (mm)

\[
H = \left(1 + \frac{c}{c + t/d}\right) t,
\]

where \( c \) — a coefficient taken in accordance with the material.

At complete flattening the distance between pressure plates shall be 2.25t.

For welded pipes or tubes, the weld shall be placed in the plane perpendicular to the direction of bending.

Test results are considered satisfactory if no cracks are discovered on the flattened specimen by visual examination.

2.16 Drift expanding tests are carried out on pipes or tubes with outside diameter \( d \) of up to 150 mm and the wall thickness of up to 9 mm. A drift shall be forced into the test specimen until the required expansion is reached.

The length of the specimen and the angle of the drift are stated in Table A10.2.16.

**Chemical analysis**

2.19 The methods of determination of chemical composition of metals and permissible deviations are stated by national standards\(^1\).

1. GOST 5640, GOST 8233.
2. GOST 52927, GOST 5521, GOST 977, GOST 26358.

---

</tbody>
</table>

Test results are considered satisfactory, if no cracks are discovered by visual examination on the specimen expanded to the prescribed dimension.

2.17 Ring expanding tests are carried out on steel pipes or tubes with diameter of 110 to 508 mm with the wall thickness not exceeding 30 mm. Ratio of the pipe thickness to its outside diameter shall be max. 0.13. Specimen is to be a pipe section 10 to 15 mm long.

The ring is to be expanded until it breaks by means of two mandrels of diameter not less than triple wall thickness. For welded pipes or tubes, the weld plane shall be perpendicular to the direction of expansion.

Test results are considered satisfactory, if no marks, burrs, burrages, cracks, exfoliations are discovered by visual examination on the specimen.

**Analysis of macro- and microstructure of the material**

2.18 Where required by the Rules, macro- and microstructure of metals is analyzed according to national standards\(^1\).

---

1. GOST 5640, GOST 8233.
Methods of non-destructive examination of materials

2.20 When performing radiography testing of the material the results shall be fixed as radiographic images with a summary of test assessment attached.

2.21 Ultrasonic testing of materials and semi-manufactured products is carried out using pulse-echo methods. Dual-search units shall be used for checking.

Single-dual and prismatic search units are used for more precise checking.

Workability and accuracy of the test equipment shall be checked regularly.

The method for determination of a flaw size is established in accordance with GOST 14782 or technical documentation agreed upon with the River Register.

The assessment criteria and size of permissible flaws shall be agreed upon with the River Register as a part of technical documentation for the product.

The surface of the products shall provide the uniform acoustic contact with the search unit.

The ultrasonic testing is performed after heat treatment at the stage of manufacture when the product is of the simplest shape.

2.22 Magnetic particle inspection shall be carried out using the equipment checked at different test conditions. The material surface under test shall have appropriate intensity of the field.

If needed, demagnetization of the product after inspection shall be prescribed in the technical documentation.

3 TESTING OF NON-METALS

Testing conditions

3.1 Conditioning of test specimens before testing shall be carried out at ambient air temperature of (23±2) °C and relative humidity of (50±5)%.

Where test conditions have no considerable effects on the stability of the test results, conditioning may be omitted.

3.2 Test specimens of rubberized woven cloth are cut in the warp or weft direction with the axis being parallel to the fibres of warp or weft, respectively.

Tensile test

3.3 Tensile strength of glass-reinforced plastic shall be determined on the test specimens made according to Fig. A10.3.3-1 with dimensions specified in Table A10.3.3-1 and Fig. A10.3.3-2.

![Fig. A10.3.3-1. Specimen for tensile test of glass-reinforced plastic](image1)

![Fig. A10.3.3-2. Specimen for tensile test of glass-reinforced plastic](image2)

3.4 The tensile strength and elongation at rupture of laminated textiles are determined on test specimens 50±1 mm wide and with original length between the grips of testing machines of 200±5 mm.

The pre-load applied is 2 N for cloths of density 200 g/m³ or less, 5 N for cloths of...
density from 200 up to 500 g/m³ and 10 N for cloths of density above 500 g/m³.

The moving rate of the testing machine grip is to be 100±20 mm/min.

Elongation at rupture shall be determined according to 2.2.4.

3.5 The tear propagation strength of laminated textiles is determined on rectangular test specimens measuring of (225±5)×(75±5) mm. An incision 80±1 mm long shall be made in the middle of one of the specimen ends parallel to its longitudinal edge. The ends of the incised specimen are then fixed in the grips of the testing machine so that the beginning of the incision made is parallel to the direction of the breaking load applied. The moving rate of the testing machine grip is 100±10 mm/min.

The breaking load is calculated as the arithmetic mean of successive maximum values.

3.6 The strength of interlayer bonds in laminated textiles is determined on rectangular test specimens of (50±1)×(200±5) mm. The specimen coating is carefully cut down to the cloth and exfoliated with a knife on 50 mm length on the side of the oblique notch as in Fig. A10.3.6 (the exfoliated element is hatched). The ends formed are clamped in the grips of the testing machine.

3.7 The tear strength of adhesive bond joints of laminated textiles is determined on test specimens made in such a manner that the middle of the joint coincides with that of the test specimen and the joint width overlaps the test specimen by 25 mm. The shape and dimensions of test specimens are determined according to 3.3. The adhesive applied shall comply with the conditions of the products manufacture.

The tear strength of retro-reflective materials is determined on specimens 25±1 mm wide with the initial length of 100±5 mm between the grips of the testing machine.

The moving rate of the testing machine grip is 100±5 mm.

Materials with an adhesive layer are tested after removal of protective paper.

The strength of the adhesive bond between the retro-reflective material and the adhesive layer is determined on specimens 25±1 mm wide and 200±5 mm long.

Before testing, protective paper is removed from the adhesive layer of the material on a length of 80±5 mm and placed on the surface being tested with dimensions of (50±5)x(90±5) mm.

The loose end of the specimen is secured in the dead lock of the testing machine. Separation of the specimen is achieved by turning the panel by 180° round the axis passing through the specimen end opposite to the loose one.

Compression tests

3.8 Compression strength of glass-reinforced plastics shall be determined on the test specimens according to Fig. A10.3.3-1 and Table A10.3.8.

Table A10.3.8

</table>

3.9 Compression strength of rigid foamed plastics shall be determined on parallelepiped specimens with side dimensions of (50.0±0.5)×
The load shall be increased uniformly. The loading rate shall not exceed 5 mm/min.

**Determination of modulus of elasticity for glass-reinforced plastics**

3.10 The modulus of elasticity shall be determined on the test specimens made: under tension according to 3.3, under compression - according to 3.8.

Extension of the test specimen is determined at initial load \( P_0 \) and maximum load \( P_{\text{max}} \) which is equal to 2 and 8 to 10\% of the breaking load, respectively.

**Bend Test**

3.11 Bend tests of rigid foamed plastics shall be carried out on the test specimens (120±1.2) mm long, (25.0±0.25) mm wide and (20.0±0.2) mm thick. The distance between the supports shall be 100 mm, radius of rounding of the punch and supports shall be (5.0±0.2) mm. The rate of punch feed shall be (10±2) mm/min.

3.12 Bend tests of glass-reinforced plastics shall be carried out on test specimens, the length of which is 20-fold their thickness and the width of 25 mm. The distance between the supports shall equal 16-fold thickness of the specimen. The load applied to the middle of the test specimen shall be smoothly increased until the latter breaks.

**Bend tests of laminated textiles**

3.13 The tests are carried out on rectangular test specimens of (300±5)×(25±5) mm which are fixed in the test device as in Fig. 10.3.13. When the specimen is fixed, the distance between the grips \( l \) shall be 30 mm.

After the test specimen has been fixed, the grips are brought together until they touch. At this time, the force upon the specimen shall be 10 N.

During the test the movable grip makes 500 cycles of reciprocating movement with a frequency of 2 Hz and an amplitude of 50 mm.

![Fixing of specimens of laminated textiles in the test device:](image)

**Determination of relative glass content in glass-reinforced plastics by mass**

3.14 A specimen of \((10±1.0)\times(10±1.0)\times t\) mm, where \( t \) is a plate thickness is placed into the muffle furnace where resin is burned away from the specimen at the temperature of \((625±25)\, ^\circ\text{C}\);°

The relative glass content by weight, in \%, is calculated by the following formula;

\[
S = \left( \frac{G_{2} - G_{0}}{G_{1} - G_{0}} \right) 100\%.
\]

where \( G_1 \) — weight of the furnace together with the test specimen before the resin burning out (g);

\( G_2 \) — mass of the furnace together with the test specimen after the resin burning out (g);
Appendix 10

$G_0$ — weight of the empty annealed furnace (g).

The weight shall be determined with an accuracy of up to 0.01 g.

**Determination of apparent density of foam plastics**

3.15 The apparent density of rigid foams shall be determined on test specimens of regular shape with a volume of at least 100 cm$^3$.

Before conditioning in accordance with 3.1 the test specimens shall be dried at (40±5) °C to their constant mass. The apparent density is determined as the ratio of the specimen weight to its volume, in m$^3$.

**Determination of shrinkage of plastics at limiting temperature**

3.16 A test specimen with dimensions of (100±1)×(100±1)×(15±0.5) mm is conditioned at the limited temperature for the tested plastic for 48 hours.

Shrinkage is determined as the ratio, in %, of linear deformation to the appropriate original size of the specimen.

**Water absorption tests**

3.17 Water absorption shall be determined on test specimens of (50±1)×(50±1) mm with a thickness equal to that of the product but not exceeding 50±1 mm.

Before testing the test specimens shall be dried to constant weight. After drying and weighing the specimens are immersed into distilled water and kept at 23±2 °C for 24 hours, then the specimens are weighed again. Water shall be removed from the specimen surface.

Water absorption is calculated as a mass fraction of absorbed water related to the weight of dry specimen.

Water absorption of foamed plastics is calculated as weight of absorbed water related to the surface area of the specimen.

3.18 A sample with dimensions determined from the required number and size of the specimens, is immersed into fresh water with temperature of 23±2 °C to a depth of 1.25 m and is soaked for 7 days.

Before testing, as well as a day or seven days after immersion, the sample is weighed.

After soaking test specimens are prepared from the sample for carrying out necessary tests.

**Aging tests**

3.19 A sample with dimensions determined depending on the required number and dimensions of test specimens, is conditioned in semi-immersed condition in the artificial sea water at a temperature of 23±2 °C for 30 days. During conditioning the sample shall be subjected every day to two-hour ultra-violet irradiation with 500 W lamp placed at a distance of 50 cm from the sample. After soaking test specimens are prepared from the sample for carrying out necessary tests.

3.20 Two samples with dimensions determined depending on the required number and dimensions of test specimens, are kept suspended for 7 days at ambient temperature of 70±1 °C, one of them being placed in a closed volume above water. After conditioning equal number of test specimens is prepared out of each sample for carrying out tests.

3.21 Folding and shape stability tests after ageing are carried out on square test specimens with the side of 100±5 mm which are folded in two directions, parallel to the edges and at right angles to each other, unfolded and then folded again along the same folds in the opposite direction. After each folding the edges are smoothed down with the fingers.

**Oil product resistance tests**

3.22 A disc-shaped test specimen with a diameter of 70±5 mm is inserted into the testing device as in Fig. A10.3.22.

The testing device is filled up to the level of 20 mm with a mixture of organic compounds, hydrocarbons and alcohols in the following proportions:

- 30% of 2,3,4-trimethylthelane;
- 50% of toluene;
1096 RCCS. Part X “Materials and Welding”

Fig. A10.3.22. Fitting of foam plastic specimen into testing device:

1 — test specimen; 2 — cylindrical chamber;
3 — base plate with an aperture of 30 mm diameter;
4 and 8 — fly-nuts; 5 and 7 — threaded pins for clasping the chamber with fly-nuts; 6 — cover

15% of diisobutylene;
5% of ethanol.
Other oil products may be used such as diesel oil, petrol etc.
The test specimen is conditioned in the above mentioned substances for 22 hours at a temperature of 20±2 °C.

When the test specimen is extracted, it shall be slightly dried, the wetted surface shall be folded in two and pressed.
The wetted surfaces shall not stick together. When touched by finger the surface shall not stain it.

3.23 A sample with dimensions determined from the required number and size of test specimens (see 6.4.4, 6.5.2 of the present Part of the Rules) is immersed in diesel oil or high-octane gasoline with the temperature of 23±2 °C to a depth of 100 mm and kept for 14 days.

After conditioning test specimens are prepared from the samples for carrying out tests provided by the present Part of the Rules.

3.25 Samples with dimensions determined from the required number and size of test specimens (see 6.4.4, 6.5.2 of the present Part of the Rules) is immersed in crude oil, fuel oil, diesel oil, high-octane gasoline or kerosene with the temperature of 23±2 °C to a depth of 100 mm and kept for 14 days.

After conditioning test specimens are prepared from the samples for carrying out tests provided by the present Part of the Rules.

Water resistance tests

3.26 A sample with dimensions determined depending on the required number and dimensions of test specimens is immersed in artificial sea water with a temperature of 23±2 °C and kept for 5 months.

After conditioning test specimens are prepared from the samples for carrying out all necessary tests.

3.27 In case of laminated textiles a sample of 300×200 mm glued along the perimeter shall be conditioned in salt water with salt concentration of 3.3 to 3.8% for 4 hours at a water temperature of 40±1 °C at a depth of 500 mm from the water surface.

3.28 Specimens of retro-reflective material of (70±5)×(150±5) mm fixed on the aluminum panel and having an X-shaped diagonal cut are conditioned in artificial sea water with a temperature of 23±2 °C in semi-submerged condition in closed volume for 16 hours.

After conditioning the salt remains on the specimen surface shall be washed off.
Specimens of retro-reflective material manufactured and mounted in conformity with 3.25 are soaked in distilled and artificial sea water for 16 h in closed volume.

3.29 Specimens of retro-reflective material of (70±5)×(150±5) mm fixed on the aluminum panel are conditioned in sprayed 5% salt solution at a temperature of 35±2 °C for 5 days.

During conditioning the specimens shall be dried for 2 hours every 22 hours.
Air permeability tests

3.30 A disc-shaped test specimen having a diameter of 350 mm is covered with wax in such a way that its central part, 290 mm in diameter, is free from wax; then it is clamped between the flanges of the testing installation as in Fig. A10.3.30.

![Fig. A10.3.30. Clamping of a disc-shaped specimen in the testing installation](image)

From below a positive air pressure of 27.5 kPa acts upon the test specimen. In 10 to 15 min the specimen is so immersed in water that its uppermost point is 13 mm below the water surface.

In 1 min all air bubbles shall be removed from the surface of the specimen.

Within the following 5 min no bubbles shall rise to the surface.

Cold resistance tests

3.31 Cold resistance testing of laminated textile is carried out on rectangular test specimens with of (100±5)×(50±5) mm. The specimens are bent by 90° after being conditioned at minus 30 to minus 35 °C for 1 hour and at minus 60 to minus 65 °C for 10 min.

For testing installation layout, see Fig. A10.3.31.

The distance between parallel parts of the specimen at the end of the test shall be 4 times its thickness.

Ozone resistance tests

3.32 A test specimen is bent through 180° round the mandrel with a diameter equal to 6 times the specimen thickness, and is exposed to air with ozone concentration of 50 ppm for 1 hour at a temperature of 30±2 °C and the relative humidity of 26%.

![Fig. A10.3.31. Testing installation layout for cold resistance tests:](image)

A sample with dimensions determined depending on the required number and dimensions of test specimens is successively exposed to ambient air at a temperature of minus 40±5 °C to +70±5 °C at 8-hour intervals for foam plastics and at 24-hour intervals for retro-reflective materials.

Vibration load tests

3.33 The test specimen with the type and size determined from the operating conditions, is mounted on a vibration-testing machine and subjected to vibration loads having the following parameters:

- oscillation amplitude — 2.5 mm;
- frequency range — 5 to 500 Hz with a frequency step of 32 Hz and an amplitude of vibration acceleration of 10 g.

Determination of retro-reflection factor

3.34 The retro-reflection factor is determined on square specimens of 150±5 mm. The entrance and observation angles are adopted in accordance with Table 6.9.7 of the present Part of the Rules.

Measurements are taken at the turning angles of reference plane between 0 and 180° with the spacing of max. 30°.

3.35 The retro-reflection factor for a material staying under a film of water is determined on specimens of (150±5)×(75±5) mm fixed on a vertical plane in the transverse direction.

During tests the specimen stays under a continuously moving film of water. Measurements are taken at the observation angle of 0.2 and entrance angle of 5°.
Adhesion tests
3.36 The adhesion test of retro-reflective materials is made on square specimens of 100±5 mm.

Two specimens are fitted between glass plates 3 mm thick, with their retro-reflective surfaces facing each other and under a load with weight of 18 kg and conditioned in the heating chamber at a temperature of 65±2 °C for 8 h.

After being conditioned, the specimens are cooled at a temperature of 23±2 °C for 5 min.

Abrasion-resistance test
3.37 The abrasion-resistance test of retro-reflective materials and laminated textiles is made on specimens of (150±5)×(425±5) mm secured on an aluminum panel.

The panel fixed in the testing machine is subjected to 1000 cycles of the reciprocating action of bristles at a frequency of 37±2 cycles per minute.

For testing, trimmed black bristles of a pig are used arranged in 60 openings 4 mm in diameter on a block of (90±5)×(40±5)×(12.5±5) mm and having a total weight of 450±15 g. The bristles shall project above the block surface by not more than 20 mm.

3.38 The contaminant-resistance test of retro-reflective materials is made on square specimens of 150±5 mm secured on an aluminum panel.

The specimens are covered with a contaminant layer 0.075 mm thick, a laboratory glass is placed above and so they are kept for 24 h.

After conditioning the specimens are wiped clean of the contaminant with a soft cloth wetted in white spirit, washed with 1% solution of a detergent and rinsed in water.

The contaminant used for testing shall have the following composition by weight: 8 parts of soot, 60 weight parts of mineral oil and 32 weight parts of white spirit.

Fungus-resistance test
3.39 Retro-reflective materials and laminated textiles are tested for fungus resistance using square specimens of 75±2 mm secured on an aluminum panel. The specimens are conditioned in the soil for two weeks. After being conditioned the specimens are wiped clean with a soft cloth wetted in the 70% solution of ethyl alcohol and then conditioned in accordance with 3.1 for 48 h. The microbiological activity of the soil is determined on untreated cotton cloth. After being soil-conditioned for 5 days, the ultimate strength of the cloth with a density of 400 to 475 g/m² shall not be less than 50% of the initial value.

4 WELDABILITY TEST
4.1 Weldability tests are performed during type approval of materials.
Rolled steel, steel castings, steel forgings and aluminum alloys used in welded ship structures are subject to weldability test.

4.2 The weldability of materials at type approval tests shall be checked during welding using the same methods that are assumed to be used during manufacture of structures. Welding methods shall be specified in the Type Approval Certificate.

4.3 During the weldability test the following shall be determined:
1. Chemical composition and mechanical properties of the parent metal;
2. Cold cracking resistance;
3. Susceptibility to ageing according to 2.11;
4. Properties of the welded joint according to 9 of the present Part of the Rules;

4.4 Features and properties specified in 4.3 are determined on metal plates or other products with maximum thickness taken from at least three different casts.

4.5 For metallic materials other than steel the weldability in specified conditions is determined according to the results of tests according to procedures approved by the River Register.
INSPECTION AND ACCEPTANCE METHODS OF MATERIALS

1 GENERAL REQUIREMENTS

1.1 Requirements of this Appendix cover inspection and acceptance methods of materials specified in 2 to 7 of the present Part of the Rules and shall be used by manufacturer's quality control departments or testing laboratories.

1.2 When developing technical documents requirements of this Appendix shall be taken into account.

2 STEEL AND CAST IRON

2.1 Hull structural steel

Sampling

2.1.1 The test samples shall be prepared as follows.

The test samples of plates and flats more than 600 mm wide shall be taken from one end so that the sample axis is located in the middle between the longitudinal axis of the plate or flat and their edge (see Fig. A11.2.1.1-1).

The test samples of plates and flats with 600 mm or less wide shall be taken from one end so that the sample axis lies at 1/3 distance from the flat edge or outside edge of the shell (see Figs. A11.2.1.1-2, A11.2.1.1-3 and A11.2.1.1-4).
The test samples of bars and other similar semi-manufactured products are taken from one end so that the sample axis is parallel to the direction of rolling. If the cross-sectional area of the test specimens is equal to the total cross-sectional area of the semi-manufactured article, they may be tested non-machined (before impact testing the test specimens shall be machined).

In other cases the specimens shall be taken so that their axes lie:

1/3 of half-diagonal from the vertex — for non-cylindrical semi-manufactured products (Fig. A11.2.1.1-5);

1/3 of radius from the outside edge — for cylindrical semi-manufactured articles (Fig. A11.2.1.1-6).

The tensile and impact test specimens are cut in such a way that their longitudinal axes is perpendicular to the direction of the last rolling of the material except sections, bars and flats 600 mm and less wide.

The test specimens for the determination of impact energy $KV$ are cut in such a way that their longitudinal axes are either parallel or perpendicular to the direction of the last rolling.

The notch is to be cut perpendicular to the rolled surface and not closer than 25 mm to a flame-cut or sheared edge.

**Scope of tests**

2.1.2 Rolled steel is presented for tests in batches. Each batch shall consist of the same type, the same cast and in the same condition of supply. Unless otherwise provided by this Appendix, one test specimen for tensile testing and one set of specimens (except for Grade E, E32, E36 and E40 steel, see 2.2 of the present part of the Rules) for impact testing shall be tested from each batch presented with the weight not exceeding 50 tonnes.

The chemical composition of steel shall be determined based on results of analysis of the samples taken from each ladle of each cast.

If the batch weight exceeds 50 tonnes, one tensile test and one impact test for the set of specimens shall be made additionally for each 50 tonnes or fraction thereof.

If the batch presented consists of plates which thickness varies by more than 10 mm, or sections and bars which thickness or diameter vary by more than 10 mm, one more test of both types shall be carried out in addition.

2.1.3 If the material is supplied in the as-rolled condition, one set of specimens for impact testing shall be tested from each batch of 25 tonnes or fraction thereof.

2.1.4 The scope of impact testing for Grade E, E32, E36 and E40 steel shall be as follows:

- for plates and wide flats — each item shall be tested;
- for sections and bars — one set shall be tested from each batch of 25 tonnes or fraction thereof.

Where sections are supplied in the as-rolled or controlled rolled condition, one set of specimens shall be tested from each batch of 15 tonnes or fraction thereof.

**Examination**

2.1.5 The surface quality and dimensions are checked for compliance with requirements
of 2.2.5 of the present Part of the Rules as well as requirements of national standards ¹.

2.2 Steel for boilers and pressure vessels

Sample preparation

2.2.1 The test samples shall be prepared in accordance with the requirements of 2.1.1.

Test specimens for determining tensile and impact toughness \( KCU \) shall be cut transverse to and those for determining the impact energy \( KV \) shall be cut longitudinally to the direction of the last rolling.

Scope of tests

2.2.2 Each rolled plate shall be submitted for testing. For rolled carbon steel plates up to 12 mm thick as well as steel sections 10% of total amount of plates (rolls) or sections but not less than two plates of the same thickness (diameter or shape), the same cast and heat treatment are allowed to be taken for the tests.

At least one specimen shall be taken from the semi-finished product for tensile and bend tests and at least one set of specimens – for impact testing.

The number of specimens for tensile and long-term strength tests at increased temperatures is specified in accordance with technical documentation agreed upon with the River Register.

From plates (rolls) with a weight exceeding 6 t or a length exceeding 15 m the samples for test specimens shall be cut out on both ends.

Examination

2.2.3 The surface quality and dimensions are checked for compliance with requirements of 2.3.3 of the present Part of the Rules as well as requirements of national standards ².

2.3 Steel pipes and tubes

Sample preparation

2.3.1 Samples for preparation of specimens shall be taken from one end of at least two pipes or tubes of the batch.

Scope of tests

2.3.2 Pipes and tubes shall be tested by batches. A batch is to consist of pipes and tubes of the same size made from steel of the same heat and heat-treated under similar conditions.

The number of pipes or tubes in a batch shall not exceed:

- 400 — for pipes and tubes with an outer diameter of max. 76 mm;
- 200 — for pipes and tubes with an outer diameter above 76 mm.

A rest of pipes or tubes which is less than half the number stated shall be included in a relevant batch and one which is half and over — to be considered a separate batch.

For testing purposes one specimen shall be taken from each sample for tensile test, flattening test or the tensile test of rings (two specimens when welded pipes and tubes are tested) and drift expanding test. All pipes shall be subjected to hydraulic pressure tests. The test pressure shall be set in accordance with national standards ³ or technical documentation agreed with the River Register and shall not be less than that stated in 10.6 Part IV of the Rules.

Examination

2.3.3 All tube and pipes are subject to visual inspection. The surface quality and dimensions are checked for compliance with requirements of 2.4.4 of the present Part of the Rules as well as requirements of national standards specified in 2.3.2.

¹ GOST 5521, GOST R 52927.
² GOST 5520, GOST 1050.
³ GOST 8731, GOST 8733, GOST 10705, GOST 1060.
2.4 Steel for chain cables

Scope of tests

2.4.1 The rolled bars as per GOST 535 are submitted for testing in batches. A batch not more than 50 t in weight shall comprise bars of the same cast and supply condition with diameters varying by max. 4 mm. One sample is taken out from each batch of rolled bars from which one tensile test specimen and, if necessary, a set of test specimens for impact testing (KV) are made.

Preparation of test specimens

2.4.2 Test specimens shall be taken from the sample in the longitudinal direction at a distance of one-sixth of the diameter from the surface or as close as possible to this position according to Fig. A11.2.4.2.

Examination

2.4.3 The surface quality and dimensions are checked for compliance with requirements of 2.5.5, 2.5.6 of the present Part of the Rules as well as requirements of technical documentation (see 2.5.2 of the present Part of the Rules).

2.5 Steel forgings

Sample preparation

2.5.1 Sample dimensions shall be sufficient for the required tests and possible repeated tests and its cross-sectional area shall be at least equal to that of that part of the forging which it represents. The samples shall be integral with each forging. The samples shall be taken in such a manner that the axes of the specimens cut of them are located at a distance not exceeding 10% its diameter or thickness.

2.5.2 Test samples shall not be cut from forgings until all heat treatment has been completed except for cases when the components are subject to carburising.

2.5.3 Generally, one tensile test specimen and a set of impact test specimens shall be prepared from a sample.

2.5.4 Forgings shall be submitted for testing individually or in batches. The location and number of sampling shall be as follows:

1. Forgings for rudder stocks, pintles, shafts, connecting rods etc.
2. one longitudinal sample shall be taken from the end of each forging according to Figs. A11.2.5.4.1-1, A11.2.5.4.1-2 and A11.2.5.4.1-3 (position A).
On agreement with the River Register a sample may be cut transverse according to positions B, C and D. Where a forging exceeds both 4t in weight and 3 m in length, one sample shall be taken from each end;

.2 Pinion forgings: one transverse sample according to Fig. A11.2.5.4.2 (position B) shall be taken if a diameter of the toothed portion after final machining exceeds 200 mm, or according to Fig. A11.2.5.4.2 (position C), where the dimensions preclude sampling in accordance with position B. Where the diameter is 200 mm or less, longitudinal samples shall be taken in accordance with Fig. A11.2.5.4.2 (position A). Where the final length of the toothed portion exceeds 1250 mm, one sample shall be taken from each end;

.3 Gear wheel forgings: one sample shall be taken from each forging in the transverse direction according to Fig. A11.2.5.4.3 (position A or B);

.4 Gear wheel rim forgings made by expanding: one sample shall be taken according to Fig. A11.2.5.4.4 (position A). Where the final diameter exceeds 2500 mm or the weight exceeds 3t, two samples shall be taken according to Fig. A11.2.5.4.4 (positions A and B);

.5 Sleeve and shell forgings: one transverse sample shall be taken according to Fig. A11.2.5.4.5 (position A or B). Where the final length exceeds 1250 mm, one sample shall be taken from each end of the forging according to Fig. A11.2.5.4.5 (positions A and B);

.6 Crank web forgings: one transverse sample shall be taken from each forging.

.7 Solid-forged crankshafts: one longitudinal sample shall be taken from the end of the forging from the coupling side according to Fig. A11.2.5.4.7 (position A).

Fig. A11.2.5.4.2. Location of sampling from pinion forgings

Fig. A11.2.5.4.3. Location of sampling from gear wheel rim forgings

Fig. A11.2.5.4.4 Location of sampling from gear wheel rim forgings made by expanding

Fig. A11.2.5.4.5. Location of sampling from sleeve and shell forgings

Fig. A11.2.5.4.7. Location of sampling from solid-forged crankshaft forgings

Where the forging weight exceeds 3 t, one sample shall be taken from each end according to 2.5.4.7 (positions A and B). Where, however, the elbow is formed by machining or flame cutting, the additional transverse sample shall be taken according to Fig. A11.2.5.4.7 (position C);
8 Crankshaft and other forgings with defined grain flow direction: the number of samples and the sampling location are established in accordance with technical documentation agreed upon with the River Register;

9 Forgings subject to carburising: unless otherwise stated in the present Part of the Rules, for both preliminary tests after forging and final tests after carburising, duplicate number of samples shall be taken from positions as detailed in subparagraphs 1 to 8 for the respective forgings. The samples shall be taken in one direction only irrespective of the dimensions and weight of the forgings. The samples shall be machined to a diameter of D/4 or 60 mm, whichever is less.

For preliminary tests after forging the samples shall pass blank carburising and heat treatment simulating that which will be subsequently applied to the forging. For the final acceptance tests samples shall pass blank carburising and heat treatment along with the forgings which they represent.

At the option of the forgings or gear manufacturer, test samples of large cross-section may be either carburised or blank carburised, but they shall be machined to the required diameter prior to the final quenching and stress relieving heat treatment.

Alternative procedures for the testing of forgings to be carburised may be used. In such a case, testing procedures shall be agreed upon with the River Register for compliance with the requirements of the Rules.

Note. For pinion and gear wheel forgings (see 2.5.4.2, 2.5.4.3 and 2.5.4.4) the specimens for mechanical tests may be cut out of the sample which is forged separately from the metal of the same heat under conditions similar to that for forgings. In this case the sample shall be heat treated together with forgings of the batch.

Scope of tests

2.5.5 Smaller forgings shall be submitted for testing in batches made up of items coming from the same heat, having the same dimensions and weight and have been heat treated in the same furnace charge. Test specimens may be prepared directly from one of the forgings of the batch or from a separately forged sample with the deformation degree being equal to the reduction ratio of the forgings and which has been heat treated together with the forgings. For each batch of forgings at least one set of test specimens shall be prepared.

The scope of tests is established according to the requirements of Table A11.2.5.5.

</tbody>
</table>

Note. If the number of forgings exceeds the specified number by 50% or more, a new batch shall be formed.

2.5.6 When a forging is intended for the preparation of a number of blanks, the required testing scope shall be determined based on the total length or weight of the forging provided that the blanks thus obtained have been subject to heat treatment in the same furnace charge.

2.5.7 A batch testing procedure may also be used for rolled sections with diameter up to 250 mm, used instead of forgings where the batch shall consist of the following:

- either material from the same rolled length of semi-manufactured product cut into individual blanks having been heat treated in the same furnace charge; or;
- rolled bars of the same diameter and heat with a total weight not exceeding 2.5t having been heat treated in the same furnace charge.

2.5.8 Hardness tests are required for:

- gear wheel forgings after completion of heat treatment of the gear teeth. The hardness shall be determined at four points equally located at the distance equal from each other around the circumference. Where the final diameter of the toothed portion exceeds 2500 mm, the hardness shall be determined in eight test points. Where the width of a gear
wheel rim forging exceeds 1250 mm, the hardness shall be determined at eight points at both ends of the forging; small crankshaft and gear forgings which have been batch tested. In such cases the hardness test shall be carried out on each forging; forgings which have undergone induction hardening, nitriding or carburising.

**Examination**

2.5.9 The surface quality is checked for compliance with requirements of 2.6.5 of the present Part of the Rules as well as requirements of national standards.

2.6 Steel castings

*Sample preparation*

2.6.1 Samples may be made directly from the casting or the test samples may be cast to it. Samples shall be at least 30 mm thick.

The use of separately cast samples is permitted; in this case the dimensions of the sample shall correspond to the dimensions of the casting.

2.6.2 Where two or more test samples are to be taken from a casting, the sampling points shall be located as far from each other as possible.

2.6.3 The samples shall be heat treated together with the castings which they represent.

2.6.4 At least one test sample shall be taken from each casting. Where one casting consists of metal from several ladles, one sample shall be taken from each of the ladles.

If the weight of a casting in cleaned condition exceeds 10t or it has a complex shape, at least two samples shall be taken.

The castings shall be submitted for inspection and control testing in the cleaned condition with sprues, heads and burrs removed.

*Scope of tests*

2.6.5 Castings may be presented for tests in batches. All castings in a batch shall be of similar dimensions and shape, cast from the same ladle of treated metal and heat treated in the same furnace charge. For batch testing specimens may be prepared either from separately cast test samples or from one of the castings of the batch.

2.6.6 At least one tensile test specimen and one set of impact test specimens shall be taken from each sample.

**Examination**

2.6.7 The surface quality is checked for compliance with requirements of 2.7.4 of the present Part of the Rules as well as requirements of GOST 977.

2.7 Steel propeller castings

*Sample preparation*

2.7.1 Separately cast samples shall be taken from the same ladle as the casting and heat treated in the same furnace charge.

For each casting or batch of castings one sample shall be taken for the preparation of specimens.

*Scope of tests*

2.7.2 Each propeller casting shall be submitted for testing.

Castings of less than 1.0 m diameter made from metal of the same cast and heat treated in the same furnace charge may be submitted in batches. For a casting or batch of castings the following tests shall be carried out:

- tensile test — at least on one specimen;
- impact test — at least on one set of specimens;
- microstructure investigation.

**Examination**

2.7.3 The surface quality is checked for compliance with requirements of 2.8.2 of the present Part of the Rules as well as requirements of national standards.

---

1 GOST 1050, GOST 8536.
2 GOST 977, GOST 8054.
### 2.8 High strength steel for welded structures

#### Sampling

2.8.1 The axes of tensile test specimens shall be perpendicular to the direction of the last rolling except for wide flats 600 mm or less wide as well as sections and bars for which the orientation of the specimen is determined in accordance with technical documentation agreed upon with the River Register. Flat tensile specimens shall be prepared in such a way that the rolled surface is preserved at least on one side of the specimen. Where cylindrical tensile test specimens are used, their axes are to be located at the distance of 0.25 thickness from the surface.

The impact testing of steel plates and wide flats more than 600 mm wide shall be performed in accordance with 2.8 Appendix 10 on specimens with the longitudinal axis being perpendicular to the direction of rolling (transverse specimens). For rolled products of other cross-sectional shape the impact testing shall be carried out on longitudinal specimens.

#### Scope of tests

2.8.2 Each plate (rolled length) shall undergo tensile and impact testing after heat treatment.

For rolled products quenched and tempered in continuous furnaces the scope of testing including the number of specimens and the direction of their cutting out, is determined in accordance with technical documentation agreed upon with the River Register.

At least one tensile specimen and three impact test specimens shall be prepared from each test sample.

Tensile testing may be performed on specimens with longitudinal axes perpendicular to the plate surface; the reduction of cross-sectional area shall be determined as well.

#### Examination

2.8.3 The surface quality and dimensions are checked for compliance with requirements of 2.9.1 of the present Part of the Rules as well as requirements of GOST R 52927.

### 2.9 Nodular graphite iron castings

#### Sample preparation

2.9.1 The test samples may be either cast separately or gated to the casting. The dimensions of the samples, when cast separately, shall be in accordance with Figs. A11.2.9.1-1, A11.2.9.1-2, A11.2.9.1-3; the sample length shall be selected according to the type of the machine for tensile testing.

![Fig. A11.2.9.1-1. Dimensions of U-shaped samples](image)

![Fig. A11.2.9.1-2. Dimensions of type II V-shaped samples](image)

![Fig. A11.2.9.1-3. Dimensions of V-shaped samples](image)

The samples may have other dimensions or they may be taken directly from one of the castings of the batch.
Where separately cast test samples are used, they shall be cast in moulds made from the same type of material as used for the casting moulds. The samples shall be stripped from the moulds at the metal temperature not exceeding 500 °C.

2.9.2 When castings are supplied in the heat treated condition, the test samples shall be heat treated together with the castings of the batch which they represent.

2.9.3 Samples for metallographic examination may be taken either parts from the tensile test specimens or separately cast sample provided that the latter is taken from the ladle at the end of the casting period.

Scope of tests

2.9.4 At least one sample shall be taken from each casting. Where one casting consists of metal from several ladles, one sample shall be taken from each of the ladles.

2.9.5 Castings with weight in cleaned condition of 1 t or less may be submitted for testing in batches. Each batch shall consist of castings of the same shape and size cast from the same ladle. One separately cast test sample shall be taken from each 2 t of cleaned castings of the batch.

2.9.6 At least one tensile test specimen and, if required, a set of impact test specimens shall be prepared from each test sample.

Examination

2.9.8 The surface quality is checked for compliance with requirements of 2.11.3 of the present Part of the Rules as well as requirements of GOST 26358.

2.10 Grey iron castings

Sample preparation

2.10.1 Samples are casted separately as cylinders gated to castings or made directly from castings.

Separately cast test samples shall be cast in moulds made from the material similar to that used for the casting moulds. The samples shall be stripped from the moulds at the metal temperature not exceeding 500 °C.

2.10.2 Where castings are supplied in the heat treated condition, the test samples shall be heat treated together with the castings of the batch which they represent.

2.10.3 A tensile test specimen shall be prepared from each sample.

Scope of tests

2.10.4 At least one sample shall be taken from each ladle. Where one casting consists of metal from several ladles, one sample shall be taken from each of the ladles.

2.10.5 Castings with weight in cleaned condition of 1 t or less may be submitted for testing in batches. Each batch shall consist of castings of the same shape and size cast from the same ladle. One separately cast test sample shall be taken from each 2 t of cleaned castings of the batch.

Examination

2.10.6 The surface quality and dimensions are checked for compliance with requirements of 2.12.2 as well as requirements of GOST 26358.

3 COPPER AND COPPER-BASE ALLOYS

3.1 Semi-manufactured products of copper and copper-base alloys

Sampling

3.1.1 Tensile test specimens from sheet material shall be cut transversely to the direction of rolling (forging), and from tubes, rods, sections and forgings — longitudinally to the direction of rolling.

Tubes, rods and sections with a diameter (or thickness) of 40 mm and less may be subject to tensile tests in rough condition.

Forging samples may be forged separately or integrally. The samples shall have the same degree of upsetting as the most loaded cross-section of the forging.
Casting samples may be cast separately, gated to the casting or taken directly from it. In all cases the samples shall be cut after the final heat treatment (in the supply condition).

**Examination**

3.1.2 The surface quality is checked for compliance with requirements of 3.1.4 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.

3.2 Propeller castings

**Sample preparation**

3.2.1 Separately cast samples for determining the mechanical properties of propeller alloys shall be taken from each ladle and shall have the dimensions as shown in Fig. A11.3.2.1.

Samples for proof testing may be taken directly from castings or be cast integrally.

**Scope of tests**

3.2.2 Out of each sample one cylindrical specimen shall undergo the tensile test according to the requirements of Table A10.2.3; for castings made of alloys of grades 1 and 2 the alpha α phase content shall be determined as well.

![Fig. A11.3.2.1. Dimensions of separately cast samples](image)

**Examination**

3.2.3 The surface quality is checked for compliance with requirements of 3.2.2 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.

4 ALUMINIUM ALLOYS

4.1 Wrought aluminium alloys

**Preparation of test specimens**

4.1.1 Samples for mechanical properties determination shall be taken so that to provide the following orientation of the longitudinal axis while preparing test specimens:

- for plates and flats less than 25 mm thick — transverse to the grain direction;
- for rods and sections — along the grain direction;
- for pressed panels — along the grain direction.

For forgings, punchings, plates and flats over 25 mm thick the sampling point, sample size and method of cutting samples are defined according to technical documentation agreed with the River Register. Samples shall be either integrally forged to forgings or taken directly from the latter.

Blanking of test specimens as well as their preparation shall be performed by methods preventing from possible change of the alloy properties due to heating or cold hardening.

Tensile testing is performed on specimens in accordance with 2.2, 2.3 of Appendix 10.

**Scope of tests**

4.1.2 Aluminium alloy semi-manufactured products are submitted for testing in batches. Each batch shall consist of semi-manufactured products of the same grade, dimensions and supply condition. Forgings or punchings in the batch shall undergo the heat treatment in the same furnace charge.

A batch of plates and pressed panels shall have a weight not exceeding 2 t, that of sections and rods — not exceeding 1 t.
For carrying out tests at least three semi-manufactured products shall be taken from each batch and at least one product — from each batch of forgings or punchings. At least one tensile test specimen shall be taken from each of semi-manufactured products.

When the test results are not satisfactory, repeated tests are carried out. For repeated testing samples shall be taken from other semi-manufactured products of the same batch. When repeated test results are satisfactory, the batch may be accepted.

**Examination**

4.1.3 The surface quality is checked for compliance with requirements of 4.1.2 of the present Part of the Rules as well as requirements of technical documentation agreed upon with the River Register for compliance with requirements of the Rules.

4.2 Cast aluminium alloys

**Sample preparation**

4.2.1 The samples may be integrally or separately cast. The sample thickness shall be not less than the minimum thickness of the casting. The cooling of the samples shall be effected in conditions similar to that of the cooling of castings.

When castings are intended for parts subject to high load values, the thickness of the samples shall be not less than that of the highest loaded zone of the casting and shall be specified in the drawing.

**Scope of tests**

4.2.2 Aluminum alloy castings are divided into test groups according to purpose of products they are intended for. The scope of testing shall correspond to Table A11.4.2.2.

The scope of testing for castings with cast-on samples shall be established in accordance with technical documentation agreed with the River Register. Tensile tests are conducted to determine the yield stress, tensile strength and elongation. In well-grounded cases yield stress determination may be omitted.

For checking of piston castings up to 120 mm in diameter, tensile tests may be omitted. In such a case, only hardness shall be determined.

**Examination**

4.2.3 The surface quality is checked for compliance with requirements of 4.2.2 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.

5 NON-METALLIC MATERIALS

5.1 Glass-reinforced plastics

**Sample preparation**

5.1.1 Sampling for specimens to determine physical and mechanical properties of glass-reinforced plastics shall be made simultaneously with the formation process of the item

<table>

using the same procedure and from the same materials with the same glass fibre content.

Samples from which specimens for tensile test and determination of glass content by weight are made shall have length of 500 mm, width of 400 mm, and samples for compression test specimens shall be 10 to 12 mm thick.

The location of samples relative to the item formed shall be specified in documentation agreed with the River Register for compliance with the requirements of the Rules.

The samples may be taken from allowances of the item formed, and in well-grounded cases — directly from the item.

Sampling shall be performed after establishment of stable physical and mechanical properties of glass-reinforced plastics. The period required for that shall be stated by the manufacturer of the adhesive compound. Modulus of elasticity and tensile strength may be determined by non-destructive examination methods as agreed upon with the River Register.

**Examination**

5.1.2 The surface quality is checked for compliance with requirements of 6.3.1 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.

5.2 Laminated textiles

**Sampling**

5.2.1 Sampling for test specimens shall be taken from each batch of laminated textiles taking into account requirements of 3.2 of Appendix 10 at the distance of 0.1 m from the edge and at least 1 m from the roll end. Samples shall be taken 24 h after fabrication at the earliest.

**Examination**

5.2.2 The surface quality is checked for compliance with requirements of 6.4.6 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.

5.3 Foam plastics

**Sample preparation**

5.3.1 Samples shall be cut out in the middle of a foam plastic block from the part with the most uniform cell structure.

**Examination**

5.3.2 The surface quality is checked for compliance with requirements of 6.5.2, 6.5.3 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.

5.4 Retro-reflecting materials for life-saving appliances

**Sample preparation**

5.4.1 The sample for the preparation of specimens is taken from each batch of retro-reflective materials at least one meter from the roll end.

Prior to preparation of specimens, the sample is conditioned for 24 hours in accordance with 3.1 of Appendix 10.

**Examination**

5.4.2 The surface quality is checked for compliance with requirements of 6.9.9 of the present Part of the Rules as well as requirements of technical documentation (see 3.4 RTSC) agreed upon with the River Register for compliance with requirements of the Rules.
TESTING METHODS FOR WELDED JOINTS AND WELDING CONSUMABLES AND ESTIMATION OF THEIR RESULTS

1 General provisions

1.1 In-process tests shall be performed on all butt welds:
   .1 for each base material;
   .2 for each welding consumable and welding method;
   .3 for each weld position.

The thickness range for each in-process test shall be established in accordance with technical documentation agreed upon with the River Register.

1.2 Tensile strength during testing of welded joints of gas tanker structures shall be not less than required for the base metal. Tensile strength of the weld metal being less than that of the base metal is allowed provided that during tensile testing of a specimen taken across the weld, tensile strength is not less than that of the weld metal as prescribed by the present Part of the Rules. In any case, the test results shall include specimen destruction point.

1.3 During bend tests of welded joints of gas tanker structures on a mandrel with diameter of 4 times the specimen thickness, there shall be no cracks at bend angle of up to 180°.

1.4 The V-notch type specimens of gas tanker structure welded joints shall be subject to impact testing at a temperature specified for basic materials to be welded (see 9 of the present Part of the Rules).

1.5 When the weld metal of gas tanker structure rolled flat products is subject to impact testing, impact energy shall be at least 27 J, for sections — at least 41 J.

1.6 Results of impact tests along fusion line, heat affected zone shall comply with requirements to the base metal for longitudinal and transverse specimens depending on the type of test specimens.

1.7 Impact tests for stainless steel and aluminum alloy welded joints of gas tanker structures may be omitted.

1.8 In-process tests of welded joints for gas tanker pipelines shall be also performed. These tests shall be similar to those specified in 1.1, 2.3, 2.7 of this Appendix.

The tests shall be performed in accordance with 1.2 to 1.6 of this Appendix.

2 Preparation of samples, specimens and estimation of the test results

Sample preparation

2.1 Samples for the purpose of determination of the deposited metal properties for all welding consumables may be prepared from hull structural steel of any grade. Butt and tee-joint weld samples shall be prepared from steel of the grade which the welding consumables are intended for. When the welding consumable is intended for welding steels of different grades, butt weld samples shall be prepared from steel of the highest grade.
Samples shall be welded at normal temperature and the subsequent pass shall be made after the previous pass has been cooled to 250 °C and less, but not less than to 100 °C; welded samples shall not be heat treated.

Before being cut into specimens, butt weld samples shall undergo the radiographic inspection, the results of which shall confirm the absence of inadmissible defects.

Samples shall be welded in the presence of the Surveyor of the River Register.

2.2 Where welding consumables shall be approved for both DC and AC welding, samples shall be DC welded.

2.3 Butt weld samples from steel plates of gas tanker hull structures shall be prepared so that the welding direction is the same as the rolling direction.

Preparation of test specimens

2.4 From the welded joint samples the specimens are taken for testing of the deposited metal, tensile, bend and impact testing of the weld metal. The dimensions of specimens are taken in accordance with requirements of Appendix 10.

Fig. A12.2.4. Dimensions of tensile test specimen

Fig. A12.2.5-1. Dimensions of impact test specimen from single-side weld sample

Fig. A12.2.5-2. Dimensions of impact test specimen from double-side weld sample;

The shape and dimensions of a cylindrical tensile test specimen shall comply with GOST 1497.

Test specimens shall be kept at a temperature not exceeding 250 °C for 16 hours prior to tensile testing in order to remove hydrogen.

2.5 Impact test specimens shall be taken from the weld sample as shown in Figs. A12.2.5-1 and A12.2.5-2.

2.6 Weld reinforcement on tensile and impact test specimens from a butt weld shall be removed on both sides flush with the base metal. Edges of a bend test specimen may be rounded to a radius of max. 2 mm.

2.7 For each gas tanker weld sample, the following procedure for testing of welding method is established:

.1 Tensile tests for specimens taken across the weld;

.2 Impact tests for specimens taken across the weld. The bend test may be performed so that the weld top or root is within the tension area or side-band test may be performed. However, where strength levels of the base material and weld metal are different, tests on specimens taken along the weld may be required instead of tests on transverse specimens;
Appendix 12

3 One set of V-notch type specimens for impact test shall be taken from points as shown in Fig. A12.2.7;

![Fig. A12.2.7](image)

Fig. A12.2.7. Sampling points for welds with single-edge preparation (a) and double-edge preparation (b)

1 — central weld line; 2 — fusion line; 3, 4 and 5 — 1, 3 and 5 mm from the fusion line, respectively

4 Macrostructure analysis and determination of deposited metal hardness.

**Estimation of test results**

2.8 Bend test results are considered satisfactory if after bending over a mandrel having a diameter equal to three times the specimen thickness no cracks occur on the extended side of the specimen.

Surface cracks less than 3 mm in length shall be ignored.

2.9 If the results of the tensile and bend tests do not comply with the requirements specified in 9 of the present part of the Rules, testing shall be repeated on a double number of specimens.

2.10 The impact testing is carried out on three specimens with temperature controlled with the accuracy of 2 °C. The average value of obtained impact energy shall meet the requirements of Tables 9.2.2-1 and 9.2.2-2 of the present Part of the Rules. The impact energy value obtained for one specimen may be below the required average value but shall not be less than 70% of the stated value.

2.11 If the results of impact testing do not comply with the requirements of Tables 9.2.2-1 and 9.2.2-2 of the present Part of the Rules, then additional tests may be carried out on a set of three specimens. Additional tests are permitted if the obtained value of the impact energy is below the required average value for not more than two specimens and is less than 70% of the required value for not more than one of them.

2.12 The hot cracking resistance tests of welding consumables shall be carried out in accordance with 3.3 of this Appendix. The test results are considered satisfactory when neither surface or inner cracks nor considerable porosity occur in tee-joint weld sample.

2.13 The cold-cracking resistance test results are estimated according to provisions of 8.1 to 8.3 of Appendix 7.

2.14 Based on the results of the sea water corrosion resistance tests of welded joints the average corrosion rate of the weld metal and heat affected zone, the average corrosion rate of the base metal in weld zone and within some distance from the weld shall be determined. The ratio of corrosion rate of welded joint components shall be within 0.9 to 1.1.

3 Testing of electrodes for manual arc welding

**Deposited metal tests**

3.1 For deposited metal testing in the downhand position two samples shall be welded; one of them is welded with the electrode 4 mm in diameter and the other — with electrodes of the largest manufactured diameter. If electrodes are manufactured only of one diameter, a single sample is sufficient.

A sample of deposited metal shall comply with Fig. A12.3.1.

The metal shall be welded by several passes, and the direction of each subsequent pass shall be opposite to the previous one. The thickness of each pass shall be at least 2 mm, but max. 4 mm.

Test results of the specimens cut out from the sample according to Fig. A12.3.1 shall be in compliance with Table 9.2.2-1 of the present Part of the Rules.
3.2 To determine the butt weld properties in each welding position (downhand, vertical-upward, vertical-downward, overhead, horizontal-vertical) for which electrodes are intended, one sample shall be welded in each position. Electrodes intended for downhand and vertical-upward positions may be used also for horizontal-vertical welding.

If the electrodes are intended only for welding in downhand position, two samples shall be welded in this position. Butt weld samples for electrode testing shall comply with Fig. A12.3.2.

From samples welded in overhead position the preparation of impact test specimens is not required.

Samples are welded taking the following into account:

Downhand position. The first pass shall be made with 4 mm diameter electrode; the other passes except the last two layers — with electrodes 5 mm or more in diameter.

The passes of the last two layers shall be made with electrode of the largest manufactured diameter.

Where the second sample in downhand position is required, the first pass shall be made...
with electrode 4 mm in diameter, the next one — with electrode 5 or 6 mm in diameter, other passes — with electrodes of the largest manufactured diameter.

**Horizontal position.** The first pass shall be made with electrode 4 or 5 mm in diameter, subsequent passes — with electrodes 5 mm in diameter.

**Vertical-upward and overhead positions.** The first pass shall be made with electrode 3.25 mm in diameter, the other passes — with electrodes 4 or 5 mm if such diameters are recommended for welding in these positions.

**Vertical-downward position.** The electrode diameter and the sequence of welding of test sample shall be taken according to manufacturer’s recommendations.

Back sealing pass is made with 4 mm diameter electrode after dressing the root pass to sound metal in the same welding position in which the base weld has been made.

Test results of the specimens cut out from the sample according to Fig. A12.3.2 shall be in compliance with Table 9.2.2-2 of the present Part of the Rules.

![Diagram of butt weld sample](image)

*Fig. A12.3.2 Butt weld sample for testing of electrodes for manual arc welding*
**Hot-cracking resistance tests**

of weld metal and welded joint

3.3 To determine hot-cracking resistance three tee-joint samples shall be prepared so as shown in Fig. A12.3.3. Test samples are welded with electrodes of different diameters.

The lower edge of the vertical plate shall be smooth and fit closely to the lower plate surface. Uneven spots shall be removed before welding.

Tack welds shall be made on the butt ends of the plates. The lower plate shall be stiffened additionally by welding of three transverse ribs to protect it against deformation.

Welding shall be performed in the gravity position according to GOST 11969. The fillet welds shall be single-pass joined at the maximum current recommended by the manufacturers for the particular type and size of electrodes.

The second weld shall be executed immediately after the first weld has been finished and shall end at that side of the sample where the first one has been started. Both welds shall be effected at constant speed without weaving.

The electrode length necessary to make a weld 120 mm long is stated in Table A12.3.3.

<table>
<thead>
<tr>
<th>Diameter of electrode (mm)</th>
<th>Consumed length of electrode (mm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>First bead</td>
</tr>
<tr>
<td>5</td>
<td>200</td>
</tr>
<tr>
<td>6</td>
<td>150</td>
</tr>
</tbody>
</table>

After welding the slag shall be removed from the welds; after the welds have got cooled completely they shall undergo examination or non-destructive control to reveal cracks.

Then the first fillet is machined or gouged and the second one is broken so that the weld root is tensioned.

**Testing of fillet weld electrodes**

3.4 Welding of a tee joint shall be carried out according to Fig. 12.3.4. Tee-joint samples shall be welded in each position, for which electrodes are intended (i.e. downhand, vertical-upward, vertical-downward, overhead). Samples shall be welded using electrodes of the diameter which is recommended by the manufacturer for the given welding position. The length of the sample shall be at least such as to allow the deposition of the entire length of the electrode being tested. The first weld on the sample shall be made...
with an electrode of the largest manufactured diameter, the second one — with an electrode of the smallest manufactured diameter. From three sections about 25 mm wide three macro-sections shall be prepared. On the macro-sections the hardness of the weld metal, the heat-affected zone and the base metal shall be measured as shown in Fig. A12.3.4.

**4 Testing of wire – flux combinations**

*General requirements*

4.1 The present requirements apply to wire – flux combinations intended for automatic multi-pass and two-pass welding. If the combination is intended for both techniques, tests shall be carried out for each technique.

*Combinations for multi-pass welding*

*Deposited metal testing*

4.2 The sample shall be welded in the downhand position according to Fig. A12.4.2. The welding direction of each subsequent layer deposited on the test assembly shall be opposite to the previous one. The thickness of each pass shall be not less than the wire diameter, but in all cases not less than 4 mm.

Test results of the specimens cut out from the sample according to Fig. A12.4.2 shall be in compliance with Table 9.2.2-1 of the present Part of the Rules.

*Butt weld test*

4.3 The sample shall be welded in the downhand position according to Fig. A12.4.3. The thickness of each pass shall be not less than the wire diameter, but in all cases not less than 4 mm. Test results of the specimens cut out from the sample according to Fig. A12.4.3 shall be in compliance with Table 9.2.2-2 of the present Part of the Rules.

*Combinations for two-pass welding*

4.4 Two samples shall be welded in accordance with Fig. A12.4.4:

- for grades 1 and 1Y (see 9.2.1 of the present Part of the Rules) one sample 12 to 15 mm thick and the other — 20 to 25 mm thick;
- for grades 2, 2Y, 3, 3Y (see 9.2.1 of the present Part of the Rules) one sample 20 to 25 mm thick and the other — 30 to 35 mm thick.

If welding consumables are intended for welding of both normal and higher strength steels, two samples shall be prepared of higher
strength steel. Two samples of normal strength steel may be additionally made.

The steel grade, the wire diameter and the edge preparation for welding shall comply with requirements of Table A12.4.4.

The gap between the plate edges shall not exceed 1 mm. The sample shall be welded in two passes. After the first pass and before the next one, the sample shall be cooled in open air down to 100 °C.

Test results of the specimens cut out from the sample according to Fig. A12.4.4 shall be in compliance with Table 9.2.2-1 and 9.2.2-2 of the present Part of the Rules.
5 Testing of wire-shielding gas combinations

General requirements

5.1 The present requirements cover wire – shielding gas combinations as well as fluxcored and flux-coated wire (for welding with or without a shielding gas).

During type approval of combinations (see Appendix 1 RTSC) intended for welding of fillet welds, the requirements of 3.4 of this Appendix shall be complied with.

When type approving combinations for automatic multi-pass welding the requirements of 4.2 of this Appendix shall be complied with, when welding the sample of the deposited metal the layer shall be at least 3 mm thick.

The composition approved for semi-automatic multi-pass welding may be applied for automatic welding without carrying out any additional tests.

Combinations for multi-pass welding

Deposited metal tests

5.2 For deposited metal tests two samples shall be welded in the downhand position according to Fig. A12.3.1: one sample — using wire of the smallest diameter, and the other — using wire of the largest diameter. If
When welding samples the thickness of each layer of the deposited metal shall be 2 to 6 mm.

Test results of the specimens cut out from the sample according to Fig. A12.3.1 shall be in compliance with Table 9.2.2-1 of the present Part of the Rules.

**Butt weld tests**

5.3 For each welding position which the combination is intended for, one sample shall be welded as in Fig. A12.3.2. When welding samples the first pass shall be made with the smallest manufactured diameter. The subsequent passes shall be executed: for downhand position — with wire of the largest manufactured diameter and for the rest positions — with wire of the largest diameter recommended by the manufacturer for the given position.

¹See 9.2.1 of the present Part of the Rules

If the combination is intended only for welding in the downhand position, an additional test sample shall be prepared using wire of the diameters other than those applied for the first sample. If the only one diameter of wire is manufactured, than one test assembly shall be prepared.

Test results of the specimens cut out from the sample according to Fig. A12.3.2 shall be in compliance with Table 9.2.2-1 and 9.2.2-2 of the present Part of the Rules.

**Combinations for automatic two-pass welding**

5.4 Tests are performed in accordance with requirements of 4.4 of this Appendix with regard to the following.

Two samples shall be prepared in accordance with Fig. A12.4.4: one 12 to 15 mm thick and the other 20 to 25 mm thick.

If the combination is intended for welding steel plates more than 25 mm thick, two samples shall be prepared: one sample about 20 mm thick and the other — of the maximum thickness provided for welding of the given combination.

Edges shall be prepared depending on the thickness of the sample to be welded as in Fig. A12.5.4.

![Fig. A12.5.4. Preparation of edges for welding;](image)

6 Testing of consumables for shielding gas arc welding

6.1 Requirements of 4.4 of this Appendix cover welding consumables for shielding gas arc welding with regard to requirements of 6.2 of this Appendix.

The welding may be conducted by a single pass and the edge preparation may be omitted.

6.2 For testing purposes two samples shall be prepared according to Figs. A12.6.2-1, A12.6.2-2 — 25 mm thick and 35 to 40 mm
Thick. Steel grades for samples shall comply with Table A12.4.4 for samples 25 to 35 mm thick.

Test results of the specimens cut out from the samples according to Figs. A12.6.2-1, A12.6.2-2 shall comply with Table 9.2.2-1 and 9.2.2-2 of the present Part of the Rules for automatic welding.

7 Tests of welding consumables for one-side backing welding

7.1 The scope and conditions of testing are determined according to requirements 3 and 4.1 to 4.4 of this Appendix or the relevant welding procedures taking the provisions below into account.

The deposited metal test sample shall be prepared according to Figs. A12.3.1 and A12.4.2 depending on the welding procedure. Two butt-weld test samples of minimum and maximum thickness shall be prepared according to Fig. A12.7.1.

The edge preparation, the gap dimensions and welding modes shall correspond to recommendations of welding consumables manufacturer.

The mechanical properties of the deposited metal shall comply with Table 9.2.2-1 of the present Part of the Rules, and those of the welded joint — with Table 9.2.2-2 of the present Part of the Rules for the relevant grades of welding consumables. Where welding consumables have been approved earlier by the River Register for standard welding procedure (without backing), only one sample for the welded joint testing shall be prepared as shown in Fig. A12.7.1.
Fig. A12.7.1. Sample for testing of welding consumables intended for standard one-side welding procedure (without backing)

8 Welding consumables for aluminum and aluminium alloys

8.1 Three butt-weld and three tee-joint test samples shall be welded for testing purposes.

8.2 For testing purposes three butt-weld test samples shall be prepared from the plates of the following thickness:
- 5 mm or less;
- approximately 10 mm;
- exceeding 10 mm.

Test samples shall be welded in the downhand position. The edge preparation for welding shall be performed in accordance with requirements of this Appendix for the welding method applied.

The dimensions of samples shall be sufficient for manufacture of all the necessary specimens taking in account the possible repeated tests. The following specimens shall be prepared from each butt-weld sample and shall be tested:
- three flat transverse specimens for tensile test. The weld reinforcement shall not be removed before testing;
- three transverse specimens for bend test. The weld reinforcement shall be removed before testing. The specimen shall be bend in such a way that the pass made in the last turn is located within the tension area;
- three cylindrical specimens for tensile test of weld metal cut out in the longitudinal direction. The specimens shall be prepared only from samples 10 mm and more thick.

8.3 Tee-joint samples shall be made according to 3.3 of this Appendix and be subject to fracture test in order to check the weld metal for fracture pattern, porosity, cracks and other flaws.
One of the three tee-joint samples shall be welded with the wire of the smallest diameter, the second one — with the wire of the largest diameter and the third one — with the wire of the medium diameter.
Part XI

ADDITIONAL REQUIREMENTS FOR SHIPS TO BE OPERATED ON EUROPEAN INLAND WATERWAYS
1 GENERAL PROVISIONS

1.1 SCOPE AND APPLICATION

1.1.1 This part of the Rules sets requirements, which, in addition to requirements of Parts 0 to X of the Rules, shall be met by ships intended for operation both on inland waterways of the Russian Federation and on European inland waterways, which mean inland waterways of European countries, except for inland waterways of European Russia and inland waterways of the Republic of Ukraine without the Danube.

1.1.2 Directive 2006/87/EC and UNECE Resolution No. 61 classify water basins of European inland waterways as follows:
- zone 1 (maximum significant wave height is up to 2.0 m with a 5% probability of overtopping)
- zone 2 (maximum significant wave height is up to 1.2 m with a 5% probability of overtopping)
- zone 3 (maximum significant wave height is up to 0.6 m with a 5% probability of overtopping)
- zone 4 (maximum significant wave height is up to 0.3 m with a 5% probability of overtopping)

Here, “significant wave height” means the average of heights of 10% of the total number of waves having the greater heights measured between wave trough and wave crest, observed over a short period.¹

UNECE Resolution No. 61 correlates zone 1 of European inland waterways with Î class basins of European Russia inland waterways with specified wave height of 2.0 m with a 1% probability of overtopping, zone 2 with Ð class basins of European Russia inland waterways with specified wave height of 1.2 m with a 1% probability of overtopping, and zone 3 with Ë class basins of European Russia inland waterways with specified wave height of 0.6 m with a 1% probability of overtopping.

Due to difference in probability of overtopping in zones of European inland waterways and Î, Ð and Ë class basins, the requirements of this part of the Rules, which are dependent on wind and wave conditions of operation basin, for ships entering European inland waterways, are stricter than the requirements of other parts of the Rules.

1.1.3 Additional (see 1.1.1) requirements for ships in this part of the Rules are grouped as per subjects corresponding to subjects of main parts of the Rules. When required, both water basin classes as classified in the Regulations for Classification and Survey of Vessels and zones of European inland waterways are specified.

¹ Definition is given in 1-1.5 of UNECE Resolution No. 61.
2 HULL AND HULL EQUIPMENT

2.1 HULL DESIGN

2.1.1 Wave bending moment shall be determined by the formula (2.2.10-2) Part I of the Rules, in which wave height \( h \) is derived from Table 2.1.1 in meters.

<table>
<thead>
<tr>
<th>Basin class</th>
<th>Wave height (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>O (zone 1 of European inland waterways)</td>
<td>2.5</td>
</tr>
<tr>
<td>P (zone 2 of European inland waterways)</td>
<td>1.5</td>
</tr>
<tr>
<td>J (zone 3 of European inland waterways)</td>
<td>0.75</td>
</tr>
</tbody>
</table>

Note. In case of any changes of the navigation conditions corresponding to the main class notation (navigation area, season, permitted wave height for specified probability of overtopping) assignment of the design wave height shall be agreed with the River Register in each particular case.

2.1.2 The following requirements are imposed to collision bulkhead arrangement:

1. In ships navigating in zones 2 and 3 (corresponding to P and J class basins) the collision bulkhead shall be between 0.04 \( L \) and 0.08 \( L \) aft of the forward perpendicular, where \( L \) is ship length;

2. In all passenger ships the distance between the collision bulkhead and the forward perpendicular shall be between 0.04 \( L \) and 0.04 \( L + 2 \) m.

2.1.3 Hydrofoil ships, strength of which complies with 5.2 – 5.5 Part I of the Rules, are considered to be fit for hull-borne navigation on wave of below height (m) in basin of class:

<table>
<thead>
<tr>
<th>Basin class</th>
<th>Wave height (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>O (zone 1 of European inland waterways)</td>
<td>2.5</td>
</tr>
<tr>
<td>P (zone 2 of European inland waterways)</td>
<td>1.5</td>
</tr>
<tr>
<td>J (zone 3 of European inland waterways)</td>
<td>0.75</td>
</tr>
</tbody>
</table>

2.1.4 When a hydrofoil is underway, design wave height \( h \) shall be taken at least equal to that specified below (m) for basin of class:

<table>
<thead>
<tr>
<th>Baseline</th>
<th>Wave height (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>O</td>
<td>1.625</td>
</tr>
<tr>
<td>P</td>
<td>1.000</td>
</tr>
<tr>
<td>J</td>
<td>0.500</td>
</tr>
</tbody>
</table>
3 STABILITY. FLOODABILITY. FREEBOARD. MANEUVERABILITY

3.1 PASSENGER SHIP STABILITY

3.1.1 Passenger ship intact stability for standard loading conditions specified in 1.3.2 Part II of the Rules is considered to be sufficient, if the following requirements are met:

.1 Maximum arm of static stability curve \( l_{\text{max}} \) shall not be less than 0.20 m at angle of heel \( \theta_{\text{max}} \geq 15^\circ \). However, if downflooding angle \( \theta_{\text{downfl}} < \theta_{\text{max}} \), arm of static stability curve at the downflooding angle \( \theta_{\text{downfl}} \) shall not be less than 0.20 m;

.2 Downflooding angle \( \theta_{\text{downfl}} \) shall not be less than 15°;

.3 Area below righting arms curve depending on position of \( \theta_{\text{downfl}} \) and \( \theta_{\text{max}} \) shall be at least equal to values specified in Table 3.1.1.3;

.4 Initial metacentric height \( h \) calculated with free surface correction taken into account shall not be less than 0.15 m;

.5 Angle of heel shall not exceed 12° for each of the following two situations:

  under combined effect of heeling moments due to one-sided accumulation of passengers and wind.

  under combined effect of heeling moments due to one-sided accumulation of passengers and centrifugal force caused by turning;

.6 Under combined effect of total heeling moment due to one-sided accumulation of passengers, wind pressure and centrifugal force caused by turning, the minimum freeboard shall not be less than 200 mm;

.7 For ships with watertight hull openings located below the bulkhead deck (deadlights and manholes closed with covers attached with closely spaced bolts, sliding doors, etc.), the residual safety clearance (i.e. vertical clearance available between maximum draught plane and lowest edges of watertight openings) shall not be less than 100 mm under combined effect of three heeling moments specified in 3.1.1.6.

3.1.2 The heeling moment \( M_t \) due to one-sided accumulation of persons in kN-m shall be determined by the formula:

\[
M_t = gP y = g \sum P_i y_i ,
\]

where \( P \) is total mass of persons on board (t) calculated by adding up the maximum permitted number of passengers and the maximum number of shipboard crew under normal operating conditions;

\( y \) is distance of centre of gravity of total mass of persons \( P \) from the centre line (m);

<table>
<thead>
<tr>
<th>Case</th>
<th>Static stability curve area ( A ), m-rad</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 ( \theta_{\text{max}} = 15^\circ )</td>
<td>0.07 m-rad to angle ( \theta = 15^\circ )</td>
</tr>
<tr>
<td>2 ( 15^\circ &lt; \theta_{\text{max}} &lt; 30^\circ )</td>
<td>( \theta_{\text{max}} \leq \theta_{\text{downfl}} ) m-rad to angle ( \theta_{\text{max}} )</td>
</tr>
<tr>
<td>3 ( 15^\circ &lt; \theta_{\text{downfl}} &lt; 30^\circ )</td>
<td>( \theta_{\text{max}} &gt; \theta_{\text{downfl}} ) m-rad to angle ( \theta_{\text{downfl}} )</td>
</tr>
<tr>
<td>4 ( \theta_{\text{max}} \geq 30^\circ ) and ( \theta_{\text{downfl}} \geq 30^\circ )</td>
<td>0.055 m-rad to angle ( \theta = 30^\circ )</td>
</tr>
</tbody>
</table>

Note. \( l_{\text{max}} \) is maximum arm of static stability curve (m); \( \theta \) is angle of heel (deg); \( \theta_{\text{downfl}} \) is downflooding angle (deg); \( \theta_{\text{max}} \) is angle of heel corresponding to maximum arm of static stability curve (deg); \( A \) is static stability curve area (m-rad).
3 Stability. Floodability. Freeboard. Maneuverability

\[ g \text{ is acceleration of gravity: } g = 9.81 \text{ m/s}^2; \]

\[ P_i = \text{mass of persons accumulated on area } A_i \text{ (t); } \]

\[ n_i = \text{number of persons per square meter; } \]

\[ n_i = 4 \text{ for free deck areas and deck areas with movable furniture; for deck areas with fixed seating furniture such as benches, } n_i \text{ shall be calculated by assuming an area of 0.45 m in seat width and 0.75 m in seat depth per person.} \]

The calculations shall be carried out for an accumulation of persons both to starboard and to port.

The distribution of persons shall correspond to the most unfavourable one from the point of view of stability. Cabins shall be assumed unoccupied for the calculation of the persons’ heeling moment.

3.1.3 The mass per person shall be taken equal to 75 kg, and the centre of gravity of a person shall be taken as 1 m above the lowest point of the deck at 0.5L ignoring any deck curvature.

A detailed calculation of deck areas, which are occupied by persons, may be dispensed with if the following values are used:

\[ P = 1.1 F_{\text{max}} \cdot 0.075 \text{ for day trip ships;} \]

\[ P = 1.5 F_{\text{max}} \cdot 0.075 \text{ for cabin ships,} \]

where \( F_{\text{max}} \) is maximum permitted number of passengers on board with \( y = B/2 \) (m).

3.1.4 The heeling moment \( M'_w \) resulting from the static wind pressure on a ship (kN·m) shall be determined by the formula:

\[ M'_w = p_w S (z_r + 0.5T), \]

where \( S \) is windage area (m\(^2\)) calculated as specified in 2.2.3 and 2.2.4 Part II of the Rules, for the loading conditions considered according to 3.1.1.

\( z_r \) is height of centre of windage above the waterplane (m) according to the loading conditions considered as specified in 3.1.1.

\( p_w \) is specific wind pressure equal to 0.15 kN/m\(^2\) for I class basins (zone 3 of European inland waterways) and 0.25 kN/m\(^2\) for O and P class basins (zones 1 and 2 of European inland waterways).

3.1.5 The heeling moment \( M_{ct} \) having effect on a ship during transient turning (kN·m) shall be determined by the formula:

\[ M_{ct} = 0.102 \delta v^2 D (z_g - 0.5T)/L, \]

where \( L \) and \( T \) are wetted length and draught, respectively (m).

\( \delta \) is block coefficient (if not known, taken as 1.0).

\( D \) is ship displacement under the given loading conditions (kN).

\( z_g \) is height of centre of gravity above the baseline (m).

\( v \) is calm-water full speed at straight course (m/s).

\( \delta \) is coefficient of 0.45.

3.1.6 The maximum permitted number of passengers shall not exceed any of the following values:

- number of passengers, for which the existing evacuation areas are proven
- number of passengers that has been assumed for the stability calculation
- number of available berths for passengers on cabin ships used for voyages including overnight stays

For cabin ships, which are also used as day trip ships, the number of passengers shall be calculated for use, both as a day trip ship and as a cabin ship, and entered in the certificate of seaworthiness.

The River Register shall set the maximum permitted number of passengers and enter this number in the certificate of seaworthiness.

The maximum permitted number of passengers shall be displayed on board of the ship.

3.2 STABILITY OF CONTAINER SHIPS

3.2.1 A cargo of containers is considered to be fixed when each individual container is firmly secured to the ship's hull and when its position cannot be altered during navigation.

3.2.2 Stability of container ships shall be verified by one of the below methods.
Method 1

3.2.3 In the case of ships carrying non-fixed containers, the following requirements shall be met to provide ship’s stability:

1. The metacentric height $h$ shall not be less than 1.00 m;

2. Under the combined action of the centrifugal force produced by the turning of the ship, the wind pressure and the flooded free surfaces, the angle of heel shall not exceed 5°, and the margin line (see 1.2.1.28 Part II of the Rules) shall not be submerged.

3.2.4 The heeling arm resulting from the centrifugal force due to the turning of the ship (m) shall be determined by the following formula:

$$l_{cf} = C_{cf}v^2 \left( z_g - 0.5T \right)/L,$$  

(3.2.4)

where $C_{cf}$ is parameter taken as 0.04 (s²/m).

$v$ is maximum speed of ship in relation to the water (m/s).

$z_g$ is height of centre of gravity of ship (m).

$T$ is midship draught of loaded ship (m).

$L$ is ship hull length measured at maximum draught level (m).

3.2.5 The heeling arm (m) resulting from the effect of wind shall be determined according to the following formula:

$$l_w = 9.81C_{w}S \left( z_r + 0.5T \right)/D,$$  

(3.2.5)

where $C_{w}$ is parameter taken as 0.025 (t/m²).

$S$ is windage area of ship (m²).

$D$ is ship’s displacement weight (kN).

$z_r$ is height of centre of windage above the waterplane under the loading condition considered (m).

3.2.6 The heeling arm (m) resulting from the free surfaces exposed to rainwater and residual water inside the hold or double bottom shall be determined according to the following formula:

$$l_{fs} = 9.81C_{fs} \sum_{i=1}^{n} \left( b_i l_i \left( b_i - 0.55I_i \right) \right)/D,$$  

(3.2.6)

where $C_{fs}$ is parameter taken as 0.015 (t/m²).

$b_i$ is breadth of $i$-th hold or $i$-th section of hold divided to compartments by longitudinal watertight bulkheads $^1$ (m).

$l_i$ is length of $i$-th hold or $i$-th section of hold divided to compartments by transversal watertight bulkheads (m).

$n$ is number of holds or sections of hold divided to compartments by transversal watertight bulkheads.

3.2.7 The stability of a ship loaded with non-fixed containers shall be considered adequate when the actual value of height of centre of gravity of ship $z_g$ is not more than the value $z_g^\text{max}$ which is the least of values calculated by formulae (3.2.7-1) and (3.2.7-2):

for various displacements covering the whole range of possible draughts (m).

$$z_g^\text{max} = \left[ z_m + 0.5B(0.5C_{cf}T - h_{oe} - h_b)/H_{fb}^a \right]/\left(0.5BC_{cf}/H_{fb}^a + 1\right),$$  

(3.2.7-1)

where $0.5B/H_{fb}^a$ shall not be less than 11.5 (11.5 = 1/tan 5°) or

$$z_g^\text{max} = z_M - 1.00;$$  

(3.2.7-2)

$z_g^\text{max}$ is maximum permissible height of centre of gravity of ship (m).

$z_M$ is metacentric height above the baseline (m) as determined from hydrostatic curves or from formulae in 3.2.8.

$H_{fb}^a$ is actual freeboard at 0.5$L$ (m).

$C_{cf}$ is value for centrifugal force produced by turning.

$$C_{cf} = (0.7v)^2/\left(9.81 \cdot 1.25L\right) = 0.04 v^2/L;$$  

(3.2.7-3)

$T$ is midship draught (m).

$v$ is maximum speed of ship before start of turning (m/s).

$l_h$ is heeling arm resulting from effect of wind (m) (see 3.2.5).

$^1$ Flooded sections of hold with free surfaces result from division into compartments by longitudinal or transversal watertight bulkheads, which form sections isolated from each other.
\( l_h \) is heeling arm resulting from the free surfaces of water inside the hold or double bottom (m) (see 3.2.6).

\( B \) is hull breadth at maximum ship draft level (m).

**3.2.8** If hydrostatic curves are unavailable, the value \( z_M \) (m) for the calculation according to 3.2.7 can be determined by the following approximation formula:

For pontoon ships

\[
    z_M = B^2 \left[ 12.5 - \left( \frac{T}{H} \right) T \right] + 0.5T ,
\]

(3.2.8-1)

where \( H \) is hull height representing the minimum vertical distance between the upper keel edge and the lowest deck point on board the ship (m);

\( T \) is defined in 3.2.7;

for other ships

\[
    z_M = B^2 \left[ 12.7 - 1.2 \left( \frac{T}{H} \right) T \right] + 0.5T ,
\]

(3.2.8-2)

**3.2.9** In case of ships carrying fixed containers, the following requirements shall be met to provide ship's stability:

1. The metacentric height \( h \) shall not be less than 0.50 m.
2. Under the combined action of the centrifugal force produced by the turning of the ship, the wind pressure and the liquid cargo's free surfaces (if any), no hull opening shall be submerged.
3. The heeling arm resulting from the centrifugal force produced by the turning of the ship, the wind pressure and the liquid cargo's free surfaces (if any) shall be determined by the formulae referred to in 3.2.4 to 3.2.6.
4. For each load case, free surface correction for half the fuel and fresh water supply must be taken into account.

**3.2.10** The stability of a ship loaded with fixed containers shall be considered adequate, if the actual value \( z_g \) is less than or equal to \( z_{g\max} \).

**Method 2**

**3.2.11** The stability of ships carrying fixed containers is considered as complying with the requirements of the Rules if criteria applicable to stability of cargo ships as specified in 3.2 Part II of the Rules are met.

**3.2.12** The stability of ships carrying non-fixed containers must satisfy the following requirements:

1. The metacentric height \( h \) shall not be less than 1.00 m;
2. The angle of heel \( \theta_{w.cf} \) resulting from the combined effect of the heeling moments produced by the static pressure of wind \( M'_w \) (see formula (3.1.4)) and the effect of the centrifugal force on turning \( M_{cf} \) (see formula (3.1.5))\(^1\) shall not exceed 5° or the critical angle \( \theta_n \), at which the upper edge of the freeboard deck is submerged, whichever of these angles is less; in other words, one of the following requirements must be satisfied:

\[
    \theta_{w.cf} \leq \theta_{perm} = 5^\circ
\]

or

\[
    \theta_{w.cf} \leq \theta_{perm} = \theta_k , \text{ if } \theta_k < 5^\circ .
\]

**3.2.13** The angle of heel \( \theta_{w.cf} \) shall be determined from the static stability curve depending on values \( M'_w \) and \( M_{cf} \) as a result of constructions given in Fig. 3.2.13, where the coordinates origin is moved to point \( 0' \) on the moment curve corresponding to the static angle of heel \( \theta_s \) resulting from the applied static moment \( M'_w \) calculated by the formula (3.1.4).

The angle of heel \( \theta_{w.cf} \) is determined by selecting a straight line \( BD \) parallel to the ordinates axis, assuming that the hatched areas \( 0'CA \) above the curve up to the moment \( M_{cf} \) and \( ABD \) below the curve are equal.

**3.2.14** In determining the permissible moment produced by the dynamic inclinations \( M_{perm} \) the permissible angle of heel \( \theta_{perm} \) shall not exceed 5°, and the margin line shall not be submerged.

**3.2.15** If the requirements stated in 3.2.12 and 3.2.14 are not satisfied, containers must be secured.

\(^1\) For calculation of \( M_{cf} \) according to the formula (3.1.5) the ship’s speed before start of turning is taken as 0.8 of the full speed.
3.3 REQUIREMENTS FOR DAMAGE
TRIM AND STABILITY OF PASSENGER
SHIPS IN CASE OF FLOODED
COMPARTMENTS

3.3.1 Buoyancy of the ship in the event of
flooding shall be proven for the standard load
conditions specified in 1.3.2 Part II of the
Rules. Proof of sufficient stability shall be
determined for the three intermediate stages
of flooding (25%, 50% and 75% of com-
partment flood buildup) and for the final stage
of compartment flooding.

3.3.2 Ships operating in zones 1, 2 and 3 of
European inland waterways shall comply with
the 2-compartment criterion, except for ships
of 45 m long and shorter and ships designed
to carry at most 250 passengers, which may
comply with the 1-compartment criterion.
However, ships required to comply with the
2-compartment criterion and operating in
zones 2 and 3 of European inland waterways,
may comply with the 1-compartment criterion
provided that they have double hull with
minimum 0.6 m distance between inner and
outer skins and the space between outer and
inner skin complies with the 2-compartment
criterion.

3.3.3 The following assumptions shall be
taken into account in the event of flooding:

.1 The extent of damage corresponding to
the 1-compartment and 2-compartment crite-
rion shall be taken according to Table 3.3.3.1;

.2 For 1-compartment floodability, the
bulkheads can be assumed to be intact if the
distance between two adjacent bulkheads is
greater than the damage length. Longitudinal
bulkheads at a distance of less than B/3 from
the outer plating measured perpendicular to
the centre line from the shell plating at the
maximum draught shall not be taken into
account for calculation purposes;

.3 For 2-compartment criterion, each
bulkhead within the extent of damage shall be
assumed to be damaged;

.4 The lowest point of every non-
watertight opening (e.g. doors, windows,
hatches) shall lie at least 0.10 m above the
damaged waterline. The bulkhead deck shall
not be immersed;

.5 The compartment permeability coeffi-
cient is assumed to be 0.95. If it is proven by
calculations that the permeability coefficient
of any compartment is less than 0.95, the
calculated value can be used instead.

In any case, the permeability coefficient
values to be adopted for the following com-
partments shall not be less than:

- passenger compartments 0.95
- engine room 0.85
- luggage and provision store rooms 0.75
- double-bottom compartments, fuel 0 or 0.95
tanks and other tanks (depending on
their intended purpose)

Free surface effect for the intermediate
stages of flooding shall be calculated depend-
ing on the damaged compartment surface
area;

.6 If any ship damage of extent less than
specified in 3.3.3.1 to 3.3.3.2 may produce
more detrimental effect to damage trim

### Table 3.3.3.1

</tbody>
</table>

**Note**: 1. b is depth at side, breadth at the bottom; h is a vertical dimension.
2. Length of damage \( l = 1.20 + 0.07L \) (m).
3 Stability. Floodability. Freeboard. Maneuverability

and/or damage stability (see 3.3.3.4, 3.3.5), such a damage shall be taken into account for floodability verification calculation purposes.

3.3.4 For all intermediate stages of flooding referred to in 3.3.1, the following conditions shall be met:

.1 The heeling angle at the equilibrium position of the ship in unsymmetrical flooding before taking any righting measures shall not exceed 15°;

.2 The maximum righting lever shall be at least 0.02 m until the first non-watertight opening becomes immersed or until heeling angle of 25° and more is reached;

.3 Non-watertight openings shall not be immersed until the equilibrium position for each intermediate stage considered has been reached.

3.3.5 In the final stage of flooding, the following conditions shall be met taking into account the heeling moment due to one-sided accumulation of passengers as calculated in 3.1.3 Part II of the Rules:

.1 The heeling angle \( \theta_2 \) (Fig. 3.3.5) shall not exceed 10°;

.2 In the equilibrium position, the positive area under the righting lever curve shall not be less than 0.0065 m·rad at righting lever value of \( l_R \geq 0.05 \) m. These conditions shall be met until the first non-watertight opening is immersed or, in any case, until heeling angle \( \theta_m = 25° \) is reached (Fig. 3.3.5);

.3 The non-watertight openings shall not be immersed until the equilibrium position has been reached; if such openings are immersed before this point, the rooms accessible through such opening are deemed to be flooded for stability calculation purposes.

3.3.6 If cross-flooding ducts to reduce asymmetrical flooding are provided in the ship hull, they shall meet the following conditions:

.1 Cross-flooding shall take place automatically;

.2 Cross-flooding ducts shall not be equipped with shut-off devices;

.3 Maximum permissible righting time shall not exceed 15 minutes.

3.4 LOAD LINE

3.4.1 Load line for ships operating in zones 1 to 4 of European inland waterways consists of a horizontal band with additional freeboard lines, which are applied as prescribed by technical documentation approved by the River Register (Fig. 3.4.1). The lower edge of this horizontal band is a trace of the maximum draught plane for zone 3 of European inland waterways. Zone 4 of European inland waterways has no equivalent on the Russian inland waterways and is characterized by standardized wave height of 0.3 m.

...
3.5 FREEBOARD AND SAFETY CLEARANCE

3.5.1 For the purpose of this chapter, ships shall be divided into three types:
- type A — decked ships;
- type B — tankers and equivalent ships;
- type C — open ships.

3.5.2 As far as the considered ships are concerned, the River Register regulates both the freeboard and safety clearance, i.e. vertical clearance measured between the maximum draught plane and the lowest point, above which the ship cannot be considered watertight.

3.5.3 Minimum freeboard height for ships of type A operating in zones 1 and 2 of European inland waterways is determined in Table 3.5.3.

Table 3.5.3

<tr>
<td>2</td>
<td>1000</td>
</tr>
</tbody>
</table>

3.5.7 For ships of types A and B operating in zone 2 of European inland waterways, the safety clearance defined in 3.5.2 shall not be less than 600 mm.

For ships of type C, as well as for other ships operating with open holds this clearance shall be increased by 400 mm in zone 2. However, this increase applies only to the coamings of open holds.

3.5.8 For ships of types A and B operating in zone 3 of European inland waterways the safety clearance shall not be less than 300 mm.

3.5.9 For ships of type C operating in zone 3 of European inland waterways the safety clearance shall not be less than 500 mm.

3.5.10 The basic freeboard $H_0$ of ships operating in zone 3 of European inland waterways with a continuous deck without superstructures or sheer shall be 150 mm.

3.5.11 In freeboard calculations for ships with superstructures or sheer, corrections for freeboard may be taken into account provided that such corrections are introduced by the designer and calculated according to 3.5.12 to 3.5.14.

3.5.12 Minimum freeboard height value $H_{\text{max}}$, mm, with a correction for freeboard for ships with superstructures shall be determined by the following formula:

$$H_{\text{min}} = H_0 (1 - \lambda) - (\beta_1 S_1 + \beta_2 S_2)/15,$$

(3.5.12)
where $H_0$ is basic freeboard (see 3.5.10) (mm).

$\lambda$ is coefficient accounting for effect of all superstructures.

$\beta_1, \beta_2$ are coefficients accounting for effect of sheer and superstructures in fore and aft parts of the ship, respectively.

$S_{e1}, S_{e2}$ are design sheers in fore and aft parts of ship, respectively (mm).

3.5.13 The coefficient accounting for effect of superstructures shall be determined by the following formula:

$$\lambda = \sum l_e / L_1,$$  \hspace{1cm} (3.5.13-1)

where $L_1$ is maximum ship hull length without rudder and bowsprit (m);

$l_e$ is design length of superstructures (m);

$$l_e = l(2.5 B - 1.5) h / (0.6 H),$$  \hspace{1cm} (3.5.13-2)

where $l$ is effective length of superstructure (m);

$b$ is average breadth of superstructure. Superstructure with $b \geq 0.6$ shall be considered in calculation;

$B$ is ship breadth in the middle of superstructure considered (m);

$h$ is average height of superstructure considered (m) measured from the deck (for cargo hatches $h$ is obtained by subtracting half the safety clearance specified in 3.5.8 to 3.5.9 from this height). In calculation $h$ shall not be more than $0.6 h_{\text{max}}$;

$h_{\text{max}}$ is maximum significant wave height characterizing the zone under consideration (m).

3.5.14 Coefficients $\beta_1$ and $\beta_2$ accounting for effect of sheer shall be calculated as per the following formulae:

$$\beta_1 = 1 - 3 l_{e1} / L_1,$$

$$\beta_2 = 1 - 3 l_{e2} / L_1,,$$

where $L_1$ is defined in 3.5.13;

$l_{e1}, l_{e2}$ is design length of fore and aft superstructures, respectively, determined by the formula (3.5.13-1). A superstructure or its part, the length of which does not exceed 0.25 $L$ from the ends, shall be taken into account.

The design sheer shall be determined by the following formula:

$$s_e = ps,$$  \hspace{1cm} (3.5.14-2)

where $s$ is effective sheer in the fore or aft end (mm). Value $s$ shall not exceed 1000 mm in the fore end and 500 mm in the aft end;

$p$ is coefficient determined from Table 3.5.14;

Table 3.5.14

<table>
<thead>
<tr>

</table>

$x$ is $x$-coordinate measured from the end to the point where sheer is equal to 0.25$s$ (Fig. 3.5.14).

![Fig. 3.5.14. Determination of $x$-coordinate](image)

For intermediate values of ratio $x/L$, coefficient $p$ is determined by linear interpolation.

When $\beta_2 s_e > \beta_1 s_e$, the value of $\beta_2 s_e$ shall be taken equal to $\beta_1 s_e$.

3.5.15 The minimum freeboard calculated as per 3.5.12 shall not be negative.

3.5.16 The safety clearance for passenger ships shall not be less than the sum of:

additional lateral immersion measured along the outside plating, resulting from the permissible heeling angle according to 3.1.1.5; residual safety clearance according to 3.1.1.7.

For ships without bulkhead deck, the safety clearance shall not be less than (mm):

- for European inland waterway zone
  - 1900
  - 1000
  - 500

3.5.17 The minimum freeboard height of passenger ships shall not be less than the sum of:

additional lateral immersion measured along the outside plating, resulting from the permissible heeling angle according to 3.1.1.5;
3.6 MANEUVERABILITY OF SHIPS

3.6.1 Requirements of this chapter apply to the following inland navigation ships:
- ships that are 20 meters long and more;
- ships with product of length, breadth and draught \( LBT \) equal to 100 \( \text{m}^3 \) and more;
- tugboats and pushers used for towing (pushing) the above ships in any way.

3.6.2 A ship is considered to meet the respective maneuverability requirements of this chapter if under load condition specified in 3.6.3 it satisfies:
- forward speed criterion (see 3.6.4);
- turning capability criterion (see 3.6.5, 3.6.7);
- course changing capability criterion (see 3.6.7);
- stopping criterion (see 3.6.8, 3.6.9, 3.6.10);
- astern propulsion criterion (see 3.6.11).

3.6.3 The maneuverability test for ships and convoys shall be conducted with ship loaded to at least 70% of its cargo carrying capacity with maximum possible uniform cargo distribution. If the test load is less, downstream navigation shall be limited to this load of the ship. Here, the ship bottom clearance shall not be less than 20% of ship draught but not less than 0.5 m.

3.6.4 Ships and convoys shall develop speed of at least 13 km/h through the water. This requirement does not apply to tugboats and pushers running without convoy.

3.6.5 The turning capability of ships and convoys whose length does not exceed 86 m and width does not exceed 22.9 m shall be considered adequate, when during an upstream turning maneuver at initial speed of 13 km/h through the water, the limit values for stopping the downstream navigating ship as determined in 3.6.9 are complied with.

3.6.6 Ships and convoys shall be capable of making evasive actions beforehand. The capability of making such actions shall be proved through respective maneuvers to be made during tests according to 3.6.7. A ship or convoy is considered to meet the requirements of the Rules for course changing capability and turning capability, if rate of turn values \( r_1 \) and \( r_2 \) resulted from the tests are not less than values, and time \( t_1 \) does not exceed values, specified in Table 3.6.7.

3.6.7 The ship capability of making evasive actions and of turning shall be tested as follows. For a ship or convoy running at constant speed through the water \( v_0 = 13 \text{ km/h} \) at the start of the maneuver (time \( t_0 = 0 \text{ s} \), rate of turn \( r_0 = 0^\circ/\text{min} \), rudder angle \( \delta_0 = 0^\circ \), selected engine speed is kept constant), evasive action to port or starboard shall be made by changing the rudder angle. When the maneuver starts, the rudder shall be turned by angle \( \delta \). The rudder angle \( \delta \) (for example, 20° to starboard) shall be kept until the rate or turn value \( r_1 \) in achieved as determined in Table 3.6.7 for appropriate sizes of the ship/convoy. After the rate of turn value \( r_1 \) is reached, the time \( t_1 \) shall be noted and the rudder shall be turned to the same angle to stop turning. The time value shall be noted. When the rate of turn \( r_1 \) is reached, the rudder shall be reversed to the same angle \( \delta \) to stop turning. The time value shall be noted. When the rate of turn \( r_1 \) is

</tr>
<tr>
<td>Note. ( h ) is water depth; ( T ) is ship draught; (*) non regulated.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The values of rate of turn \( r_1 \) and \( r_3 \) required to reach rate of turn \( r_4 = 0 \) depending on sizes of ships/convoys and water depth \( h \) are specified in Table 3.6.7.

The following maneuvers shall be completed:

- a turn to starboard with rudder angle of 20°;
- a turn to port with rudder angle of 20°;
- a turn to starboard with rudder angle of 45°;
- a turn to port with rudder angle of 45°.

**3.6.8** Ships and convoys are considered to be capable of stopping in proper time when moving downstream, if requirements 3.6.9 and 3.6.10 are met.

**3.6.9** In running water (current velocity of 1.5 m/s), the ship stopping distance shall not exceed the following values:

- 550 m for ships and convoys \( L > 110 \) m long or \( B > 11.45 \) m wide
- 480 m for ships and convoys \( L \leq 110 \) m long and \( B \leq 11.45 \) m wide.

Stopping is considered to be complete, if the ship has been stopped relative to the bank.

**3.6.10** In still water (current velocity less than 0.2 m/s) the ship stopping distance shall not exceed the following values:

- 350 m for ships and convoys \( L > 110 \) m long or \( B > 11.45 \) m wide
- 305 m for ships and convoys \( L \leq 110 \) m long and \( B \leq 11.45 \) m wide.

**3.6.11** A ship is considered to meet the requirements for astern propulsion, if during astern motion in still water the ship can reach a speed of not less than 6.5 km/h.

**3.6.12** In addition to requirements in 3.6.4 to 3.6.11, the following requirements shall be met:

- For manually operated control systems, a single turn of the wheel shall correspond to a rudder angle of at least 3°.
- For powered control systems, when the rudder blade is fully immersed, it shall be possible to achieve an average angular velocity of 4°/s within the entire range of rudder angles. This requirement shall also be met with ship at full speed, for rudder angles from 35° of a side to 35° of other side. In addition, it should be ascertained that the rudder is capable of keeping maximum angle at maximum
propulsion power. For active steering equipment or special types of rudder, this provision applies with their peculiarities taken into account.
4 FIRE PROTECTION

4.1. FIRE PROTECTION OUTFIT STANDARDS

4.1.1 Ships shall be provided with fire protection outfit as per standards specified in Table 6.1.5 Part III of the Rules. Besides, requirements in 4.1.2 to 4.1.8 shall be met.

4.1.2 Besides two sets of fire outfit, on the passenger ships the additional sets shall be provided for every 80 m (of part thereof) of total length of all passenger and service rooms on the deck where they are located or, if such decks are more than one, on the deck with the greatest total length of those rooms, i.e. two sets of fire outfit and two emergency breathing apparatuses (see 7 Part III of the Rules).

4.1.3 Two additional sets of fire outfit for each vertical fire zone shall be provided on the passenger ships carrying more than 36 passengers.

4.1.4 No additional sets of fire outfit shall be provided for stairway enclosures that form separate vertical fire zones and for vertical fire zones in the ship ends that do not contain accommodations and machinery spaces.

4.1.5 At least two sets of fire outfit on the passenger ships shall be stored in accessible places of each vertical fire zone.

4.1.6 Two spare bottles or two spare apparatuses shall be provided for each required self-contained breathing apparatus. All air bottles for apparatuses shall be interchangeable.

4.1.7 The passenger ships carrying not more than 36 passengers and the cargo ships fitted with means for complete recharging air bottles with purified air may have only one spare bottle or one spare breathing apparatus for each required self-contained breathing apparatus.

4.1.8 The passenger ships carrying more than 36 passengers shall have two spare bottles or two spare apparatuses for each required self-contained breathing apparatus.
5 POWER INSTALLATION AND SYSTEMS

5.1 POWER INSTALLATION

5.1.1 The power installation of a loaded inland navigation self-propelled ship (or of a pusher with loaded convoy) shall provide speed at least 13 km/h at calm water \(^1\) and at least 6 km/h made good when moving upstream.

5.1.2 The power installation of the ship with a single main engine, when the main engine turbo supercharger has been failed, shall provide such a motion speed that the ship could remain steerable.

5.2 SYSTEMS

5.2.1 Control stations, stairwells and internal evacuation areas on the passenger ships carrying more than 36 passengers shall be fitted with natural or mechanical smoke extraction systems. Smoke extraction systems shall satisfy the following requirements:

- They shall have sufficient smoke extraction capacity;
- They shall comply with the operating conditions for passenger ships;
- If smoke extraction systems also serve as general-purpose ventilation for the rooms, this shall not hinder their function as smoke extraction systems in the event of fire;
- Smoke extraction systems shall have a manually operated triggering device;
- Mechanical smoke extraction systems shall additionally be able to be operated from a station permanently manned by crewmembers;
- Natural smoke extraction systems shall be fitted with an opening mechanism operated either manually or by a power source inside the fan;
- Manually operated triggering devices and opening mechanisms shall be accessible from inside or outside the room being protected.

---

\(^1\) Calm water is a water area with current velocity of less than 0.1 km/h and still water surface (slight ripple is allowed) at wind speed of up to 3 m/s.
6 SHIP ARRANGEMENTS AND OUTFIT

6.1 STEERING GEAR

6.1.1 Lower journal of rudderstock shall be protected with a stainless steel liner or in some other way agreed with the River Register.

Keyed taper connection of rudderstock with rudder blade or steerable nozzle shall be protected from corrosion.

6.1.2 If ship is equipped with a rate-of-turn regulator, this regulator shall meet the following requirements:

.1 Operation of rate-of-turn regulator shall not result in spontaneous motion of rudder;

.2 Where, in addition to the rate-of-turn regulator, there are other steering control systems, it shall be possible to distinguish clearly at the steering position which of these systems is active. It shall be possible to shift from one system to another immediately;

.3 Requirements of 7.1.1 to 7.1.5 shall be met.

6.2 ANCHOR ARRANGEMENT

6.2.1 Total weight $\Sigma m_a$ of bow anchors of ships to be operated in zones 1 and 2 of European inland waterways shall be determined through calculations using dependences specified in Table 6.2.1.

A ship shall be equipped with anchors whose total weight complies with the design value $\Sigma m_a$ within 15% tolerance.

6.2.2 Ships shall be equipped with stern anchors whose total weight is not less than 0.25 of total design weight of bow anchors.

Ships with overall length exceeding 86 m shall be equipped with stern anchors whose total weight shall be not less than 0.5 of total design weight of bow anchors.

</tbody>
</table>
6.2.3 Number of stern anchors shall be selected at the ship owner’s discretion. For pushers and ships with overall length exceeding 86 m total weight of stern anchors may be distributed to one or two anchors.

The lightest anchor weight shall not be less than 45% of the total weight of stern anchors.

Ships may not be equipped with stern anchor, if total weight of stern anchors determined according to 6.2.2 for normal holding power anchors is less than 150 kg. Stern anchors are not required for pushed barges.

6.2.4 Minimum required length of a bow anchor chain for displacement ships is specified in Table 6.2.4.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Obtained value $l_a$ shall be rounded for ships equipped with two bow anchors to the nearest value $L_a$ multiple of shot length, and for ships equipped with one bow anchor to the nearest value $L_a$ from the range of manufactured anchor chains (m).

If the total length of anchor chains of two bow anchors is characterized with odd number of shots, then length of one of the chains shall be taken one shot more and connected to a heavier anchor if anchors are different in weight.

6.2.5 Length of each chain of stern anchors shall not be less than 40 m. However, length of each chain of stern anchors for ships to be anchored with bow downstream shall not be less than 60 m.

6.3 LIFE-SAVING APPLIANCES

6.3.1 All deck areas intended for passengers and not enclosed on passenger ships shall be provided with lifebuoys according to European standard EN 14144:2003 on both sides of the ship with maximum 20 m spacing between them.

Half of all the prescribed lifebuoys shall be fitted with buoyant lines of at least 30 m in length and 8 to 11 mm in diameter. The other half of the prescribed lifebuoys shall be fitted with self-igniting battery-powered lights, which will not be extinguished in water.

6.4 SPECIAL WHEELHOUSE ARRANGEMENTS FOR RADAR STEERING BY ONE PERSON

6.4.1 Noise level at the navigator’s head level in the steering position under the specified operation conditions shall not exceed 70 dB(A).

6.4.2 No posts, pillars, window frames or any above-deck obstacles shall be placed in the navigator’s normal line of vision.

6.4.3 The wheelhouse for steering by one person shall be designed in such a way that the navigator shall be able to accomplish his/her task while seated. All indicators or instruments, as well as all ship controls shall be so arranged that the navigator can use them conveniently during the voyage without leaving his/her seat and without losing sight of the radar screen, and the ventilation system capacity in the wheelhouse shall be sufficient to provide trouble-free operation of equipment control systems built in the control panel at high ambient air temperatures.

6.4.4 The radar display shall be placed in the wheelhouse forward of the navigator’s position in such a way that the navigator can observe the image on the screen with no change in his/her position. The radar image shall not be disturbed by masking or screening effect and shall continue to be perfectly visible without hood or glare shield, irrespective to lighting conditions inside or outside the wheelhouse. The rate-of-turn indicator shall be installed directly above or below the radar screen or be incorporated within.

6.4.5 When a rate-of-turn meter is used, it shall be possible to switch off the rate-of-turn meter in any assigned position with no change in the selected speed.
The meter's control shall be able of turning through an arc so as to provide precision of required positioning. The neutral position of the meter control shall clearly differ from other positions. It shall be possible to smoothly control the meter scale illumination.

6.4.6 The navigation lights shall be controlled from the navigation lights control switchboard, where light indicators shall be arranged so as to match the actual arrangement of the navigation lights. Failure of a navigation light shall result in the respective light indicator to go out, and the navigation light failure alarm shall be generated.

6.4.7 It shall be possible to generate an audible warning signal while performing steering operations.

6.4.8 The automatic light indicators to indicate operation of the navigation lights according to 10.7.7 Part VI of the Rules shall be installed on the control panel of the wheelhouse. The navigation light switches shall be used at the same time as switches for the respective automatic light indicators of those navigation lights operation.

6.4.9 The colour of the automatic light indicators of navigation light operation shall match the actual colour of the navigation lights.

6.4.10 It shall be possible to activate audible warning signals with foot when simultaneously performing steering operations. That requirement shall not apply to the "do not approach" signal referred to in the police regulations for the navigation of the European countries in case of traffic incident or onboard accident, which might result in leakage of dangerous carried materials (this audible signal represents short sound continuously repeated for at least 15 minutes and followed by a long one).

6.4.11 A ship shall be steerable with a rudder control lever. This lever shall be manipulated manually by the navigator. The angular movement of the lever relative to the ship axis shall exactly match the movement of the rudder blade(s). Each movement of the rudder control lever shall be accompanied by exact indication of the rudders position. The rudders shall remain in position when the control lever position does not change. The neutral position of the lever shall be indicated by a perceptibly and audibly distinguishable click.

6.4.12 If ship is equipped with special rudders, for example, those used for astern motion only or a bow thruster, these rudders and bow thruster shall be operated with special levers as prescribed by 6.4.11.

This requirement also applies to convoys, if the steering gear of a ship other than propelling the convoy is used during motion of the convoy.

6.4.13 Requirements of 11.12 Part IV of the Rules shall be met as applicable.

6.4.14 Devices shall be available to provide remote dropping anchors for emergency stop of the ship from the ship control position.

6.4.15 A ship of more than 86 m long and more than 23 m wide shall be equipped with devices to remotely drop the bow anchor of the ship being controlled or moored alongside.

6.4.16 The navigator shall be enabled to control the swivelling spotlight when performing steering operations.

6.4.17 There shall be a voice intercommunication system on board.

It shall enable the navigator to communicate with the ship bow or the head barge of the convoy, the master's cabin, the crew accommodation, and the ship stern or last barge of the convoy, if no other means of direct communication from the wheelhouse is possible. The voice intercommunication system shall be so arranged that the navigator can easily use it from his/her seat while carrying out the steering operations. At all locations equipped with such an intercommunication system reception shall be by loudspeaker and transmission by microphone. Transmission/reception mode shall be selected with a button.
Communication between the ship bow and ship stern between the head and the last barge of the convoy may be arranged by radiotelephone.

6.4.18 Where a ship complies with requirements 6.4.1 to 6.4.17, the following statement shall be entered in the documents issued by the River Register for this ship: “The ship has special wheelhouse arrangements for radar steering by one person”.

6.5 SIGNAL MEANS

6.5.1 In addition to navigation lights prescribed by 9.2 Part V of the Rules, ships shall be equipped with all-round blue flashing light with visibility range of 3.7 km.
7 ELECTRIC EQUIPMENT

7.1 RATE-OF-TURN METER

7.1.1 The rate-of-turn meter power supply shall be separated from power supply of other electrical consumers.

7.1.2 The gyroscopes, sensors and rate-of-turn indicators used in the rate-of-turn meters shall meet the minimum technical requirements and test conditions for rate-of-turn indicators for the inland waterways.

7.1.3 Electronics in the rate-of-turn meters shall meet requirements in 6, 7, as well as 9.5, 10.4, 14.2 of Appendix 15 to RTSC, and rate-of-turn indicator shall meet requirements 3.13 Part VIII of the Rules.

7.1.4 The proper functioning of the rate-of-turn meter shall be displayed at the steering position in the wheelhouse by means of a green warning light.

7.1.5 Any lack of or unacceptable variations in the supply voltage and an unacceptable fall of the gyroscope rotation speed shall be indicated at the steering position in the wheelhouse.
Part XII

REQUIREMENTS FOR CNG-FUELLED SHIPS
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 This Part of the Rules specifies requirements for ships with onboard equipment fuelled with compressed natural gas (CNG) subject to requirements stated in Parts 0–XI of the Rules.

1.1.2 This Part of the Rules applies to ships, except oil tankers, on which main and auxiliary engines and independent boilers are fuelled with CNG containing more than 85% methane (hereinafter gas-fuelled ships).

1.1.3 The requirements stated in this Part of the Rules shall be used for design, construction and operation of ships given in 1.1.2, and for conversion of ships in service of other types to gas-fuelled ships.

1.2 TERMS AND DEFINITIONS

1.2.1 Terms related to the Rules common terminology and their definitions are stated in 2.1 and 2.2 Part 0 of the Rules. Terms and definitions relating to ship power unit and systems are given in 1.2.1 Part IV of the Rules.

1.2.2 The following terms are used in this Part of the Rules:

1. Non-hazardous atmosphere means gaseous atmosphere in ship spaces and within open decks, in which natural gas (methane) concentration is below the settings of high gas concentration alarm;

2. Gas-hazardous zone means a zone with gas containing systems and facilities, including superimposed open deck spaces;

3. Gas-hazardous space means a space as follows:
   a hold space where a CNG tank is located;
   an enclosed or semi-enclosed deck space where a CNG tank is located;
   open deck within a gas-hazardous zone and within 2.4 m vertically from it;
   a space within 3 m from external surface of an unenclosed gas-containing system on open deck;
   open deck and spaces located less than 3 m in any direction from CNG ventilation outlets, gas-outlet pipes and similar arrangements;
   a space with direct access to any gas-hazardous space or to any space within a gas-hazardous zone, except as mentioned above, which has no arrangement for permanent maintenance of non-hazardous atmosphere certified by the River Register as compliant with the Rule requirements.

The following is not considered as gas-hazardous:

a space containing CNG-fuelled installation conforming to requirements stated in 4, 5, 6, 7, 8 and 9 of this Part;
control stations, accommodation and utility spaces not located above gas-hazardous space and having inlets and openings conforming to requirements stated in 2 of this Part;

a space beyond the open deck space containing CNG tank and equipment conforming to requirements 2, 6 and 7 of this Part, provided that a hold space located below is not gas-hazardous;
4. **Gas-containing system** means a system designed for CNG storage and supply to consumers;

5. **CNG tank** means a tank designed as a primary gas fuel tank;

6. **Semi-enclosed space** means a space bounded by structures protecting from precipitations and damage of internal equipment during transport operations but providing free ventilation of the space;

7. **Hold space of gas-hazardous zone** means a space bounded by hull structures and comprising a gas-containing system or a part thereof.

### 1.3 INFORMATIVE INSTRUCTIONS

1.3.1. There shall be informative instructions on safe use of CNG fuel onboard a gas-fuelled ship. These instructions shall contain at least the following information:

- description of CNG physical and chemical properties;
- measures to be taken in case of CNG leakage;
- fire-fighting methods and agents;
- methods for draining, purging andstripping CNG tanks, as well as systems, piping and ship equipment with gas-filled chambers;
- emergency actions;
- guide for use of protective equipment provided on a gas-fuelled ship;
- guide for emergency actions to be taken by officers in case of natural gas leakage or fire related to CNG use;
- first aid guide;
- onboard prohibitions on:
  - open fire;
  - smoking;
  - use of sparking equipment or tools;
  - use of equipment operating at temperature above gas mixture self-ignition point (for natural gas mixture with air, at temperature above 400 °C);
  - use of chemicals reacting actively with gas.
2 GAS-FUELED SHIP HULL AND SUPERSTRUCTURE

2.1 GENERAL REQUIREMENTS

2.1.1 CNG tanks shall be arranged in the hull or directly on open deck of a ship.

In case of open deck location, CNG tanks shall be installed in the aft part of the ship beyond the crew’s main workplaces in a such way to provide gas-fueled ship safety under normal operating conditions and in any emergencies, including those caused by damage of CNG tanks.

In case of open deck location, CNG tanks shall be installed in a semi-enclosed space at a distance not less than 0.2B from outer shell, where B is ship’s beam.

2.1.2 CNG tanks shall be attached to the hull in such way to preclude them from displacement caused by dynamic and static loads.

CNG tank design shall allow for compression and expansion of structures due to temperature changes without any near-limit stresses in the tank’s elements and hull structures.

CNG tank attachments shall be designed for static loads as per formula:

\[ F_{1st} = 1.5mg \]  
\[ F_{2st} = 1.3mg \]

where \( F_{1st} \) and \( F_{2st} \) are static loads (N) acting on CNG tank attachments in the longitudinal and transverse directions respectively;

\( m \) — mass (kg) of a tank fully filled with CNG;

\( g \) — acceleration of gravity taken equal to 9.81 m/s²

2.1.3 CNG tank attachments shall include stops designed to withstand horizontal forces arising at ship collision and equal to 0.5 and 0.25 of CNG tank weight and directed to the bow and to the aft respectively, to protect structural elements of CNG tanks from damage.

There shall be arrangements (wedges, stops, etc.) provided to prevent CNG tank floating-up under buoyancy force in case of space flooding up to the full-load draught.

Stresses in hull structure elements shall not exceed the yield point.

2.1.4 The strength calculation of CNG tanks and their supports shall assume independent action of loads given in 2.1.2 and loads arising at list of 30°, as well as no superimposing such loads with forces arising from the hull deformation on the seaway.

2.1.5 Structural provisions shall be taken to prevent CNG tanks displacement relatively to the hull under inertia force due to rolling.

2.1.6 Machinery, cargo and utility spaces shall be isolated from hull spaces where CNG tank are located by means of cofferdams or A-60 fireproof structures.

2.1.7 The access to gas-hazardous spaces shall be provided for their inspection. The access shall be provided:

1. into hull spaces — directly from open deck through openings, hatches and manholes with clear size at least 800×800 mm;
2. to open deck spaces — through openings or manholes in vertical walls with clear size at least 800×800 mm.

2.1.8 Gas-hazardous deck shall have a sparkproof coating.

Door and hatch fasteners of gas-hazardous zone spaces shall be made of a sparkproof material.
Tools for operation in gas-hazardous zone, as well as gear of relevant personnel shall have sparkproof design.

2.1.9 Measures shall be taken to seal hull located gas-hazardous spaces in the points where piping and cables pass through bulkheads to prevent gas penetration from a gas-hazardous space to adjacent spaces.

2.1.10 Entries and openings to control stations, accommodation and utility spaces shall be located on bulkheads not faced to the gas-hazardous zone. If top edges of entries and openings are below the level of CNG tank, such entries and openings may be located on bulkheads faced to the gas-hazardous zone.

2.1.11 Portholes in external bulkheads of superstructures and deckhouses faced to a gas-hazardous zone shall be of blind (non-opening) type. This requirement does not apply to wheelhouse windows.

2.1.12 Location of ship gear control stations and ship stores within a gas-hazardous zone is prohibited.
3 CNG TANKS

3.1 GENERAL REQUIREMENTS

3.1.1 CNG tanks shall comply with applicable requirements stated in Part IV of the Rules. Standard cylinders designed for operating pressure up to 25 MPa or tanks custom fabricated for the gas-fuelled ship may be used as CNG tanks.

Operating pressure in standard cylinders shall be assigned according to the specification of cylinder manufacturer, which is to have River Register's Recognition Certificate. Operating pressure in CNG tanks custom fabricated for a gas-fuelled ship shall be assigned basing on results of the River Register's review of relevant tank specifications and on results of the tank testing to design pressure according to 6.2.41–6.2.42 RTSC.

3.1.2 CNG tanks shall be grouped. Each group of 2–4 tanks shall be equipped with a separate stop valve. A group of gas cylinders/tanks shall be divided into sections, each of them shall be provided with a stop valve.

3.1.3 CNG tanks shall be painted in red and marked with inscription “Methane”.

3.1.4 CNG tanks/cylinders shall not be located in the same spaces with oxygen or compressed air cylinders.

3.1.5 Gas cylinders shall be placed on frames (racks). There shall be soft gaskets provided between clamps and cylinder surfaces, as well as between support surfaces of frames (racks). Gaskets shall be manufactured of a noncombustible material.

3.1.6 Each CNG tank shall be equipped with a pressure relief valve according to applicable requirements of 8.17.9, 8.17.10, 8.17.11 Part IV of the Rules.

Pressure relief valves of CNG tanks located in the hull or on open deck of a gas-fuelled ship, shall be connected to gas-outlet pipes conforming to requirements of 4.1.11.

3.1.7 Filling CNG tanks shall be provided from both sides of the ship.

Filling (bunkering) piping shall be designed not only for CNG tank filling (bunkering) but also for CNG discharge from these tanks (until their full emptying). If it is impossible or impracticable to use CNG filling piping for CNG discharge, there shall be dedicated piping for CNG discharge conforming to the same requirements as applied to CNG filling piping.

Each filling (bunkering) piping shall be provided with two stop valves mounted serially. One of them shall function as an emergency valve, and one of them shall be remotely controlled from wheelhouse and bunkering control station (if any).

Filling piping shall be connected to external flexible bunkering piping through a quick connection installed on filling piping end section; type and sizes of such a connection shall be approved by the River Register for CNG bunkering operations.

The end section of ship filling piping shall be equipped with gas-tight blind manufactured of a sparkproof material.

The blind shall be permanently attached to the end section of filling piping by chain or cable with length sufficient for blind removal and replacing to prevent blind loss when it is removed for bunkering.
Provisions shall be made for purging external flexible piping connected to the end section of the filling piping, as well as any part of the filling piping between stop valves mounted on it or other stop valves and CNG tank, by pressurized compressed inert gas, which is to be discharged to gas-outlet pipes.

Bunkering piping components designed for connection with onshore piping shall be manufactured of a sparkproof material.

Provisions shall be made for ship grounding by means of onshore ground connector during CNG filling from shore.

3.1.8 If ship filling piping is fitted with equipment for gas fuel sampling and for gas quantity/quality testing (e.g. gas fuel pressure indicators, meters, mixture analyzers, etc.), such equipment shall be installed downstream of the filling piping's inboard stop valve in such a way, that any item of given equipment may be cut off from ship filling piping without affecting this piping capacity.

Above equipment for gas fuel quantity/quality testing shall have the River Register's Compliance Certificate.

End connection of a sampling device shall be closed with a blind conforming to the same requirements as end blinds of ship filling piping or with such device's regular sampling container.

Containers with gas fuel samples shall be stored within well ventilated areas outside the ship spaces.

3.1.9 The inert gas system shall be provided for stripping CNG residues from cavities, which are supposed to be further filled with CNG, by means of purging with inert gas, which is then discharged to gas-outlet pipes.

It is recommended to use a system, which uses nitrogen supplied from shore as an inert gas. Amount of nitrogen in high pressure cylinders shall be sufficient for three purgings of all the cavities designed to be filled with CNG or inert gas. Inert gas piping shall be routed to all cavities, which are to be purged. Nitrogen storage cylinders shall comply with requirements applicable to CNG storage tanks.

Inert gas may also be prepared on board by means of nitrogen generators or inert gas generators having the Compliance Certificate issued by the River Register.
4 EQUIPMENT FOR CNG SUPPLY TO CONSUMERS

4.1 GENERAL REQUIREMENTS

4.1.1 Equipment for the CNG supply to consumer shall include the following:

.1 pressure regulators for CNG supplied to consumers (main and auxiliary engines, self-contained boiler)
.2 pressure-relief and shut-off valves
.3 CNG supply pipelines
.4 instruments, alarm and protection system
.5 gas-outlet pipes for extraction and removal of natural gas
.6 pipeline covers, cowls and trunks
.7 auxiliary equipment and spare parts for installation, operation and repair
.8 inert gas system specified in 3.1.9 as well as used for filling protective jackets with inert gas if so stipulated by ship design

4.1.2 Equipment for CNG supply may be located in the engine room if the requirements specified in this section are met.

The pipelines and any devices, which may be the source of CNG leakage, shall be located on the open deck outside the engine room and other bilge spaces. CNG pipelines shall not be laid closer than 760 mm from the outer shell plating.

In order to avoid flame propagation in the CNG pipelines they shall be fitted with flame arresters.

4.1.3 Main gas valve outside the engine room shall be provided to stop natural gas supply from the CNG tanks to consumers. Design of the main gas valve shall enable its manual control at the place of installation, as well as automatic closing.

Remote opening and closing the main gas valve from the wheelhouse shall be provided.

Installation of two sequential main gas valves (one provided with manual control and the other one automatic with remote control) is allowed.

4.1.4 Each CNG consumer shall be equipped with three automatic valves. Two valves shall be installed sequentially in the pipeline supplying gas to the consumer. The third valve shall be installed in the gas-outlet pipeline, which vents gas to atmosphere from the gas supply pipeline section between the two sequential valves.

Control of these valves shall be arranged to provide automatic closing the two sequential valves and simultaneous automatic opening the gas-outlet valve in case of CNG consumer shutdown or any fault that requires stopping CNG supply to the consumer.

One of the two stop valves and the gas-outlet valve may be combined in one valve box arranged in such a way that to provide closing the gas supply pipeline and opening the gas-outlet pipe in case of a fault that requires stopping CNG supply to the consumer.

The design of the stop and gas-outlet valves with automatic control shall enable their manual closing and opening.

4.1.5 The part of the CNG pipeline between the main gas valve and stop valves on the pipelines supplying gas to individual consumers shall be equipped with pressure-relief valves connected to the gas-outlet system.

If CNG pressure regulator installed at CNG tank outlet has an integral pressure-
relief valve, no pressure-relief valve on the pipelines after the main gas valve is required.

4.1.6 CNG pipelines shall not be laid through control stations, accommodation and service spaces, in the cargo holds, through ship's ventilation trunks and ducts.

CNG pipelines may be laid inside other ship spaces if the following conditions are met:

.1 CNG pipeline is a double-wall pipeline with gas fuel in the inner pipe;
.2 The space between the pipeline walls is filled with inert gas under pressure exceeding the gas fuel pressure;
.3 Inert gas pressure in the pipeline system is constantly monitored with the alarm system sensors;
.4 Upon alarm actuation, two sequential valves on the pipeline, which supplies gas to the consumer (see 4.1.4), close automatically before inert gas pressure falls below the gas fuel pressure, and the third valve on the gas-outlet pipeline opens automatically;
.5 After the main gas valve (see 4.1.3) is closed, the inner gas fuel supply pipeline between the main gas valve and respective CNG consumer is automatically purged with inert gas;
.6 A system where the space between the pipeline walls is ventilated by an exhaust ventilation system may be considered equivalent to provisions of 4.1.6.2 to 4.1.6.5. Capacity of such a ventilation system shall be determined by calculation from gas fuel rate and structure and location of the jacket pipes/ducts. The requirements of 4.1.8 shall be met as well.

4.1.7 CNG pipelines shall be protected against corrosion using a method agreed with the River Register.

The gas fuel pipelines in vicinity to connections with the CNG tanks/cylinders shall have circle bends to prevent pipeline damage from hull structure vibrations.

4.1.8 The following requirements are imposed upon CNG pipeline jacket duct ventilation system:

.1 Circulation rate shall not be less than 30 air changes per hour;
.2 Pressure in the jacket duct shall be less than the atmospheric pressure;
.3 The fan motors shall be located outside the jacket ducts;
.4 The ventilation outlet openings shall be located in places where explosive natural gas and air mixture cannot be ignited;
.5 The ventilation inlet openings shall be located to avoid ingress of natural gas or mixture of natural gas and air into the ventilation system. Those openings (ventilation inlets) shall be equipped with non-return devices unless ventilation system inlets are equipped with gas detectors;
.6 The ventilation system shall start automatically when gas fuel supply to CNG pipeline is started, and shall keep operating continuously as long as the gas is supplied through the pipeline;
.7 When the ventilation system fails to provide the required air change rate, the main gas valve (see 4.1.3) shall close automatically;
.8 The sensors of a gas detection system shall be places in the jacket ducts; this system may be part of the CNG supply equipment alarm and automatic protection system. Upon actuation of these sensors or the alarm system, the requirement of 4.1.6.4 shall be met;
.9 Inertisation (inert gas supply) and degassing of the part of the CNG pipeline system located in the engine space shall be provided.

4.1.9 CNG pipelines may transit through a space where natural gas is not used may be allowed if the requirements of 4.1.6 to 4.1.8 are met. CNG pipelines and their jackets shall have no detachable joints or fittings within these spaces.

4.1.10 CNG pipeline jacket ducts with exhaust ventilation shall end at a ventilation cowl or trunk.

Ventilation cowls or trunks shall be located nearby flanges, valves, pressure regulators and other gas equipment, including those installed directly at the CNG consumers.
Ventilation cowl or trunk shall be connected to exhaust ventilation system and shall be arranged so that air could to flow over the CNG consumer and be evacuated through the upper part of that ventilation cowl or trunk.

The air flowing through the ventilation cowl or trunk shall be continuously monitored by the natural gas detection system linked to the alarm and automatic protection system.

4.1.11 CNG pipelines and gas equipment shall be connected to the gas-outlet pipe system through the gas-outlet valves specified in 4.4 and through pressure-relief valves.

The gas-outlet pipe system shall be designed to direct the outgoing natural gas upwards.

The exhaust opening of the gas-outlet pipes shall be located above the open deck at height at least 1 m higher than wheelhouse.

For explosion/fire safety the gas/air mixture discharged from the gas-outlet pipes shall be additionally diluted with air supplied from the continuously operating ventilation systems in order to decrease total concentration of natural gas in the gas/air mixture.

Protective screens shall be installed at the discharge openings of the gas-outlet pipes to avoid ingress of foreign objects.

Instead of or in addition to the specified gas-outlet pipe system, a system may be provided to supply gas/air mixture from the gas-outlet pipes to combustion chamber of a self-contained boiler or a high-temperature organic heating fluid heater in order to force oxidation of the natural gas in the gas/air mixture from the gas-outlet pipes.

4.1.12 No stop valves may be installed on the pipelines connecting the pressure-relief valves to the gas-outlet pipe system.

4.1.13 CNG pressure indication devices shall be provided:
   .1 after the main gas valve
   .2 after each pressure regulator (reduction valve) in the system
   .3 before each consumer (when one pressure regulator serves a group of consumers)

4.1.14 The alarm system shall provide light and sound signals on deviation of a monitored parameter from the normal value and on actuation of the automatic protection in the following cases:
   .1 CNG pressure drop at the main gas valve
   .2 CNG pressure drop before each consumer
   .3 inert gas pressure drop in the protective jacket of the pipeline (see 4.1.6)
   .4 loss of vacuum or power supply to fans of the CNG pipeline jacket duct exhaust ventilation system
   .5 detection of natural gas in air running through CNG pipeline jacket ducts, ventilation cowls or trunks;
   .6 low or no valve pneumatic drive air pressure
   .7 loss of power supply of units/devices included in the equipment

4.1.15 In case of faults specified in 4.1.14, except for CNG drop before any individual consumer, the protection system shall actuate and the main gas valve shall automatically close.

When all the consumers shut down or switch to liquid petrol fuel, the main gas valve shall automatically close.

If the backup stop valves on pipelines supplying CNG to consumers and the gas-outlet valves are equipped with automatic drives, then automatic closing of the stop valves and opening of the gas-outlet valves shall be provided in case of faults specified in 4.1.14 except for CNG pressure drop before any individual consumer or all consumers shutdown or switching to liquid petrol fuel.

4.1.16 The design of automatic stop valves, including the main gas valve, shall provide automatic closing the valves in case of power loss on their drives.

The automatic gas-outlet valves shall open at power loss on their drives.
4.1.17 Indicators of parameters specified in 4.1.13 shall be installed in the engine room. CNG pressure after the main gas valve indicator shall be installed in the wheelhouse.

Signaling devices of the alarm and automatic protection system pertaining to cases listed in 4.1.14 shall be installed in the engine room and in the wheelhouse.

4.1.18 CNG pipelines shall be painted yellow with red rings.

4.1.19 If CNG tanks are located on a barge connected to the pusher with automatic coupling device, the requirements of 3.1.9 shall be met. Measures shall be taken to exclude damage and/or leakage of the pipeline supplying gas to the pusher as a result of the barge motions relative to the pusher. The use of standard flexible rubber/metal hoses for this purpose is allowed.

4.1.20 Two stop valves shall be installed sequentially before the detachable joint of the pipeline supplying gas from the CNG tanks on the barge to the pusher. These valves and the pipeline nearby shall meet the requirements of 3.1.9.

4.1.21 A gas heating equipment shall be provided for the gas supplied to CNG pressure regulators, in order to avoid icing gas equipment as a result CNG cooling due to pressure drop.

Only hot water from the inner engine cooling loop or the room heating system may be used for heating CNG.

4.1.22 The gas supply pipes from CNG tanks to consumers shall be seamless.

Where pressure is low (the final sections just before the consumers), standard rubber/metal hoses may be used.

The gas-outlet pipes shall be seamless.

4.1.23 CNG filtration shall be provided for removal of resins and mechanical impurities. The gas filter shall be installed on the gas line before the first stage reduction valve.

4.1.24 The gas fuel receiving stations shall be located on the open deck naturally ventilated.

4.1.25 A stop valve with manual local control and remote control from a safe accessible place shall be provided on each gas fuel intake pipeline near the inlet flange.
5 CNG CONSUMERS

5.1 MAIN AND AUXILIARY ENGINES

5.1.1 The engines of gas-fueled ships shall be adopted for using CNG in accordance with requirements specified in this section; this shall be confirmed by the manufacturer's documents and the River Register's documents on compliance with the Rules.

5.1.2 Power installation of a ship with dual fuel (gas + diesel oil) engines shall enable ship cruising and maneuvering using either gas or liquid petrol fuel.

5.1.3 If dual fuel (gas + diesel oil) engines are used at a gas-fueled ship, the following requirements shall be met:
   - The main engines shall operate stably with either natural gas or liquid petrol fuel at medium and high loads.
   - Auxiliary engines, which are used to drive generators of the ship's electric power plant, shall be made gas-fueled only if prolonged medium or high loading of the diesel generators can be ensured.
   - The engines shall start, stop (except for emergency shutdown), run idle and run slow using liquid petrol fuel. Switching between liquid fuel and gas fuel shall be carried out automatically.
   - The engine shall be provided with an emergency shutdown device.

5.1.4 The following requirements shall be met if gas (gas reciprocating) engines with spark ignition are used on a gas-fueled ship:
   - The main engines and ship's electric power plant (except for emergency diesel generators) shall be located in two separate machinery spaces.
   - Power of the main engines shall be enough to provide ship's speed as specified in 1.12 Part IV of the Rules and ship maneuverability as specified in 6, Part II of the Rules, with shaft generators simultaneously running.
   - The engines specified in 5.1.3 shall operate using combined cycle (liquid petrol fuel for ignition only) and using liquid petrol fuel only without any need in readjustment.
   - During switch of the dual-fuel main engines from liquid petrol fuel to gas fuel and back, engine shaft rpm may change by 5% to 10% for maximum 15 s.
   - Flame arresters shall be provided at engine exhaust pipelines.

5.1.5 A fuel supply control system shall automatically switch the dual-fuel engine from CNG to liquid petrol fuel when engine load rises above the threshold value, at which intermittent supply of liquid petrol fuel still enables stable natural gas operation. Interlocking shall be provided to prevent the fuel equipment from switching to CNG if the engine load is below that threshold.

5.1.6 When the main engine threshold load specified in 5.1.7 is reached, the engine shall be automatically switched from CNG to liquid petrol fuel and back, upon operator's commands from a remote or local control station.

5.1.7 The dual-fuel engine automatic control system shall:
   - Automatically stop CNG supply and switch the engine to liquid petrol fuel when
pressure in the CNG supply system falls below the setpoint;

2. Start CNG supply to the engine only after the cooling water reaches the temperature setpoint;

3. Automatically stop CNG supply in case of any spontaneous shutdown of the engine (including automatic protection);

4. Automatically stop CNG supply and switch the engine to liquid petrol fuel when the alarm system generates alarm on any monitored parameter;

5. Generate command pulses to the automatic control system of the CNG supply equipment in cases that require stop of CNG supply to the engine.

5.1.10 The alarm and remote/local indication systems of dual-fuel engine shall be supplemented with components for:

.1 indication of actual operation using CNG or liquid petrol fuel in the wheelhouse and at the local control station

.2 indication of CNG pressure before the engine at the local control station

.3 light and sound alarm on actuation of the engine automatic protection in the wheelhouse

5.1.11 Measures shall be taken to prevent from explosive concentration of vapours and gas in the engine crankcase due to natural gas leakage into the crankcase from the engine cylinders.

It is allowed to ventilate the crankcase by connecting it to the engine intake line and to provide a flame arrester at the crankcase ventilation pipeline.

5.2 SELF-CONTAINED BOILERS

5.2.1 A forced draught system shall be provided for self-contained boiler to make a draught as required for natural gas operation.

5.2.2 Combustion chamber of the self-contained boiler shall have no spaces or cavities where natural gas may accumulate.

5.2.3 The boiler's combustion burners shall be able to use liquid petrol fuel, CNG or liquid petrol fuel and CNG simultaneously.

5.2.4 The gas burners shall be arranged so that the CNG is ignited by flame of the liquid petrol fuel nozzle. When the boiler uses gas fuel, a permanent ignition source for the gas/air mixture shall be installed in the gas burner flame. The power of that ignition source shall be enough for immediate reignition of the flame.

5.2.5 Measures specified in 4.1.4 shall be taken to provide purging of the pipelines supplying CNG to the burners.

5.2.6 The boiler automation system shall:

.1 Automatically stop natural gas supply when CNG pressure before the boiler is below the setpoint;

.2 Automatically stop natural gas supply and stop the boiler when the boiler alarm system generates alarm on any monitored parameter;

.3 Automatically ignite natural gas by activating the liquid petrol fuel nozzle, then automatically deactivate the liquid petrol fuel nozzle if the boiler uses CNG only;

.4 Automatically stop CNG supply in case of flame failure;

.5 Indicate actual operation using CNG or liquid petrol fuel in the wheelhouse and at the local station;

.6 Generate light and sound alarm on actuation of the boiler automatic protection in the wheelhouse;

.7 Generate command pulses to the automatic control system of the CNG supply equipment in cases that require stop of CNG supply to the boiler.

5.2.7 If the self-contained boiler is used for burning or forced inertisation of the gas/air mixture from the gas-outlet pipes, its furnace or combustion chamber shall be equipped with a nozzle for gas/air mixture supply to the furnace or chamber from gas-outlet manifold. There shall be provided some means for vapour condensation or cooling of water or high-temperature organic heating fluid heater at the boiler output for situations when the boiler produces more heat than it is needed for the ship.
6 VENTILATION OF SPACES

6.1 NORMALLY MANNED SPACES

6.1.1 The enclosed spaces, including the machinery spaces, which accommodate gas-containing system components subject to systematic inspection for their technical condition and proper operation and fixed gas analyzers, shall be equipped with induced ventilation independent of other ventilation systems and operated from outside these spaces.

Measures shall be provided to start the ventilation system of these spaces before maintenance personnel enters them. The warning sign to start the ventilation system shall be placed at the entry of these spaces.

6.1.2 The ventilation system of the machinery spaces with the gas fuel engines and boilers shall be independent of the ventilation systems serving other spaces. Ventilation of the machinery space shall be of supply-and-exhaust type to provide necessary depressurisation in the space.

The use of the main engines as means of exhaust ventilation is allowed if gas control system sensors are located at the engine's air intake points.

Natural ventilation of the machinery space shall be provided for idle time.

The ventilation system of gas-hazardous machinery spaces or engine rooms shall provide at least 30 air changes per hour. The air circulation shall involve the whole volume of the space without dead zones. Such spaces may also be served by a ventilation system that provides 15 air changes per hour in case of no gas in the space and automatically increases air change rate up to 30 air changes per hour as soon as gas is detected in the space.

6.1.3 The exhaust ventilation ducts shall evacuate the gas/air mixture upwards. The exhausts openings shall be located above the deck and in such a way to exclude gas ingress into the superstructure spaces.

6.1.4 Machinery space supply ventilation inlet openings shall be located so as to minimize induction of outgoing gas from any ventilation exhaust opening.

6.1.5 The exhaust ventilation ducts of the gas-hazardous spaces shall not pass through the machinery space, accommodation and service spaces, control stations.

The exhausts of these ducts shall have spark arresters.

6.1.6 The fan motors shall be located outside the ventilation ducts.

The exhaust fans of the enclosed gas-hazardous spaces and machinery space shall be installed outside these spaces.

6.1.7 The machinery and other spaces where potentially explosive concentration of the natural gas may form up (volumetric concentration of methane in the air between 4.4 % and 17 %) shall be provided with emergency exhaust ventilation. This ventilation shall be automatically started when methane concentration reaches 1 % by volume in the served space; at the same time, natural gas supply to consumers shall be stopped.

6.1.8 The semi-closed spaces on the open deck, which accommodate gas-containing system components, shall have natural ventilation to prevent accumulation of natural gas in any part of these spaces.
6.1.9 The in-hull spaces accommodating CNG tanks (or cylinders) shall be equipped with induced ventilation providing at least 30 air changes per hour.

6.2 OCCASIONALLY MANNED AND OTHER SPACES

6.2.1 The bilge spaces and other occasionally manned spaces where natural gas may accumulate shall have induced ventilation to prevent formation of explosive concentration of the natural gas, which may get ignited when these spaces are entered.

The fans shall comply with the requirements of 6.1.6.

6.2.2 Inlet openings of the ventilation system that serves accommodation spaces, service spaces and control stations shall not be face toward the gas-hazardous zone. They shall be so located to prevent induction of gas from the gas-outlet pipes, gas-hazardous space exhaust ventilation openings, exhaust pipes of the gas engines and boilers.
7 GAS CONTROL IN SPACES

7.1 GENERAL REQUIREMENTS

7.1.1 The spaces located in the gas-hazardous zone (including machinery spaces and CNG tank spaces) shall be equipped with a methane detection system.

7.1.2 Light and sound alarm shall actuate in the spaces with the methane detection system sensors and in the wheelhouse if methane concentration in the air reaches 0.5% by volume.

Gas supply to the machinery space shall be automatically stopped and alarm shall be simultaneously generated when methane concentration in the air reaches 1% by volume at any measurement point.

7.1.3 The places for fixed natural gas detection system's sensors shall be selected depending on methane density, presence and direction of air flows, and most probable places of CNG leakage.

7.1.4 Methane concentration in the place of any sensor shall be observed using a secondary indicating device located in a permanently manned space.

7.1.5 Portable equipment may be used for gas control of spaces in the gas-hazardous zone except for the machinery space and closed bilge space with CNG tanks, if such an equipment is used for testing before entering the space and every 30 minutes during staying in the space.

7.1.6 The ship shall be equipped with at least two sets of portable gas control equipment.

Devices shall be provided to enable sampling air from spaces in the gas-hazardous zone using portable equipment while staying outside such spaces.

7.1.7 Explosion-proof sensors with intrinsically safe circuit shall be used.

7.1.8 Design of the methane detection system components shall enable their testing and calibration. Calibration and tests shall be carried out within the time frames specified by the equipment manufacturer.

7.1.9 The gas control alarm system shall have an automatic switchover device to switch to an emergency source in case of ship mains power loss.

7.1.10 Gas concentration in accommodation and service spaces shall be tested with portable equipment specified in 7.1.6.
8.1 GENERAL REQUIREMENTS

8.1.1 Fire protection of the gas-fueled ships shall comply with the requirements of Part III of the Rules. The list of used fire equipment and fire fighting systems shall be determined depending on class, type and purpose of the ship considering the requirements specified in this section.

8.1.2 The spaces for storage of CNG tanks and ventilation ducts serving those spaces shall be separated from accommodation, service, cargo and machinery spaces with A-60 structural boundaries. The spaces for storage of CNG tanks may be separated from other (low fire hazard) spaces with A-0 structural boundaries.

Gas fuel tanks located on the open deck shall be separated from accommodation, service, cargo and machinery spaces with an appropriate screen compliant with requirements to A-60 boundaries.

8.1.3 The machinery space and in-hull spaces, which accommodate CNG tanks, as well as other enclosed spaces of the gas-hazardous zone shall be equipped with a fire fighting system in accordance with Part III of the Rules.

8.1.4 Fire smothering system shall be provided for the machinery space and other spaces accommodating gas-containing system components.

When determining the design volume of the protected space, the volume of the equipment located inside the space shall not be deducted from the total volume of the space.

8.1.5 The spaces accommodating gas-containing system components shall be equipped with automatic fire detection alarm system and fire smothering system release warning system.
9 ELECTRIC EQUIPMENT

9.1 GENERAL REQUIREMENTS

9.1.1 The explosion hazardous spaces on the gas-fueled ships using CNG include (in addition to those specified in Table 1.4.1, Part III of the Rules) the internal volumes of the gas-outlet pipes and exhaust/supply ventilation ducts of spaces in the gas-hazardous zone.

9.1.2 Protection degree of electric equipment installed in the explosion-hazardous spaces of the gas-hazardous zone shall not be less than specified in 16.2, Part VI of the Rules for the spaces of appropriate category.

In the bilge spaces accommodating gas tanks, there may be laid cable routes and may installed explosion-proof indication and alarm instruments compliant with GOST R 51330.0 with pressurised or explosion-resistant enclosures, as well as electric drives for pipeline valves with explosion-resistant enclosures.

9.1.3 All the cables passing through the explosion-hazardous spaces and areas shall be laid in steel gastight seamless pipes.

9.1.4 Metal mechanical protections for cables laid on the upper deck and passing through the explosion-hazardous areas shall be grounded, at least, at both ends of each protection (casing, steel pipe, armouring braid).

9.1.5 The following consumers shall be compulsorily supplied from the main switchboard buses:

.1 switchboard for methane-in-air alarm
.2 switchboard for control and alarm of equipment for CNG supply to consumers
.3 switchboard of fans serving gas-hazardous spaces, ventilation ducts and trunks, and fans used to pressurise explosion-proof electric equipment

9.1.6 The following consumers shall be compulsorily supplied from the emergency switchboard buses through individual lines:

.1 switchboard for methane-in-air alarm
.2 switchboard of fans used to pressurise explosion-proof electric equipment

9.1.7 Start of electric fans serving explosion-hazardous spaces shall be interlocked with opening doors into these spaces and starting the electric equipment in these spaces, in such a manner that entry into these spaces and start of electric equipment are possible not before the fans started and operated for a time as necessary for ten air changes in the space.

9.1.8 Lighting system of the explosion-hazardous spaces and areas shall be subdivided into at least two circuits supplied from different switchboards.

9.1.9 The switches and protective devices of the lighting system of the explosion-hazardous spaces and areas shall be installed outside these spaces and areas and shall be able to brake all phase lines.

9.1.10 Lighting fixtures of the explosion-hazardous spaces and areas shall be explosion-proof with pressurised enclosure or explosion-resistant enclosure.

9.1.11 Any sparking electric devices shall be located so that they are not flown by ventilation air, which may be contaminated by leaked natural gas.
10 PERSONNEL PROTECTION

10.1 GENERAL REQUIREMENTS

10.1.1 The ships with gas-containing system equipment installed in enclosed spaces in the hull shall be provided with at least two sets of protective outfit suitable for safe entering spaces filled with natural gas and working in these spaces. This outfit shall be accessible.

The watch personnel shall be equipped with personal portable gas detectors.

10.1.2 The set of protective outfit mentioned in 10.1.1 shall include the following:

1. self-contained breathing apparatus operating with compressed air, with cylinders of capacity at least 1200 NL. Each cylinder shall have a protective coating to prevent from sparking upon contact with metal surfaces;

2. protective clothing, footwear, gloves made of an antistatic material, and tight protective goggles;

3. steel-cored life line and intrinsically safe belt;

4. explosion-proof lamp;

5. toxic compound detector.

10.1.3 For breathing apparatuses mentioned in 10.1.2.1, charged spare air cylinders with total capacity of at least 3600 NL per apparatus shall be provided.

10.1.4 Compressed air devices of the breathing apparatuses shall be inspected for compliance with the Rules requirements and tested once a year according to RTSC.

10.1.5 Special footwear of the crew members shall have non-sparking brass or wooden nails or no nails at all.
Part XIII

EQUIPMENT OF PASSENGER SHIPS
FOR CARRYING DISABLED PERSONS ONBOARD
1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 This Part complements 9 and 10 Part I, 3 Part III, 6 and 8 Part V as well as 11 Part VI of these Rules and establishes requirements to the design and equipment of passenger, pleasure and crew ships in order to provide for carrying disabled persons.

1.2 TERMS AND DEFINITIONS

1.2.1 Terms related to the Rules common terminology and their definitions are stated in 2.1 and 2.2 Part 0 of these Rules. The following terms are used in these Rules:

1. Disabled persons means persons capable of moving without any assistance as defined in 1.2.1.2 and having difficulties in using transport and seeking attention and adaptation of services commonly rendered to all passengers to their specific needs. The disabled persons include elderly people, people on wheelchairs, people with congenital physical defects or physical defects caused by any physical (sensor or motor, permanent or temporal), mental or psychosocial disease or deterioration, pregnant women and people accompanying children;

2. Unassisted movement ability means capability of moving in a space without any assistance, keeping body balance during movement, at rest and postural change, using a public transport:

First degree means ability to move without any assistance but for longer time periods, partial performance and at a reduced distance with the help of auxiliary technical means, if required.

Second degree means ability to move with regular partial assistance with the help of auxiliary technical means, if required.

Third degree means inability to move without any assistance and requirement for permanent assistance.

1.3 INFORMATION SUPPORT

1.3.1 For marking of spaces and equipment, areas and sections as well as routes of movement for the disabled person, the symbols and pictograms adopted in GOST 52131 shall be used.

Direction signs and rules of conduct on board the ship shall be attached on walls. The letters shall be at least 15 mm high.

1.3.2 Muster lists and safety plan shall be displayed prominently in areas designated for disabled persons.

These lists and plan shall be placed at a height allowing them to be clearly read by people on wheelchairs with the text clearly perceptible to vision impaired people.

1.3.3 The crew muster lists shall indicate ship areas designated to be used by disabled persons.

These lists shall also contain special measures to be taken in case of emergency situation with respect to disabled persons.

1.3.4 Information on assistance shall be readily available on the movement routes and within the spaces designated for disabled persons.

---

1 As defined in the revision of "b", 6 of the Order of the Ministry of Labour of the Russian Federation dated 20/11/2014 No.664 n.

2 GOST R 12.4.026, GOST R 51671.
2 PASSAGES, DOORS, SILLS AND COAMINGS

2.1 REQUIREMENTS TO PASSAGES

2.1.1 Clear width of passages within main corridors of passenger, accommodation and public spaces as well as deck passages leading to lifeboat and liferaft embarkation areas shall be at least 1.3 m.

2.1.2 Passages stated in 3.1.1 shall ensure free movement of disabled persons.

2.1.3 The areas where there are inclinations (ramps, deck deflections) as well as passages and corridors shall be provided with non-slip coating, which does not build up static electricity, handrails and other arrangements, which may be held on to.

2.1.4 The clear width of escapes from spaces designated for disabled persons shall be at least 0.90 m.

The clear width of side openings used for embarkation and disembarkation of disabled persons shall be at least 1.50 m.

2.2 REQUIREMENTS TO DOORS

2.2.1 Doors of passenger spaces except for those with escapes into corridors shall open outwards. When in open position, the doors shall rest against the wall and be secured in this position.

Door openings shall be at least 0.90 m wide.

Doors of lavatories designated for disabled persons shall open outwards or shall be of sliding type. Locking arrangements shall be integral with door handles.

The width of door openings shall provide for free movement of disabled persons including people on wheelchairs, but in any case shall be at least 0.90 m.

2.2.2 In the direction of opening of doors for disabled persons there shall be a platform of at least 0.60 m between the internal edge of the door frame from the lock and adjacent wall perpendicular to the edge.

2.2.3 Doors of specific design (revolving doors, double-swing doors) are not allowed.

Where sliding doors are fitted, guideway shall be below the floor level.

The lift cabin door shall be of sliding or folding type with clear width of at least 0.9 m.

2.2.4 The distance between the internal edge of the door frame from the lock side and adjacent vertical wall shall be at least 0.50 m.

2.2.5 The passenger space doors shall be designed to prevent their unauthorized locking or otherwise fastening.

2.3 REQUIREMENTS TO SILLS AND COAMINGS

2.3.1 Door sills shall be avoided within passenger areas. Where door sills are provided, they shall be max. 25 mm high.

The height of coamings on weather decks shall be as low as possible provided the hull strength and integrity are not degraded. Where drain openings covered with fine mesh with water discharge overboard are provided for hull integrity, coamings may be completely excluded.

Where height of door sills and coamings exceeds 25 mm, they shall be of removable type or consist of low soft rubber sections or there shall be arrangements (removable ramp) providing for free movement of disabled persons including people on wheelchairs.
3 LADDERS, GANGWAYS, RAMPS, LIFTS

3.1 REQUIREMENTS TO LADDERS

3.1.1 Inclination angle of ladders for movement of disabled persons shall not exceed 32°. Ladders shall be oriented along the ship. The ladders shall have soiling in accordance with GOST 26314 and clear width of at least 0.9 m.

Ladder handrails shall be designed according to 4.1.3.

3.1.2 Ladder steps shall have non-slip coating and be free of any projections or recessions. Ladder steps shall be max. 0.18 m high and at least 0.30 deep.

3.1.3 Transverse step plates shall be max. 0.3 m long and max. 0.03 m high to allow for movement of wheelchairs along the ladders. Openings in the perforated surface shall be max. 0.01 wide or 0.03 m long. To eliminate difference in levels between ladder and pier or deck, flaps at each end of the ladder shall be used.

3.2 REQUIREMENTS TO STAIRS

3.2.1 The stairs inclination angle shall not exceed 38°. Stairs shall be of straight type and located aft or forward of the ship. Stairs steps shall be max. 0.18 m high and at least 0.30 deep.

Note that a person on wheelchairs is incapable of coping with an inclination steeper than 1:20 (3°) without any assistance and come up an inclination steeper than 1:4 (14°) is extremely difficult even with the assistance. Where a ladder with high inclination (for example, 1:4) is required on some quays, the ladder shall be max. 2 m long.

Stairs steps shall have non-slip coating and be free of any projections or recessions. Stairs shall be equipped with handrails according to 4.1.4.

The deck area directly upstream of stairs or steps shall be marked with plating made of material with color standing in contrast with that of the rest deck plating.

3.3 REQUIREMENTS TO GANGWAYS

3.3.1 Passenger gangways shall be at least 0.9 m wide. Gangways shall be equipped with handrails according to 4.1.5.

3.3.2 Gangways shall be provided with flaps from both sides to exclude difference in levels between the gangway and deck and/or quay.

3.4 REQUIREMENTS TO RAMPS

3.4.1 The inclination of ramps on routes for movement of disabled persons and inclined deck areas shall not exceed 5%.

3.5 REQUIREMENTS TO LIFTS

3.5.1 A lift or elevator shall be provided between decks for movement of disabled persons. Passenger lift and elevator electrically driven from the ship's electric powerplant shall be provided with a standby drive included into emergency consumer list to be supplied from emergency diesel generator in case of failure in the ship's electric powerplant.

Elevator shall be also provided with a standby manual drive.

3.5.2 Lifts designated for disabled persons shall meet the following requirements:
Cabin shall be at least 1.1 m wide and at least 1.4 m deep.

Lift control panel shall be 0.9 to 1.2 m above the floor.

Handrails shall be arranged within the lift according to 4.1.1.

Free space in front of the lift cabin door shall be at least 1.4×1.4 m.
4 GUARD RAILS AND HANDRAILS

4.1 GENERAL REQUIREMENTS

4.1.1 Handrails arranged 0.9 m above the deck level shall be fitted along the walls of corridors and deck superstructures as well as within lifts as guides and supports for disabled persons.

The corridors above 1.5 m wide shall be fitted with handrails from both sides.

Handrails shall be of circular section 40 to 50 mm in diameter. Distance between handrails and wall shall be at least 60 mm. Ends of handrails shall be bent towards the wall.

4.1.2 The clear width of passages in guard rails used for embarkation and disembarkation of disabled persons shall be at least 1.50 m.

4.1.3 Passenger ladders shall be equipped with handrails from both sides, with some handrails located 0.9 m and others 0.75 m above the leading edge of the step. Handrails shall extend beyond the ladder by at least 0.30 m at entry and exit areas. Each handrail shall have at least three stanchions. These handrails shall be restrict the movement along other routes.

4.1.4 Handrails at both sides of stairs shall be located 0.90 m above the leading edge of the step, be continuous over the entire length of stairs and extend by 0.3 m downwards and upwards.

4.1.5 Gangways shall be equipped with handrails from both sides, with some handrails located 1.0 m and others 0.75 m above the gangway surface and extending by 0.3 m from both ends. Each handrail shall have at least three stanchions.

4.1.6 Exposed deck areas designated for disabled persons shall be surrounded by fixed bulwarks or guardrails at least 1.1 m high.

4.1.7 Rails shall be located at least 1.1 m above the deck.
5 REQUIREMENTS TO SPACES

5.1 GENERAL REQUIREMENTS

5.1.1 Spaces for disabled persons shall not be located below the embarkation decks.

Passenger cabins for disabled persons shall be arranged on the same deck where public spaces are located (lounges, saloons, restaurants, dining rooms, sanitary rooms) close to emergency escapes.

5.1.2 Area for disabled persons within passenger compartment with seats shall be located near embarkation areas, lavatory and areas for life saving appliances.

Passenger compartment where area for disable persons is provided, shall have no steps above 30 mm high or inclinations steeper than 5 %. These spaces shall be provided with non-slip flooring.

5.1.3 Passenger service areas (for example, information offices and ticket desks) shall be accessible for disabled persons on wheelchairs.

5.1.4 Tables and chairs shall be designed to prevent their tilting over when used as a support, or tables and chairs shall be able to be secured for heavy weather. Distance between the tabletop and floor shall be at least 0.7 m.

Where tables and chairs in accommodation spaces and on decks are rigidly fixed, provision shall be made for a certain amount of seats (one per 100 persons, but at least four seats) specifically equipped and designated for people with motor system disturbance in accordance with requirements of 5.1.5.2.

5.1.5 Spaces designed for disabled persons shall meet the following requirements:

.1 the number of wall projections shall be as minimum as possible;
.2 sharp corners of spaces and furniture shall be rounded;
.3 wardrobes, racks and lockers shall be incorporated into walls;
.4 vertical pipelines shall be arranged in recesses or corners.

5.1.6 Provision shall be made for baby care room.

5.2 LAVATORIES AND TOILET COMPARTMENTS

5.2.1 Provision shall be made for at least one lavatory and one toilet compartment equipped so as to be used by disabled persons.

Dimensions of lavatory for disabled persons including those on wheelchairs shall be at least 1.65×1.8 m.

5.2.2 There shall be vertically and horizontally oriented handles of folding, rotary and fixed type on lavatory walls near toilet bowls. Handles shall be tightly fixed to the wall and secured by stay racks. Handles shall be arranged so as to allow disable persons to remove from the wheelchair to the toilet bowl and back without any assistance. Handles in the bathroom shall not prevent access to the toilet bowl and washbasin.

5.2.3 Toilet bowl seat shall be arranged approximately at a height of 0.45 m.

Provision shall be made to locate the toilet paper holder near the bowl and to allow it to be used with one hand.

5.2.4 In lavatories and toilet compartments: provision shall be made for non-slip flooring;
provision shall be made for adequate stability and reliable fastening of sanitary equipment;
provision shall be made for buried laying of pipes and buried wiring;
edges of furniture and bath shall not be sharp or shall be protected by specific coatings.

5.2.5 Provision shall be made for free space 0.60 m high and 0.70 m wide under washbasin sink. The distance between upper edge of the washbasin and floor shall be 0.80 to 0.85 m. Mirrors, towel holders and other accessories shall be arranged at a height accessible for people on wheelchairs. The mirror shall be lowered to the level of washbasin sink if required.

5.2.6 The faucet shall allow for easy operation and shall not require great forces to be applied to switch on/off (for example, it should be faucet with extended lever or elbow operated faucet). For vision impaired people provision shall be made for a faucet with dark handle standing in contrast with light surface of sink or bath.

5.2.7 For disabled person, provision shall be made for the following washbasin sinks:
- sink where drain, trap and pipeline are located near the wall with trap connected horizontally in order to be able to drive close to such a washbasin on a wheelchair;
- ergonomic washbasin with leading edge of sink or table curved inwards providing for support during washing up;
- sinks with position (height or inclination angle) to be easily changed by user at his discretion.

5.2.8 Lighting switches in spaces for disabled persons shall be arranged at least 0.9 m but max. 1.0 m above the deck.
6 SAFETY MEASURES

6.1 GENERAL REQUIREMENTS

6.1.1 Provision shall be made for at least one platform at least 1.5 m wide and at least 1.4 m deep for embarkation-disembarkation of disabled persons on the main deck on each side of the ship.

In addition, provision shall be made for at least one emergency escape 1.0 m wide from this deck.

6.1.2 Lifeboats and liferafts shall be arranged not more than 50 m from spaces occupied by disabled persons. Provision shall be made for disabled persons to change from wheelchairs to lifeboats and liferafts prior to their launching.

6.1.3 Life jackets shall be located in areas readily accessible for disabled persons provided in passages leading to exits.

Cabins designated for disabled persons shall be provided with additional life jackets in quantity equal to the number of berths in the cabin.

6.1.4 The collective life-saving appliances shall have additional seats for disabled persons in excess of those specified in 8.2 Part V of these Rules in a quantity of at least 10% of total number of persons, which are provided with collective life-saving appliances.

6.1.5 Ladders and areas available for disabled persons shall be lighted on a 24-hour basis.

Signs indicating the direction to emergency escapes as well as prohibitory and prescriptive signs shall be lighted.

6.1.6 Sills, ramps, rails and handrails shall be coated with paint standing in contrast with surroundings in accordance with GOST R 12.4.026.

6.1.7 Deck space in front of ladders or individual steps shall be coated with paint standing in contrast with surroundings.

Ladder handrails, front side of the first and last steps as well as coating of ladder ends shall be marked with yellow.

6.1.8 Spaces designated for disabled persons including lifts and lavatories shall be provided with emergency lighting.

6.1.9 For passenger ships of O and M class equipped for carrying disabled persons, provision shall be made for securing wheelchairs for heavy weather in passenger spaces.

6.1.10 Fire valves of ventilation pipelines shall be capable of closing automatically, if air temperature within the pipeline exceeds 70 °C. Provision shall be made for manual closing of these valves from the station continuously manned with ship officers and/or crew.

6.1.11 Doors and bulkheads between passenger corridors and cabins as well as between cabins themselves, walls and ladder doors connecting more than two decks as well as ceilings and bulkhead coatings and plating shall be made of fire-resistant materials.

6.1.12 Ladders, stairs, gangways and other areas available for disabled persons shall be well-lighted at all times. For artificial lighting daylight lamps shall be used.
7 ALARM AND COMMUNICATION SYSTEMS

7.1 GENERAL REQUIREMENTS

7.1.1 Provision shall be made for the audible and visual alarm system to provide disabled persons with current information.

Lifeboats, liferafts including those designated for disabled persons shall be marked with signs of information display for people on wheelchairs according to GOST 52131.

Visual and audible beacons shall be fitted near life-saving appliances to provide for orientation of vision and hearing impaired people.

Visual information means shall be provided with lighting including emergency lighting.

7.1.2 Arrangement for visual and audible general alarm shall be available on board the ship.

7.1.3 Two-way public address device shall be provided in public spaces in areas for disabled persons. Provision shall be made for visual and audible alarm indicating operation of this device.

7.1.4 Lavatories and lifts equipped for disabled persons shall be provided with two-way communication devices to call for help or emergency alarm actuation device in accordance with 16.1.14.1 Part VI of these Rules.

7.1.5 Provision shall be made for giving visual and audible alarm in spaces where disabled persons are not readily visible for crew members, ship's personnel or other passengers.

7.1.6 Loudspeaker system shall provide for clearly audible messages on all decks and in spaces available for passengers. Loud-speakers shall have an adequate power in order to make the transmitted messages clearly audible under noise level of at least 70 dB(A).
RUSSIAN RIVER REGISTER

RULES
FOR PREVENTION OF ENVIRONMENT POLLUTION FROM SHIPS
(RPPS)

MOSCOW 2015
The Rules for Prevention of Environment Pollution from Ships (RPPS) have been approved by the Order of Federal Autonomous Institution “Russian River Register” No. 38-п dated 12.10.2015 and brought into force since 01.09.2016 on the basis of the Decree of the Ministry of Transport of Russian Federation МС-126-р dated 01.09.2016.

It is strictly prohibited to make photocopy, store in a retrieval system, publish, perform in public, adapt, broadcast, transmit, record or reproduce the present edition in any form or by any means for sale purposes without the prior written permission of the Federal Autonomous Institution “Russian River Register”.

1 GENERAL PROVISIONS

1.1 SCOPE OF APPLICATION

1.1.1 The requirements of the Rules for prevention of environment pollution from ships (hereinafter referred to as the Rules) apply to the ships specified in 1.4 Part 0 of the Rules for Classification and Construction of Ships (RCCS), which engineering designs are submitted to Russian River Register after the present Rules has come into force, as well as to the ship machinery and equipment for prevention of environment pollution from these ships.

The Rules apply to ships in service excepting 2.1.2.4, 2.1.11, 2.2.3, 2.2.4.3, 2.8.1 – 2.8.9, 3.2.2, 3.2.4.5, 5.5.1, 5.5.8, 5.10.1 – 5.10.8, 7.1.1, 7.1.2.

Unless otherwise specified in future editions of the Rules, the Rules applicable during the ship construction apply to the ship components covered by 2.1.2.4, 2.1.11, 2.2.3, 2.2.4.3, 2.8.1 – 2.8.9, 3.2.2, 3.2.4.5, 5.5.1, 5.5.8, 5.10.1 – 5.10.8, 7.1.1, 7.1.2 of these Rules.

1.1.2 Survey of ships in service and technical supervision during manufacture and repair of ship machinery and equipment for prevention of environment pollution from ships are carried out in accordance with normative legal acts and other documents stated in 1.2 Part 0 RCCS.

1.1.3 Structures, arrangements and systems specified in 1.1.1 as well as ship machinery and equipment for prevention of environment pollution from ships in addition to the requirements of the present Rules shall comply with applicable requirements of the relevant parts of the RCCS.

1.1.4 Sea-going ships shall comply with the requirements of the Rules and applicable requirements of documents stated in Merchant Shipping Code of the Russian Federation in what concerns the provisions on the environment protection.

1.1.5 Ships engaged on international voyages shall comply with the requirements of the Rules and applicable requirements of the international agreements of the Russian Federation in what concerns the provisions on the environment protection.

1.2. TERMS AND DEFINITIONS

1.2.1 Terms related to the Rules common terminology and their definitions are stated in 2.1 Part 0 RCCS.

1.2.2 In the Rules the following terms are used:

1. Navigation endurance due to environmental safety conditions means the duration of ship service without need for coming to reception facilities for delivery of sewage, oil containing water, refuse and other wastes;

2. Clean ballast means ballast water loaded into a tank cleaned after the last oil carriage to a such extent as to prevent from the formation of visible oil traces, oil residues or emulsion on the water surface or under it as well as on the adjoining coastlines when discharging the ballast from the vessel immovable as regards the water surface into clean calm water at clear weather;

3. Boom barrier means the device for prevention of oil spreading along the water surface or changing its direction to collect it;
.4 Wet exhaust gases means exhaust gases whose humidity content corresponds to the complete formulation of the fuel combustion products;

.5 Harmful substances means any substances, which, being spilled into water, can damage human health or living resources, water flora and fauna, worsen rest conditions or impede other kinds of legal use of water resources; carbon monoxides (CO), nitrogen oxides (NOx) and hydrocarbons (CH) contained in exhaust gases and rendering them properties harmful for people and environment;

.6 Harmful substance emission means an amount of harmful substance emitted to the atmosphere with exhaust gases per unit time;

.7 Exhaust gases means a mixture of complete and uncomplete combustion products and excess air passing to the engine exhaust system;

.8 Opacity means visible dispersion of fluid and solid substances in exhaust gases formed as a result of incomplete burning of fuel and evaporated oil in engine cylinders;

.9 Sorbent boom means barrier made of sorbent material restricting oil spreading over deck;

.10 Pollution means a discharge of harmful substances or wastes containing it into the water environment;

.11 Incinerator (installation for refuse incineration) means an installation for incineration of refuse, oil sludge, oil sediments, oil residues and sewage sludge;

.12 Carbon monoxide concentration means volume fraction of carbon monoxide in exhaust gases in volume percent (hereinafter referred to as the vol. %)

.13 Concentration of nitrogen oxides reduced to NO2 means volume fraction of nitrogen oxides in exhaust gases, which they could take if transformed to equivalent volume of ideal gas with molecular mass of 13.85 and molecule ionization energy equal to propane C3H8 ionization energy, vol. %;

.15 Manifold means a pipeline with fittings located on the deck and designed for cargo handling or bunkering operations;

.16 MARPOL 73/78 means the International Convention for the Prevention of Pollution from Ships, 1973, as amended by the Protocol of 1978 relating thereto, approved by the IMO Marine Environment Pollution Committee;

.17 Instantaneous intensity of oil discharge is the intensity of oil discharge in litres per hour at any moment divided by the ship speed in knots at the same moment;

.18 Refuse (R) means any kind of food, domestic and operational wastes formed during normal ship operation subject to continuous or periodical removal;

.19 Oil means petroleum in any form including crude oil, oil fuel, oil residues, oil sediments and oil products;

.20 Oil-containing mixture means a mixture containing any amount of oil.

.21 Oil-containing water (OCW) means a mixture of water with any amount of oil;

.22 Oil sludge means separated sludge, oil from oil tanks drainage or any leakage from the equipment of the machinery spaces and exhausted oil;

.23 Oil sediments means the oil fraction, which cannot be piped or processed due to its consistency and requires for special methods or equipment to be removed from the ship;

.24 Oil residues mean any residues containing petroleum;

.25 Normative value of the permissible oil contents in the discharge means marginal normative value of oil concentration in the discharge as adopted by international (for sea waters) and national (for inland waterways) normative documents;
.26 Ozone-depleting substances mean chemical compounds based on chloro-, fluoro- and bromo hydrocarbons capable to react with ozone molecules in stratosphere, subject to control, defined in Article 1 Montreal Protocol on Substances that Deplete the Ozone Layer (1987), and listed in Appendices A, B, C and E to that Protocol;

.27 Carbon monoxide means a gaseous product of incomplete carbon oxidation making part of hydrocarbon fuel (identified by symbol "CO");

.28 Nitrogen oxides mean a mixture of various nitrogen oxides formed as a result of burning fuel and exhausting combustion products from engine cylinders (identified by symbol NOx);

.29 Domestic wastes mean wastes having been used as storage collectors or package before discharging as well as all kinds of objects made of plastics, paper, textile, glass etc. of other equivalent materials;

.30 Food wastes mean a kind of refuse consisting of wastes from preliminary food cookery and non-disposed remains;

.31 Operational wastes mean wastes formed as a result of any manufacturing or repair work as well as operation of the power plant and other ship equipment;

.32 Settling tank means a tank intended for collecting and settling tank washing water, contaminated ballast water, oil residues and other oil-containing mixtures;

.33 Deck oil-gathering system means a set of means and materials for oil spill response on deck;

.34 Half-port means a shutter in bulwark or in guard line for water drainage from deck;

.35 Maximum permissible specific average weighted emission of harmful substance means value of specific average weighted emission of harmful substances, above which the operation of engine is prohibited;

.36 Reception facilities mean offshore or coast facilities for the reception of all kinds of pollutants from the vessel to be passed for purification, disposal, destruction etc.

.37 Collecting tank means a tank for the collection and storage of non-treated fluids contaminated with harmful substances;

.38 Discharge means a release of harmful substances or wastes containing such substances from a ship, regardless of its reason, including any leakage, drain, removal, spill, overflow, pumping, emission or emptying;

.39 An alarm device is a device warning in case the normative value of permissible oil contents in the discharge has been exceeded;

.40 Sorbent means a porous, powdered or fibre material facilitating collection of oil due to its absorption, density and viscosity increase;

.41 Standard discharge connection means connection for discharge of oil-water mixture or sewage water corresponding to GOST R 7608-2013;

.42 TOW station means oil-containing water treatment plant;

.43 TDSW station means sewage water treatment and disinfection plant;

.44 Sewage water (SW) means drainage and other wastes from all types of lavatories, toilet bowls and urinals, drainage from wash bowls, bathrooms and scuppers located in medical accommodations (dispensary, sick bay etc.), drainage from rooms intended for animals, waste water from bathrooms, showers, baths and scuppers, waste water from laundries, waste water from sinks and other equipment of galleys, canteens etc., other kinds of sewage mixed with wastes named above;

.45 Emergency oil spill localization pack means a set of equipment and materials for localization and collection of oil spilled into the water;

.46 Oil handling operations means oil transfer to, from, and within the ship;

.47 Hydrocarbons mean vapour mixtures (identified by symbol CH) of all unburnt and partially oxidized hydrocarbons
of fuel and lubricating oil formed as a result of burning fuel and exhausting combustion products from engine cylinders;

48 Specific average weighted emission of harmful substance means amount of harmful substance emitted to the atmosphere with exhaust gases per 1 kW·h of effective engine operation during the full test cycle;

49 Sewage treatment plant means a sewage purifying and disinfecting plant;

50 Refuse-collecting facility means a tank or other equipment for refuse collecting and storage;

51 Refuse treatment plant means equipment for refuse grinding and reducing in volume;

52 Filtering equipment means filters or any combination of separators and filters so designed as to reduce oil contents in the discharge down to the normative value.
2 REQUIREMENTS TO SHIP'S EQUIPMENT AND FACILITIES FOR PREVENTION OF POLLUTION BY OIL

2.1 GENERAL REQUIREMENTS

2.1.1 Self-propelled ships and non-self-propelled ships with internal combustion engines on board shall be fitted with:
   .1 collection tank for oil-containing water;
   .2 oil-containing water pumping and delivery system;
   .3 standard discharge connections for delivering oil-containing water to reception facilities.

2.1.2 If the calculation performed according to the procedure described in Appendix 1 shows that equipment listed in 2.1.1.1 does not provide for the required navigation endurance due to environmental safety conditions, then ships shall be in addition fitted with:
   .1 filtering equipment;
   .2 an alarm device;
   .3 purified oil-containing water discharge system;
   .4 device for automatic interruption of discharge;
   .5 a collecting tank for oil residues.

2.1.3 The information on the navigation endurance due to environmental safety conditions shall be recorded in the ship’s documents.

2.1.4 The oil-containing water may be collected in portable tanks and in the machinery space bilges on the following ships (if so provided by information on stability and floodability):
   .1 less than 25 m in length;
   .2 with the total output of all internal combustion engines less than 220 kW (dealing with the requirements for onboard equipment and arrangements preventing the oil pollution);
   .3 for dynamically supported ships.

The accumulated oil-containing waters shall be discharged to reception facilities.

2.1.5 Cargo tanks and fuel tanks shall not be used as ballast tanks.

2.1.6 In the machinery space there shall be diagrams of fuel and lubricating oil systems located on a visible place showing the location of tanks as well as air, measuring and overflow pipes.

2.1.7 In oil tankers the cargo system diagrams and loading instructions shall be placed at the loading/unloading control station.

The diagrams shall indicate the location of tanks, fittings and gas, overflow and measuring lines.

In non-crewed non-self-propelled oil tankers the above diagrams and instructions shall be kept on the relevant tugs and pushboats.

2.1.8 Ships intended for handling oil and oil products (self-propelled and non-self-propelled fuelers, oil pumping stations, bilge and tank-stripping stations, ships for collection, storage, neutralization and disposal of oil-containing water and oil residues) shall be fitted with oil spill localization means complying with the requirements of 2.7.

2.1.9 Oil tankers as well as ships intended for handling oil and oil products (see 2.1.8) shall be designed and fitted with equipment suitable for restriction and collection of oil spills on deck during the oil handling opera-
tions and complying with the requirements of 2.8.

2.1.10 Collecting tanks and systems of collection, pumping, treatment and delivery of oil-containing water including all its equipment and pipelines shall be used neither for purposes other than their direct purpose nor combined with other systems.

2.1.11 Locations of facilities for reception and discharge of fuel shall be fitted with guard to contain possible oil spills. The upper edge of the guard shall be raised at least 150 mm above the device for connecting bunker hose. The guard shall be fitted with half-ports capable to being closed during bunkering operations or shall be fitted with splash-proof cover.

2.2 COLLECTING TANKS

2.2.1 The total capacity of collecting tanks shall be proved by the calculation performed according to the method described in Appendix 1.

2.2.2 Collecting tanks if located in the machinery spaces shall meet the requirements of 1.9.7 Part IV RCCS.

2.2.3 Collecting tanks of oil-containing water shall meet the requirements of 2.4.139 – 2.4.141 Part I RCCS.

2.2.4 A collecting tank shall be fitted with:

- an access hole for inner access and cleaning;
- an air pipe with a flame-arrester;
- a device sending visual and audible alarm to the wheelhouse or central control station when the tank is filled up to 80 per cent of the permissible liquid level;
- a system measuring the liquid level.

2.2.5 Collecting tanks shall be fitted with heating devices when:

- using heavy fuel for ship needs;
- a collecting tank is located in place where it may be subject to negative temperature during operation.

2.2.6 The heaters shall comply with the requirements of 10.13.9 – 10.13.15 Part IV and 16.2.32 – 16.2.34 Part VI RCCS.

2.2.7 Inner surfaces of collecting tanks intended for collection of post-separation oil residues shall be smooth (the tanks shall be designed with outer framing); the bottom shall be inclined towards the reception pipe.

2.3 PUMPING, DELIVERY AND DISCHARGE SYSTEMS

2.3.1 Arrangement and passage of system pipelines shall comply with the requirements of 10 Part IV RCCS.

2.3.2 Collecting tanks, fittings and pipelines of systems shall be calculated to pressure at least 1.5 of working pressure in the system.

2.3.3 Lines of the system of oil-containing water delivery to reception facilities shall be led to port and starboard. The pipelines may be led to one side only for ships listed in 2.1.4.

2.3.4 Oil-containing water delivery lines shall not be combined with other delivery lines.

2.3.5 Standard discharge connections for delivery of oil-containing water to reception facilities shall be located in places accessible for hose connections and be marked as provided by GOST R ISO 7608-2013.

2.3.6 The vessels intended for oil-containing water collection shall be fitted with standard discharge connections (see 1.2.2.41).

The vessels intended for reception of oil-containing water from river-sea navigation and sea-going ships shall be fitted with standard discharge flange connections of international type (see 5.4.2). Adapter couplings may be used for compatibility of standard discharge flange connections of international type with standard discharge connections.

2.3.7 Oil-containing water delivery systems shall be handled by pumps intended for these purposes.
2.3.8 Either a control station with remote control of discharge facilities or an effective communication system between the control station and the controlled discharge point shall be arranged near standard oil-containing water discharge connection.

Discharge equipment shall be started and stopped manually.

2.3.9 Shut-off fittings of oil-containing water delivery and purified oil-containing water discharge systems shall be so designed as to make them available for lead-sealing. This requirement does not apply to ships not fitted with their own means for pumping oil-containing water.

Note: The purified oil-containing water may be discharged from ships overboard if purification efficiency of oil-containing water corresponds to the specified standard, but only outside the areas specified in 257(d) of Technical Regulations on Safety of Inland Marine Transport Facilities approved by the Decree of the Government of the Russian Federation No. 623 dated 12.08.2010.

2.4 FILTERING EQUIPMENT

2.4.1 Filtering equipment shall provide for the effluent oil concentration in the mixture not exceeding the normative value at any incoming oil concentration in the mixture charged into the filtering equipment.

2.4.2 Filtering equipment shall be fitted with safety devices with pipes coming to the collecting tank. The safety device shall be adjusted for a pressure exceeding the working pressure by not more than 10%.

2.4.3 Elements of filtering equipment shall undergo hydraulic tests by a pressure equal to 1.5 of the working pressure before being covered with a protective coating.

2.4.4 The filtering equipment shall have a workable design. The total capacity of maintenance pumps shall not exceed the discharge capability of filtering equipment.

2.4.5 The filtering equipment shall be fitted with devices for oil-containing mixture discharge.

2.4.6 When filtering equipment is designed with preheating of oily mixture, the preheating may be carried out by means of steam or water coils. Electric heating shall be carried out in accordance with requirements of 16.2.32 – 16.2.34 Part VI RCCS.

2.4.7 Filtering equipment shall be designed so as to operate automatically.

2.4.8 Filtering equipment shall be fitted with local control stations capable to manually control the equipment and monitor its operation.

2.4.9 Pumps, filtering equipment and other facilities shall be fitted with pressure, temperature and level monitoring sensors as well as warning alarm and protection system.

2.4.10 Pumps, filtering equipment and other facilities in places where oil-containing water may be leaked, shall be fitted with leakage collecting facilities meeting the requirements of 10.13.17–10.13.21 Part IV RCCS.

2.4.11 Vertical sections of inlet pipes for oil-containing water and drainage of purified water from the filtering equipment shall be fitted with a sampling device of design approved by the River Register.

2.5 ALARM DEVICE

2.5.1 Alarm device shall be actuated when the oil content in the discharged water reaches the normative value.

2.5.2 Alarm device shall actuate the following signals:

1. a command for automatic interruption of a discharge;
2. a discharge interruption warning signal;
3. visual and audible signals when the oil content in the discharged water exceeds the normative value;
4. a signal on any malfunction of the alarm device.

All signals shall be sent to the place of watchkeeping.

2.5.3 The actuation time of the alarm device determined during the tests shall not exceed 20 sec.
2.5.4 The alarm device shall be so designed as to be fastened reliably; the electronic part of the device shall be designed taking into account the operating conditions.

2.5.5 The alarm device shall be fitted with inscriptions or symbols clarifying its purposes and operation.

2.5.6 The location of alarm device, the length of sampling pipe and the velocity of liquid flowing in it are to be so selected as the total actuation period shall not exceed 40 sec (the time from the moment of changing the oil concentration in the discharge till the moment when the signal for the discharge interruption is generated).

2.5.7 Sampling points shall be provided at all discharge lines subject to monitoring. The sampling device shall be fitted on vertical sections of the discharge line. It may be fitted on horizontal section when the drain pipe is completely filled by liquid during the whole discharge period.

2.6 DEVICE FOR AUTOMATIC INTERRUPTION OF DISCHARGE

2.6.1 A device for automatic interruption of discharge shall interrupt the oil-containing water discharge under the signal of the alarm device (see 2.5).

2.7 EMERGENCY OIL SPILL LOCALIZATION PACK

2.7.1 Ships specified in 2.1.8 shall be fitted with emergency oil spill localization pack providing oil spill collection when weight of spilled oil is 1.5 t or more.

Equipment being a part of the pack shall be delivered in accordance with the technical documentation approved by the River Register.

2.7.2 Emergency oil spill localization pack shall include:

- .1 floating boom barrier;
- .2 floating anchor buoy;
- .3 anchor of not less than 10 kg weight;
- .4 anchor chains and towing ropes;
- .5 sorbent
- .6 device for sorbent supply;
- .7 oil and waste sorbent collecting device;
- .8 capacity for storage and transportation of waste sorbent;
- .9 set of working clothes;
- .10 service manual for emergency oil spill localization pack.

2.7.3 Service manual for emergency oil spill localization pack shall include operation instructions on oil spill response from ship, as well as maintenance and disposal instructions.

2.7.4 Equipment being a part of emergency oil spill localization pack shall have Certificates issued by the River Register and meet the following requirements:

- .1 to ensure safe operation if it is stored at the air temperature of –30 up to +50 °C;
- .2 to ensure safe operation at the water temperature of –1 up to +30 °C;
- .3 to be rot-resistant, corrosion-resisting and to withstand influence of oil, oil products, sea water and fungi;
- .4 keep its characteristics during long-term exposure to sunlight.

2.7.5 Equipment of emergency oil spill localization pack, which tends to deteriorate with time, shall be marked with indication of service life and date of next inspection or replacement.

Boom barrier

2.7.6 The length of boom barrier is determined with regard to navigation area and oil spill localization technology in various operating situations, but in either case shall be not less than double ship’s breadth.

2.7.7 Parameters of the boom barrier shall comply with those specified in Table 2.7.7.

2.7.8 Boom barrier shall stand dropping afloat from the height not less than 5.5 m without being damaged and keep draught and freeboard constant on a seaway.

2.7.9 Materials used for construction of boom barriers shall be incombustible or combustible with slow flame propagation.

2.7.10 Boom barrier shall be so designed that to enable its manual installation or with the use of ship arrangements and lifting the barrier aboard by means of ship machinery.

2.7.11 Displacement of boom barrier floats per unit length considering ballast weight and forces arising from barrier mooring shall ensure the necessary freeboard of not less than value required by 2.7.7.

2.7.12 Ballast weight per unit length of the boom barrier shall be sufficient to keep it upright and to provide deviation of the boom skirt from the vertical axis in design operating conditions at an angle of not more than 15°.

2.7.13 Boom barrier shall be fitted with a device for fastening mooring ropes to the mooring arrangement, anchored buoys and the shore.

2.7.14 A number of boom barrier sections and design of its connections shall be chosen to provide suitable conditions for putting the boom barrier afloat, lifting aboard and oil spill localization.

2.7.15 Strength of boom barrier elements taking longitudinal tensile force shall be tested by the greatest forces generated in the boom barrier during its operation. Maximum permissible breaking strength shall be specified in boom barrier documentation.

2.7.16 Boom barrier shall be fastened on the ship by means of easily detachable fastenings.

Sorbent

2.7.17 The sorbet amount \( V_c \) required for oil collection is calculated by the formula (m³):\[
V_c = 1500/(H_c a_c),
\]
where \( H_c \) is sorbent’s oil capacity at water temperature 0°C (kg of oil per kg of sorbent); \( a_c \) is sorbent bulk density, kg/m³.

2.7.18 Water adsorption of the sorbent shall not exceed 10 kg of water per kg of sorbent. The guaranteed shelf life of sorbent shall be at least 1 year.

2.7.19 Devices for sorbent supply to oil spill area shall comply with the following requirements:

.1 sorbent spraying device supply rate shall be not less than 0.6 m³/h;

.2 devices may be manually operated, portable with autonomous power source or stationary powered by shipborne power sources.

Oil and waste sorbent collecting devices

2.7.20 Oil collecting devices shall have capacity corresponding to the water flow speed, spill amount and boom barrier design.

Set of working clothes

2.7.22 Set of working clothes shall include a jacket and trousers or coverall, special boots, gloves, protective hermetic glasses, respirator and head wear.

Material and seams of working clothes shall be water- and oil-tight.

Quantity of working clothes sets shall be not less than 4.

2.8 SHIP DESIGN AND EQUIPMENT FOR RESTRICTION AND COLLECTION OF OIL SPILLS ON DECK

Deck structures and systems

2.8.1 Cargo zone and oil storage spaces on deck shall have bar guards of not less than 150 mm high. Bars running along the side...
shall have half-ports to be closed during cargo handling operations.

2.8.2 To remove oil spilled during cargo handling from deck a drainage system equipped with scuppers, drain pipes and tank located under manifold shall be provided.

2.8.3 The drain tank shall be equipped with independent drainage means.

2.8.4 Drain holes shall be fitted with devices for preventing the admission of water into the drain tank upon completion of cargo handling operations.

2.8.5 Work platforms shall be provided under the manifold cargo connections; tanks for collection of spilled oil shall be provided under the work platforms.

2.8.6 The work platform and tank for reception of spilled oil shall be extended behind the cargo connections installed in the fore and aft parts of the manifold. The depth of the tank for collection of spilled oil shall be not less than 300 mm.

2.8.7 Covering of work platform shall be made of grating, through which the oil spilled from manifold could easily enter the tank for collection of spilled oil. The grating shall be composed of removable sections providing free access to the tank for collection of spilled oil. The grating surface shall not be slippery.

2.8.8 Edge of the work platform at the board side shall be faired with radius of 50 mm to prevent damage of cargo hoses during connecting/disconnecting.

Cargo area lighting

2.8.9 Location of manifold and other working areas of the deck shall be lighted.

2.8.10 The lighted zone shall include the outboard lightship waterline area to provide sufficient visibility of onshore terminal area, at which the cargo handling operations are performed.

Onboard equipment for removing oil from deck

2.8.11 Ships specified in 2.1.9 shall be equipped with deck oil-gathering systems for oil spill response on deck during cargo handling and bunkering operations.

2.8.12 The deck oil-gathering facilities shall restrict the spillage and collect the spilled oil of amount not less than 10 kg.

2.8.13 The list of deck oil-gathering facilities is specified in Table 2.8.13.

2.8.14 The deck oil-gathering facilities shall be stored on deck near the connection points of cargo and bunkerage hoses in containers, which shall be floating, weathertight and attached to the ship's hull.

2.8.15 The container shall be made according to the documentation approved by the River Register and using materials complying with the requirements of 2.7.4. It shall be painted in bright green water-resistant paint and fitted with plate indicating the list of stored items.
3 REQUIREMENTS TO SHIP'S EQUIPMENT AND FACILITIES FOR PREVENTION OF POLLUTION BY SEWAGE

3.1 GENERAL REQUIREMENTS

3.1.1 Crewed vessels shall be fitted with:
   1. a flushing system;
   2. a sewage collecting tank;
   3. standard discharge connections (see 1.2.2.41) for the delivery of sewage to reception facilities;

3.1.2 If the calculation performed according to the method described in Appendix 1 shows that equipment stated in 3.1.1.2 does not provide for the navigation endurance due to environmental safety conditions, then ships shall be additionally fitted with sewage treatment plant.

3.1.3 Collecting tanks, capacities, systems of collection, pumping, treatment and delivery of sewage water including all its equipment and pipelines shall be used neither for purposes other than their direct purpose nor combined with other systems (excepting 3.3.8 and 3.4.6).

3.2 COLLECTING TANKS

3.2.1 The total capacity of collecting tanks shall be proved by the calculation performed according to the method described in Appendix 1.

3.2.2 The collecting tanks shall comply with the requirements 2.4.138, 2.4.142 and 2.4.143 Part I RCCS.

3.2.3 Where applicable, collecting tanks shall be designed with the external framing. The bottom shall be inclined towards the reception pipe.

3.2.4 Collecting tanks shall be fitted with:
   1. an access hole for inner access and cleaning;
   2. a system for sediment loosening;
   3. a washing system;
   4. an air pipe;
   5. a device sending visual and audible alarm to the wheelhouse or central control station when the tank is filled up to 80 per cent of the permissible level;
   6. a system measuring the liquid level.

3.2.5 Collecting tanks located in places where they may be subject to negative temperature during operation shall be fitted with heating devices.

3.2.6 Collecting tanks shall be designed so to withstand the pressure not less than 1.5 of operating pressure in the system.

3.2.7 Water, vapour or compressed air may be used as a loosening agent.

3.2.8 Air pipes of collecting tanks shall be led to the open deck with outlets located in such a way that to prevent the smell of untreated sewage from getting into the ship's accommodation and service spaces.

3.2.9 Collecting tanks may be located in cargo spaces not intended for transportation of food or food products as well as in the machinery spaces.

3.3 PUMPING, DELIVERY AND DISCHARGE SYSTEMS

3.3.1 Pumping, delivery and discharge systems shall be designed and the lines shall be located in accordance with the requirements of Section 10 Part IV RCCS.
3.3.2 Fittings and lines of sewage pumping, delivery and discharge systems shall be designed to withstand pressure not less than 1.5 of operating pressure in the system.

3.3.3 Lines of the system of sewage delivery to reception facilities shall be led to port and starboard.

3.3.4 Sewage delivery lines shall not be combined with other discharge lines.

3.3.5 Standard discharge connections for delivery of sewage to reception facilities shall be located in places accessible for hose connections and shall be marked as provided by GOST R ISO 7608-2013.

3.3.6 The vessels intended for sewage collection shall be fitted with standard discharge connections (see 1.2.2.41).

The vessels intended for reception of sewage from river-sea and sea-going ships shall be fitted with standard discharge flange connections of international type (see 5.11.7). Adapter couplings may be used for compatibility of standard discharge flange connections of international type with standard discharge connections.

3.3.7 Sewage delivery systems shall be handled by pumps intended for these purposes.

3.3.8 Provision shall be made for outboard water washing of sewage delivery system pipes including hoses; used washing water shall be discharged to reception facilities or ship’s collecting tank.

3.3.9 Shut-off fittings of sewage discharge system shall be so designed as to make them available for lead-sealing operations.

Note: The purified sewage water may be discharged from ships overboard if sewage water purification efficiency corresponds to the specified standard, but only outside the areas specified in 257(d) of Technical Regulations on Safety of Inland Marine Transport Facilities approved by the Decree of the Government of the Russian Federation No. 623 dated 12.08.2010.

This requirement does not apply to ships not fitted with their own means for pumping sewage water.

3.3.10 Exhaust pumps shall be actuated and stopped manually. In the area of outlet location shall be provided either a station for observation and remote stop of pumps or telephone or radio communication between a place of observation and control post of exhaust means.

3.4 SEWAGE TREATMENT PLANT

3.4.1 Sewage treatment plant shall have a capacity corresponding with designed water consumption on a ship.

3.4.2 Sewage treatment plant with relevant pumps, pipes and fittings contacting with sewages shall be protected from the attack of pumped medium.

3.4.3 Sewage treatment plant should ensure the purification efficiency regulated by normative documents in force. Standardised purification efficiency shall be reached by sewage purification and disinfection only. Dilution of sewage to reach the required purification efficiency is not permitted.

3.4.4 Sewage treatment plant shall be tested at the manufacturer by test pressure equal to 1.5 working pressure and on the ship — by working pressure.

3.4.5 The space containing the sewage treatment plant shall be fitted with artificial exhaust ventilation.

3.4.6 Provision shall be made for washing and disinfection system of the sewage treatment plant and handling mechanisms, pipelines and fittings in order to ensure safety of maintenance, inspection and repair of the plant.

3.4.7 Sewage treatment plant shall be fitted with a sampling device for treated water.

3.4.8 Sewage treatment plant shall be designed for automatic operation as well as shall be fitted with local control stations capable to manually control the equipment and monitor its operation.
4 REQUIREMENTS TO SHIP'S EQUIPMENT AND FACILITIES FOR PREVENTION OF POLLUTION BY REFUSE

4.1 GENERAL REQUIREMENTS

4.1.1 Ships with people on board shall be fitted with refuse collecting facilities. Refuse generated onboard shall be collected and stored for delivery to reception facilities or shall be burned in ship's incinerator.

4.1.2 Ships may be fitted either with refuse treatment installations or incinerators at the option of the shipowner.

4.1.3 In ships mentioned in 2.1.4 the refuse may be collected in disposable dense polyethylene bags.

4.2 REFUSE COLLECTING FACILITIES

4.2.1 The total capacity of refuse collecting facilities shall be determined by calculation performed according to the method described in Appendix 1.

4.2.2 Refuse collecting facilities shall be attachable or built-in and have tightly-closing lids.

4.2.3 Refuse collecting facilities shall have smooth inner surfaces and fittings allowing them to be securely attached in the ship.

4.2.4 Refuse collecting facilities shall be installed on the open deck or in rooms ventilated and isolated from the accommodation and service spaces.

4.2.5 Inner surfaces of integrated refuse collecting facilities shall have bottom inclination not less than 30° towards the discharge outlet. The discharge outlets shall have no beads in the lower part and be fitted with lids so driven as to provide for the reliable operation under any service conditions of the ship.

4.3 INCINERATORS

4.3.1 For incinerators fitted with a feeding hopper locking lids of the latter shall be provided with a blocking device to avoid its simultaneous opening. Restrictions for the loading substances, if any (e.g. exhausted lubricating oil, oil sludge etc.) shall be indicated on a plate attached to the incinerator on a visible place.

4.3.2 For incinerators not fitted with a feeding hopper a loading hatch shall be fitted with a blocking device preventing from its opening:

1. during air supply to the combustion chamber for the burning process;
2. when temperature in the combustion chamber exceeds the flash point of the fuel used in a ship.

4.3.3 The incineration process shall be controlled either directly (visually) or indirectly (by instrument readings).

4.3.4 Design of the fuel nozzles or other devices for the fuel supply shall be approved by the River Register.

4.3.5 Fuel nozzles shall have a blocking device, which provides for a supply of oil fuel only in the following cases:

1. if a nozzle is in a working condition;
2. if air is supplied to the furnace;
3. if the feeding hopper is closed.

4.3.6 Fuel nozzles shall be fitted with devices which shut-off the fuel supply within not more than 5 seconds in cases when:
1. No air is supplied to the furnace;
2. The furnace flame is failed;
3. The electrical supply is broken;
4. The fuel pressure is below the permissible working pressure. Automatic fuel feeding cut-off shall be accompanied by visual and acoustic alarm.

**4.3.7 Fuel supply to nozzles shall be also stopped if it is not ignited for more than five seconds from the beginning of supply.**

**4.3.8 Fuel nozzles shall be shut-off by two shut-off devices one of which shall be located outside the space containing the incinerator.**

**4.3.9 In the absence of a separate exhaust ventilator for long-lasting operation the control program of fuel nozzles with automatic ignition fuel shall include:**

1. The furnace ventilation within at least three minutes before the ignition;
2. The furnace ventilation within at least three minutes after the fuel feeding has been shut-off.

**4.3.10 Incinerators with automatically controlled burning process shall be fitted with a protection and alarm as stated in Table 4.3.10.**

**4.3.11 Fuel and gas-discharging systems of the incinerators shall meet the requirements of 10 Part IV RCCS.**

**4.3.12 Heating surfaces of the incinerators shall be insulated as per 1.9.2 Part IV RCCS.**

**4.3.13 Burning residues shall be stored in removable locking capacities reliably protected against shifting.**

**4.3.14 Installation of incinerators in accommodation spaces is prohibited.**

When mounted in the machinery space, the incinerator shall be shielded from adjacent equipment; it shall be so located and fastened that to meet the requirements of 1.9 and 1.10 Part IV RCCS.

**4.3.15 When the incinerator is located in a separate compartment, the latter shall be fitted with: exhaust and input ventilation which provides for efficient air supply required for the operation of the incinerator, automatic fire alarm according to 11.4 Part IV RCCS.**

### 4.4 REFUSE TREATMENT DEVICES

**4.4.1 Devices for grinding of refuse shall grind it until the size of particles will be capable to pass through a hole of not more than 25 mm.**

**4.4.2 Refuse pressing devices shall decrease its initial volume in the mean by at least 5 times.**

5 ADDITIONAL REQUIREMENTS TO SHIPS OF M-ÇП, M-ÇИП AND O-ÇИП CLASSES

5.1 SCOPE OF APPLICATION GENERAL REQUIREMENTS

5.1.1 The requirements of present Section are applied to ships of M-ÇП, M-ÇИП and O-ÇИП classes when they navigate in sea areas.

5.1.2 Requirements 1–4 of present Section of the Rules are applied to ships specified in 5.1.1 when they navigate in basins not attributed to sea areas.

5.1.3 Control devices, instruments and other parts of equipment for prevention of pollution by oil comprising electrical and electronic elements shall comply to the requirements of Part VI RCCS.

5.1.4 The monitoring and control devices shall bear distinct inscriptions or generally accepted symbols clarifying its purposes and operation.

5.2 FILTERING EQUIPMENT

5.2.1 Any vessel with gross tonnage of 400 and over shall be equipped with filtering equipment as per 2.4.1–2.4.11.

5.2.2 The requirement of 5.2.1 is not applied to vessels covered by the requirements of 5.5.2.

5.2.3 Oil-containing water filtering systems shall preclude the water discharge with oil concentration exceeding its maximum normative value (see Appendix 2).

5.3 ALARM DEVICE

5.3.1 The ship fitted with filtering equipment shall be equipped with an alarm device.

5.3.2 The requirements of 5.3.1 do not apply to the following ships:

.1 mentioned in 5.3.1 if they store contaminated ballast for delivering it to reception facilities; the ship shall undertake measures preventing from unforeseen discharge of contaminated ballast;

.2 fitted with collecting tank (tanks) to store all oil-containing water on board of the ship for delivering it to reception facilities occupied solely during voyages within special areas identified by MARPOL 73/78.

5.3.3 Ships fitted with an alarm device shall be equipped with an automatic discharge interrupting device which meets the requirements of 2.6. The automatic discharge-interrupting device may be dispensed with, when a ship does not discharge wastes in special areas identified by MARPOL 73/78.

5.3.4 The alarm device shall meet the requirements of 2.5.1–2.5.7 and 5.1.4 as well as applicable provisions of IMO resolutions.

5.3.5 The permitted accuracy of the alarm device readings shall be not lower than ±5 ppm.

5.3.6 The alarm device shall be made from seawater-resistant materials.
5.4 REQUIREMENTS TO PUMPING, DELIVERY AND DISCHARGE SYSTEMS OF OIL-CONTAINING WATER

5.4.1 Pumping, delivery and discharge systems of oil-containing water shall meet the requirements of 2.3.1 – 2.3.9.

5.4.2 Every ship shall be supplied with standard discharge flange connections of international type (see Fig. 5.4.2). The flange of standard discharge connection of international type is intended for pipes with an internal diameter of up to 125 mm and shall be made of steel or an equivalent material with a flat machined surface. The flange together with a gasket of oil-resistant material shall be designed for a working pressure of 0.6 MPa. Coupling is effected by means of six 20-mm screw bolts. Outlet branches shall be fitted with closures.

Fig. 5.4.2 Standard flange discharge connections of international type

5.4.3 Discharge lines for oil-containing mixture shall be led out to the open deck or board above the waterline at the maximal draught of the ship.

5.4.4 Ballast discharging lines from clean ballast tanks may be led out to a ship’ side below the waterline.

5.4.5 The pipes shall be capable of being drained to reception facilities.

5.5 COLLECTING TANKS

5.5.1 Ship shall be fitted with a tank (tanks) for the collection of oil-containing water (collecting tanks) which capacity is determined by the formula, m³:

\[ V = 0.35K T, \]  

(5.5.1)

where \( K \) is factor:

<table>
<thead>
<tr>
<th>Output of the main engines, kW</th>
<th>( K )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 110</td>
<td>0.4</td>

</tr>
<tr>
<td>&gt; 441</td>
<td>1.6</td>
</tr>
<tr>
<td>&gt; 735</td>
<td>2.0</td>
</tr>
</tbody>
</table>

\( T \) is duration of voyage between ports equipped with reception facilities available for oil-containing bilge water reception, in days (\( T \) shall be taken for 7 days if not determined).

Ships with the total output of all main engines less than 220 kW may accumulate oil-containing water in portable tanks or in the machinery space bilges if it is stipulated in stability and floodability information.

5.5.2 Any vessel may be fitted only with oil-containing water collecting tanks when being in service within special areas determined by MARPOL 73/78. In this case the following conditions shall be complied with:

- the ship collecting tanks comply with the requirements of 5.5.1;
- all oil-containing water is kept on board for delivering it to reception facilities;
- the information about adequacy of reception facilities in calling ports and terminals of the vessel shall be submitted to the River Register;
- the Certificate of Prevention of Environment Pollution from Ship shall contain the record about ship’ servicing only in voyages listed in this paragraph.

5.5.3 Collecting tanks of ships with main engine running on heavy fuel with density exceeding 940 kg/m³ at 15 °C shall be fitted with devices for heating oil-containing water before discharging the tank (tanks) through the filtering equipment.
5.5.4 Every ship fitted with filtering equipment shall be fitted with a tank (tanks) for the collection of oil residues (sludge tanks) which minimum capacity shall be calculated by the formulas, m³:

1. for vessels not carrying water ballast in the fuel tanks:
   \[ V_1 = K_1 CT, \]  
   (5.5.4.1)

   where \( K_1 \) is the factor equal to 0.015 for vessels with heavy fuel for main engines subject to purification before use, or 0.005 for vessels where diesel and heavy fuel does not require purification before use;

   \( C \) is a daily fuel discharge, m³/d;

   \( T \) is the maximal duration of voyage between ports equipped with reception facilities available for oil residues reception, in days (\( D \) shall be taken for 30 days if it is not determined);

2. for vessels equipped with homogenizers, incinerators for oil residues or other onboard facilities for neutralization of oil residues approved by the River Register:
   \[ V_1 \] is taken equal to 50% of the value determined in 5.5.4.1 or 1 m³ at gross tonnage from 400 up to 4000, or 2 m³ at gross tonnage of 4000 and over, whichever is the greatest;

3. for vessels carrying ballast water in the fuel tanks:
   \[ V_2 = V_1 + K_2 V_B, \]  
   (5.5.4.3)

   where \( V_1 \) see in 5.5.4.1 or 5.5.4.2;

   \( K_2 \) is coefficient equal to:
   0.01 — for heavy fuel bunker tanks;
   0.005 — for diesel oil bunker tanks;

   \( V_B \) is the capacity of ballast tanks which may be used also for carrying oil fuel, tons.

5.5.5 To discharge the content of sludge tanks to the reception facilities a dedicated pump shall be installed. The pump shall meet the requirements of 5.5.12.

5.5.6 Provision shall be made to prevent sludge from discharge to bilges, tanks and pipelines of oil-containing water. Discharge line of the sludge tanks can be connected to the oil-containing water line leading to discharge connections specified in 5.4.2.

5.5.7 If ship is fitted with a separate tank for drainage and oil spilling storage, it shall have a capacity \( V_s \), m³:
\[ V_s = 2TP/10^4, \]  
(5.5.7)

where \( T \) is the maximal duration of voyage between ports equipped with reception facilities available for oil drainage and spilling reception, in days (if not determined, \( D \) is taken for 30 days);

\( P \) is the power of the main engines, kW.

5.5.8 Capacity of a separate shipboard tank (tanks) for exhaust oil storage shall be half times more than exhausted lubricating oil supplied from crankcases of all internal combustion engines and all installed ship machinery as well as lubricating oil of hydraulic drive contained in these system tanks.

5.5.9 Washing water from fuel and oil separators shall be discharged to special tank or to sludge tank.

5.5.10 A sludge tank shall be located directly under the heavy fuel separator. Where impracticable, the sludge tank shall be located near the heavy fuel separator in such way that to provide the largest possible inclination, possible straightness or big radius elbows of the inlet drainage pipe.

5.5.11 The sludge tank shall be so designed as to provide for free access of oil sludge to the suction line. Where impracticable, the suction line inlet or a submersible pump shall be so located as to provide the minimal distance for oil sludge to reach the suction inlet.

5.5.12 A pump for sludge pumping shall be self-priming, positive-displacement, be capable of operation in dry friction conditions and with delivery pressure of at least 0.4 MPa. The pump capacity may be calculated by the formula, m³/h:
\[ Q = V_s/t, \]  
(5.5.12)

where \( V_s \) is the capacity of a sludge tank determined as per 5.5.4, m³;

\( t \) is the duration of emptying which is equal to 4 hours.

In any case the pump capacity shall be at least 2 m³/h. The pump suction side shall
be connected only to the pipe leading on a
deck and to the sludge incinerator facilities
when provided in a ship. The suction height
shall not exceed 3 m.

5.5.13 Collecting tanks shall comply with
the requirements of 2.2.1 – 2.2.7.

5.5.14 The sludge tanks shall be fitted with
preheating systems. Preheating pipes shall be
located so as they are led along the tank pe-
rimeter beginning from the inlet opening and
then across the whole bottom on the level
sufficient to prevent it from complete cover-
ing with bottom deposits. The tank preheating
system shall be so designed that to provide for
preheating up to 60 °C.

5.5.15 The sludge tank throats shall provide
for access at any tank space. One of the
throats shall be located at the upper side of
the tank to provide for the operation of sub-
mersible pump.

5.5.16 The sludge tanks shall be designed
and arranged so to provide cleaning of tanks
and delivering of residues to the reception
facilities.

5.6 GENERAL REQUIREMENTS
TO OIL TANKERS

5.6.1 Length of any cargo tank of an oil
tanker or a cargo space of a ship not being
an oil tanker which is intended for oil trans-
portation in bulk with a capacity of at least
200 m³ and over, shall not exceed 10 m or
one of figures of Table 5.6.1 whichever is the
greatest.

5.6.2 Pipelines designed to pump the oil
and oil-containing water shall not be led
through the ballast tanks, excepting pipe sec-
tions made of seamless pipes equal in strength
to the ballast tank structures.

5.7 AUTOMATIC MONITORING AND
CONTROL SYSTEMS FOR DISCHARGE

5.7.1 Every oil tanker with gross tonnage of
150 and over shall be fitted with the auto-
matic monitoring and control systems for dis-
charge (for the purposes of this Chapter, hereinafter referred to as the System) in ac-
cordance with regulation 31 of Appendix I to
MARPOL 73/78 with the exception of the
following cases:

1 oil tanker is sailing in sea areas being
part of special areas delineated by Appendix I
to MARPOL-73/78;

2 oil tanker is sailing only within the sea
areas outside the special areas at a distance of
less than 50 nautical miles from the nearest
coast.

In this case the following conditions shall
be complied with:

all oil-containing mixtures is kept on board
for delivering to reception facilities;

the Certificate of Prevention of Environ-
ment Pollution from Ships contains the record
about ship’s servicing only in voyages listed in
5.7.1.1 and 5.7.1.2;

the Oil Record Book contains the record
about the discharged amount, time and dis-
charge port.

### Table 5.6.1

<td>(0.25b/B + 0.15)L</td>
</tr>
</tbody>
</table>

**Note.** b is the minimal distance from a ship side to outer bulkhead of the given tank, m, measured from the inner surface of outer plating at right angle to the longitudinal central plane on a level cor-
responding to assigned summer freeboard.

B is breadth of a ship at design waterline; L is length of a ship at design waterline.
5.7.2 The System equipment and applicable technical requirements shall comply with IMO Resolution MEPC.108(49) Revised Guidelines and Specifications to Automatic Monitoring and Control Systems for Oil Discharge for Oil Tankers.

5.7.3 The System shall be activated with any discharge of oil-containing mixture to the sea and automatically stop the discharge if the instantaneous intensity of the discharge does not exceed 30 litres per mile.

5.7.4 The System shall operate in all weather conditions, in which an oil tanker can be operated under normal conditions.

5.7.5 Any system fault shall result in the discharge interruption.

5.8 REQUIREMENTS TO DETECTORS OF OIL-WATER PHASE DIVISION BOUNDARY

5.8.1 Detectors of the oil-water phase division boundary may be either fixed or portable. When using only fixed devices they shall be installed in every settling tank.

5.8.2 The devices shall determine the position of the oil-water phase division boundary in the tank at any level.

5.8.3 The location of a fixed device or hatches for a portable one shall be selected considering the tank construction and influence of the ship motions.

5.8.4 The controls and the indicator of oil-water phase division boundary position of the fixed devices shall be located at the control station of cargo operations or in similar space.

5.8.5 Fixed devices should sustain the jet impact force of the tank washing facilities.

5.8.6 The device may be designed to determine the phase division boundary of fluids with densities that differ considerably. The device shall bear the plate indicating the conditions for its application and the necessary restrictions.

5.8.7 The device shall be so designed as to allow for its installation in explosive spaces. The device shall not generate radio interference noise.

5.8.8 The device shall be made from seawater-resistant materials.

5.8.9 The device shall operate in the ambient temperature range from –30 up to +55 °C.

5.8.10 The device shall indicate the oil–water phase division boundary by means of an indicating device. The constant indication of oil-water phase division boundary is not mandatory.

5.8.11 The device accuracy shall provide for the indication of oil-water phase division boundary within limits of ±25 mm from the actual.

5.8.12 It shall be possible to check the performance of the device on a ship.

5.9 SETTLING TANKS

5.9.1 Oil tanker with gross tonnage of 150 and over shall be fitted with a settling tank or a system of settling tanks.

5.9.2 The capacity of a settling tank or a system of settling tanks shall be at least 3 per cent of oil carrying capacity of an oil tanker with the exception of the following cases:

1. if tank washing facilities fitted on a ship are such as the settling tank or tanks are filled with washing water in a quantity sufficient for tank washing and feeding pumps with working liquid including ejectors, the reduction of settling tanks capacity may be admitted down to 2 per cent of oil carrying capacity of oil tanker;

2. when an oil tanker is fitted with tanks intended for clean ballast only, it may allow settling tank capacity equal to 2 per cent of oil carrying capacity. If on that ship tank washing facilities are such as the settling tank
or tanks are filled with washing water in a quantity sufficient for tank washing and feeding pumps with working liquid including ejectors, the reduction of settling tanks capacity may be admitted down to 1.5 per cent of oil carrying capacity of oil tanker;

.3 if on a combination carrier oil cargo is carried only in tanks with smooth walls, it can admit the reduction of settling tanks capacity down to 1 per cent of oil carrying capacity. If on that ship tank washing facilities are such as the settling tank or tanks are filled with washing water in a quantity sufficient for tank washing and feeding pumps with working liquid including ejectors, the reduction of settling tanks capacity may be admitted down to 0.8 per cent of oil carrying capacity of oil tanker.

5.9.3 The settling tanks shall be designed so that arrangement of input and output holes as well as baffles and water drains (if any) does not cause excessive turbulence and entrapping of oil and emulsion by water.  

5.9.4 The requirements of 5.9.1 – 5.9.3 may not be applied to an oil tanker when:

.1 she is engaged solely in voyages lasting not more than 72 h within the range of 50 miles clear of the nearest coast provided that she is keeping on board all oil-containing mixtures for delivering it to reception facilities;

.2 she is occupied with asphalt carrying provided that she is keeping on board all asphalt residues for delivering it as well as all washing water to reception facilities.

5.9.5 The requirements of 5.9.1 – 5.9.3 are applied to vessels not being oil carriers but fitted with cargo spaces built and used specially for oil transportation with the total capacity of 200 m³ and over.

5.9.6 If there is a line for oil-containing water discharge from bilges of the machinery spaces to the settling tanks, it shall include suitable facilities preventing from cargo and gas leakage into the machinery spaces.

5.10 REQUIREMENTS TO OIL TANKERS FOR PREVENTION OF POLLUTION BY OIL IN THE EVENT OF COLLISION OR TAKING THE GROUND

5.10.1 The requirements of the present Chapter are applied to oil tankers with a gross tonnage of 600 tons and over.

5.10.2 Oil tankers shall be fitted with ballast tanks not being oil tanks which are designed according to the requirements of 5.10.3–5.10.7.

5.10.3 Side ballast tanks shall be extended along the whole length of the cargo tanks and on the whole board depth or from the inner bottom plating up to the main deck; the distance from the cargo tanks to the moulded line of the outside plating taken in any cross-section perpendicular to the side plating shall not be less than the distance w (Fig. 5.10.3).

Fig. 5.10.3 Determining the sizes of side ballast tanks

5.10.4 Double bottom ballast tanks shall be extended along the whole length of the cargo tanks and in any cross-section to have the height h between the moulded line of the bottom plating and the cargo tank bottom (see Fig. 5.10.3) taken along the perpendicular to the bottom plating.

5.10.5 The distance w (see 5.10.3) and height h (see 5.10.4) shall be taken from Table 5.10.5.

5.10.6 In the bilge turn area or places where the bilge turn is not clear, at different h and w specified in 5.10.3–5.10.5 the distance w is preferable on levels exceeding 1.5h above the base line as shown at Fig. 5.10.3.

5.10.7 The ballast, measuring and ventilation lines coming to the ballast tanks shall not be led through the cargo tanks, excepting short sections provided they are all-welded or of equivalent construction.
5.10.8 Cargo pump rooms of the oil tankers with deadweight of 5000 tons and more shall be fitted with the double bottom so that the height of double bottom space in any cross-section is not less than 1 m.

Ballast pipelines may be located in double bottom of the cargo pump rooms provided any damage of these lines does not affect on the cargo system operation.

Suction wells in double bottom of both cargo tanks and cargo pump rooms shall be as small as practicable. The distance between the well bottom and the base plane of a ship measured at a right angle to this plane shall be not less than half height of double bottom space.

**5.11 REQUIREMENTS TO SHIP'S EQUIPMENT AND FACILITIES FOR PREVENTION OF POLLUTION BY SEWAGE**

5.11.1 The requirements of this Chapter apply to the following ships:

.1 of gross tonnage of 200 and over;

.2 of gross tonnage less than 200 with a number of people on board over 10 persons;

.3 which may carry people on board over 10 persons.

5.11.2 The ships shall be fitted with the following equipment:

.1 a sewage treatment plant and a collecting tank. Collecting tank may be used for collection of non-treated sewage, activated sludge or sludge from the sewage treatment plant; or

.2 collecting tanks.

5.11.3 Provision shall be made to prevent from the discharge of purified and disinfected sewage as well as non-treated sewage in areas where the discharge is forbidden.

5.11.4 Collecting tanks shall comply with the requirements of 3.2.1–3.2.8.

5.11.5 Installations for the treatment of sewage water shall comply with the requirements of 3.4.1–3.4.8.

5.11.6 The equipment for discharge of sewage water shall comply with the requirements of 3.3.7–3.3.10.

5.11.7 The ship shall be supplied with standard discharge connections of international type (see Fig. 5.11.7).

![Fig. 5.11.7 Standard flange discharge connection of international type](image)

The flange of standard discharge connection of international type is intended for pipes with an internal diameter of up to 100 mm and shall be made of steel or an equivalent material with a flat machined surface. The flange together with a gasket shall be designed for a working pressure of 0.6 MPa. Coupling shall be affected by means of four 16-mm screw bolts. Outlet branches shall be fitted with closures.

* For separate tanks with oil fuel tonnage of less then 500 m³, the minimum value is taken equal to 0.76.

**Note.** B — breadth of a ship at design waterline.
6 REQUIREMENTS FOR PREVENTION OF AIR POLLUTION FROM SHIPS

6.1 SCOPE OF APPLICATION

6.1.1 The present Section applies to the marine diesel engines and specifies the normative values of harmful substance emission and exhaust gases opacity.

6.1.2 The values of harmful substance emission and exhaust gases opacity from marine spark-ignition engines as well as from marine gas turbines and compressed gas engines shall not exceed the values set by normative documents and/or international agreement of the Russian Federation.

6.2 NORMATIVE VALUES OF HARMFUL SUBSTANCES EMISSION AND EXHAUST GASES OPACITY

6.2.1 The regulated parameter of gas components of harmful substances with exhaust gases is specific average weighted emission in grams per kWh of effective engine operation during the full test cycle imitating typical operating conditions.

6.2.2 Maximum permissible values of regulated parameters if gas components of emissions for new engines during bench tests are listed in Tables 6.2.2-1 and 6.2.2-2.

6.2.3 Maximum permissible values of regulated parameters of emission gas components for engines after thorough repair are taken in accordance with Tables 6.2.2-1 and 6.2.2-2 with multiplication by correction factors listed in Table 6.2.3.

6.2.4 Regulated parameters of exhaust gases opacity are:

<table>
<thead>
<tr>
<th>Engine crankshaft revolution frequency n, min⁻¹</th>
<th>Maximum permissible value of average weighted emission of nitrogen oxides (NOₓ) reduced to NO₂, g/kW·h for engines in production</th>

</tbody>
</table>

Note. For radial cylinder engines, the standard values of exhaust gas opacity are to be set as required by the customer.

6.2.5 Exhausted gas flow $V_{exh}$ reduced to the normal conditions, depending on which the Table 6.2.4 establishes the opacity values, is determined by direct measurement or calculated by the formula (6.2.5-1), m$^3$/h:

$$V_{exh} = \dot{B}_T F_T$$  \hspace{1cm} (6.2.5-1)

where $\dot{V}_a$ is air flow rate reduced to the normal atmospheric conditions ($T_a = 273$ K, $p_a = 101.3$ kPa, density = 1.293 kg/m$^3$), m$^3$/h;

$F_T$ is fuel mass flow per hour, kg/h;

$T$ is coefficient of reducing the flow of undiluted combustion products of different fuels (mixture ratio) to the normal atmospheric conditions, m$^3$/kg, taken according to Table 6.2.5 for dry and wet conditions of exhaust gases.

For wet exhaust gases, which density is equal to 1.293 kg/m$^3$, $V_{exh}$ is calculated by the formula (6.2.5-2), m$^3$/s:

$$V_{exh} = 0.214810^{-3} (B_T + \dot{B}_T)$$  \hspace{1cm} (6.2.5-2)

where $B_T$ is hourly fuel rate calculated by the formula (6.2.5-3), kg/h,

$$B_T = \dot{h} P_{out}$$  \hspace{1cm} (6.2.5-3)

where $\dot{h}$ is specific effective fuel rate of the engine at the rated power (as per engine specification), kg/kWh;

$P_{out}$ is engine's rated power (as per engine specification), kW.

$$\dot{B}_T = \phi \alpha L_s B_T$$  \hspace{1cm} (6.2.5-4)

where $\phi = 1.05 - 1.2$ is blowing factor,

$\alpha$ is total excess air factor, minimum value as per engine specification. The $\alpha$ values depend on mixture formation type.
28 Rules for Prevention of Environmental Pollution from Ships (RPPS)

For engines

- with film mixture formation: $\alpha = 1.2$ to $1.5$
- with spray mixture formation: $\alpha = 1.9$ to $2.2$
- with spray-film mixture formation: $\alpha = 1.7$ to $2.0$
- for swirl-chamber diesel engines: $\alpha = 1.5$ to $1.9$
- for prechamber diesel engines: $\alpha = 1.3$ to $1.6$

$L_0'$ is stoichiometric ratio, i.e. amount of air in kg theoretically required for burning 1 kg of fuel, kg/kg. For diesel fuel of average elementary composition (C = 0.87, H = 0.126, O = 0.004) $L_0' = 14.33$ kg/kg.

6.2.6 Permissible values of regulated opacity parameters for engines after thorough repair shall not exceed the values specified in Table 6.2.4 by more than 29%.
7 PREVENTION OF USE OF OZONE-DEPLETING SUBSTANCES

7.1 OZONE-DEPLETING SUBSTANCES AND THE MONTREAL PROTOCOL

7.1.1 The ozone-depleting substances listed in the Montreal Protocol are prohibited except hydrochlorofluorocarbons (HCFC) stated in Appendix C to the Montreal Protocol which can be used till January 1, 2020.

7.1.2 The ozone-depleting substances listed in the Montreal Protocol and equipment containing ozone-depleting substances when removing from ships shall be disposed according to the procedure established by normative documents of the Russian Federation.
CALCULATION METHOD OF SHIP’S NAVIGATION ENDURANCE DUE TO ENVIRONMENTAL SAFETY CONDITIONS

1. The navigation endurance is calculated for each ship. Navigation endurance may be calculated for a series of ships of the same design provided that the equipment and facilities installed in those ships, which may influence the ship’s environmental safety, are identical.

2. Navigation endurance is determined for the following pollutants:
   - oil-containing water (OCW);
   - sewage water (SW);
   - refuse (R).

3. For ships fitted with filtering equipment and sewage treatment plant complying with the requirements of the Rules, navigation endurance is taken as non-limited for those pollutants.

4. Navigation endurance for oil-containing water $T_{ocw}$ is calculated by the formula, in days:
   \[ T_{ocw} = 0.9 \frac{V_{ocw}}{Q_{ocw}}, \]  
   (A1.4)
   where $V_{ocw}$ is the volume of collecting tank for OCW, m$^3$. If no special tank for oil-containing water is provided, $V_{ocw}$ is determined as the volume of bilge space of the machinery spaces considering the requirements of 2.1.4 of the Rules or volume of portable tanks;
   $Q_{ocw}$ is the design daily accumulation of OCW, m$^3$/day, which depends upon the type of a ship and the power of main engines and is taken according to norms stated in Table A1.4.

\begin{table}
\centering
\caption{Design daily accumulation of oil-containing water $Q_{ocw}$, m$^3$/days}
\begin{tabular}{|c|c|c|}
\hline
Output of the main engines, kW & $Q_{ocw}$, m$^3$/days & \\
\hline
Transport vessels & & \\
\hline
Coast ships, auxiliary ships, crew boats, technical fleet vessels & & \\
\hline
Over 55 to 220 & 0.03 to 0.12 & 0.02 to 0.08 \\
\hline
$\leq 440$ & 0.12 to 0.18 & 0.08 to 0.14 \\
\hline
$> 440$ & 0.18 to 0.24 & 0.14 to 0.20 \\
\hline
$> 890$ & 0.24 to 0.30 & 0.20 to 0.25 \\
\hline
\end{tabular}
\end{table}

Notes. 1. For ships not older than 5 years an adjusting factor 0.8 may be applied.
2. For dynamically supported ships and high speed craft, $Q_{ocw}$ is taken for 0.07 m$^3$/day irrespective of the output and number of main engines.
3. For dredges, output of engines working on a soil pump or a scoop drive shall be taken as output of main engines.
4. In specific operating conditions along with $Q_{ocw}$ values stated in the Table other methods may be used which take into consideration specific character of operating conditions in a basin or at a shipowner.
5. For a ship for which the main engine output is within one of the intervals stated in the table, $Q_{ocw}$ is determined by linear interpolation of the tabulated data.

5. Navigation endurance for sewage water $T_{sw}$ is determined for all types of ships by the formula, in days:
   \[ T_{sw} = 0.9 \frac{V_{sw}}{Q_{sw}}, \]  
   (A1.5)
   where $V_{sw}$ is the volume of collecting tank for SW, m$^3$. 

\( Q_{sw} \) is the specific accumulation of sewage water for different types of vessels, m\(^3\)/person-day; it is stated in Table A1.5; 
\( n \) is a number of persons onboard.

**Table A1.5**

<table>
<thead>
<tr>
<th>Type of a ship</th>
<th>( Q_{sw} ), m(^3)/person-day</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cruise and passenger vessels with all utilities in cabins</td>
<td>0.18</td>
</tr>
<tr>
<td>Passenger vessels with wash-stands in cabins and common shower-baths</td>
<td>0.14</td>
</tr>
<tr>
<td>Passenger vessels with wash-stands in cabins</td>
<td>0.12</td>
</tr>
<tr>
<td>Cargo vessels and tugboats with main engine power of 900 kW and above</td>
<td>0.12</td>
</tr>
<tr>
<td>Cargo vessels and tugboats with main engine power from 400 to 900 kW</td>
<td>0.09</td>
</tr>
<tr>
<td>Cargo vessels and tugboats with main engine power of below 400 kW</td>
<td>0.07</td>
</tr>
<tr>
<td>Passenger intracity fleet and high speed craft</td>
<td>0.09</td>
</tr>
<tr>
<td>Worksite craft and non-self-propelled manned vessels*</td>
<td>0.003</td>
</tr>
</tbody>
</table>

* For a dredge convoy the accumulation shall be calculated proceeding from a number of persons on board of all ships of the convoy.

Navigation endurance for sewage water shall not exceed six days with gradual filling the collecting tanks.

6 Navigation endurance for refuse \( T_r \) calculated by the formula, in days:

\[
T_r = 0.9 V_r/(Q_r n),
\]  
(A1.6)

where \( V_r \) is the volume for collecting facilities of dry refuse and food wastes, m\(^3\);

\( Q_r \) is the design daily accumulation of dry refuse and food wastes, m\(^3\)/person-day); it is stated in Table A1.6;

\( n \) is a number of persons onboard.

**Table A1.6**

(for reference)

<table>
<thead>
<tr>
<th>Type of pollutant</th>
<th>( Q_r ), m(^3)/person-day</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dry refuse</td>
<td>0.002</td>
</tr>
<tr>
<td>Solid food remains</td>
<td>0.0004</td>
</tr>
</tbody>
</table>

Notes: 1. \( Q_r \) is taken according to SanPin 2.5.2-703-98.
2. For technical fleet the daily accumulation shall be calculated proceeding from a number of persons on board of all ships of the dredge convoy.

7 For ships fitted with incinerators complying with the requirements of the Rules, navigation endurance for refuse is taken as non-limited for kinds of refuse to be destroyed in the incinerator.
APPENDIX 2
(normative)

NORMATIVE VALUES OF OIL-CONTAINING AND SEWAGE WATER TREATMENT ON INLAND AND RIVER-SEA NAVIGATION SHIPS OPERATED IN INLAND WATERWAYS

Table A2.1
